

# MAX17823H

## 12-Channel, High-Voltage Data-Acquisition Systems

### General Description

The MAX17823H are data-acquisition systems for the management of high-voltage battery modules. The systems feature a 12-bit SAR ADC that can measure 12 cell voltages and two temperatures in 161 $\mu$ s. There are 12 internal switches for cell balancing and extensive built-in diagnostics. Up to 32 devices can be daisy-chained together to manage 384 cells and monitor 64 temperatures.

Cell voltages (0 to 5V) are measured differentially over a 65V common-mode range. Cell measurements have a typical accuracy of 2mV (3.6V cell, +25°C). If oversampling is enabled, up to 128 measurements per channel can be averaged internally with 14-bit resolution. The system can shut itself down in the event of a thermal overload by measuring its own die temperature.

The systems use Maxim's battery-management UART protocol for robust communications and when used in conjunction with the MAX17880 12-channel battery monitor, they are ideal for automotive battery-management systems that require a high safety-integrity level.

### Applications

- High-Voltage Battery Stacks
- Electric Vehicles (EVs)
- Hybrid Electric Vehicles (HEVs)
- Electric Bikes
- Battery-Backup Systems (UPS)
- Super-Cap Systems
- Battery-Powered Tools

**Ordering Information** appears at end of data sheet.

### Benefits and Features

- AECQ-100 Grade 2 Temperature Range
  - -40°C to +105°C
- Operating Voltage from 9V to 65V
- Ultra-Low Power Operation
  - Standby Mode: 2mA
  - Shutdown Mode: 2 $\mu$ A
- 12 Cell-Voltage-Measurement Channels
  - 2mV Accuracy (3.6V, +25°C)
  - 5mV Accuracy (0°C to +45°C)
  - 10mV Accuracy (-40°C to +105°C)
- 12 Cell-Balancing Switches
  - Up to 650mA per Switch
  - Emergency-Discharge Mode
- Two Temperature-Measurement Channels
- Die Temperature Measurement
- Automatic Thermal Protection
- 29 Voltage Threshold Alerts
  - 12 Overvoltage Faults
  - 12 Undervoltage Faults
  - Two Overtemperature Faults
  - Two Undertemperature Faults
  - One Cell-Mismatch Alert (Highest Cell vs. Lowest Cell)
- Four GPIOs
- Built-in Diagnostics to Support ASIL D and FMEA Requirements
- Battery-Management UART Protocol
  - Daisy-Chain Up to 32 Devices
  - Communication Port Isolation
  - Up to 2Mbps Baud Rate (Autodetect)
  - 1.5 $\mu$ s Propagation Delay per Device
  - Packet-Error Checking (PEC)
- Factory-Trimmed Oscillators
  - No External Crystals Required
- 10mm x 10mm Package (64-Pin LQFP)

SHDNL to AGND .....	-0.3 to $V_{DCIN} + 0.3V$	Soldering Lead Temperature (10s, max) .....	300°C
CTG to AGND .....	-0.3V to +6V		
RXLP, RXLN, RXUP, RXUN to AGND .....	-30V to +30V		
TXLP, TXLN to GNDL2 .....	-0.3V to +6V		
TXUP, TXUN to GNDL3 .....	-0.3V to +6V		

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

- Note 1:** Balancing switches disabled.
- Note 2:** One balancing switch enabled, 60s maximum.
- Note 3:** Average power for time period  $\tau$  where  $\tau$  is the time constant (in  $\mu s$ ) of the transient diode current during hot-plug event. For, example, if  $\tau$  is 330 $\mu s$ , the maximum average power is 0.793W. Peak current must never exceed 2A. Actual average power during hot-plug must be calculated from the diode current waveform for the application circuit and compared to the maximum rating.
- Note 4:** Multilayer board. For  $T_A > 70^\circ C$  derate 25mW/ $^\circ C$ .

**Electrical Characteristics**

( $V_{DCIN} = +48V$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted, where  $T_{MIN} = -40^\circ C$  and  $T_{MAX} = +105^\circ C$ . Typical values are at  $T_A = +25^\circ C$ . Operation is with the recommended application circuit.) (Note 5)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
<b>POWER REQUIREMENTS</b>						
Supply Voltage	$V_{DCIN}$		9		65	V
DCIN Current, Shutdown Mode	$I_{DCSHDN}$	$V_{SHDNL} = 0V$		0.1	2	$\mu A$
DCIN Current, Standby Mode (Note 16)	$I_{DCSTBY}$	$V_{SHDNL} > 1.8V$ , UART in idle mode, not in acquisition mode, BALSWEEN, CTSTEN = 0000h	1.4	2.0	2.6	mA
DCIN Current, Acquisition Mode (Note 16)	$I_{DCMEAS}$	MEASUREEN = 0FFFh, acquisition mode	3.5	5.4	8.5	mA
Incremental DCIN Current, Communication Mode (Note 16)	$I_{DCCOMM}$	Baud rate = 2Mb/s (0% idle time preambles mode), 200pF load on TXUP, 200pF on TXUN, TXL not active, not in acquisition mode, BALSWEEN, CTSTEN = 0000h		1.5	3	mA
HV Current, Acquisition Mode	$I_{HVMEAS}$	Acquisition mode, MEASUREEN = 0FFFh, $V_{HV} = V_{DCIN} + 5.5V$	0.9	1.1	1.3	mA

**Electrical Characteristics (continued)**

( $V_{DCIN} = +48V$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted, where  $T_{MIN} = -40^{\circ}C$  and  $T_{MAX} = +105^{\circ}C$ . Typical values are at  $T_A = +25^{\circ}C$ . Operation is with the recommended application circuit.) (Note 5)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Incremental HV Current, Cell-Balancing Mode	$I_{HVBAL}$	$V_{HV} = V_{DCIN} + 5.5V$ , n balancing switches enabled	(n+1) x 5	(n+1) x 15.5	(n+1) x 26	$\mu A$

RX Fall Time (Notes 7, 8)	$t_{FALL}$				0.5	$t_{BIT}$
RX Rise Time (Notes 7, 8)	$t_{RISE}$				0.5	$t_{BIT}$

**Electrical Characteristics (continued)**

( $V_{DCIN} = +48V$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted, where  $T_{MIN} = -40^{\circ}C$  and  $T_{MAX} = +105^{\circ}C$ . Typical values are at  $T_A = +25^{\circ}C$ . Operation is with the recommended application circuit.) (Note 5)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Propagation Delay (RX Port to TX Port)	$t_{PROP}$			2.5	3	$t_{BIT}$
Startup Time from SHNDL High and $V_{AA} = 0V$ , to RXUP/RXUN Valid	$t_{STARTUP}$			1		ms

- Note 5:** Unless otherwise noted, limits are 100% production tested at  $T_A = +25^{\circ}C$ . Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization.
- Note 6:** Maximum limited by application circuit.
- Note 7:** Guaranteed by design and not production tested.
- Note 8:** Fall time measured 90% to 10%; rise time measured 10% to 90%.
- Note 9:** Differential signal ( $V_{RXP} - V_{RXN}$ ) where  $V_{RXP}$  and  $V_{RXN}$  do not exceed a common-mode voltage range of  $\pm 25V$ .
- Note 10:**  $I_{SHDNL}$  measured with  $V_{SHDNL} = 0.3V$ , STOP characters, zero idle time,  $V_{RX\_PEAK} = 3.3V$
- Note 11:**  $V_{CELLn} = V_{Cn} - V_{Cn-1}$ , range over which measurement settling time and accuracy is guaranteed.
- Note 12:**  $V_{CELLn} = V_{Cn} - V_{Cn-1}$ ,  $V_{CELLn} = V_{CELLn-1}$ , and  $V_{DCIN} = 12 \times |V_{CELLn}|$  (9V min). No oversampling enabled (OVSAMPL[2:0] = 0). Average of 64 acquisitions.
- Note 13:**  $V_{DDL} = V_{DDL2}$  for lower port and  $V_{DDL} = V_{DDL3}$  for upper port.
- Note 14:** As measured during specified diagnostic mode.
- Note 15:** Not production tested. See the Cell-Balancing section for details on the maximum allowed balancing current. Duty cycle is calculated for a 10-year device lifetime.
- Note 16:** Acquisition mode (ADC conversions) is entered when the SCAN bit is set and ends when SCANDONE is set. With the typical acquisition duty cycle very low, the average current ( $I_{DCIN}$ ) is much less than  $I_{DCMEAS}$ . Total supply current during communication  $I_{DCIN} = I_{DCCOMM} + I_{DCSTBY}$ .
- Note 17:** In daisy-chain applications, the bit time of the second stop bit may be less than specified to account for clock-rate variation and sampling error between devices.
- Note 18:** Charge-pump efficiency =  $\Delta I_{LOAD} / \Delta I_{SUPPLY}$ , where  $I_{LOAD}$  is applied from HV to AGND,  $\Delta I_{LOAD} = 5mA$ , and  $\Delta I_{SUPPLY} = I_{DCIN}$  (for  $I_{LOAD} = 5mA$ ) -  $I_{DCIN}$  (for  $I_{LOAD} = 0$ ).

**Typical Operating Characteristics**

Pin Configuration

## Pin Description

PIN	NAME	FUNCTION	DESCRIPTION
1	N.C.	N.C.	Not Connected. Connect to ground or leave unconnected.
2	AGND	Ground	Analog Ground. Connect to negative terminal of cell 1 and ground plane.
3	SHDNL	Input	Shutdown Active-Low Input. Drive > 1.8V to enable operation, and drive < 0.6V to reset device and place in shutdown mode. +72V tolerant. If not driven externally, this input can be controlled solely through UART communication and software control. Bypass with a 1nF capacitor to AGND. For single-ended UART, SHDNL must be driven externally.
4	AGND	Ground	Analog Ground. Connect to negative terminal of cell 1 and ground plane.
5	V <sub>AA</sub>	Power	3.3V Regulator Output Used to Supply V <sub>DDL1</sub> , V <sub>DDL2</sub> , and V <sub>DDL3</sub> . Bypass with a 1μF capacitor to ground.
6	TXUN	Output	Negative Output for Upper-Port Transmitter. Driven between V <sub>DDL3</sub> and GNDL3.
7	TXUP	Output	Positive Output for Upper-Port Transmitter. Driven between V <sub>DDL3</sub> and GNDL3.
8	GNDL1	Ground	Digital Ground. Connect to ground plane.
9	V <sub>DDL1</sub>	Power	3.3V Digital Supply. Connect externally to V <sub>AA</sub> and bypass with 0.47μF capacitor to GNDL1.
10	GNDL3	Ground	Ground for Upper-Port Transmitter. Connect to ground plane.
11	V <sub>DDL</sub>	Power	3.3V Supply for Upper-Port Transmitter. Connect externally to V <sub>AA</sub> and bypass with 0.47μF capacitor to GNDL3.
12	RXUN	Input	Negative Input for Upper-Port Receiver. Tolerates ±30V.
13	RXUP	Input	Positive Input for Upper-Port Receiver. Tolerates ±30V. Connect to ground for single-ended operation.
14	GPIO3	I/O	General-Purpose I/O 3. Driven between V <sub>DDL1</sub> and GNDL1. 2MΩ internal pulldown.
15	GPIO2	I/O	General-Purpose I/O 2. Driven between V <sub>DDL1</sub> and GNDL1. 2MΩ internal pulldown.
16	GPIO1	I/O	General-Purpose I/O 1. Driven between V <sub>DDL1</sub> and GNDL1. 2MΩ internal pulldown.
17	GPIO0	I/O	General-Purpose I/O 0. Driven between V <sub>DDL1</sub> and GNDL1. 2MΩ internal pulldown.
18	N.C.	N.C.	Not Connected. Connect to ground or leave unconnected.
19	N.C.	N.C.	Not Connected. Connect to ground or leave unconnected.
20	TXLP	Output	Positive output for lower port transmitter. Driven between V <sub>DDL2</sub> and GNDL2.
21	TXLN	Output	Negative Output for Lower-Port Transmitter. Driven between V <sub>DDL2</sub> and GNDL2.
22	V <sub>DDL2</sub>	Power	3.3V Supply for Lower-Port Transmitter. Connect externally to V <sub>AA</sub> and bypass with 0.47μF capacitor to GNDL2.
23	GNDL2	Ground	Ground for Lower-Port Transmitter. Connect to ground plane.
24	RXLP	Input	Positive Input for Lower-Port Receiver. Tolerates ±30V. Connect to ground for single-ended operation.

## Pin Description (continued)

PIN	NAME	FUNCTION	DESCRIPTION
25	RXLN	Input	Negative Input for Lower-Port Receiver. Tolerates $\pm 30V$ .
26	N.C.	N.C.	Not Connected. Connect to ground or leave unconnected.
27	N.C.	N.C.	Not Connected. Connect to ground or leave unconnected.
28	CTG	Input	Reserved for Factory Use. Connect to ground.
29	AUXIN2	Input	Auxiliary Voltage Input 2 to Measure External Temperature. Connect to a voltage-divider consisting of a 10k $\Omega$ pullup to THRM and 10k $\Omega$ NTC thermistor to ground. If not used, connect to the pullup only.
30	AUXIN1	Input	Auxiliary Voltage Input 1 to Measure External Temperature. Connect to a voltage-divider consisting of a 10k $\Omega$ pullup to THRM and a 10k $\Omega$ NTC thermistor to ground. If not used, connect to the pullup only.
31	AGND	Ground	Analog Ground. Connect to negative terminal of cell 1 and ground plane.
32	THRM	Power	3.3V Switched Output Used to Supply the Voltage-Dividers for the Auxiliary Inputs. The output is enabled only during measurements, or as configured by THRM <sub>MODE</sub> [1:0]. This output can source up to 2mA.
33	SW0	Input	Balance Input for Cell 1 Negative
34	C0	Input	Voltage Input for Cell 1 Negative. Connect to AGND.
35	SW1	Input	Balance Input for Cell 1 Positive (Cell 2 Negative)
36	C1	Input	Voltage Input for Cell 1 Positive (Cell 2 Negative)
37	SW2	Input	Balance Input for Cell 2 Positive (Cell 3 Negative)
38	C2	Input	Voltage Input for Cell 2 Positive (Cell 3 Negative)
39	SW3	Input	Balance Input for Cell 3 Positive (Cell 4 Negative)
40	C3	Input	Voltage Input for Cell 3 Positive (Cell 4 Negative)
41	SW4	Input	Balance Input for Cell 4 Positive (Cell 5 Negative)
42	C4	Input	Voltage Input for Cell 4 Positive (Cell 5 Negative)
43	SW5	Input	Balance Input for Cell 5 Positive (Cell 6 Negative)
44	C5	Input	Voltage Input for Cell 5 Positive (Cell 6 Negative)
45	SW6	Input	Balance Input for Cell 6 Positive (Cell 7 Negative)
46	C6	Input	Voltage Input for Cell 6 Positive (Cell 7 Negative)
47	SW7	Input	Balance Input for Cell 7 Positive (Cell 8 Negative)
48	C7	Input	Voltage Input for Cell 7 Positive (Cell 8 Negative)
49	SW8	Input	Balance Input for Cell 8 Positive (Cell 9 Negative)

## Pin Description (continued)

PIN	NAME	FUNCTION	DESCRIPTION
50	C8	Input	Voltage Input for Cell 8 Positive (Cell 9 Negative)
51	SW9	Input	Balance Input for Cell 9 Positive (Cell 10 Negative)
52	C9	Input	Voltage Input for Cell 9 Positive (Cell 10 Negative)
53	SW10	Input	Balance Input for Cell 10 Positive (Cell 11 Negative)
54	C10	Input	Voltage Input for Cell 10 Positive (Cell 11 Negative)
55	SW11	Input	Balance Input for Cell 11 Positive (Cell 12 Negative)
56	C11	Input	Voltage Input for Cell 11 Positive (Cell 12 Negative)
57	SW12	Input	Balance Input for Cell 12 Positive
58	C12	Input	Voltage Input for Cell 12 Positive
59	V <sub>BLKP</sub>	Input	Block Voltage Positive Input. Internal 10M $\Omega$ pulldown during measurement.
60	NC	NC	Not Connected. Connect to ground or leave unconnected.
61	HV	Power	Decoupling-Capacitor Connection for the HV Charge Pump. $V_{HV} = V_{DCIN} + 5.5V$ (typ). Bypass with a 50V, 4.7 $\mu$ F capacitor to DCIN.
62	DCIN	Power	DC Supply for the Low-Voltage Regulator, HV Charge Pump, and SHDNL Charge Pump. Connect to a voltage source between 9V and 65V through a 100 $\Omega$ series resistor. Bypass with a 100V, 2.2 $\mu$ F capacitor to ground.
63	CPP	Power	Positive Capacitor Connection for the HV Charge Pump. Connect a 100V, 0.1 $\mu$ F capacitor from CPP to CPN.
64	CPN	Power	Negative Capacitor Connection for the HV Charge Pump

## Detailed Description

The MAX17823H data-acquisition systems consist of the major blocks shown in [Figure 1](#) and described in [Table 1](#).

**Table 1. System Blocks**

BLOCK	DESCRIPTION
ADC	Analog-to-digital converter. Uses a 12-bit successive-approximation register (SAR) with a reference voltage of 2.307V and supplied by $V_{AA}$ .
HVMUX	12-channel, high-voltage (65V) differential multiplexer for $C_n$ inputs.
HV CHARGE PUMP	High-voltage charge-pump supply ( $V_{DCIN} + 5.5V$ ) for the HVMUX, ALTMUX, BALSU, and LSAMP circuits, which must switch high-voltage signals. Supplied by DCIN.
LSAMP	Level-shifting amplifier with a gain of 6/13. The result is that a 5V differential signal is attenuated to 2.307V, which is the reference voltage for the ADC.
LVMUX	Multiplexes various low-voltage signals including the level-shifted signals and temperature signals to the ADC for subsequent A-to-D conversion.
ALTMUX	12-channel, high-voltage differential multiplexer for $SW_n$ inputs.
BALSU	Cell-balancing switches.
LINREG	3.3V ( $V_{AA}$ ) linear regulator used to power the ADC and digital logic. Supplied by DCIN (9V to 65V).
REF	2.307V precision reference voltage for ADC and LINREG. Temperature compensated.
ALTREF	1.242V precision reference voltage used for diagnostics.
16MHz OSC	16MHz oscillator with 2% accuracy for clocking state-machines and UART timing.
32kHz OSC	32,768Hz oscillator for driving charge pumps and timers.
LOWER PORT	Differential UART for communication with host or downstack devices. Auto-detects baud rates of 0.5Mbps, 1Mbps, or 2Mbps.
UPPER PORT	Differential UART for communication with upstack devices.
CONTROL AND STATUS	ALUs, control logic, and data registers
DIE TEMP	A proportional-to-absolute-temperature (PTAT) voltage source used to measure the die temperature.

