### 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI

## General Description

The MAX17242/MAX17243 high-efficiency, synchronous step-down DC-DC converters with integrated MOSFETs operates over a 3.5 V to 36 V input voltage range, and can operate in drop-out condition by running at $99 \%$ duty cycle. The converters deliver up to 2A (MAX17242) and 3A (MAX17243) output current and generate fixed output voltages of $3.3 \mathrm{~V} / 5 \mathrm{~V}$, along with the ability to program the output voltage between 1 V to 10 V .
The devices use a current-mode-control architecture and can be operated in the pulse-width modulation (PWM) or pulse-frequency modulation (PFM) control schemes. PWM operation provides constant frequency operation at all loads, and is useful in applications sensitive to switching frequency. PFM operation disables negative inductor current and additionally skips pulses at light loads for high-efficiency operation. The low-resistance, on-chip MOSFETs ensure high efficiency at full load and simplify the layout.
The devices are available in a compact 20-pin ( $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ ) TQFN package with exposed pad. These parts are rated for $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ operation.

## Applications

- Distributed Supply Regulation
- Wall Transformer Regulation
- General-Purpose Point-of-Load

## Ordering Information appears at end of data sheet.

## Benefits and Features

- Eliminates External Components and Reduces Total Cost
- No Schottky-Synchronous Operation for High Efficiency and Reduced Cost
- Simple external RC Compensation for Stable Operation at Any Output Voltage
- All-Ceramic Capacitor Solution: Ultra-Compact Layout with as Few as Eight External Components
- PGOOD Output and High-Voltage EN Input Simplify Power Sequencing
- Reduces Number of DC-DC Converters to Stock
- Pin Compatibility for 2A/3A Options
- Fixed Output Voltage with $\pm 2 \%$ Accuracy ( $5 \mathrm{~V} / 3.3 \mathrm{~V}$ ) or Externally Resistor Adjustable (1V to 10V) with $\pm 1 \%$ FB Accuracy
- 220 kHz to 2.2 MHz Adjustable Frequency with External Synchronization
- Reduces Power Dissipation
- 93\% Peak Efficiency
- Shutdown Feature Blocks Current Flow from Input-to-Output or Vice-Versa
- Less Than $5 \mu \mathrm{~A}$ (typ) in Shutdown
- Low $15 \mu \mathrm{~A}$ (typ) Quiescent Current in Standby Mode
- Operates Reliably
- 42V Input Voltage Transient Protection
- Fixed 8ms Internal Software Start Reduces Input Inrush Current
- Cycle-by-Cycle Current Limit, Thermal Shutdown with Automatic Recovery
- Reduced EMI Emission with Spread-Spectrum Control

## Typical Application Circuit/Block Diagram

### 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI

| Absolute Maximum Ratings |
| :---: |
| SUP, SUPSW, |
| SUP to SUPSW........................................-0.3V to +0.3V |
| BIAS to AGND .............................................-0.3V to +6 V |
|  |
| FSYNC, PGOOD, FB to AGND............--0.3V to (VBIAS +0.3 V ) |
| OUT to PGND ...........................................-0.3V to +12 V |
| BST to LX ................................................ 0.3 V to +6 V |
|  |

Output Short-Circuit Duration...................................Continuous
Continuous Power Dissipation $\left(\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}\right.$ )
20-Pin TQFN (derate $33.3 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ). .2666 .7 mW
Operating Temperature Range............................................................................................................... $+30^{\circ} \mathrm{C}$
Junction Temperature ................................................. $260^{\circ} \mathrm{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Package Thermal Characteristics (Note 1)

TQFN
Junction-to-Ambient Thermal Resistance $\left(\theta_{\mathrm{JA}}\right) \ldots \ldots . . . . .30^{\circ} \mathrm{C} / \mathrm{W}$
Junction-to-Case Thermal Resistance ( $\theta_{J C}$ ) $\qquad$ $2^{\circ} \mathrm{C} / \mathrm{W}$