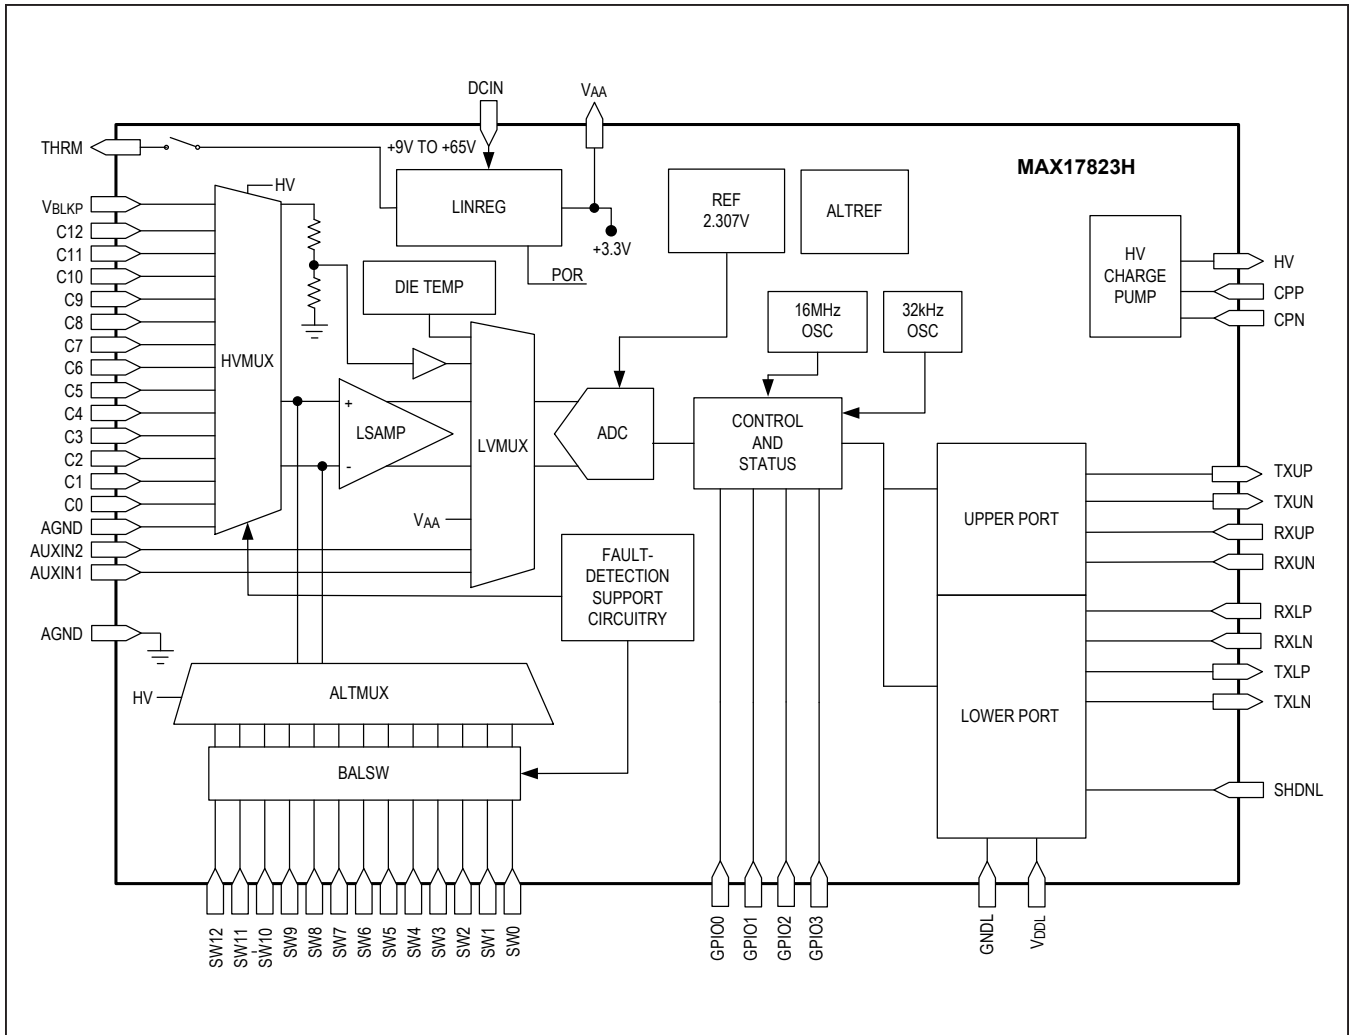

Figure 1. Functional Block Diagram

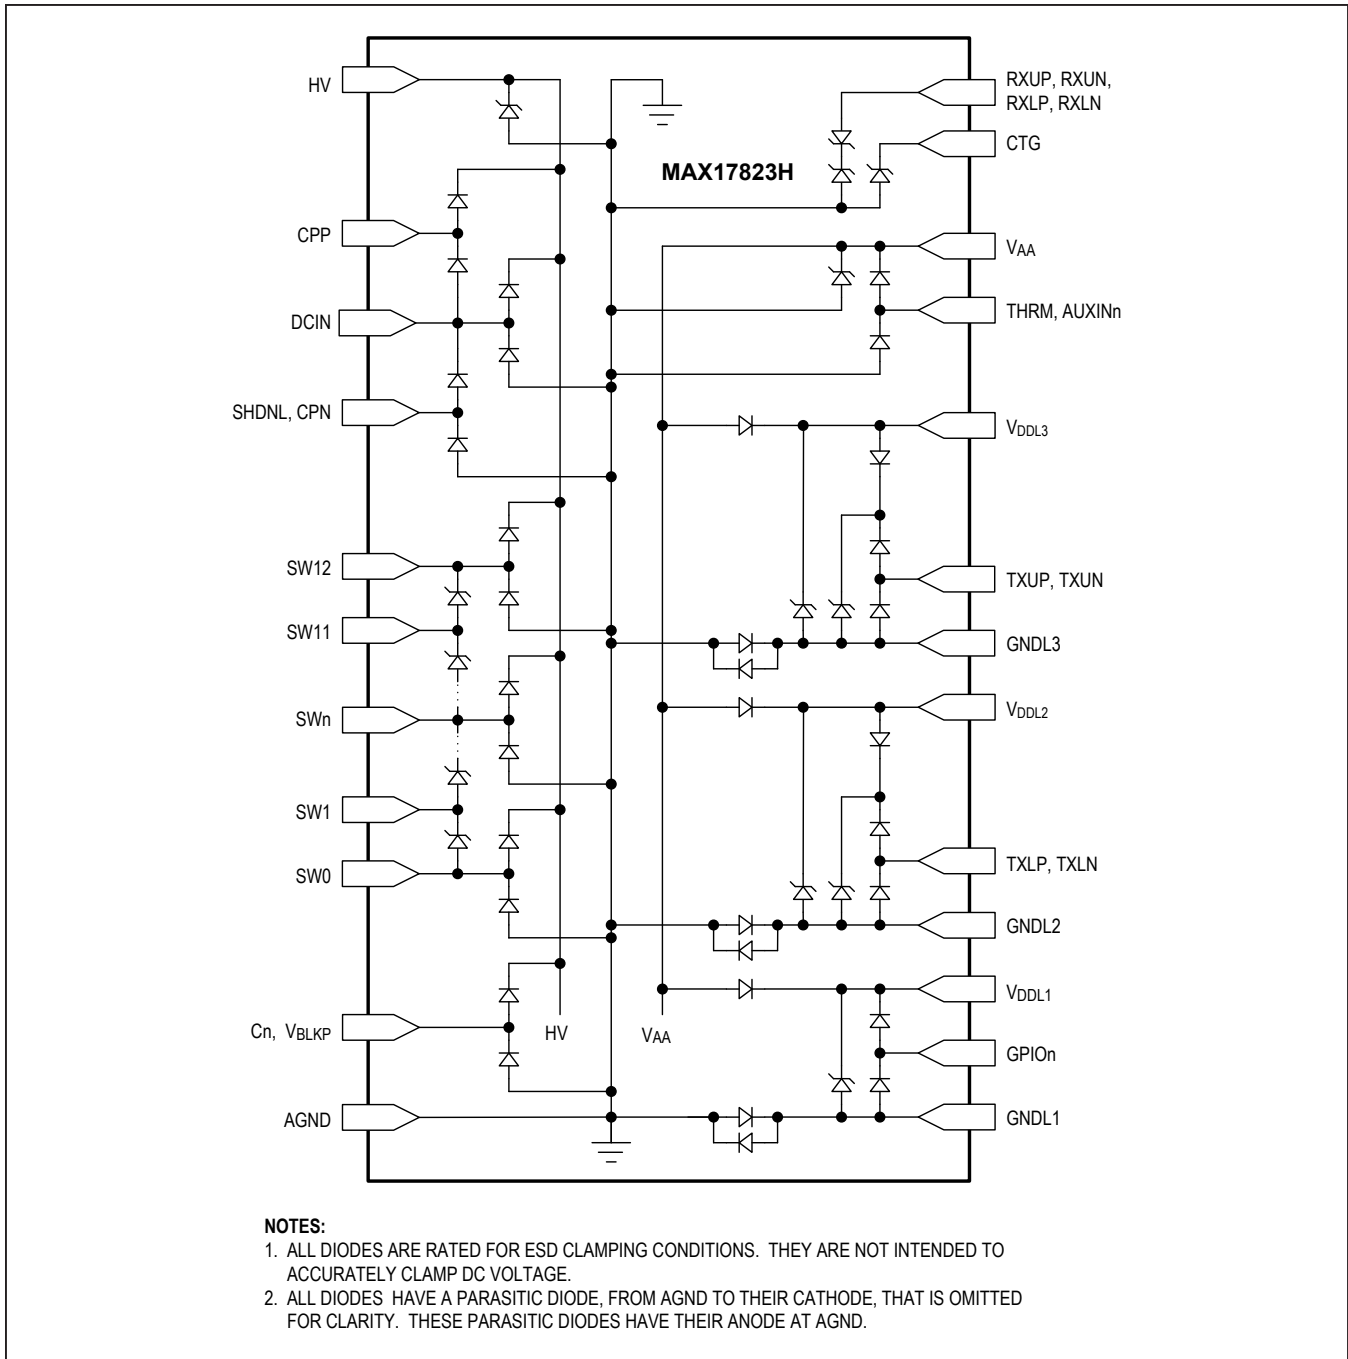

Figure 2. ESD Diodes

Figure 3. Analog Front-End

### Data Conventions

Representation of data follows the conventions shown in [Table 2](#). All registers are 16-bit words.

### Data Acquisition

A data acquisition is composed of the distinct processes defined in [Table 3](#) and controlled by various configuration registers described in this section. Configuration changes should be made prior to the acquisition in which the changes are to be effected.

### Precision Internal Voltage References

The measurement system uses two precision, temperature-compensated voltage references. The references are completely internal to the device and do not require any external components. The primary voltage refer-

ence, or REF, is used to derive the linear regulator output voltage and to supply the ADC reference. An alternate, independent reference, ALTREF, can be used to verify the primary reference voltage as described in the [Diagnostics](#) section.

### Measurement Calibration

The acquisition system is calibrated at the factory and cannot be changed afterwards. The calibration parameters are stored in a ROM consisting of 12 read-only registers, CAL0–CAL10 and CAL15. ROMCRC[8:0] is an 8-bit CRC value based on the calibration ROM and is stored in ID2[15:8] at the factory. ROMCRC[8:0] can be used to check the integrity of the calibration as described in the [Diagnostics](#) section.

**Table 2. Numeric Conventions**

DESCRIPTION	CONVENTION	EXAMPLE
Binary number	0b prefix	0b01100001 = 61h
Hexadecimal address	0x prefix	0x61
Hexadecimal data	h suffix	61h

**Table 3. Data Acquisition Processes**

PROCESS	DESCRIPTION
Conversion	The ADC samples a single input channel, converts it into a 12-bit binary value, and stores it in an ALU register.
Scan	The ADC sequentially performs conversions on all enabled cell input channels.
Measurement cycle or Sample	The ADC performs two scans for the purpose of minimizing error. The conversions (two for each input channel) are averaged together to form a single 14-bit binary value called a measurement. <b>Note:</b> The auxiliary inputs are only scanned once to create the auxiliary measurements.
Acquisition or Acquisition mode	If oversampling is enabled, the ADC takes sequential measurements and averages them together to form one 14-bit binary value for each input channel sampled. If there is no oversampling, the acquisition is essentially a single measurement cycle. <b>Note:</b> The auxiliary inputs are never oversampled and are stored as 12-bit values.

**Cell Inputs**

Up to 12 voltage measurements can be sampled differentially from the 13 cell inputs. The differential signal  $V_{CELLn}$  is defined as  $V_{Cn} - V_{Cn-1}$  for  $n = 1$  to 12.

The cells to be measured are selected by MEASUREEN[11:0]. During the scan, each selected signal is multiplexed into the level-shifting amplifier (LSAMP) as shown in Figure 3. Since the common-mode range of the input signals is 0V to 65V, the signal must be level-shifted to the common-mode range of the amplifier. The amplifier has a gain of 6/13 so that a 5V differential signal will be attenuated to 2.307V, which is the ADC reference voltage.

Once the signal is properly conditioned the ADC can start the conversion. The 12-bit conversion is stored in an ALU register where it can be averaged with subsequent conversions. The ALU output is a 14-bit value and is ultimately stored in a 16-bit register with the two least-significant bits zero. Disabled channels result in a measurement value of 0000h. Unless stated otherwise, measurement values are assumed to be 14-bit values. The 16-bit register values can be converted to 14-bit values by dividing by 4 (and

vice-versa). To convert the measurement value in register CELLn to a voltage, convert the 14-bit hexadecimal value to a decimal value and then convert to voltage as follows:  $V_{CELLn} = CELLn[15:2] \times 5V/16384 = CELLn[15:2] \times 305.176\mu V$ .

**Input Range**

The input range in unipolar mode is nominally 0V to 5V. However, the ADC has reduced linearity at its range extents and so accuracy is specified for the input range 0.2V to 4.8V. Some applications may require specified accuracy below 0.2V or even below 0V. To this end, the bipolar mode (POLARITY = 1) has a nominal input range of -2.5V to 2.5V as shown in Table 4 with accuracy specified from -2.3V to 2.3V.

The input range can effectively be extended from -2.5V to 5V by taking one bipolar measurement and one unipolar measurement. Any bipolar measurements over 2.3V should be replaced with the unipolar measurement.

**Note:** Conversions for some diagnostic modes automatically use either bipolar or unipolar mode regardless of the POLARITY bit value.

**Table 4. Input Range**

CELL INPUT VOLTAGE		CELLn[15:2] (14 BITS)		CELLn[15:0] (16 BITS)
BIPOLAR MODE	UNIPOLAR MODE	HEXADECIMAL	DECIMAL	
-2.5V	0V	0000h	0d	0000h
0V	2.5V	2000h	8192d	8000h
2.5V	5V	3FFFh	16383d	FFFCh

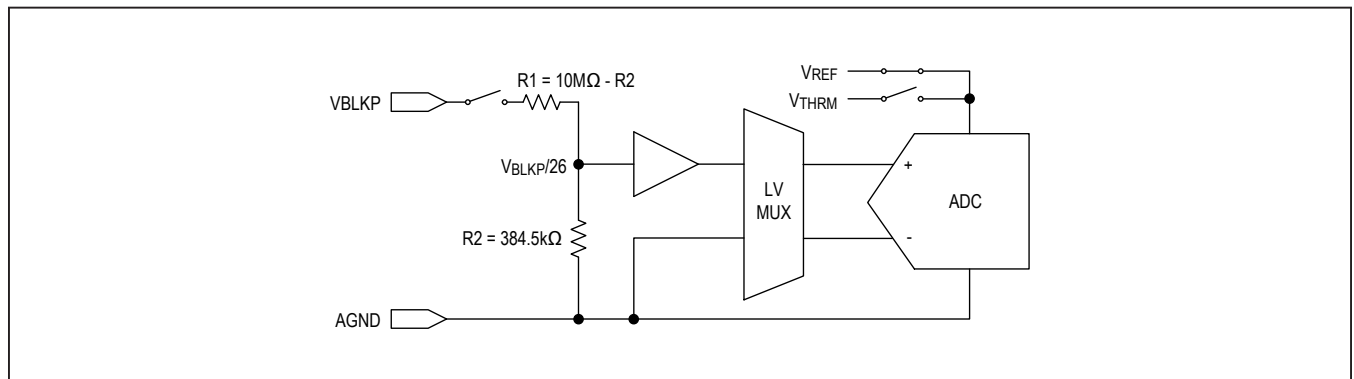

Figure 4.  $V_{BLKP}$  Measurement

**Block Voltage Input**

The  $V_{BLKP}$  input (total module voltage) is selected for measurement by MEASUREEN[14]. The measurement is stored in the VBLOCK register with a full-scale value of 60V (3.662mV/bit). It can be compared to the sum of the cell voltages as a diagnostic. To pre-condition  $V_{BLKP}$  for conversion it is voltage-divided by a factor of 26. The divider is disconnected by default to minimize power consumption. The divider is connected by setting MEASUREEN[15] (BLKCONNECT = 1) with sufficient settling time prior to the acquisition. For high acquisition rates, BLKCONNECT can remain enabled to reduce cycle time.

**Auxiliary Inputs**

The AUXIN1 and AUXIN2 inputs can be used to measure external temperatures by enabling MEASUREEN[13:12]. These inputs have a common-mode input range of 0V to  $V_{AA}$ . For these measurements, the ADC reference voltage is  $V_{THRM}$  which is switched from  $V_{AA}$  as shown in Figure 5. The auxiliary inputs are not oversampled even if oversampling is enabled; they are measured only once and stored as 12-bit values in the AIN1 and AIN2 registers.

To measure external temperature the auxiliary input is connected to a voltage divider consisting of a 10K $\Omega$  pullup to THRM and a 10K $\Omega$  NTC thermistor to ground as shown in Figure 6.