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

## Pin Configuration

## Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :--- |
| 1 | FOSC | Resistor-Programmable Switching Frequency Setting Control Input. Connect a resistor from FOSC to <br> AGND to set the switching frequency. |
| 2 | OUT | Switching Regulator Output. OUT also provides power to the internal circuitry when the output voltage of <br> the converter is set between 3V to 5V during standby mode. |
| 3 | FB | Feedback Input. Connect an external resistive divider from OUT to FB and AGND to set the output <br> voltage. Connect to BIAS to set the output voltage to 5V or 3.3V. |
| 4 | COMP | Error Amplifier Output. Connect an RC network from COMP to AGND for stable operation. See the <br> Compensation Network section for more details. |
| 5 | BIAS | Linear Regulator Output. BIAS powers up the internal circuitry. Bypass with a minimum of 2.2 <br> capacitor to AGND. ceramic |
| 6 | AGND | Analog Ground |
| 7 | EN | SUP Voltage-Compatible Enable Input. Drive EN low to PGND to disable the devices. Drive EN high to <br> enable the devices. |
| 10 | SUP | SUPSW <br> Internal High-Side Switch Supply Input. SUPSW provides power to the internal switch. Bypass SUPSW <br> to PGND with a 0.1 $\mu$ F and 4.7 $\mu$ F ceramic capacitors. |
| 11 | PGOOD | Open-Drain, PGOOD Output. PGOOD asserts when Vout is above 95\% regulation point. PGOOD goes <br> low to AGND when V VUT is below 92\% regulation point. |

Pin Description (continued)

| PIN | NAME | FUNCTION |
| :---: | :---: | :--- |
| 12 | SPS | Spread-Spectrum Pin. Pull high for spread spectrum on and low to AGND for spread spectrum off. |
| 13,14 | PGND | Power Ground |
| 15 | BST | High-Side Driver Supply. Connect a $0.1 \mu$ F capacitor between LX and BST for proper operation. |
| $16-18$ | LX | Inductor Switching Node |
| 19 | N.C. | No Connection |
| 20 | FSYNC | Synchronization Input. The devices synchronize to an external signal applied to FSYNC. Connect <br> FSYNC to AGND to enable PFM mode operation. Connect to BIAS or to an external clock to enable <br> fixed-frequency, forced-PWM mode operation. |
| - | EP | Exposed Pad. Connect EP to a large-area contiguous copper ground plane for effective power <br> dissipation. Do not use as the only IC ground connection. EP must be connected to PGND. |

### 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI

Figure 1. Internal Block Diagram

# 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI 

## Detailed Description

The MAX17242/MAX17243 are 2A/3A current-mode stepdown converters with integrated high-side and lowside MOSFETs. The low-side MOSFET enables fixedfrequency, forced-PWM operation in light-load applications. The devices operate with input voltages from 3.5 V to 36 V while using only $15 \mu \mathrm{~A}$ quiescent current at no load. The switching frequency is resistor programmable from 220 kHz to 2.2 MHz and can be synchronized to an external clock. The devices' output voltage is available as $5 \mathrm{~V} / 3.3 \mathrm{~V}$ fixed or adjustable from 1 V to 10 V . The wide input voltage range, along with its ability to operate at $99 \%$ duty cycle during undervoltage transients, makes the devices ideal for many applications.
In light-load applications, a logic input (FSYNC) allows the devices to operate either in PFM mode for reduced current consumption, or fixed-frequency, forced-PWM mode to eliminate frequency variation and help minimize EMI. Protection features include cycle-by-cycle current limit, and thermal shutdown with automatic recovery.