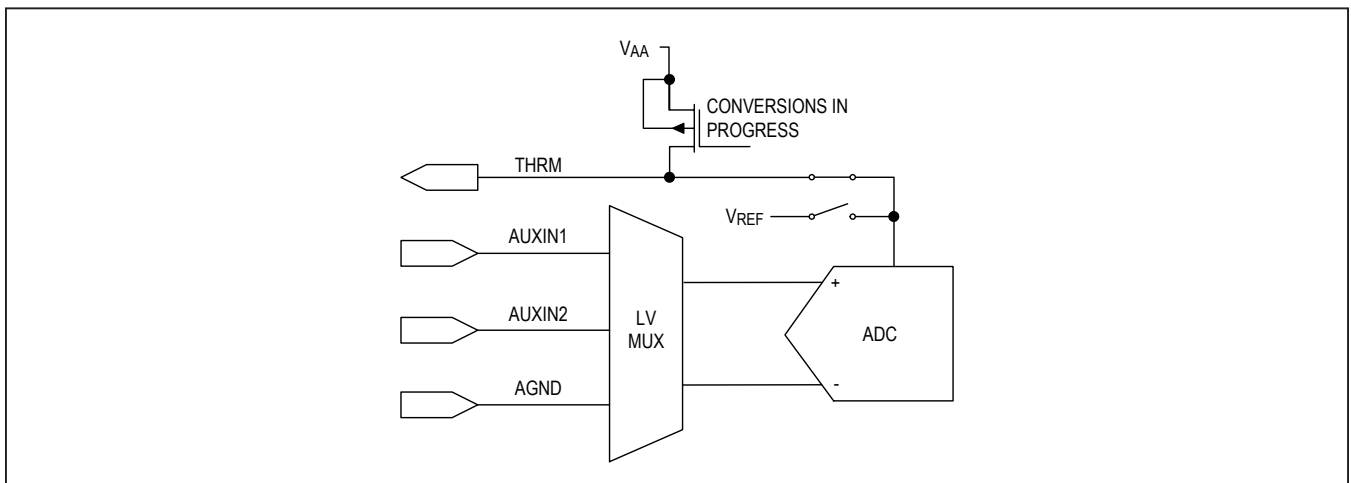

Figure 5. Auxiliary Measurement

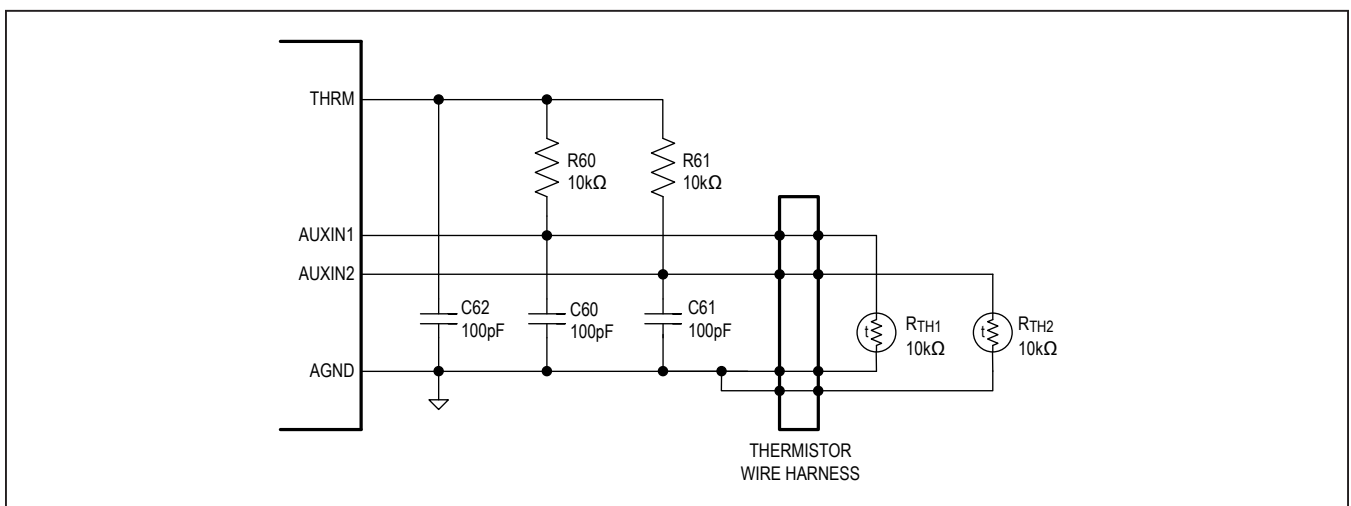

Figure 6. Auxiliary Application Circuit

## THRM Output

The THRM output has 2 modes of operation, automatic and manual as shown in [Table 5](#).

The automatic mode minimizes power consumption, but after the THRM output is enabled, the AUXIN voltages must be allowed to settle before the conversion. Since the auxiliary inputs are the last inputs measured, the duration of the measurement cycle itself may provide sufficient settling time depending on what measurements are enabled and the time constants for the auxiliary input circuit. Up to 384µs of additional settling time, if required, can be configured by ACQCFG[5:0] as shown in [Table 6](#) or by utilizing the manual mode. The ability to configure the settling time allows for a range of time constants to be considered in designing the auxiliary application circuit.

## Computing Temperature

In [Figure 6](#),  $V_{AUXINn} = V_{THRM} \times R_{TH} / (10K\Omega + R_{TH})$  and this measurement is stored in the AINn register. The thermistor resistance can then be solved for as follows:

$$R_{TH} = (V_{THRM} \times 10K\Omega) / (V_{THRM} - V_{AUXINn}) \text{ where } V_{THRM} = 3.3V \text{ nominally}$$

The resistance of an NTC thermistor increases as the temperature decreases and is typically specified by its resistance  $R_0$  at  $T_0 = +25^\circ\text{C} = 298.15\text{K}$  and a material constant  $\beta$  (3400K typical). To the first order, the resistance  $R_{TH}$  is at a temperature  $T$  in Kelvin can be computed as follows:

$$R = R_0 e^{(\beta(1/T - 1/T_0))}$$

The temperature  $T$  of the thermistor (in  $^\circ\text{C}$ ) can then be calculated as follows:

$$T \text{ (in } ^\circ\text{C)} = (\beta / \ln((R_{TH}/10K\Omega) + (\beta/298.15K))) - 273.15K$$

**Table 5. THRM Output**

MODE	ACQCFG[9:8]	DESCRIPTION
Automatic	00b	THRM output enabled at the beginning of the acquisition and disabled at the end of the acquisition.
	01b	
Manual	10b	THRM output is enabled
	11b	THRM output is disabled

## Temperature Alerts

Auxiliary voltage measurements can be directly compared to pre-calculated voltages in the AINUT and AINOT registers that correspond to specific over- and under-temperature thresholds. When a measurement exceeds the AINUT or AINOT threshold level, the ALRTCOLD or ALRTHOT bits respectively are set in the STATUS register. An alert is cleared only by a new measurement that is within threshold.

## Die Temperature Measurement

The die temperature measurement allows the host to compute the device temperature ( $T_{DIE}$ ) as it relates to the acquisition accuracy and allows the device to automatically shut itself down when  $T_{DIE} > 145^\circ\text{C}$ . The measurement employs a source whose voltage,  $V_{PTAT}$ , is proportional to absolute temperature (PTAT) as shown in [Figure 7](#). The VPTAT measurement is enabled by setting DIAGSEL[2:0] to 0b110 and the 14-bit measurement is stored in DIAG[15:2]. The die temperature measurement requires a settling time of 50µs from the start of the measurement cycle until the diagnostic conversion. As long as 2 or more cell measurements are enabled, there will be sufficient settling time for this measurement. Refer to [Figure 9](#) and [Table 8](#) for a detailed view of this timing.

The PTAT voltage is computed as follows:

$$V_{PTAT} = (\text{DIAG}[15:2] / 16384d) \times V_{REF}$$

Where  $V_{REF} = 2.307\text{V}$ . The measured voltage can be converted into  $^\circ\text{C}$  as follows:

$$T_{DIE} \text{ (in } ^\circ\text{C)} = (V_{PTAT} / A_{V\_PTAT}) + T_{OS\_PTAT} - 273^\circ\text{C}$$

Refer to the [Electrical Characteristics](#) table for  $A_{V\_PTAT}$  and  $T_{OS\_PTAT}$  values.

**Table 6. AINTIME**

ACQCFG[5:0] (AINTIME)	ADDITIONAL SETTLING TIME PER ENABLED AUXILIARY CHANNEL = $6\mu\text{s} + (\text{AINTIME} \times 6\mu\text{s})$
00h	$6\mu\text{s}$
01h	$12\mu\text{s}$
02h	$18\mu\text{s}$
...	...
1Fh	$384\mu\text{s}$

### Die Temperature Alert

The ALRTTEMP bit is updated at the end of each measurement cycle for which  $\text{DIAGSEL}[2:0] = 0b110$ . If ALRTTEMP is set, it signifies that  $T_{\text{DIE}} > T_{\text{ALRTTEMP}}$  or that the diagnostic measurement did not have sufficient settling time ( $< 50\mu\text{s}$ ) and therefore may not be accurate. If ALRTTEMP is set, the host should consider the possibility that the acquisition does not meet the expected accuracy specification, or that the die temperature measurement itself may be inaccurate due to insufficient settling time ( $< 2$  cell measurements enabled).

### Acquisition Mode

The host enters the acquisition mode by writing a logic-one to the SCAN bit in the SCANCTRL register. This write is actually an automatic strobe of the bit since SCAN always reads logic-zero. In daisy-chained devices, acquisitions in upstack devices are delayed by the propagation delay,  $t_{\text{PROP}}$ , of the command packet through each device. The acquisition is complete when the device sets the SCANDONE bit. The basic acquisition process is outlined below with a detailed flowchart in [Figure 8](#).

- 1) Disable HV charge pump
- 2)  $V_{\text{BLKP}}$  conversion, if enabled
- 3) All enabled cell conversions (first)
  - a. ascending order (1 through 12) if pyramid mode or
  - b. descending order (12 through 1) if top-down mode
- 4) All enabled cell conversions (second)
  - a. descending order (12 through 1)
- 5)  $V_{\text{BLKP}}$  conversion (second), if enabled
- 6) Diagnostic conversion (first), if enabled
- 7) Diagnostic conversion (second) if enabled
- 8) Enable HV charge pump for recovery period unless
  - a.  $\text{OVSAMP}[2:0] = 0$  (no oversampling) or
  - b. all oversample measurements are complete
- 9) Repeat steps 1 through 8 until all oversamples are done
- 10) All enabled auxiliary conversions, ascending order (AUXIN1, AUXIN2)
- 11) Set SCANDONE bit

Figure 7. Die Temperature Measurement

### Oversampling

Oversampling mode performs multiple measurement cycles in a single acquisition and averages the samples in the ALU to reduce the measurement noise and effectively increase the resolution of each measurement result. In oversampling mode, acquisition times are proportional to the number of oversamples as shown in [Table 8](#). The number of oversamples can be configured from 4 to 128 by  $\text{OVSAMPL}[2:0]$  as shown in [Table 7](#). The AUXIN measurements are never oversampled, even in oversampling mode.

To add  $n$  bits of measurement resolution requires at least  $2^{2n}$  oversamples. Since the ADC resolution is 12 bits, 13-bit resolution requires at least 4 oversamples and to achieve the maximum 14-bit resolution requires at least 16 oversamples. Therefore with no oversampling, only the higher 12-bits of the measurement are statistically significant and with 4 or 8 oversamples, only the higher 13 bits are statistically significant. Taking more than 16 oversamples further reduces the measurement variation.

Of course with no oversampling, measurements can be averaged externally to achieve increased resolution but at a higher computational cost for the host.

### Acquisition Watchdog Timeout

If the acquisition does not finish within a predetermined time interval, the SCANTIMEOUT bit is set, the ADC logic is reset, the ALU registers are cleared, and the measurement data registers are also cleared. In double-buffer mode ( $\text{DBLBUF} = 1$ ), the data registers are not cleared, however, once data is moved from the ALU registers to the data registers, either automatically or manually (with the DATAMOVE bit), then data registers are cleared as a consequence of the ALU register having been cleared. The acquisition watchdog timeout interval depends on the oversampling configuration as shown in [Table 7](#).

Table 7. Oversampling

OVSAMPL[2:0]	OVERSAMPLES	THEORETICAL RESOLUTION	ACQUISITION WATCHDOG TIMEOUT
000b (default)	0	12 bits	1.10ms
001b	4	13 bits	2.08ms
010b	8	13 bits	3.36ms
011b	16	14 bits	5.92ms
100b	32	14 bits	10.99ms
101b	64	14 bits	21.18ms
110b	128	14 bits	41.56ms
111b	128	14 bits	41.56ms

Figure 8. Acquisition Mode Flowchart

**Scan Modes**

The cell, block, and diagnostic measurement cycle consists of two conversion phases. In each phase, the ADC scans through the enabled input channels. There are two scan modes configured by the SCANMODE bit. If SCANMODE = 0, the mode is pyramid mode as shown in Figure 9. If SCANMODE = 1, the mode is top-down mode. In pyramid mode, the ADC scans first ascending and then descending. In top-down mode, the ADC scans descending in both phases. In the second scan, the amplifier inputs are inverted to effectively chop out any offset and

reference-induced errors. The two conversions are then offset corrected and averaged in the ALU.

After the cell and block scans are complete, the diagnostic conversions are made, if enabled, and finally, the auxiliary inputs, if enabled, are converted. The auxiliary inputs are measured using a single conversion and stored in the AIN1 and AIN2 registers. Any extra settling time, if configured by AINCFG[5:0], is implemented just before the conversion for each AUXIN channel and so if both inputs are enabled, the extra settling time occurs twice.

Figure 9. Acquisition, OVSAMP[2:0] = 0h and SCANMODE = 0

Figure 10. Acquisition, OVSAMP[2:0] > 0 and SCANMODE = 0

**Acquisition Time**

The total acquisition time can be calculated by summing all the required processes as shown in [Table 8](#) and [Table 9](#). There is one measurement cycle per oversample.

**Measurement Data Transfer**

By default, all ALU data is automatically transferred to the data registers (CELLn, VBLOCK, AIN1, AIN2, DIAG,

MINMAXCELL and TOTAL) at the end of each acquisition. The transfer occurs in parallel, that is, all data registers are loaded at the same time. When this occurs, the DATARDY bit is set and the host can read out the data. In the simplest, sequential approach, the host will initiate the acquisition by setting SCAN, wait for the acquisition to complete (SCANDONE = 1), read the data registers, and then repeat the cycle.

**Table 8. Acquisition Time**

PROCESS	TIME (MS)	CONDITION	FREQUENCY
Initialization	13	Always	Once per acquisition
VBLKP measurement	27	If VBLKP is enabled	Every measurement cycle
Cell scan setup	12.5	If cell input(s) enabled & VBLKP enabled	
	20	If cell input(s) enabled & VBLKP disabled	
Cell scans	9 x n	For n = # of enabled cell inputs	
Diagnostic measurement (if enabled)	11.4	If zero-scale ADC output diagnostic enabled	
	11.4	If full-scale ADC output diagnostic enabled	
	86.2	If V <sub>ALTREF</sub> diagnostic enabled	
	22.9	If any other diagnostic mode enabled	
AUXIN measurement (if enabled)	10	If AUXIN1 is enabled	Once per acquisition
	6µs x AINCFG[5:0]		
	10	If AUXIN2 is enabled	
	6µs x AINCFG[5:0]		
HV recovery (if oversampling enabled)	100.3 x m	For m = # of oversamples	After every measurement cycle except last

**Table 9. Acquisition Time Examples (with AINCFG[5:0] = 00h)**

ENABLED MEASUREMENTS	NO OVERSAMPLING	4 OVERSAMPLES	8 OVERSAMPLES
12 cells	141.0µs	825.9µs	1739.1µs
12 cells, VBLKP	160.5µs	903.9µs	1895.1µs
12 cells, AUXIN1&2	161.0µs	845.9µs	1759.1µs
12 cells, VBLKP, AUXIN1&2	180.5µs	923.9µs	1915.1µs
12 cells, VBLKP, die temperature, AUXIN1&2	203.4µs	1015.5µs	2098.3µs

**Double-buffer Mode**

The double-buffer mode (DBLBUFEN = 1) enables reduced cycle times by allowing the host to read out data registers during the acquisition mode. In this mode, the automatic transfer of measurement results from the ALU to the data registers is delayed until the start of the next acquisition. This delay allows the host to start reading out the first acquisition data while the second acquisition is taking place and to finish reading out the first acquisition even as the second acquisition completes. The host can then start a new acquisition and repeat the cycle.

If the first acquisition data is needed before starting the second acquisition, the host can perform a manual data transfer by setting DATAMOVE. The manual transfer cannot occur in acquisition mode so the host may first verify that SCANDONE = 1. Flowcharts for operation of double-buffer mode are shown in [Figure 12](#) and [Figure 13](#).

**Note:** An alternate double-buffer mode may be enabled (DBLBUFSEL = 1) that offers an even higher degree of pipelining but at the cost of increased complexity in the application code. Contact Maxim Applications for details regarding the alternate double-buffer mode.

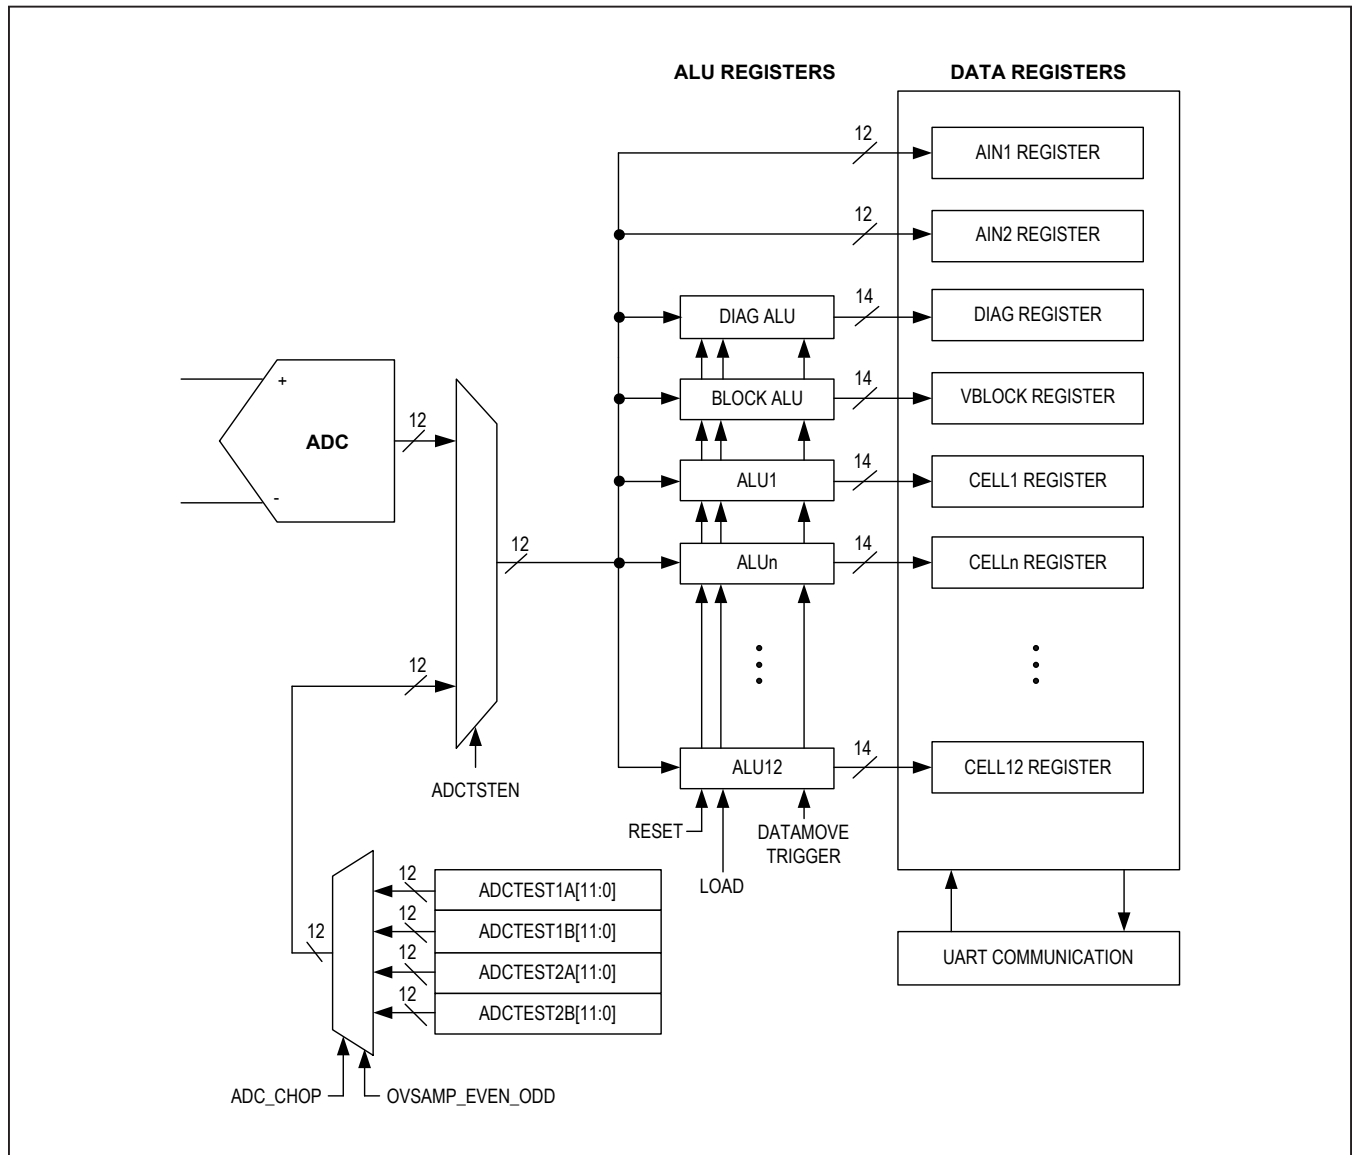

Figure 11. Measurement Data Flow

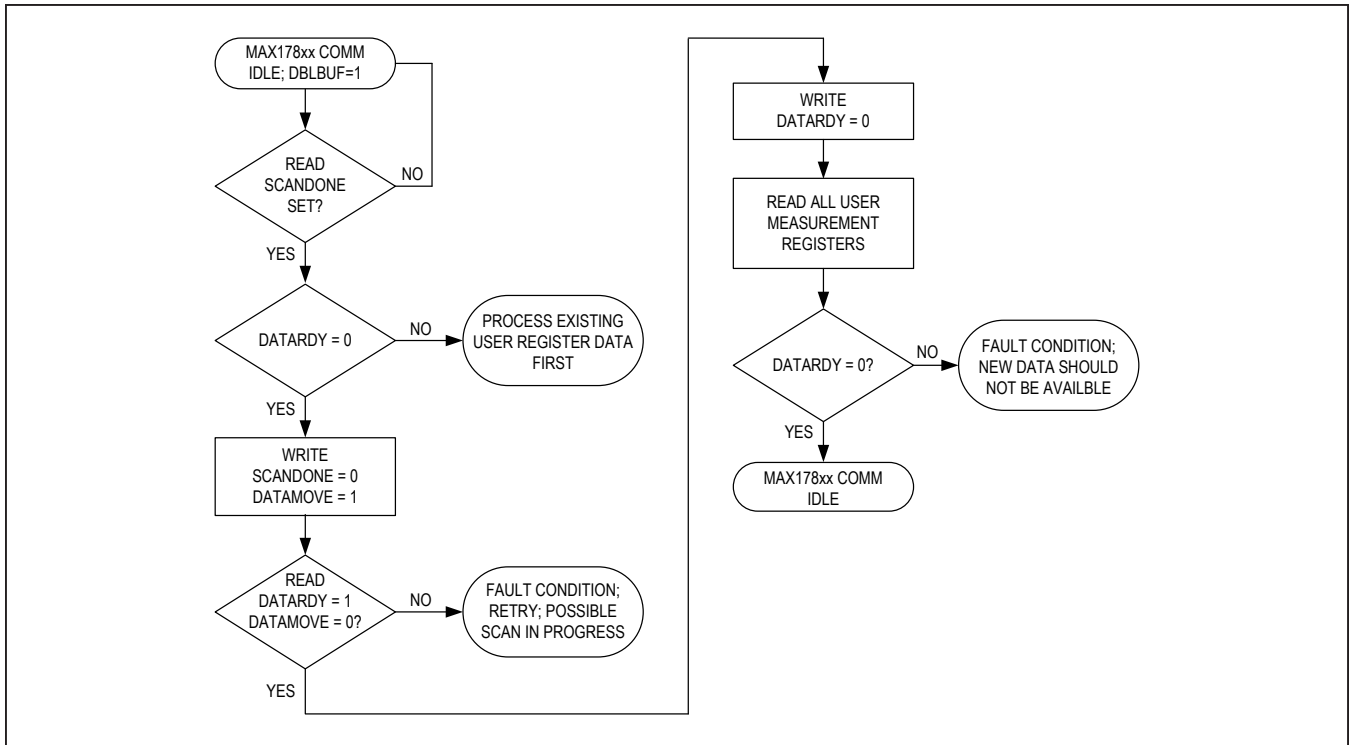

Figure 12. Double-Buffer Mode DATAMOVE

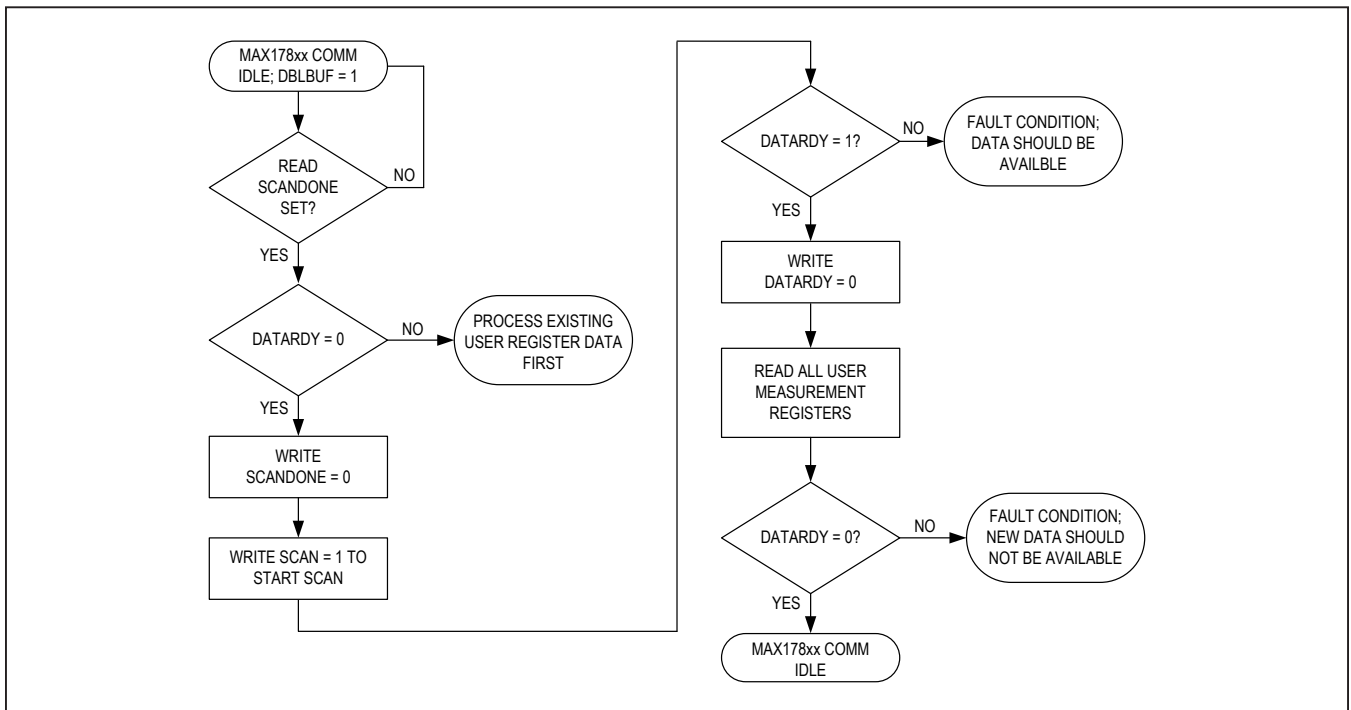

Figure 13. Double-Buffer Mode Register Read

## Measurement Alerts

After the measurement cycle, the ALU compares the enabled measurements to the various configured thresholds (see [Table 10](#)), and sets the alert bits before the ALU data is transferred to the data registers. In oversampling mode, the alert status is updated after the last oversample. The alerts are updated whether or not the data is moved from the ALU registers to the data registers and are only updated for those measurements enabled in the MEASUREEN register.

### Voltage Alerts

Use the ALRTOVEN and ALRTUVEN registers to enable voltage alerts for the cell and auxiliary inputs. If a cell voltage alert is enabled, the cell input voltage is compared against the programmable overvoltage and undervoltage thresholds after every acquisition as shown in [Figure 14](#). Separate thresholds for setting the alert and for clearing the alert provide hysteresis. Configure the set thresholds for cell undervoltage ( $V_{UVTHSET}$ ) and overvoltage ( $V_{OVTHSET}$ ) using the OVTHSET and UVTHSET registers. Configure the clear thresholds for cell undervoltage ( $V_{UVTHCLR}$ ) and cell overvoltage ( $V_{OVTHCLR}$ ) using the OVTHCLR and UVTHCLR registers.

Alert flags in the ALRTOVCELL register are set, if enabled, when the acquired cell voltage is over  $V_{OVTHSET}$ . Alerts in the ALRTUVCELL register are set, if enabled, when the acquired cell voltage is under  $V_{UVTHSET}$ . The alerts are cleared when the cell voltage moves in the opposite direction and crosses the clear threshold. The voltage

must cross the threshold; if it is equal to a threshold, the alert flag does not change. Therefore, setting the overvoltage-set threshold to full scale, or setting the undervoltage-set threshold to zero scale, effectively disables voltage alerts.

The ALRTOV and ALRTUV bits in the STATUS register are set when any alert flag is set in the ALRTOVCELL or ALRTUVCELL registers, respectively. ALRTCELL $_n$  is the logical OR of ALROVCELL $_n$  and ALRTUVCELL $_n$ .

### Cell Mismatch

Enable the mismatch alert to signal when the minimum and maximum cell voltages differ by more than a specified voltage. The MSMTCH register sets the 14-bit threshold ( $V_{MSMTCH}$ ) for the mismatch alert (ALRTMSMTCH). Whenever  $V_{MAX} - V_{MIN} > V_{MSMTCH}$ , then ALRTMSMTCH = 1. The alert bit is cleared when a new acquisition does not exceed the threshold condition. To disable the alert, write FFCH to the MSMTCH register (default value).

### Cell Statistics

The cell numbers with the lowest and highest voltages are stored in the MINMAXCELL register. When multiple cells have the same minimum or same maximum voltage, only the highest cell position having that voltage is reported. The sum of all enabled cell voltages is stored in the TOTAL register as a 16-bit value. For acquisitions with no enabled cell inputs, the MINMAXCELL and TOTAL registers are not updated.

**Table 10. Measurement Alerts**

DESCRIPTION	CONDITION OR RESULT	ALERT BIT	LOCATION
Cell overvoltage (OV)	$V_{Cn} - V_{Cn-1} > V_{OVTHSET}$	ALRTOV, ALRTOV $_n$	STATUS, ALRTOVCELL
Cell undervoltage (UV)	$V_{Cn} - V_{Cn-1} < V_{UVTHSET}$	ALRTUV, ALRTUV $_n$	STATUS, ALRTUVCELL
Cell Mismatch	$V_{MAX} - V_{MIN} > V_{MSMTCH}$	ALRTMSMTCH	STATUS
Cell with minimum voltage	$n$ where $V_{CELLn} = V_{MIN}$	None	MINMAXCELL
Cell with maximum voltage	$n$ where $V_{CELLn} = V_{MAX}$	None	MINMAXCELL
Total of all cell voltages	$\sum V_{CELLn}$ for $n = 1$ to 12	None	TOTAL
AUXIN $_x$ overvoltage (undertemperature)	$V_{AUXINx} > V_{AINUT}$	ALTRTCOLD, ALRTOVAIN $_x$	STATUS, ALRTOVCELL
AUXIN $_x$ undervoltage (overtemperature)	$V_{AUXINx} < V_{AINOT}$	ALRTHOT, ALRTUVAIN $_x$	STATUS, ALRTUVCELL

**Temperature Alerts**

Temperature alerts, if enabled, occur when the acquired AUXINn input voltages fall outside the thresholds configured by the AINOT and AINUT registers. Unlike the cell-voltage alerts, the temperature thresholds do not have the hysteresis afforded by separate set and clear thresholds.

**Cell Balancing**

**Cell-Balancing Switches**

Cell balancing can be performed using any of the 12 internal cell-balancing switches to discharge cells. The cell-balancing current is limited by the external balancing resistors and the internal balancing-switch resistance ( $R_{SW}$ ). Enabling adjacent balancing switches simultaneously may increase the balancing current significantly, so care must be taken to not exceed the device's maximum operating conditions. Fault detection is described in the [Diagnostics](#) section.

Figure 14. Cell Voltage Alert Thresholds

Figure 15. Internal Cell Balancing

### Maximum Cell-Balancing Current

The maximum balancing current is limited by package power dissipation, average die temperature, average duty cycle of the switch, and the number of switches conducting current at any one time.

The power dissipation must not exceed the absolute maximum rating of the package, nor should the die temperature go outside the range specified for the desired level of measurement accuracy. Higher die temperatures and higher average duty cycles increase the probability of internal electromigration, so the maximum balancing current is lowered accordingly for an assumed 10-year device lifetime, as shown in [Table 11](#).

### Cell-Balancing Watchdog

Even if the host fails to disable the cell-balancing mode, the cell-balancing watchdog can automatically disable the cell-balancing switches, regardless of the BALSWMEN configuration. The cell-balancing watchdog does not modify the

contents of the BALSWMEN register. Use the WATCHDOG register to configure the timeout value from 1s to 3840s (64min), as shown in [Table 12](#). The pre-divider configuration, CBPDIV[2:0], effectively sets the rate at which the CBTIMER[3:0] counts down (see [Figure 16](#)).

The host should periodically update CBTIMER to ensure that it does not count down to zero. If the countdown timer is allowed to reach zero, the cell-balancing switches are disabled until the timer is either disabled or refreshed by writing a non-zero value.

To allow timed balancing with no host interaction, the GPIO3 pin is configured to output a logic-high level while the timer is counting using the GPIO3TMR configuration bit of the GPIO register. An external diode is connected from GPIO3 to SHDNL to prevent shutdown while the timer is counting. Once the timer expires, the device shuts down. The host may intervene prior to the timer expiring to keep the device active and to reconfigure the device.

**Table 11. Maximum Allowed Balancing Current per Switch**

AVERAGE LIFETIME DUTY CYCLE (10 YEARS)	T <sub>DIE</sub> = 85°C	T <sub>DIE</sub> = 105°C	T <sub>DIE</sub> = 125°C
15%	650mA	650mA	650mA
20%	650mA	650mA	650mA
25%	650mA	650mA	650mA

Figure 16. Cell-Balancing Watchdog

**Table 12. Cell-Balancing Watchdog Configuration**

CBPDIV[2:0]	TIMER LSB PERIOD	RANGE OF CBTIMER[3:0]	
		MINIMUM	MAXIMUM
000b	Timer Disabled	Timer Disabled	
001b	1s	1s	15s
010b	4s	4s	60s
011b	16s	16s	240s
100b	64s	64s	960s
101b	128s	128s	1920s
110b	256s	256s	3840s

### Emergency-Discharge Mode

The emergency-discharge mode performs cell balancing in a controlled manner so that the cells can be discharged to a safe level in the event of an emergency. The BALSWDCHG and DEVCFG2 registers provide control for this mode. A timeout value for the mode is configured by DISCHGTIME[7:0] as shown in [Table 13](#).

The emergency-discharge mode is activated by setting the EMGCYDCHG bit with DCHGTIME[7:0] ≠ 00h. In emergency-discharge mode the following occurs:

- 1) The CBTIMER[3:0] is cleared to prevent the cell-balancing watchdog from disabling the cell-balancing.
- 2) Cell-balancing switches are controlled by BALSWDCHG, not BALSWEN.
- 3) The discharge timer starts to countdown.
- 4) The read-only counter DCHGCNTR[3:0] increments at a 2Hz rate with periodic roll-over at Fh. The host can read this counter periodically to confirm that the mode is active.
- 5) The GPIO3 pin is driven high while the countdown is active.

The emergency-discharge mode alternates between a 1-minute discharge cycle for odd cells and a 1-minute discharge cycle for even cells. There is a 62.5ms minimum off time at the end of each discharge cycle to ensure no overlap between even and odd discharge cycles. The duty cycle of each discharge cycle can be configured by DCHGWIN[2:0], as shown in [Table 13](#).

By clearing EMGCYDCHG, the emergency-discharge mode terminates and the following occurs:

- 1) The discharge timer is reset.
- 2) Control of the cell-balancing switches reverts to the BALSWEN register.
- 3) Control of GPIO3 reverts to the GPIO register.

The emergency-discharge mode also terminates if DCHGTIME[7:0] = 0h, or the discharge time has reached the configured timeout.

To prevent the emergency-discharge mode from terminating prematurely due to a device shutdown (which could occur due to an extended lapse in host communications), connect an external diode from GPIO3 to SHDNL to keep SHDNL high while the timer is counting.

**Table 13. Emergency-Discharge Mode**

FUNCTION	REGISTER FIELD	CONFIGURATION	BEHAVIOR
Duty cycle	DCHGWIN[2:0] 7.5s/bit	0h	Switches on for 7.5s, off for 52.5s
		1h	Switches on for 15s, off for 45s
		...	...
		7h	Switches on for 59.94s, off for 62.5ms
Timeout	DCHGTIME[7:0] 2 hours/bit	00h	Discharge mode disabled
		01h	Discharge mode disabled after 4 hours
		02h	Discharge mode disabled after 6 hours
		...	...
		FFh	Discharge mode disabled after 512 hours

**Low-Voltage Regulator**

An internal linear regulator supplies low-voltage power ( $V_{AA}$ ) for the ADC and digital logic. The regulator is disabled when SHDNL is active-low or when the die temperature ( $T_{DIE}$ ) exceeds  $145^{\circ}\text{C}$ , as shown in Table 14. Once  $V_{AA}$  decays below 2.95V (typ), an internal power-on reset (POR) is generated (see Figure 22). This event can

be detected with the ALRTRST bit, as shown in Table 15. After a thermal shutdown, the regulator is not enabled until  $T_{DIE} < 130^{\circ}\text{C}$  due to hysteresis.

The low-voltage regulator is continuously monitored for undervoltage, as described in Table 15.