## Wide Input Voltage Range

The devices include two separate supply inputs (SUP and SUPSW) specified for a wide 3.5 V to 36 V input voltage range. $V_{\text {SUP }}$ provides power to the device and VSUPSW provides power to the internal switch. Often in a system, severe transient conditions can cause the voltage at SUP and SUPSW pins to drop below the programmed output voltage. In a system where severe transient conditions can cause the voltage at the SUP and SUPSW pins to drop below the programmed output voltage. Under such conditions, the devices operate in a high duty-cycle mode to facilitate minimum dropout from input to output.

## Maximum Duty-Cycle Operation

The devices have a maximum duty cycle of $98 \%$ (typ). The IC monitors the off time (time for which the low-side FET is on) in both PWM and PFM modes during every switching cycle every switching cycle. Once the off time of 100ns (typ) is detected continuously for $12 \mu \mathrm{~s}$, the low-side FET is forced on for 150 ns (typ) every $12 \mu \mathrm{~s}$. The input voltage at which the devices enter dropout changes depending on the input voltage, output voltage, switching frequency, load current, and the efficiency of the design.
The input voltage at which the devices enter dropout can be approximated as:

$$
V_{\text {SUP }}=\frac{V_{\text {OUT }}+\left(\mathrm{IOUT} \times \mathrm{R}_{\text {ON_H }}\right)}{0.98}
$$

Note: The equation above does not take into account the efficiency and switching frequency but is a good first-order approximation. Use the RON_H number from the max column in the Electrical Characteristics table.

## Linear Regulator Output (BIAS)

The devices include a 5 V linear regulator ( $\mathrm{V}_{\mathrm{BIAS}}$ ) that provides power to the internal circuit blocks. Connect a $2.2 \mu \mathrm{~F}$ ceramic capacitor from BIAS to AGND.

## Power-Good Output (PGOOD)

The devices feature an open-drain power-good output (PGOOD). PGOOD asserts when Vout rises above 95\% of its regulation voltage. PGOOD deasserts when VOUT drops below 92.5\% of its regulation voltage. Connect PGOOD to BIAS with a $10 \mathrm{k} \Omega$ resistor to AGND.

## Synchronization Input (FSYNC)

FSYNC is a logic-level input useful for operating-mode selection and frequency control. Connecting FSYNC to BIAS or to an external clock enables fixed-frequency, forced-PWM operation. Connecting FSYNC to AGND enables PFM-mode operation.
The external clock frequency at FSYNC can be higher or lower than the internal clock by $20 \%$. If the external clock frequency is greater than $120 \%$ of the internal clock, contact the factory applications team to verify the design. The devices synchronize to the external clock in two cycles. When the external clock signal at FSYNC is absent for more than two clock cycles, the devices use the internal clock.

## System Enable (EN)

An enable control input (EN) activates the devices from their low-power shutdown mode. EN is rated up to 42 V , allowing direct connection to SUP or through a resistor divider to set the desired input undervoltagelockout threshold.
EN turns on the internal regulator. Once $\mathrm{V}_{\text {BIAS }}$ is above the internal lockout threshold, VUVBIAS $=3.15 \mathrm{~V}$ (typ), the converter activates and the output voltage ramps up within 8 ms .
A logic-low to PGND at EN shuts down the device. During shutdown, the internal linear regulator and gate drivers turn off. Shutdown is the lowest power state and reduces the quiescent current to $5 \mu \mathrm{~A}$ (typ). Drive EN high to bring the devices out of shutdown.

# 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI 

## Spread-Spectrum Option

The spread spectrum can be enabled on the device using a pin. When the SPS pin is pulled high the spread spectrum is enabled and the operating frequency is varied $\pm 3 \%$ centered on FOSC. The modulation signal is a triangular wave with a period of $110 \mu \mathrm{~s}$ at 2.2 MHz . Therefore, FOSC ramps down $3 \%$ and back to 2.2 MHz in $110 \mu$ s and also ramps up $3 \%$ and back to 2.2 MHz in $110 \mu \mathrm{~s}$. The cycle repeats.
For operations at FOSC values other than 2.2 MHz , the modulation signal scales proportionally (e.g., at 400 kHz , the $110 \mu \mathrm{~s}$ modulation period increases to $110 \mu \mathrm{~s} \mathrm{x}$ $2.2 \mathrm{MHz} / 0.4 \mathrm{MHz}=550 \mu \mathrm{~s})$.
The internal spread spectrum is disabled if the devices are synchronized to an external clock. However, the devices do not filter the input clock on the FSYNC pin and pass any modulation (including spread spectrum) present on the driving external clock. Drive the SPS pin low to AGND to disable spread spectrum.