**Table 14. Low-Voltage Regulator**

<b>INPUT:</b>	DCIN
<b>INPUT VOLTAGE:</b>	9V to 65V
<b>OUTPUT:</b>	$V_{AA}$
<b>OUTPUT VOLTAGE:</b>	3.3V
<b>DISABLE:</b>	$V_{SHNDL} < 0.6\text{V}$ or $T_{DIE} > 145^{\circ}\text{C}$

FAULT	CONDITION	ALERT	LOCATION
$V_{AA}$ undervoltage	$V_{AA} < 2.95\text{V}$	ALRTRST	STATUS15

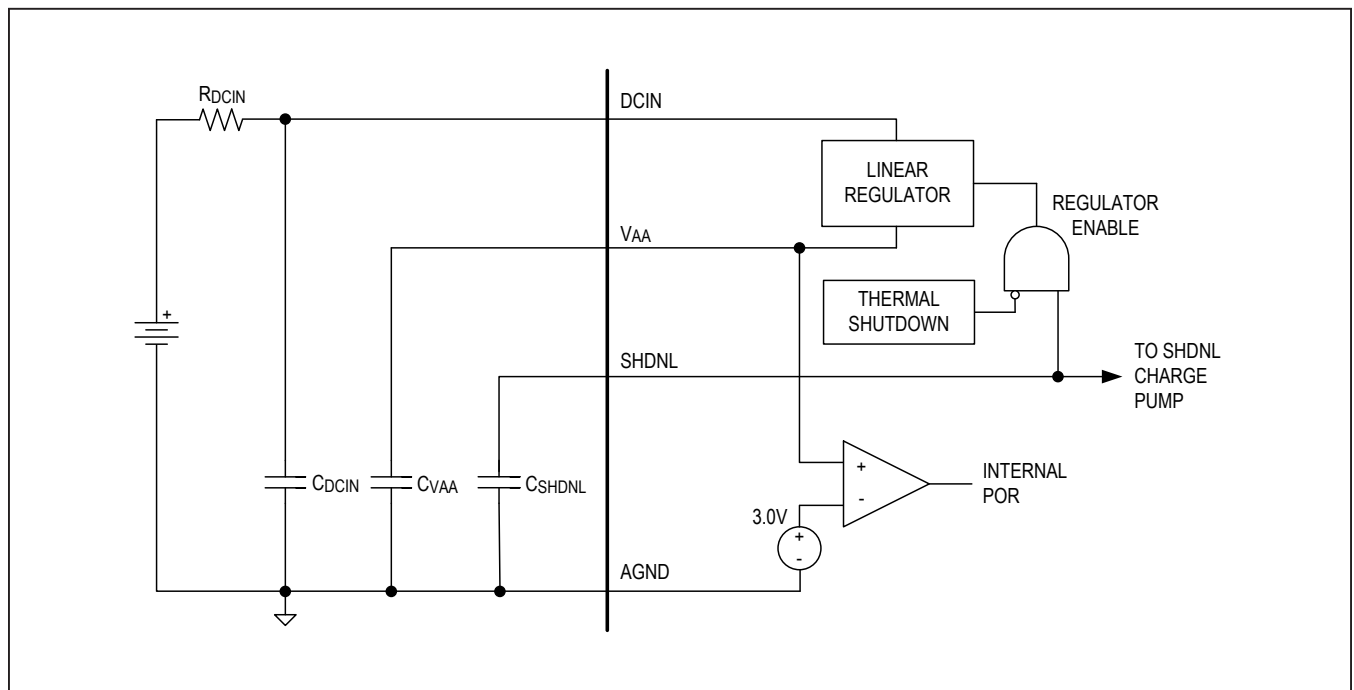

Figure 17. Low-Voltage Regulator

**HV Charge Pump**

The high-voltage multiplexers must be powered by a supply higher than any monitored voltage. To this end, an internal charge pump draws power from the DCIN input to provide a high-voltage supply ( $V_{HV}$ ), which is regulated to  $V_{DCIN} + 5.5V$  (nominal). When the charge pump achieves regulation, charge pumping stops until the voltage drops by 20mV. The charge pump is automatically disabled during shutdown and during the measurement cycle to eliminate charge-pump noise. The charge pump can also be disabled manually by setting the HVCPDIS bit in the DEVCFG2 register.

If  $V_{HV} - V_{DCIN}$  drops below  $V_{HVUV}$ , the HV undervoltage flag (ALRTHVUV) is set. If  $V_{HV}$  drops too low relative to

the C12 input, there is insufficient headroom to guarantee that the HVMUX switch resistance is sufficiently low for an accurate acquisition of the channel. To properly identify this fault condition, if  $V_{HV} - V_{C12}$  is too low during the acquisition, the HV headroom alert flag (ALRTHVH DRM) is set in the FMEA2 register. The HV undervoltage and HV headroom alert functions can be verified by disabling the HV charge pump (HVCPDIS = 1) and allowing  $V_{HV}$  to decay while in acquisition mode. An overvoltage comparator disables the charge pump in the case where  $V_{HV} - V_{DCIN}$  exceeds 8.5V. This condition is indicated by the ALRTHVOV bit in the FMEA2 register. The ALRTHVOV alert does not necessarily indicate a condition that affects measurement accuracy. HV charge-pump diagnostics are summarized in [Table 16](#).

**Table 16. HV Charge-Pump Diagnostics**

FAULT	CONDITION	ALERT BIT	LOCATION
$V_{HV}$ undervoltage	$V_{HV} - V_{DCIN} < V_{HVUV}$	ALRTHVUV	FMEA1[3]
$V_{HV}$ overvoltage	$V_{HV} - V_{DCIN} > V_{HV OV}$	ALRTHVOV	FMEA2[0]
$V_{HV}$ low headroom	$V_{HV} - V_{C12} < V_{HVH DRM}$ (min.)	ALRTHVH DRM	FMEA2[2]

Figure 18. HV Charge Pump

**Oscillators**

Two factory-trimmed oscillators provide all timing requirements: a 16MHz oscillator for the UART and control logic, and a 32.768kHz oscillator for HV charge pump and timers. A special diagnostic counter clocked by the 16MHz signal is employed to check the 32kHz oscillator. Every two periods of the 32kHz clock, the counter is sampled. If the count varies more than 5% from the expected value the ALRTOSC1 bit is set, as shown in Table 17. A redundant alert bit (ALRTOSC2) increases the integrity level. If the 16MHz oscillator varies by more than 5%, communication errors will be indicated

**Device ID Number**

The ID1[15:0] register together with ID2[7:0] contain a 24-bit manufacturing identification number, DEVID[23:0]. The ID combined with the manufacturing date provides a means of uniquely identifying each device. A device ID of zero is invalid.

**Power-On and Shutdown**

Applications that remain connected continuously to the power source rely on the SHDNL input to shut down and reset the device. When  $V_{SHDNL} < 0.6V$ , the regulator is disabled, the POR signal asserted, and the device goes into an ultra-low-power shutdown mode. When  $V_{SHDNL} > 1.8V$ , POR is deasserted, the regulator enabled, and the device becomes fully operational in the standby mode.

**Power-On Method**

The SHDNL input can be driven externally or it can be controlled using UART communication only. In differential mode, the signaling on the lower-port receiver drives an internal charge pump that charges up the external 1nF capacitor connected to the SHDNL input (see Figure 19).  $V_{SHDNL}$  reaches 1.8V in 200µs (typ). The charge pump then self-regulates to  $V_{SHDNLIMIT}$  and can maintain  $V_{SHDNL}$  at a logic-one, even with the UART idle 98% of the time.

**Table 17. Oscillator Diagnostics**

FAULT	CONDITION	ALERT BIT	LOCATION
32.768kHz oscillator	$31.129kHz > f_{osc\_32k} > 34.406kHz$	ALRTOSC1	FMEA1[15]
32.768kHz oscillator	$31.129kHz > f_{osc\_32k} > 34.406kHz$	ALRTOSC2	FMEA1[14]
16MHz oscillator	$15MHz > f_{osc\_32k} > 17MHz$	ALRTMAN or ALRTPAR	STATUS[4], or STATUS[2]

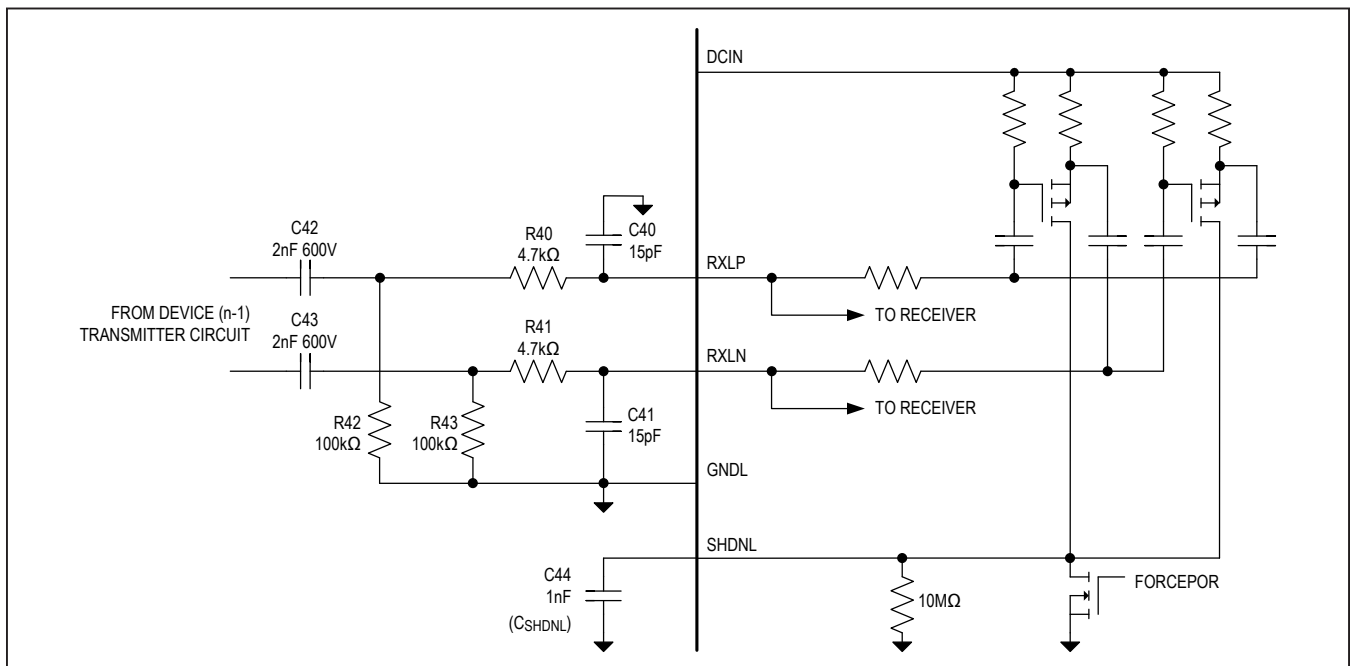

Figure 19. SHDNL Charge Pump

**Power-On Sequence**

Once  $V_{SHNDL} > 1.8V$ , the regulator is enabled. After  $V_{AA}$  reaches 3V (typ), the POR signal is deasserted, the oscillators enabled, and the HV charge pump enabled. Once the HV charge pump is stable, the logic is enabled. The device is fully operational (standby mode) within 1ms from the time communication is first received in the shutdown mode. The power-on sequence is shown in [Figure 20](#).

Figure 20. Power-On Sequence

**Shutdown Mode**

Shutdown is performed by bringing  $V_{SHDNL} < 0.6V$ . [Table 18](#) summarizes the methods by which this can be achieved.

The quickest shutdown can be achieved by driving SHDNL externally with a driver pulldown impedance not exceeding 1kΩ. If SHDNL is not driven externally, the host can discharge  $C_{SHDNL}$  under software control by setting the FORCEPOR bit. This will enable a pulldown (4.7kΩ nominal) to discharge the capacitor with a 4.7μs time constant.

The slowest method is for the host to simply cease communication. With the UART idle, there is no charge pumping and the capacitor discharges through an internal 10MΩ resistor with a 10ms time constant. If shutdown faster than 10ms is desired when power is disconnected from the device, a 200kΩ resistor can be connected externally from SHDNL to AGND to create a 200μs time constant.

If only a reset is required, the host can issue a soft-reset by setting the SPOR bit. This resets the device registers and disables high-voltage operation, but low-voltage operation remains enabled (the regulator is not disabled).

**Note:** For single-ended communication, SHDNL must be driven externally since the charge-pump operation requires a differential signal.

**Shutdown Sequence**

The shutdown sequence and timing is shown in [Figure 21](#), [Figure 22](#), and [Figure 23](#). The ALRTSHDNL status bit is set and the low-voltage regulator disabled as soon as  $V_{SHDNL} < 0.6V$ . When the  $V_{AA}$  and  $V_{DDL}$  decoupling capacitors discharge below the POR threshold (2.95V typ), the device registers are reset and the HV charge pump is disabled. The device is then in an ultra-low-power state until  $V_{SHDNL} > 1.8V$ .

**Table 18. Shutdown Timing**

SHUTDOWN METHOD	$R_{PULLDOWN}$		$C_{SHDNL}$	RC
1. Host drives SHDNL pin low	1kΩ	External	1nF	1μs
2. Host sets FORCEPOR bit	5kΩ	Internal		5μs
3. Disconnect DCIN	200kΩ	External		200μs
4. Host places UART in idle mode	10MΩ	Internal		10,000μs

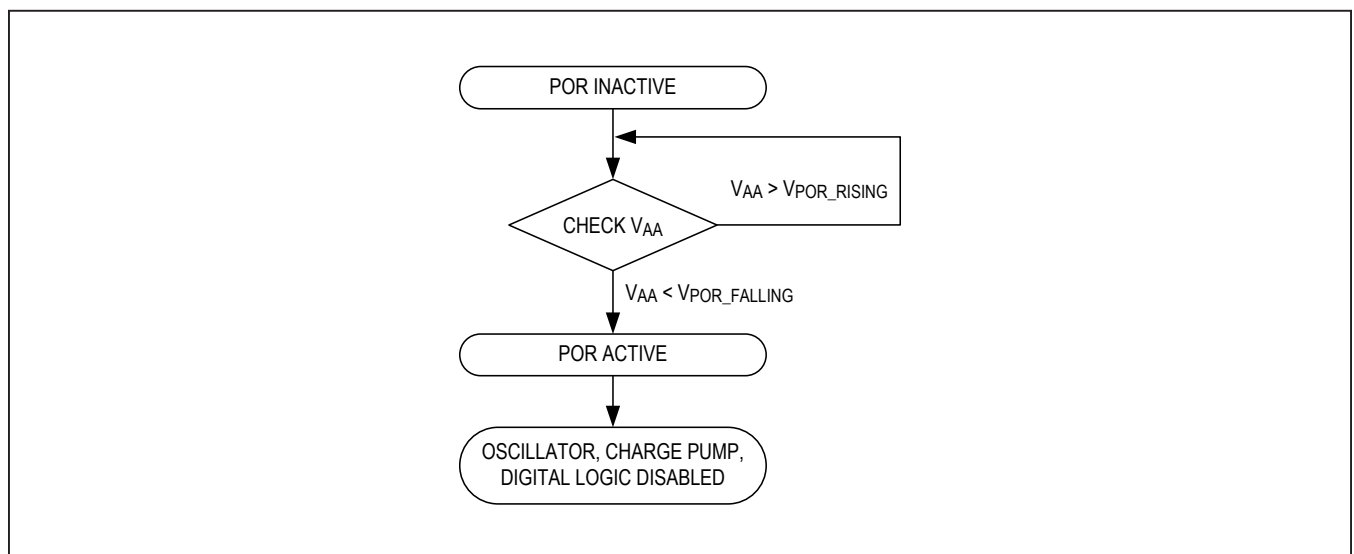

Figure 21. Shutdown Sequence

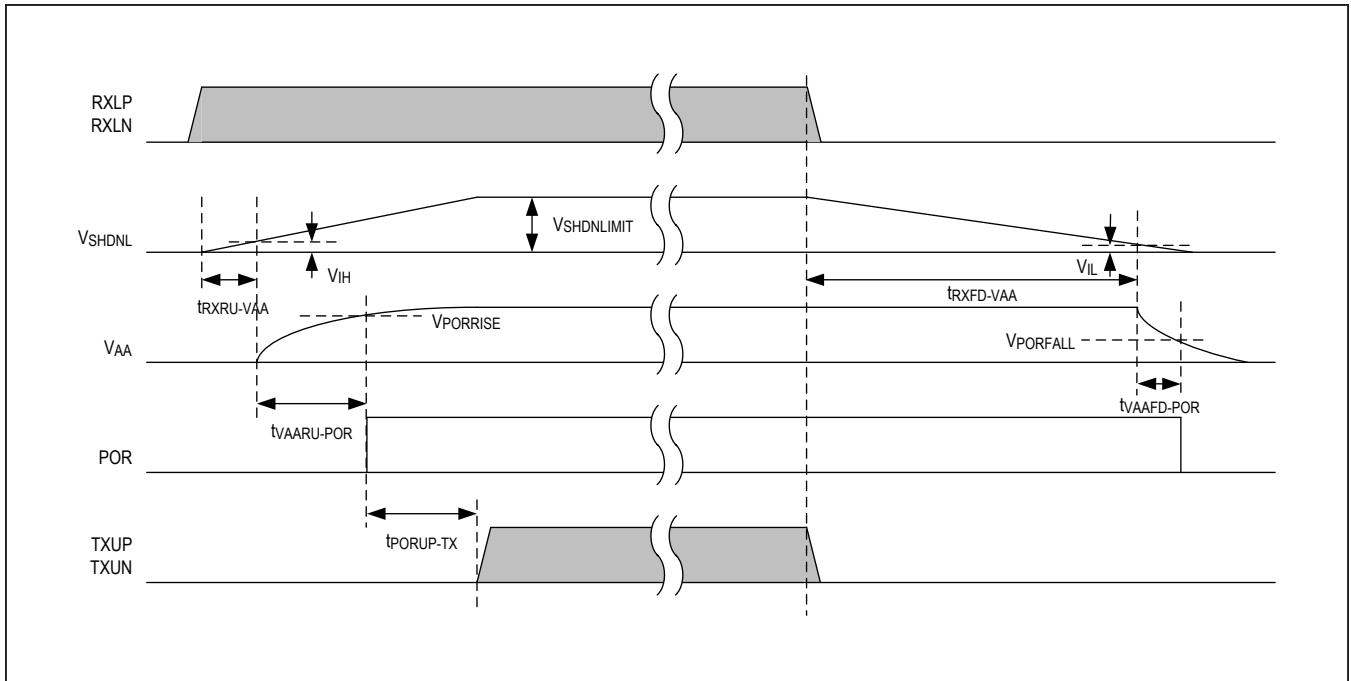

Figure 22. Power-On and Shutdown Timing (UART Control)

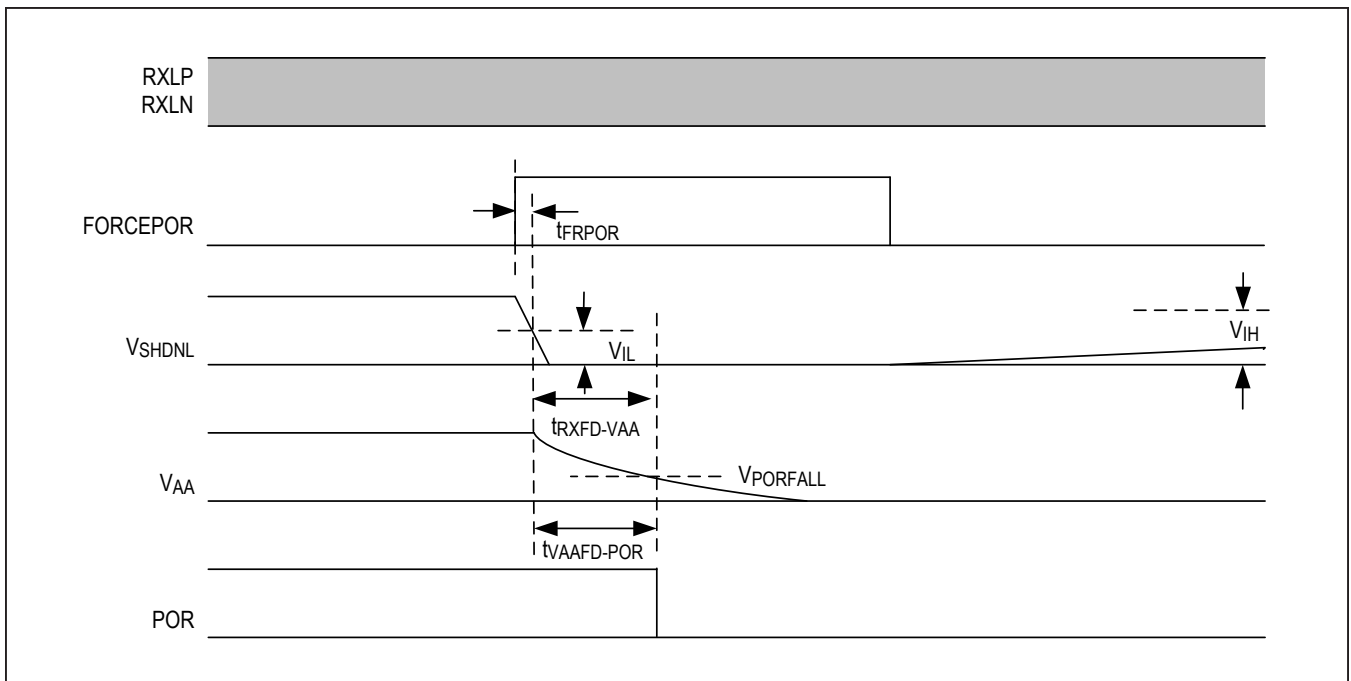

Figure 23. Shutdown Timing (Software Control)

**UART Interface**

The battery-management UART protocol allows up to 32 devices to be connected in daisy-chain fashion (see Figure 24). The host initiates all communication with the daisy-chain devices through a UART interface such as the MAX17841B. The data flow is always unidirectional from the host, up the daisy-chain (upstack) and then loops back down the daisy-chain (downstack) to the host (see Figure 24).