## Internal Oscillator (FOSC)

The switching frequency ( $\mathrm{f}_{\mathrm{SW}}$ ) is set by a resistor ( $\mathrm{R}_{\text {FOSC }}$ ) connected from FOSC to AGND. For example, a 400 kHz switching frequency is set with $\mathrm{R}_{\text {FOSC }}=73.2 \mathrm{k} \Omega$. Higher frequencies allow designs with lower inductor values and less output capacitance. Consequently, peak currents and 12 R losses are lower at higher switching frequencies, but core losses, gate-charge currents, and switching losses increase. See Typical Operating Characteristics section.

## Overtemperature Protection

Thermal overload protection limits the total power dissipation in the device. When the junction temperature exceeds $175^{\circ} \mathrm{C}$ (typ), an internal thermal sensor shuts down the internal bias regulator and the step-down converter, allowing the IC to cool. The thermal sensor turns on the IC again after the junction temperature cools by $15^{\circ} \mathrm{C}$.

## Applications Information

## Setting the Output Voltage

Connect FB to BIAS for a fixed $+5 \mathrm{~V} / 3.3 \mathrm{~V}$ output voltage. See Ordering Information. To set the output to other voltages between 1 V and 10 V , connect a resistive divider from output (OUT) to FB to AGND (Figure 2). Select R ${ }_{\text {FB2 }}$ (FB to AGND resistor) less than or equal to $500 \mathrm{k} \Omega$. Calculate $\mathrm{R}_{\mathrm{FB} 1}$ (OUT to FB resistor) with the following equation:

$$
\mathrm{R}_{\mathrm{FB} 1}=\mathrm{R}_{\mathrm{FB} 2}\left[\left(\frac{\mathrm{~V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{FB}}}\right)-1\right]
$$

where $\mathrm{VFB}=1 \mathrm{~V}$ (see the Electrical Characteristics table).

Figure 2. Adjustable Output-Voltage Setting

### 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI

## Forced-PWM and PFM Modes

In PWM mode of operation, the devices switch at a constant frequency with variable on-time. In PFM mode of operation, the converter's switching frequency is load dependent. At higher load current, the switching frequency does not change and the operating mode is similar to the PWM mode. PFM mode helps improve efficiency in light-load applications by allowing the converters to turn on the high-side switch only when the output voltage falls below a set threshold. As such, the converters do not switch MOSFETs on and off as often as in the PWM mode. Consequently, the gate charge and switching losses are much lower in PFM mode. The operation mode of the device is set by FSYNC pin.

## Inductor Selection

Three key inductor parameters must be specified for operation with the devices: inductance value (L), inductor saturation current (ISAT), and DC resistance (RDCR). To select inductor value, the ratio of inductor peak-to-peak AC current to DC average current (LIR) must be selected first. A good compromise between size and loss is a 30\% peak-to-peak ripple current to average-current ratio (LIR = 0.3). The switching frequency, input voltage, output voltage, and selected LIR then determine the inductor value as follows:

$$
L=\frac{\left(V_{\text {SUP }}-V_{\text {OUT }}\right) \times V_{\text {OUT }}}{V_{\text {SUP }} \times f_{\text {SW }} \times I_{\text {OUT }} \times \text { LIR }}
$$

where $\mathrm{V}_{\text {SUP, }} \mathrm{V}_{\text {OUT, }}$ and IOUT are typical values (so that efficiency is optimum for typical conditions). The switching frequency is set by RFOSC (see TOC 8 in the Typical Operating Characteristics section).

## Input Capacitor

The input filter capacitor reduces peak currents drawn from the power source and reduces noise and voltage ripple on the input caused by the circuit's switching.
The input capacitor RMS current requirement ( $\mathrm{I}_{\mathrm{RMS}}$ ) is defined by the following equation:

$$
\mathrm{I}_{\mathrm{RMS}}=\mathrm{I}_{\mathrm{LOAD}(\mathrm{MAX})} \times \frac{\sqrt{\mathrm{V}_{\mathrm{OUT}} \times\left(\mathrm{V}_{\mathrm{SUP}}-\mathrm{V}_{\mathrm{OUT}}\right)}}{\mathrm{V}_{\mathrm{SUP}}}
$$

IRMS has a maximum value when the input voltage equals twice the output voltage:

$$
\mathrm{V}_{\text {SUP }}=2 \times \mathrm{V}_{\text {OUT }}
$$

therefore:

$$
\mathrm{I}_{\mathrm{RMS}}=\frac{\mathrm{I}_{\mathrm{LOAD}(\mathrm{MAX})}}{\mathrm{V}_{\mathrm{SUP}}}
$$

Choose an input capacitor that exhibits less than $+10^{\circ} \mathrm{C}$ self-heating temperature rise at the RMS input current for optimal long-term reliability.
The input-voltage ripple is comprised of $\Delta V_{Q}$ (caused by the capacitor discharge) and $\Delta V_{E S R}$ (caused by the ESR of the capacitor). Use low-ESR ceramic capacitors with high ripple-current capability at the input. Assume the contribution from the ESR and capacitor discharge equal to $50 \%$. Calculate the input capacitance and ESR required for a specified input voltage ripple using the following equations:

$$
\mathrm{ESR}_{\mathrm{IN}}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\mathrm{I}_{\mathrm{OUT}}+\frac{\Delta \mathrm{l}_{\mathrm{L}}}{2}}
$$

where:

$$
\Delta \mathrm{I}_{\mathrm{L}}=\frac{\left(\mathrm{V}_{\mathrm{SUP}}-\mathrm{V}_{\mathrm{OUT}}\right) \times \mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{SUP}} \times \mathrm{f}_{\mathrm{SW}} \times \mathrm{L}}
$$

and:

$$
\begin{gathered}
\mathrm{C}_{\mathrm{IN}}=\frac{\mathrm{I}_{\mathrm{OUT}} \times \mathrm{D}(1-\mathrm{D})}{\Delta \mathrm{V}_{\mathrm{Q}} \times \mathrm{f}_{\mathrm{SW}}} \\
\mathrm{D}=\frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {SUPSW }}}
\end{gathered}
$$

where: lout is the maximum output current and $D$ is the duty cycle.

## Output Capacitor

The output filter capacitor must have low enough equivalent series resistance (ESR) to meet output-ripple and loadtransient requirements. The output capacitance must be high enough to absorb the inductor energy while transitioning from full-load to no-load conditions without tripping the overvoltagefault protection. When using high-capacitance, low-ESR capacitors, the filter capacitor's ESR dominates the outputvoltage ripple, so the size of the output capacitor depends on the maximum ESR required to meet the output-voltage ripple (VRIPPLE(P-P)) specifications:

$$
\mathrm{V}_{\mathrm{RIPPLE}(\mathrm{P}-\mathrm{P})}=\mathrm{ESR} \times \mathrm{I}_{\mathrm{LOAD}(\mathrm{MAX})} \times \operatorname{LIR}
$$

The actual capacitance value required relates to the physical size needed to achieve low ESR, as well as to the chemistry of the capacitor technology. Thus, the capacitor is usually selected by ESR and voltage rating rather than by capacitance value.