Each device first receives data at its lower RX port and immediately retransmits data from its upper TX port to the lower RX port of the next upstack device. The last device transmits data from its upper TX port directly into its upper RX port and then immediately retransmits the data from its lower TX port to the upper RX port of the next downstack device. The protocol supports fixed baud rates of 2Mb/s, 1Mb/s, or 0.5Mb/s. The baud rate is set by the host and is automatically detected by the device.

Figure 24. UART Interface

**UART Ports**

Two UART ports are utilized, a lower port (RXL/TXL) and an upper port (RXU/TXU). Each port consists of a differential line driver and differential line receiver. DC-blocking capacitors or transformers can be used to isolate daisy-chained devices that are operating at different common-mode voltages. During communication, the character encoding provides a balanced signal (50% duty cycle) that ensures charge neutrality on the isolation capacitors.

**UART Transmitter**

When no data is being transmitted by the UART, the differential outputs must be driven to a common level to maintain a neutral charge difference between the AC-coupling capacitors or to avoid saturation of the isolation transformers. In the default idle mode (low-Z), the transmitter drives both outputs to a logic-low level to balance the charge on the capacitors; this also works well with transformer coupling. The high-Z idle mode (TXLHIZIDLE, TXUHIZIDLE = 1) places the TX pins in a high-Z state in idle mode, which may be desirable to minimize the effects of charging and discharging the isolation capacitors. The idle mode for the upper and lower ports can be controlled independently through the TXLHIZIDLE and TXUHIZIDLE configuration bits.

**UART Receiver**

The UART receiver has a wide common-mode input range to tolerate harsh EMC conditions. It can be operated in differential mode or single-ended mode per [Table 19](#). By default, the UART receivers are configured for differential mode. In single-ended mode, the RXP input is grounded and the RXN input receives inverse data as described in the [Applications Information](#) section (see [Figure 64](#)). In single-ended mode, the receiver input threshold is negative so that a zero differential voltage ( $V_{RXP}, V_{RXN} = 0V$ ) is considered to be a logic-one and a negative differential voltage ( $V_{RXN}$  high) is a logic-zero.

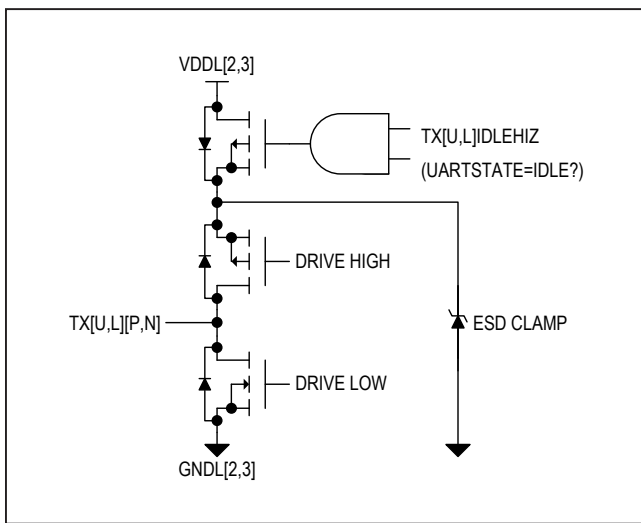

Figure 25. UART Transmitter

Figure 26. UART Receiver

## UART RX Modes

During the first preamble received after a reset, the receiver automatically detects if the received signal is single-ended and if so, places the receiver in single-ended mode; therefore, the device must be reset for any change in the RX-mode hardware configuration to be detected.

The receiver mode is indicated by the ALRTCOMMSEL bit (for lower port) and ALRTCOMMSEU bit (for upper port) of the FMEA1 register, as shown in [Table 19](#). If the RXP input is open circuit, the RX-mode detection places the UART in single-ended mode so the port can still operate, albeit with reduced noise immunity. The host can diagnose this condition by checking ALRTCOMMSEL and ALRTCOMMSEU after any POR event. Any other faults result in communication errors.

## UART Loopback

For the last device in the stack, the data must be looped back from the upper transmitter to the upper receiver. This is known as loopback and can be configured externally (default) or internally.

## External Loopback Mode

External loopback mode (default) uses a two-wire cable to connect the upper transmitter (TXU) to the upper receiver (RXU). The external loopback has two advantages:

- 1) It is quicker to determine device count for applications where the host does not assume what the device count is.
- 2) It helps to match the supply current of the last device to that of the other daisy-chained devices (because the hardware configuration is identical).

## Internal Loopback Mode

Internal loopback mode (LASTLOOP = 1) routes the upper-port transmit data internally to the upper-port receiver. Any signal present on the upper-port receiver input pins is ignored in the internal loopback mode; therefore, when LASTLOOP is set, the write command that was forwarded to any upstack devices is interrupted in the downstack direction. The host should expect this and read the LASTLOOP bit to verify that the write was successful. If the MAX17841B interface is used, its receive buffer should be cleared before changing LASTLOOP, and cleared again after changing the loopback configuration because the communication was interrupted.

Internal loopback mode is useful to diagnose the location of a daisy-chain signal break by enabling the internal loopback mode on the first device, checking communication, then moving the loopback mode to the next device, and continuing up the stack until communication is lost.

## Baud-Rate Detection

The UART can operate at a baud rate of 2Mb/s (default), 1Mb/s, or 0.5Mb/s. The baud rate is controlled by the host and is automatically detected by the device when the first preamble character is received after reset. If the host changes the baud rate after reset, it must issue another reset (which can be done by setting the SPOR bit) and resend a minimum of  $2 \times n$  preambles (where  $n$  is the number of devices). The  $2 \times n$  preambles are necessary since the transmitter for the upper port will not transmit data until the lower-port receiver has detected the baud rate and likewise, the transmitter on the lower port will not transmit data until the upper-port receiver has detected the baud rate. A simple way to do this is for the host to start transmitting preambles and stop when a preamble has been received back at the host RX port.

**Table 19. UART RX Modes**

RXP	RXN	ALRTCOMMSEn	RX MODE
Connected to data	Connected to inverse data	0	Differential mode (normal)
Grounded	Connected to inverse data	1	Single-ended mode (normal)
Open circuit (fault)	Connected to inverse data	1	Single-ended mode (low noise immunity)
Connected to data	Open circuit (fault)	0	Differential mode (communication errors)

**Battery-Management UART Protocol**

The battery-management UART protocol uses the following features to maximize the integrity of the communications:

- All transmitted data bytes are Manchester-encoded, where each data bit is transmitted twice, with the second bit inverted (G.E. Thomas convention).
- Every transmitted character contains 12 bits that include a start bit, a parity bit, and two stop bits.
- Read/write packets contain a CRC-8 packet-error checking (PEC) byte
- Each packet is framed by a preamble character and stop character.
- Read packets contain a data-check byte for verifying the integrity of the transmission.

The protocol is also designed to minimize power-consumption by allowing slave devices to shut down if the

UART is idle for a specified period of time. The host must periodically transmit data to prevent shutdown unless the SHDNL input is driven externally.

**Command Packet**

A command packet is defined as a sequence of UART characters originating at the host. Each packet starts with a preamble character, followed by data characters, and ending with a stop character (see Figure 27). After sending a packet, the host either goes into idle mode or sends another packet.

**Preamble Character**

The preamble is a framing character that signals the beginning of a command packet. It is transmitted as an unencoded 15h with a logic-one parity bit and a balanced duty cycle. If any bit(s) other than the stop bits deviate from the unique preamble sequence, the character is not interpreted as a valid preamble, but rather as a data character.

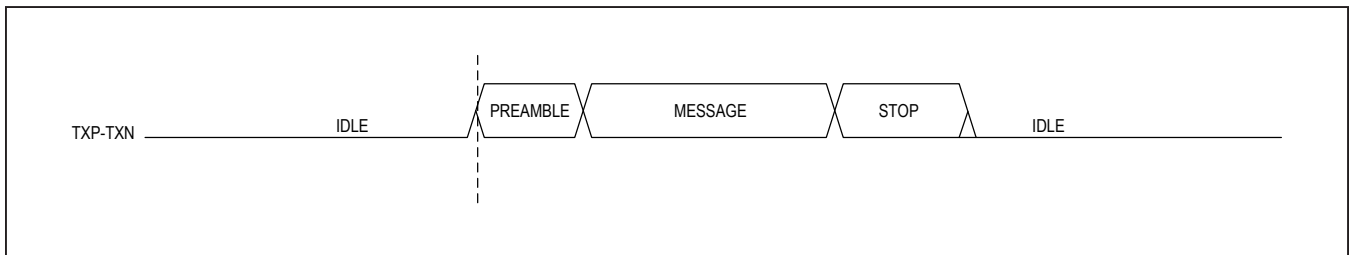

Figure 27. Command Packet

Figure 28. Preamble Character

**Data Characters**

Each data character contains a single-nibble (4-bit) payload, so two characters must be transmitted for each byte of data. All data is transmitted least-significant bit, least-significant nibble, and least-significant byte first (see [Figure 29](#)). The data itself is Manchester-encoded, which means that each data bit is followed by its complement. If the UART detects a Manchester-encoding error in any received data character, it sets the ALRTMAN bit in the STATUS register.

The parity is even, which means that the parity bit's value should always result in an even number of logic-one bits in the character. Given that the data is Manchester-encoded and there are two stop bits, the parity bit for data characters is always transmitted as a logic-zero. If the UART detects a parity error in any received data character, it sets the ALRTPAR bit in the STATUS register. [Table 20](#) provides a list of data character descriptions.

**Table 20. Data Characters**

BIT	NAME	SYMBOL	DESCRIPTION
1	Start	S	First bit in character, always logic-zero
2	Data0		Least-significant bit of data nibble (true)
3	Data0/		Least-significant bit of data nibble (inverted)
4	Data1		Data bit 1 (true)
5	Data1/		Data bit 1 (inverted)
6	Data2		Data bit 2 (true)
7	Data2/		Data bit 2 (inverted)
8	Data3		Most-significant bit of data nibble (true)
9	Data3/		Most-significant bit of data nibble (inverted)
10	Parity	E	Always logic-zero (even parity)
11	Stop	P	Always logic-one
12	Stop	P	Last bit in character, always logic-one

Figure 29. Data Characters

**Stop Character**

The stop character is a framing character that signals the end of a command packet (see [Figure 30](#)). It is transmitted as an unencoded 54h with a logic-one parity bit and a balanced duty cycle.

**UART Idle Mode**

In the low-Z (default) idle mode, the transmitter outputs are both driven to 0V (see [Figure 31](#)). In the high-Z idle mode, the transmitter outputs are not driven by the UART. The MAX17841B interface automatically places its transmitter in idle mode immediately after each command packet and remains in idle mode until either the next

command packet is sent or it goes into keep-alive mode, sending periodic stop characters to prevent the daisy-chained device(s) from going into shutdown.

**UART Communication Mode**

When transitioning from idle mode to communication mode, the TXP pin must be pulled high (logic-one) prior to signaling the start bit (logic-zero) (see [Figure 31](#)). The duration of the logic-one is minimized to maintain a balanced duty cycle while still meeting the timing specification. When transitioning from the stop bit back to idle mode, the delay, if any, is also minimized.

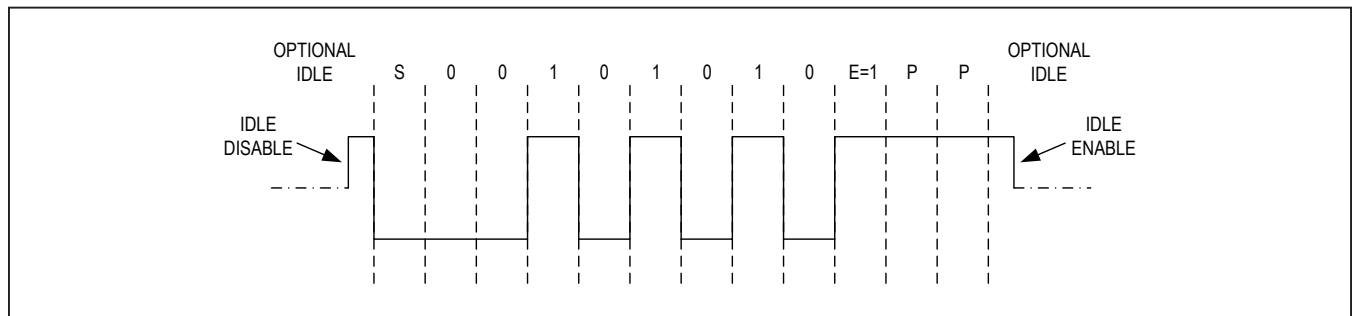

Figure 30. Stop Character

Figure 31. Communication Mode

### Data Types

The battery-management UART protocol employs several different data types, as described in [Table 21](#).

### Command Bytes

The battery-management UART protocol supports six command types, which are summarized in [Table 22](#).

### Command Byte Encoding

Command bytes encoding is described in [Table 23](#). For READDEVICE and WRITEDEVICE commands, the device address is encoded in the command byte. The device ignores those commands containing a device address other than its own.

**Table 21. Data Types**

DATA TYPE	DESCRIPTION
Command byte	A byte defining the command-packet type, generally either a read or a write.
Register address	A byte defining the register address to be read or written.
Register data	Register data bytes being read or written.
Data-check byte	An error and alert status byte sent and returned with all reads.
PEC byte	A packet-error checking byte sent and returned with every packet except HELLOALL.
Alive counter	A byte functioning as a device counter on all reads and writes, if ALIVECNTEN = 1.
Fill byte	Bytes transmitted in READALL command packets for clocking purposes only.

**Table 22. Command-Packet Types**

COMMAND	DESCRIPTION	DATA CHECK	PEC	ALIVE COUNTER	PACKET SIZE (CHARACTERS)
HELLOALL	Writes a unique device address to each device in the daisy-chain. Required for system initialization.	No	No	No	8
WRITEALL	Writes a specified register in all devices.	No	Yes	Yes	14
WRITEDEVICE	Writes a specified register in a single device.	No	Yes	Yes	14
READALL	Reads a specific register from all devices.	Yes	Yes	Yes	12 + (4z)
READDEVICE	Reads a specified register from a single device.	Yes	Yes	Yes	16
ROLLCALL	Reads the ADDRESS register for 32 devices.	Yes	Yes	Yes	138

**Note:** z = Total number of devices, ALIVECNTEN = 1, packet size includes framing characters.

**Table 23. Command-Byte Encoding**

COMMAND	BYTE*	7	6	5	4	3	2	1	0
HELLOALL	57h	0	1	0	1	0	1	1	1
ROLLCALL	01h	0	0	0	0	0	0	0	1
WRITEDEVICE	04h	DA4	3	DA2	DA1	DA0	1	0	0
WRITEALL	02h	0	0	0	0	0	0	1	0
READDEVICE	05h	DA4	DA3	DA2	DA1	DA0	1	0	1
READALL	03h	0	0	0	0	0	0	1	1

\*Assumes DA[4:0] = 0x00, where DA[4:0] is the device address in the ADDRESS register.

## Register Addresses

All register addresses are single-byte quantities and are defined in the [Register Map](#). In general, if the register or device address in a received command is not a valid address for the device, the device will ignore the read or write and simply pass through the packet to the next device.

## Register Data

All registers are 16-bit words (two data bytes) and are defined in the [Register Map](#).

## Data-Check Byte

The host uses the returned data-check byte to promptly determine if any communication errors occurred during the packet transmission and to check if alert flags are set in any devices, as shown in [Table 24](#). The data-check byte is returned by the READALL and READDEVICE commands. For READDEVICE, the data-check byte is updated only by the addressed device.

The data-check byte sent by the host is a seed value normally set to 00h, although non-zero values can be used as a diagnostic. Each device logically ORs the received data-check byte with its own status and transmits it to the next device. A PEC error detected by any device will set the ALRTPEC bit in the STATUS register, and by extension, the ALRTPEC and ALRTSTATUS bits in the data-check byte.

## PEC Byte

The PEC byte is a CRC-8 packet-error check sent by the host with all read and write commands. If any device receives an invalid PEC byte, it sets the ALRTPEC bit in the STATUS register. During any write transaction, a device does not execute the write command internally unless the received PEC matches the expected calculated value. For read commands, the device must return its own calculated PEC byte based on the returned data. The host should verify that the received PEC byte matches the calculated value; if an error is indicated, the data should

be discarded. See the [Applications Information](#) section for details on the PEC calculation.

## Alive-Counter Byte

The alive-counter byte is the last data byte of the command packets (except HELLOALL) if the ALIVECNTEN bit is set in the DEVCFG1 register. The host typically transmits the alive-counter seed value as 00h, but any value is permitted. For WRITEALL or READALL commands, each device retransmits the alive counter incremented by one. For WRITEDEVICE or READDEVICE commands, only the addressed device increments it. The alive counter is not used in the HELLOALL command. If the alive counter reaches FFh, the next device increments it to 00h.

Since the alive counter comes after the PEC byte, an incorrect PEC value will not affect the incrementing of the alive-counter byte. Also, the PEC calculation does not include the alive-counter byte. The host should verify that the alive counter equals the original seed value + the number of devices, considering that if the alive counter reaches FFh, the next device increments it to 00h.

## Fill Bytes

In the READALL command, the host sends two fill bytes for each device in the daisy-chain. The fill bytes are the locations within the packet and are used by the device to place the read data. The fill-byte values transmitted by the MAX17841B interface alternates between C2h and D3h. As the command packet propagates through the device, the device overwrites the appropriate fill bytes with the register data. The device uses the ADDRESS register to determine which specific fill bytes in the packet should be overwritten.