### 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI

#### Abstract

When using low-capacity filter capacitors, such as ceramic capacitors, size is usually determined by the capacity needed to prevent voltage droop and voltage rise from causing problems during load transients. Generally, once enough capacitance is added to meet the overshoot requirement, undershoot at the rising load edge is no longer a problem. However, low-capacity filter capacitors typically have highESR zeros that can affect the overall stability.

## Compensation Network

The devices use an internal transconductance error amplifier with its inverting input and its output available to the user for external frequency compensation. The output capacitor and compensation network determine the loop stability. The inductor and the output capacitor are chosen based on performance, size, and cost. Additionally, the compensation network optimizes the control-loop stability.
The converter uses a current-mode-control scheme that regulates the output voltage by forcing the required current through the external inductor. The devices use the voltage drop across the high-side MOSFET to sense inductor current. Current-mode control eliminates the double pole in the feedback loop caused by the inductor and output capacitor, resulting in a smaller phase shift and requiring less elaborate error-amplifier compensation than voltage-mode control. Only a simple single series resistor $\left(\mathrm{R}_{\mathrm{C}}\right)$ and capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$ are required to have a stable, high-bandwidth loop in applications where ceramic capacitors are used for output filtering (see Figure 3). For other types of capacitors, due to the higher capacitance and ESR, the frequency of the zero created by the capacitance and ESR is lower than the desired closed-loop crossover frequency. To stabilize a nonceramic output-capacitor loop, add another compensation capacitor ( $\mathrm{C}_{\mathrm{F}}$ ) from COMP to ground to cancel this ESR zero.
The basic regulator loop is modeled as a power modulator, output feedback divider, and an error amplifier. The power modulator has a DC gain set by $\mathrm{gm}_{\mathrm{m}} \times \mathrm{R}_{\text {LOAD }}$, with a pole and zero pair set by RLOAD, the output capacitor (COUT), and its ESR. The following equations help to approximate the value for the gain of the power modulator ( $\mathrm{GAIN}_{\mathrm{MOD}}(\mathrm{dc})$ ), neglecting the effect of the ramp stabilization. Ramp stabilization is necessary when the duty cycle is above $50 \%$ and is internally done for the devices:

$$
\begin{gathered}
\operatorname{GAIN}_{\mathrm{MOD}(\mathrm{dc})}=\mathrm{g}_{\mathrm{mc}} \times \mathrm{R}_{\mathrm{LOAD}} \\
\text { where } \mathrm{R}_{\mathrm{LOAD}}=\mathrm{V}_{\mathrm{OUT}} / \mathrm{l}_{\mathrm{OUT}(\mathrm{MAX})} \text { in } \Omega \text { and } \mathrm{g}_{\mathrm{mc}}=3 \mathrm{~S} .
\end{gathered}
$$

In a current-mode step-down converter, the output capacitor, its ESR, and the load resistance introduce a pole at the following frequency:

$$
\mathrm{f}_{\mathrm{pMOD}}=\frac{1}{2 \pi \times \mathrm{C}_{\text {OUT }} \times \mathrm{R}_{\text {LOAD }}}
$$

The output capacitor and its ESR also introduce a zero at:

$$
\mathrm{f}_{\mathrm{ZMOD}}=\frac{1}{2 \pi \times \mathrm{ESR} \times \mathrm{C}_{\mathrm{OUT}}}
$$

When Cout is composed of " n " identical capacitors in parallel, the resulting COUT $=n \times \operatorname{COUT}(E A C H)$, and $E S R=\operatorname{ESR}(E A C H) / n$. Note that the capacitor zero for a parallel combination of alike capacitors is the same as for an individual capacitor.
The feedback voltage-divider has a gain of GAIN $_{\text {FB }}=$ $\mathrm{V}_{\mathrm{FB}} / \mathrm{V}_{\text {OUT }}$, where $\mathrm{V}_{\mathrm{FB}}$ is 1 V (typ).
The transconductance error amplifier has a DC gain of $\operatorname{GAIN}_{\mathrm{EA}(\mathrm{DC})}=g_{m_{2} E A} \times$ ROUT_EA, where $g_{m_{2} E A}$ is the error amplifier transconductance, which is $700 \mu \mathrm{~S}$ (typ), and ROUT_EA is the output resistance of the error amplifier ( $50 \mathrm{M} \Omega$ ).