For a READDEVICE command, only two fill bytes are required since only one device responds (returning two data bytes). Also, fill bytes are not required for write commands because the data received is exactly the same as the data retransmitted.

**Table 24. Data-Check Byte**

BIT	NAME	DESCRIPTION
7	ALRTPEC	ALRTPEC is set.
6	ALRTFMEA	ALRTFMEA1 or ALRTFMEA2 is set.
5	ALRTSTATUS	STATUS bit other than ALRTFMEA1, ALRTFMEA2, ALRTOV, and ALRTUV is set.
4	CHECK	Check bit. Value that is received is forwarded.
3	CHECK	Check bit. Value that is received is forwarded.
2	ALRTOV	ALRTOV is set.
1	ALRTUV	ALRTUV is set.
0	CHECK	Check bit. Value that is received is forwarded.

## Battery-Management UART Protocol Commands

### HELLOALL Command

The purpose of the HELLOALL command is to initialize the device addresses of all daisy-chained devices. The device address is stored in the DA[4:0] bits of the ADDRESS register. The highest address possible is 0x1F, so a maximum of 32 devices can be addressed. The command must be issued after POR to reinitialize all device addresses.

When the HELLOALL command is first sent by the host, the address specified in the HELLOALL command is stored to the DA[4:0] bits of the ADDRESS register in the first daisy-chained device. The command is then forwarded to the next device in the chain with the DA[4:0] bits of the address byte incremented by 1, as shown in [Table 25](#). This continues in the upstack direction for each device. The downstack communication path does not increment the address. The advantage of the host choosing a first address of 0x00 is that it is not necessary to write the first address (FA[4:0]) to all the devices since the default value of FA[4:0] is 0x00. **Note:** The host should set the first address so no assigned device address increments from 0x1F to 0x00 during the HELLOALL.

The DA[4:0] value returned to the host is one greater than the address assigned to the last device. Once this last address is known, the host can determine how many devices are in the daisy-chain, which is required for subsequent READALL commands. A READALL command should be used to verify the ADDRESS registers.

Special considerations exist if the host wants to use internal loopback instead of external loopback. The first HELLOALL command is not returned to the host because the internal loopback bit for the top device has not yet been written. If the number of devices is known to the

host, the host can use a WRITEDEVICE to set the internal loopback bit on the last device and then verify with a READALL. If the number of devices is unknown, the internal loopback bit must be set on the first device, verified and then cleared. It can then be set on the second device and verified, and so on incrementally until there is no response (end of stack). With the number of devices known, the loopback bit can be reset on the last device and all ADDRESS registers verified.

When a device receives a valid HELLOALL command, it clears the ADDRUNLOCK bit of the DEVCFG1 register. When this bit is 0, HELLOALL commands are ignored to prevent inadvertently changing any device address. In order to reconfigure the device address, the ADDRUNLOCK bit must first be set to '1' or a POR event must occur. After configuring the device addresses, they should be verified using the READALL or ROLLCALL commands.

### WRITEALL Command

The WRITEALL command writes a 16-bit value to a specified register in all daisy-chained devices. Since most configuration information is common to all the devices, this command allows faster setup than writing to each device individually. If the register address is not valid for the device, the command is ignored. The command sequence is shown in [Table 26](#).

The register value is written immediately after the valid PEC byte is received or, if NOPEC is set, after the last byte is received. If the received PEC byte does not match the internal calculation, the command is not executed, but is still forwarded to the next device. The PEC is calculated from the first 4 bytes of the command starting after the preamble. A PEC error will generate a PEC alert in the device STATUS register.

**Table 25. HELLOALL Sequencing (z = Total Number of Devices)**

HOST TX	DEVICE (n) RXL	DEVICE (n) TXU	HOST RX
Preamble	Preamble	Preamble	Preamble
57h	57h	57h	57h
00h	00h	00h	00h
{0b000,ADDR[4:0]}	{0b000,ADDR[4:0]+n-1}	{0b000,ADDR[4:0]+n}	{0b000,ADDR[4:0]+z}
Stop	Stop	Stop	Stop

**WRITEDEVICE Command**

The WRITEDEVICE command writes a 16-bit value to the specified register in the addressed device only. If the register address is not valid for the device, the command is ignored. The command sequence is shown in [Table 27](#).

The register value is written immediately after the valid PEC byte is received or, if NOPEC is set, after the last byte is received. If the received PEC byte does not match the internal calculation, the command is not executed, but is still forwarded to the next device. The PEC is calculated from the first 4 bytes of the command starting after the preamble. A PEC error sets the ALRTPEC bit in the STATUS register. A PEC error can only occur in the addressed device.

**READALL Command**

The READALL command returns register data from the specified register for all daisy-chained devices. The data

for the first device (connected to the host) is returned last. The command sequence is shown in [Table 28](#). If the received PEC byte does not match the calculated value, the ALRTPEC bit of the data-check byte and ALRTPEC bit of the STATUS register are set, but the command proceeds. A Manchester error immediately switches the data propagation from read mode to write (pass-through) mode, ensuring that the Manchester error is propagated through the daisy-chain and back to the host.

The fill byte values transmitted by the MAX17841B interface alternate between C2h and D3h as shown. As the packet propagates through the device, the device retransmits it in the order shown in the sequencing table (device TXU column). The device knows which bytes to overwrite since its ADDRESS register contains the first device address and its own device address; therefore, it knows where in the data stream it belongs.

**Table 26. WRITEALL Sequencing (Unchanged by Daisy-Chain)**

HOST TX	DEVICE (n) RXL	DEVICE (n) TXU	HOST RX
Preamble	Preamble	Preamble	Preamble
02h	02h	02h	02h
[REG ADDR]	[REG ADDR]	[REG ADDR]	[REG ADDR]
[DATA LSB]	[DATA LSB]	[DATA LSB]	[DATA LSB]
[DATA MSB]	[DATA MSB]	[DATA MSB]	[DATA MSB]
[PEC]	[PEC]	[PEC]	[PEC]
[ALIVE]*	[ALIVE]*	[ALIVE]*	[ALIVE]*
Stop	Stop	Stop	Stop

\*If alive-counter mode is enabled.

**Table 27. WRITEDEVICE Sequencing (Unchanged by Daisy-Chain)**

### READDEVICE Command

The READDEVICE command returns a 16-bit word read from the specified register in the addressed device only. If the register address is not valid for the device, the command is ignored. The command sequence is shown in [Table 29](#).

The command packet is forwarded up the daisy-chain until it reaches the addressed device. The addressed device overwrites the received fill bytes with the 2 bytes of register data and forwards the packet to the next device. The alive-counter byte is only incremented by the addressed device. A Manchester error immediately switches the data propagation from read mode to write (pass-through)

mode, ensuring that the Manchester error is propagated through the daisy-chain and back to the host.

### ROLLCALL Command

While not required for system initialization, the ROLLCALL command (01h) can be used to verify that all devices are responding, regardless of the value of FA[4:0]. The response of each device is identical to that of a READALL command of the ADDRESS register, where the first device address (FA[4:0]) is 00h, and there are 32 devices; therefore, the ROLLCALL command is sent with 64 fill bytes and each device places the data-check and PEC bytes after the 32nd register data word. This ensures that each device can return its ADDRESS register data.

**Diagnostics**

Built-in diagnostics support ISO 26262 (ASIL) requirements by detecting specific fault conditions, as shown in [Table 30](#). The device automatically performs some of the diagnostics while the host performs others during initialization (e.g., at key-on), or periodically during operation,

as required by the application. Diagnostics performed automatically by the device are previously described in the relevant functional sections. A description of the diagnostics requiring specific configurations are provided in this section.

<b>PROCEDURAL DIAGNOSTICS</b>			
<b>FAULT</b>	<b>DIAGNOSTIC PROCEDURE</b>	<b>OUTPUT</b>	
SHDNL stuck high	Idle mode	ALRTSHDNL	
HVMUX switch open	Acquisition with HVMUX test sources	ALRTOV, ALRTUV	
HVMUX switch short	ALTREF diagnostic	DIAG[15:0]	
HVMUX test sources	Acquisition with HVMUX test sources	CELLn	
Cn pin open	Acquisition with cell test sources	ALRTOV, ALRTUV	
Cn short to SWn	Acquisition with balancing switches	CELLn	
Cn pin leakage	ALTMUX vs. HVMUX acquisition	CELLn	
Voltage comparator fault	ALTMUX acquisition with balancing switches	CELLn	
Voltage comparator fault	ALTMUX acquisition with balancing switches	CELLn	
ALRTHVUV comparator	Acquisition with HV charge pump disabled	ALRTHVUV	
HVMUX sequencer	Acquisition with cell test sources	CELLn	
ALU Data Path	Acquisition with ADCTEST = 1	CELLn, VBLKP, DIAG, and AUXINn	
AUXINn Pin Open	Acquisition with AUXIN test sources	AUXINn	
Calibration corruption	Read CALx, IDx, perform CRC	ID2	

**Note:** Pin faults such as an open pin or adjacent pins shorted to each other must be detectable. Pin faults do not result in device damage but have a specific device response such as a communication error, or are detectable through a built-in diagnostic. Analyzing the effect of pin faults is referred to as a pin FMEA. Contact Maxim Applications to obtain pin FMEA results.

**ALTREF Diagnostic Measurement**

The ALTREF diagnostic measurement (DIAGSEL[2:0] = 0b001) checks the primary voltage reference of the ADC by measuring the alternate reference voltage (V<sub>ALTREF</sub>). The result is available in the DIAG register after a normal acquisition. See [Figure 32](#).

The ALTREF voltage is computed from the result in the DIAG register as follows:

$$V_{ALTREF} = (DIAG[15:2]/16384d) \times 5V$$

Since  $1.23V < V_{ALTREF} < 1.254V$  and  $V_{ALTREF} = 1.242V$  nominally, the expected range for DIAG[15:2] is  $(1.23V/5V) \times 16384d = 4030d$  to  $(1.254V/5V) \times 16384 = 4109d$ ; therefore,  $0FB8h \leq DIAG[15:2] \leq 100Dh$ . To use the 16-bit register value, the 14-bit values must be shifted or multiplied by 4 so that  $3EF8h \leq DIAG[15:0] \leq 4034h$ .

**V<sub>AA</sub> Diagnostic Measurement**

The V<sub>AA</sub> diagnostic measurement (DIAGSEL[2:0] = 0b010) verifies that V<sub>AA</sub> is within specification. This diagnostic measures V<sub>REF</sub>, but using V<sub>THRM</sub> as the ADC reference. See [Figure 33](#).

The voltage into the ADC is computed from the result in the DIAG register as follows:

$$(6/13) \times V_{REF} = (DIAG[15:2]/16384d) \times V_{THRM}$$

Assuming V<sub>THRM</sub> = V<sub>AA</sub>, then V<sub>AA</sub> is given by:

$$V_{AA} = (6/13) \times V_{REF} \times 16384d/DIAG[15:2],$$

where V<sub>REF</sub> = 2.307V

The result for V<sub>AA</sub> should fall within the range provided in the [Electrical Characteristics](#) table for V<sub>AA</sub>.

Figure 32. ALTREF Diagnostic

Figure 33. V<sub>AA</sub> Diagnostic

**LSAMP Offset Diagnostic Measurement**

The LSAMP diagnostic measurement (DIAGSEL[2:0] = 0b011) measures the level-shift amplifier offset by shorting the LSAMP inputs during the diagnostic portion of the acquisition. The result is available in the DIAG register after a normal acquisition. For this measurement, the ADC polarity is automatically set to bipolar mode to allow accurate measurement of voltages near zero. This measurement eliminates the chopping phase to preserve the offset error. If the diagnostic measurement exceeds the valid range for  $V_{OS\_LSAMP}$ , as specified in the [Electrical Characteristics](#) table, the chopping function may not be able to cancel out all the offset error, and acquisition accuracy could be degraded accordingly. See [Figure 34](#).

The LSAMP offset is computed from the result in the DIAG register as follows:

$$LSAMP\ Offset = (|DIAG[15:2] - 2000h | / 16384d ) \times 5V$$

The validity of measurements through LSAMP is further confirmed by the ALTREF and  $V_{AA}$  diagnostics, and comparison of the  $V_{BLKP}$  measurement to the sum of the cell measurements.

**Zero-Scale ADC Diagnostic Measurement**

Stuck ADC output bits can be verified with a combination of the zero-scale and full-scale diagnostics. The zero-scale ADC diagnostic measurement (DIAGSEL[2:0] = 0b100) verifies that the ADC conversion results in 000h when its input is at  $-V_{AA}$  in bipolar mode (since for an input  $\leq -2.5V$ ,  $DIAG[15:0] = 0000h$ ). For this measurement, the ADC is automatically set to bipolar mode. See [Figure 35](#).

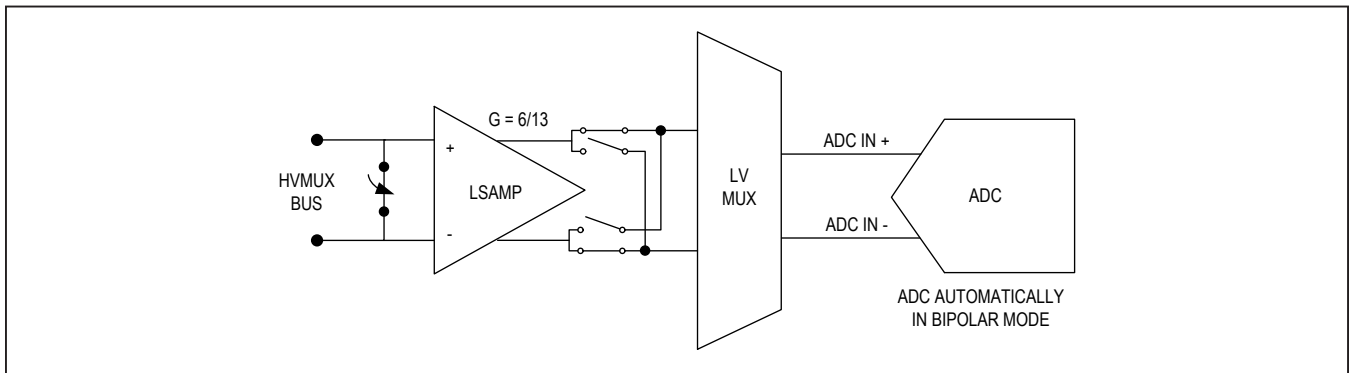

Figure 34. LSAMP Offset Diagnostic

Figure 35. Zero-Scale ADC Diagnostic

**Full-Scale ADC Diagnostic Measurement**

Stuck ADC output bits can be verified with a combination of the zero-scale and full-scale diagnostics. The full-scale ADC diagnostic measurement (DIAGSEL[2:0] = 0b101) verifies that the ADC conversion results in FFFh when its input is at V<sub>AA</sub> in bipolar mode (since for an input ≥ 2.5V, DIAG[15:0] = FFF0h). For this measurement, the ADC is automatically set to bipolar mode. See [Figure 36](#).

**BALSW Diagnostics**

Four balancing switch-diagnostic modes are available to facilitate the following diagnostics:

- Balancing switch shorted (BALSWDIAG[2:0] = 0b001)
- Balancing switch open (BALSWDIAG[2:0] = 0b010)
- Odd sense wire open (BALSWDIAG[2:0] = 0b101)
- Even sense wire open (BALSWDIAG[2:0] = 0b110)

Enabling any of these modes automatically preconfigures the acquisition (e.g., enables the ALTMUX measurement path). The host must initiate the acquisition, but the diagnostic mode automatically compares the measurements to the specific thresholds and sets any corresponding alerts. The host presets the thresholds, as determined by the minimum and maximum resistance of the switch (R<sub>SW</sub>) specified in the [Electrical Characteristics](#) table and the intended cell-balancing current.

During any balancing switch-diagnostic mode, ALRTOV, ALRTUV, and ALRTMSMTC comparisons are disabled.

Figure 36. Full-Scale ADC Diagnostic

After BALSWDIAG[2:0] is cleared, the modified configurations automatically return to their prior setting. The same configurations and comparisons could be implemented manually but at the expense of more host operations.

**BALSW Short Diagnostic**

A short-circuit fault in the balancing path could be a short between SW<sub>n</sub> and SW<sub>n-1</sub> (see [Figure 37](#)) or that the balancing FET is stuck in the conducting state. In the short-circuit state, the voltage between SW<sub>n</sub> and SW<sub>n-1</sub> (switch voltage) is less than the voltage between C<sub>n</sub> and C<sub>n-1</sub> (cell voltage).

When enabled, the balancing switch short-diagnostic mode (BALSWDIAG[2:0] = 0b001) functions as follows:

- Disables the balancing switches automatically
- Configures the acquisition using ALTMUX path automatically
- Host initiates the acquisition
- Compares the measurement to the BALSHRTTHR threshold value automatically ([Table 32](#))
- If outside the threshold, sets the corresponding flag in ALRTBALSW automatically

For the best sensitivity to leakage current, set the threshold value based on the minimum cell voltage minus a small noise margin (100mV), then update the threshold value periodically or every time a measurement is taken, depending on how fast the cell voltages are expected to change.