Figure 3. Compensation Network

### 3.5V-36V, 2A/3A, Synchronous Buck Converter with $15 \mu \mathrm{~A}$ Quiescent Current and Reduced EMI

A dominant pole ( $f_{d p E A}$ ) is set by the compensation capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$ and the amplifier output resistance (ROUT EA). A zero ( $f_{\text {ZEA }}$ ) is set by the compensation resistor $\left(\bar{R}_{C}\right)$ and the compensation capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$. There is an optional pole (fPEA) set by $\mathrm{C}_{\mathrm{F}}$ and $\mathrm{R}_{\mathrm{C}}$ to cancel the output capacitor ESR zero if it occurs near the crossover frequency ( $\mathrm{f}_{\mathrm{C}}$, where the loop gain equals $1(0 \mathrm{~dB})$ ). Thus:

$$
\begin{gathered}
f_{z E A}=\frac{1}{2 \pi \times C_{C} \times R_{C}} \\
f_{\text {pdEA }}=\frac{1}{2 \pi \times C_{C} \times\left(R_{O U T}, E A+R_{C}\right)} \\
f_{p E A}=\frac{1}{2 \pi \times C_{F} \times R_{C}}
\end{gathered}
$$

The loop-gain crossover frequency ( $\mathrm{f}_{\mathrm{C}}$ ) should be set below $1 / 5$ of the switching frequency and much higher than the power-modulator pole ( $\mathrm{f}_{\mathrm{pMOD}}$ )

$$
f_{\mathrm{PMOD}} \ll \mathrm{f}_{\mathrm{C}} \leq \frac{\mathrm{f}_{\mathrm{SH}}}{5}
$$

The total loop gain as the product of the modulator gain, the feedback voltage divider gain, and the error amplifier gain at $\mathrm{f}_{\mathrm{C}}$ should be equal to 1 . So:

$$
\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})} \times \frac{\mathrm{V}_{\mathrm{FB}}}{\mathrm{~V}_{\mathrm{OUT}}} \times \mathrm{GAIN}_{\mathrm{EA}(\mathrm{fC})}=1
$$

For the case where $f z M O D$ is greater than ${ }^{f} \mathrm{C}$ :

$$
\mathrm{GAIN}_{\mathrm{EA}(\mathrm{fC})}=g_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}}
$$

Therefore:

$$
\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})} \times \frac{\mathrm{V}_{\mathrm{FB}}}{V_{\mathrm{OUT}}} \times \mathrm{g}_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}}=1
$$

Solving for $\mathrm{R}_{\mathrm{C}}$ :

$$
\mathrm{R}_{\mathrm{C}}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~g}_{\mathrm{m}, \mathrm{EA}} \times \mathrm{V}_{\mathrm{FB}} \times \mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})}}
$$

Set the error-amplifier compensation zero formed by $\mathrm{R}_{\mathrm{C}}$ and $C_{C}\left(f_{z E A}\right)$ at the $f_{p M O D}$. Calculate the value of $C_{C}$ a follows:

$$
\mathrm{C}_{\mathrm{C}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{pMOD}} \times \mathrm{R}_{\mathrm{C}}}
$$

If $\mathrm{f}_{\mathrm{ZMOD}}$ is less than $5 \times \mathrm{f}_{\mathrm{C}}$, add a second capacitor $\left(\mathrm{C}_{\mathrm{F}}\right)$ from COMP to GND and set the compensation pole formed by $R_{C}$ and $C_{F}\left(f_{p E A}\right)$ at the $f_{Z M O D}$. Calculate the value of $C_{F}$ as follows:

$$
\mathrm{C}_{\mathrm{F}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{zMOD}} \times \mathrm{R}_{\mathrm{C}}}
$$

As the load current decreases, the modulator pole also decreases; however, the modulator gain increases accordingly and the crossover frequency remains the same. For the case where $f_{Z M O D}$ is less than $f_{C}$ :
The power-modulator gain at $\mathrm{f}_{\mathrm{C}}$ is:

$$
\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})}=\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{dc})} \times \frac{\mathrm{f}_{\mathrm{pMOD}}}{\mathrm{f}_{\mathrm{zMOD}}}
$$

The error-amplifier gain at $f_{C}$ is:

$$
\mathrm{GAIN}_{\mathrm{EA}(\mathrm{fC})}=\mathrm{g}_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}} \times \frac{\mathrm{f}_{\mathrm{zMOD}}}{\mathrm{f}_{\mathrm{C}}}
$$

Therefore:

$$
\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})} \times \frac{\mathrm{V}_{\mathrm{FB}}}{V_{\mathrm{OUT}}} \times \mathrm{g}_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}} \times \frac{\mathrm{f}_{\mathrm{zMOD}}}{\mathrm{f}_{\mathrm{C}}}=1
$$

Solving for RC:

$$
\mathrm{R}_{\mathrm{C}}=\frac{\mathrm{V}_{\mathrm{OUT}} \times \mathrm{f}_{\mathrm{C}}}{g_{\mathrm{m}, \mathrm{EA}} \times \mathrm{V}_{\mathrm{FB}} \times \mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})} \times \mathrm{f}_{\mathrm{zMOD}}}
$$

Set the error-amplifier compensation zero formed by $\mathrm{R}_{\mathrm{C}}$ and $C_{C}$ at the $f_{p M O D}\left(f_{z E A}=f_{p M O D}\right)$.

$$
\mathrm{C}_{\mathrm{C}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{pMOD}} \times \mathrm{R}_{\mathrm{C}}}
$$

If $\mathrm{f}_{\mathrm{ZMOD}}$ is less than $5 \times \mathrm{f}_{\mathrm{C}}$, add a second capacitor $\mathrm{C}_{\mathrm{F}}$ from COMP to AGND. Set $f_{p E A}=f_{z M O D}$ and calculate $C_{F}$ as follows:

$$
C_{F}=\frac{1}{2 \pi \times f_{z M O D} \times R_{C}}
$$

## PCB Layout Guidelines

Careful PCB layout is critical to achieve low switching losses and clean, stable operation. Use a multilayer board whenever possible for better noise immunity and power dissipation. Follow these guidelines for good PC board layout:

1) Use a large contiguous copper plane under the device package. Ensure that all heat-dissipating components have adequate cooling. The bottom pad of the devices must be soldered down to this copper plane for effective heat dissipation and getting the full power out of the devices. Use multiple vias or a single large via in this plane for heat dissipation
2) Isolate the power components and high current path from the sensitive analog circuitry. This is essential to prevent any noise coupling into the analog signals.
3) Keep the high-current paths short, especially at the PGND terminals. This practice is essential for stable, jitter-free operation. The high current path comprising of input capacitor, high-side FET, inductor, and the output capacitor should be as short as possible.
4) Keep the power traces and load connections short. This practice is essential for high efficiency. Use thick copper PCBs (2oz vs. 1oz) to enhance full-load efficiency.
5) The analog signal lines should be routed away from the high-frequency planes. This ensures integrity of sensitive signals feeding back into the IC.
6) The ground connection for the AGND and PGND section should be close to the IC. This keeps the ground current loops to a minimum. In cases where only one ground is used, adequate isolation between analog return signals and high-power signals must be maintained.