Figure 37. Balancing Switch Short

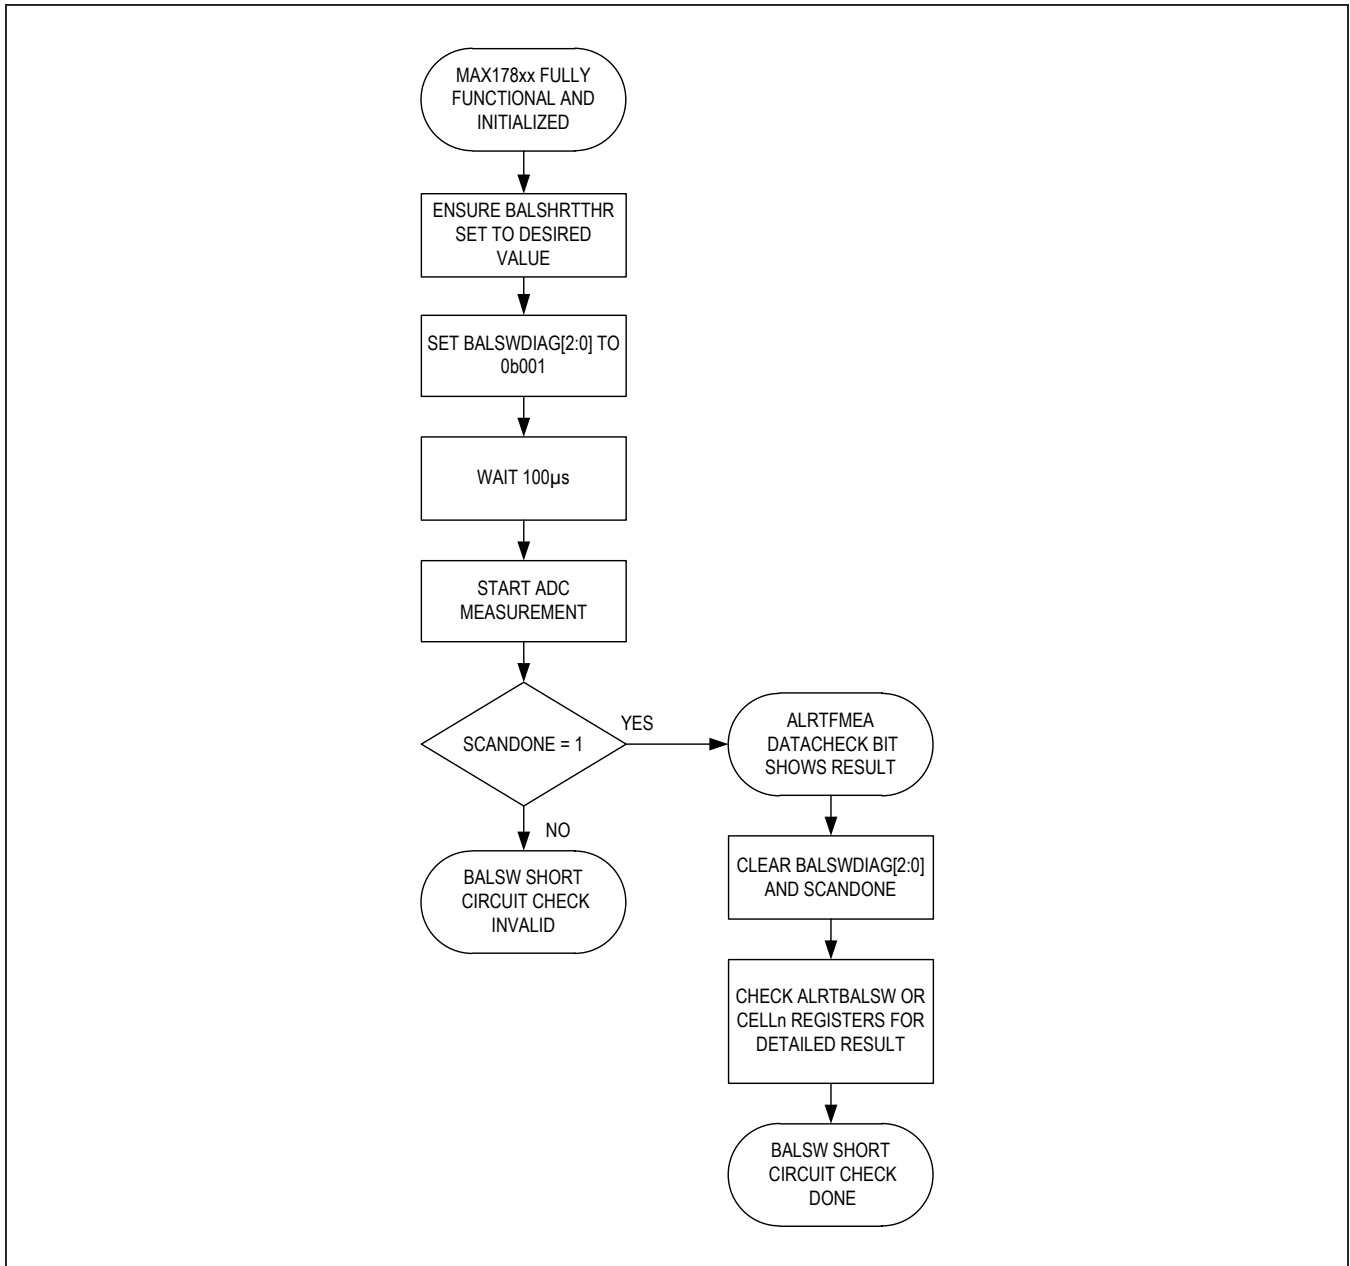

Figure 38. BALSWS Short Diagnostic

**Table 31. BALSWS Short-Diagnostic Auto Configuration**

CONFIGURATION BITS	AUTOMATIC SETTING	PURPOSE
MEASUREEN[14:12]	0b000	Disable AUXIN and V <sub>BLKP</sub> measurements
BALSWEN[11:0]	000h	Disable all balancing switches
DIAGCFG.ALTMUXSEL	1	Enable ALTMUX measurement path

**BALSW Open Diagnostic**

The BALSW open diagnostic (BALSWDIAG[2:0] = 0b010) verifies that each enabled balancing switch is conducting (not open) as follows:

- Automatically configures acquisition for bipolar mode (for measuring voltages near zero)
- Automatically configures acquisition for ALTMUX path
- Automatically configures acquisition to measure switch voltages for those switches enabled by BALSWEEN

- Host initiates acquisition
- Automatically compares measurement to the threshold value BALLOWTHR and BALHIGHTHR (Table 32)
- If outside the threshold, automatically sets the corresponding flag in ALRTBALSW

Set the thresholds by taking into account the minimum and maximum  $R_{SW}$  of the switch itself, as specified in the *Electrical Characteristics* table and the balancing current for the application. See Figure 39 and Table 33.

**Table 32. BALSW Diagnostics**

BALSW	$V_{SWn}$	FAULT INDICATED?	POSSIBLE FAULT CONDITION
On	> V(BALHIGHTHR)	Yes	Switch open circuit, or overcurrent
	> V(BALLOWTHR)	No	None
	< V(BALHIGHTHR)		
	< V(BALLOWTHR)	Yes	Path open circuit or short circuit
Off	> V(BALSHRTTHR)	No	None
	< V(BALSHRTTHR)	Yes	Short circuit or leakage current

**Table 33. BALSW Open-Diagnostic Auto Configuration**

CONFIGURATION BITS	AUTOMATIC SETTING	PURPOSE

MEASUREEN[11:0]	BALSWEEN[11:0]	Measure only active switch positions
DIAGCFG.ALTMUXSEL	1	Enable ALTMUX measurement path
SCANCTRL.POLARITY	1	Enable bipolar mode

Figure 39. BALSW Open Diagnostic

**Even/Odd Sense-Wire Open Diagnostics**

If enabled, the sense-wire open-diagnostic modes detect if a cell-sense wire is disconnected as follows:

- Automatically closes nonadjacent switches (even or odd)
- Automatically configures acquisition to use the ALTMUX path

- Host waits 100µs for settling and then initiates the acquisition
- Automatically compares result to the BALHIGHTHR and BALLOWTHR register
- If outside thresholds, automatically sets flags in ALRTBALSW

See [Figure 40](#), [Figure 41](#), [Table 34](#), [Table 35](#), and [Table 36](#).

SCANCTRL.POLARITY	1	Enable bipolar mode

**Diagnostic Test Sources**

Diagnostic test current sources (see [Figure 42](#)) can be enabled prior to the acquisition mode for detecting both internal and external hardware faults in the measurement path. One set of test sources is connected to the HVMUX input side and another set is connected to the HVMUX output side. The basic premise in these diagnostics is for a symmetrical measurement channel with no faults, the test currents can be applied symmetrically to the differential channel and there should only be almost no change in the channel measurement. On the other hand, if an asymmetric fault exists on the channel, the resulting change will indicate the nature of the fault (e.g., an open or shorted pin).

For the 15 test current sources on the input channels (13 C<sub>n</sub> and 2 AUXIN<sub>n</sub>):

- The test currents are individually enabled per CTSTEN[12:0] and AUXINTSTEN[2:1]
- The test current ranges from 6.25µA up to 100µA per CTSTDAC[3:0] (applies to all enabled sources)
- The test current sources from V<sub>AA</sub> or sinks to AGND per the CTSTSRC bit (applies to all enabled sources)

For the two test current sources on the HVMUX output side:

- The test currents are enabled by the MUXDIAGEN bit
- The test current always sources from the HV supply

- The test current ranges from 3.125µA up to 50µA per CTSTDAC[3:0] (applies to all enabled sources)
- The test current, by default, is applied to both HVMUX outputs (even and odd outputs); however, if MUXDIAGPAIR is set, the test current is applied to only one of the output lines per MUXDIAGBUS. This mode is used to test the test sources themselves (see [Table 37](#) for HVMUX output assignments)

**Table 37. HVMUX Output Assignment**

INPUT SIGNAL	HVMUX OUTPUT

C0	Even bus
REF	Odd bus
ALTREF	Odd bus
AGND	Even bus

Figure 42. Test Current Sources

**Shutdown Diagnostic**

The shutdown diagnostic, as shown in [Table 38](#), verifies that no hardware fault is preventing the device from shutting down, such as the SHDNL input being stuck at logic-one. To perform the diagnostic, the host attempts a shutdown. The timing shown in [Figure 43](#) is for a UART idle-mode shutdown. Once  $V_{SHDNL} < 0.6V$ , the ALRTSHDNL bit is set in the STATUS register and the regulator is disabled;

however, the STATUS register may still be read as long as  $V_{AA}$  has not decayed below 2.95V (typ), which takes about 1ms. The host should verify that ALRTSHDNL is set. By reading the bit, the charge pump drives  $V_{SHDNL} > 1.8V$  in about 200 $\mu$ s and enables the regulator. The host must clear the ALRTSHDNL bit to complete the diagnostic. The ALRTSHDNLRT bit is a real-time version of ALRTSHDNL, which automatically clears when  $V_{SHDNL} > 1.8V$ .

**Table 38. Shutdown Diagnostic**

FAULT	COMPARISON	ALERT BIT	LOCATION
SHDNL input stuck	$V_{SHDNL} < 0.6V?$	ALRTSHDNL	STATUS[12]
SHDNL input stuck	$V_{SHDNL} < 0.6V?$	ALRTSHDNLRT	STATUS[11]

Figure 43. Shutdown Diagnostic Timing

**HVMUX Switch Open Diagnostic**

Since an open HVMUX switch causes the measured voltage to go to either zero or full scale, it is possible to execute the test by looking for an overvoltage or undervoltage alert following the diagnostic measurement, without analyzing the measurement data. It is possible to read all voltage measurements and let the host compare the results by splitting the test into several segments.

The procedure in Figure 44 is quick and efficient. For higher sensitivity to faults, each cell-voltage measurement in the diagnostic mode can be compared to a threshold of 100mV by the host to determine if the HVMUX path is working correctly. The threshold is derived from the worst-case HVMUX resistance mismatch and the worst-case diagnostic current-source value variation. See Table 39 for the HVMUX switch open-fault locations

Figure 44. HVMUX Switch Open Diagnostic

**Table 39. HVMUX Switch Open Diagnostic**

		HVMUX SWITCH OPEN-FAULT LOCATION

	Cell12	NC	NC	NC	NC	NC	NC	NC	NC	NC	NC	NC	0V	5V

Note: NC = No change.

**HVMUX Switch Shorted Diagnostic**

A shorted mux switch is detectable in two ways based on corrupted measurement values. First, the ALTREF diagnostic will report a large error. Also, during normal cell measurements, a shorted HVMUX switch will cause the LSAMP to saturate, which is also easily detectable.

**HVMUX Test Source Diagnostic**

The two current sources attached to the HVMUX even bus and the HVMUX odd bus can be enabled independently instead of as a pair setting the MUXDIAGPAIR bit. MUXDIAGBUS controls which source is enabled (MUXDIAGBUS = 1 for odd bus source). This causes every measurement to have a definable change as the sources are enabled and disabled. By taking measurements while alternating which current source is enabled, it is possible to verify that each current source is working (see [Table 40](#)).

**Table 40. HVMUX Test Source Diagnostic**

HVMUX TEST SOURCE FAULT:	EVEN TEST SOURCE SHORTED TO HV	EVEN TEST SOURCE OPEN CIRCUIT	ODD TEST SOURCE SHORTED TO HV	ODD TEST SOURCE OPEN CIRCUIT

**Note:** I = Test source current, R = HVMUX resistance.

**Cn Open Diagnostic**

If the cell is disconnected from the input, the corresponding cell test source (sinking to AGND) will pull the cell input voltage toward 0V (except for C0, where source to V<sub>AA</sub> current source will pull the cell input voltage to V<sub>AA</sub>) A new measurement is taken with the current sources enabled, and a change in measurement value is detected. If no open circuit exists, then the measurement value will change by only the value of the test current across the application circuit series resistor to the Cn pin. See [Table 41](#).

**Table 41. Cn Pin Open Diagnostic**

**Note:** NC = no change.

**Cn Shorted to SWn Diagnostic**

Short circuits between the SWn pins and the cell input pins are detectable. A shorted SWn pin can be detected by an acquisition with the relevant cell balancing switch off and then again with it on. If the SWn pin is not shorted to an adjacent cell input pin, no change in the measured value should be observed for the two cases. If the SWn

pin is shorted to the Cn pin, then the measured value will change by approximately 40-50% when the balancing switch is turned on based on the values of RBALANCE, and the balancing switch resistance. A short circuit from SWn to Cn-1 produces the same effect. By comparing both the VCELLn measurement value along with the VCELLn+1 and VCELLn-1 values, it is possible to determine exactly where the short circuit is located.

Figure 45. SWn to Cn Short

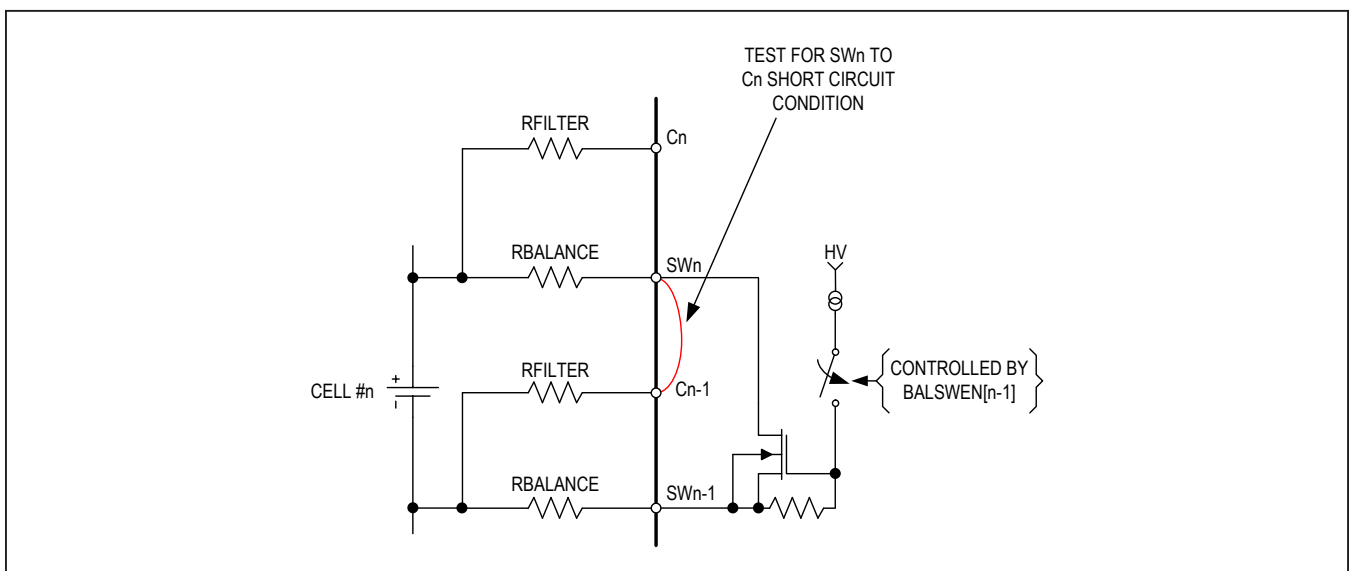

Figure 46. SWn-1 to Cn Short

**Cn Leakage Diagnostic**

Leakage at the Cn inputs can cause the voltage seen by the ADC to be different than that at the voltage source due to the resistance of the external filter circuit. By utilizing an alternate measurement path, any voltage errors as a result of Cn pin leakage may be detected. The SWn pins are connected to the cell sources through an alternate path. Implementing an HVMUX connection from the SWn pins to the LSAMP completes the redundant measurement path. This alternate measurement path for the cell measurements can be enabled by setting the ALTMUXSEL bit of the DIAGCFG register. When this bit is set and a measurement cycle is started, all cell measurements are taken using the alternate path instead of the Cn pin HVMUX connections. Measurements taken with the normal and alternate paths can be compared and should be nearly identical for a system with no faults. Since the SWn pins typically have a smaller external filter time constant than the Cn pins, increasing the oversampling setting for this diagnostic measurement may be beneficial for reducing measurement noise when the measurement is taken while the cells are exposed to transient loads.

**Cell Overvoltage Diagnostic**

Enabling balancing switches can be used to generate a voltage up to  $2 \times V_{CELL}$  at the ALTMUX inputs to test the input range capability, assuming the cell is sufficiently charged.

A cell-position input voltage is elevated by approximately  $1.5 \times V_{CELLn}$  turning on either BALS $W_{n+1}$  or BALS $W_{n-1}$ . When the adjacent switch is turned on, the SWn pin shared with the switch is moved by  $0.5 \times V_{CELL}$ , which causes  $V_{CELLn}$  to increase by that amount when measured with the ALTMUX path. For the topmost cell position, BALS $W_{n-1}$  must be used, and for the bottom cell position, BALS $W_{n+1}$  must be used. By turning on two adjacent switches instead of one, such as BALS $W_{n+1}$  and BALS $W_{n+2}$ , the measured voltage is approximately  $2 \times V_{CELL}$ , assuming all cells are at approximately the same voltage. This technique can create an input voltage that exceeds the overvoltage threshold to verify the higher end of the input range and the overvoltage alert function.

Input range can also be verified by using the cell-test sources to induce a higher cell channel voltage. If the change is as expected, it shows that the system can measure voltages above the present nominal input voltage.

Figure 47. Redundant HVMUX Paths

**Cell Undervoltage Diagnostic**

Turning on the balancing switch can be used to generate a near-zero voltage at any input channel to the ALTMUX path. By successfully measuring this near-zero voltage, the diagnostic verifies the lower-end of the input range and the undervoltage alert function.

Input range can also be verified by using the cell-test sources to induce a lower-cell channel voltage. If the change is as expected, it shows that the system can measure voltages below the present nominal input voltage.

**ALRTHVUV Comparator Diagnostic**

The ALRTHVUV comparator functionality can be verified by setting the CPEN bit (to disable the HV charge pump) and then discharging the external HV capacitor by performing an acquisition for 5ms (such as 12 cells, 32 oversamples), or by enabling using one or more of the cell-test current sources for an appropriate amount of time. The ALRTHVUV bit should be set after the voltage has decayed.

**HVMUX Sequencer Diagnostic**

The HVMUX control sequence can be checked using the sources attached to the Cn pins. The sources are controlled by the CTSTEN bits of the CTSTCFG register. The basic test method is as follows:

- 1) Perform an acquisition.
- 2) Turn on a cell-test source.
- 3) Wait for sufficient settling time.
- 4) Perform an acquisition.
- 5) Check that the cell(s) sharing the pin whose current source was turned on had the expected measurement change and other cells had no changes.
- 6) Repeat steps 1–5 for other pins to confirm there are no logic errors in the HVMUX control sequencer.

The cell-test sources can be turned on for individual pins to create a detectable measurement variation that is determined by the current source value and the series resistance of the cell input filter circuit. The settling time needed for a certain change in measurement value depends on the size of the external filter capacitors and the amplitude of the test-current source. A longer settling time gives the full-voltage change, while a shorter settling time saves test time and should still produce an easily detectable voltage difference. By detecting the expected measurement variation for a given cell input pair and running a sequence of tests to cover all cases, the HVMUX sequencer operation is verified.

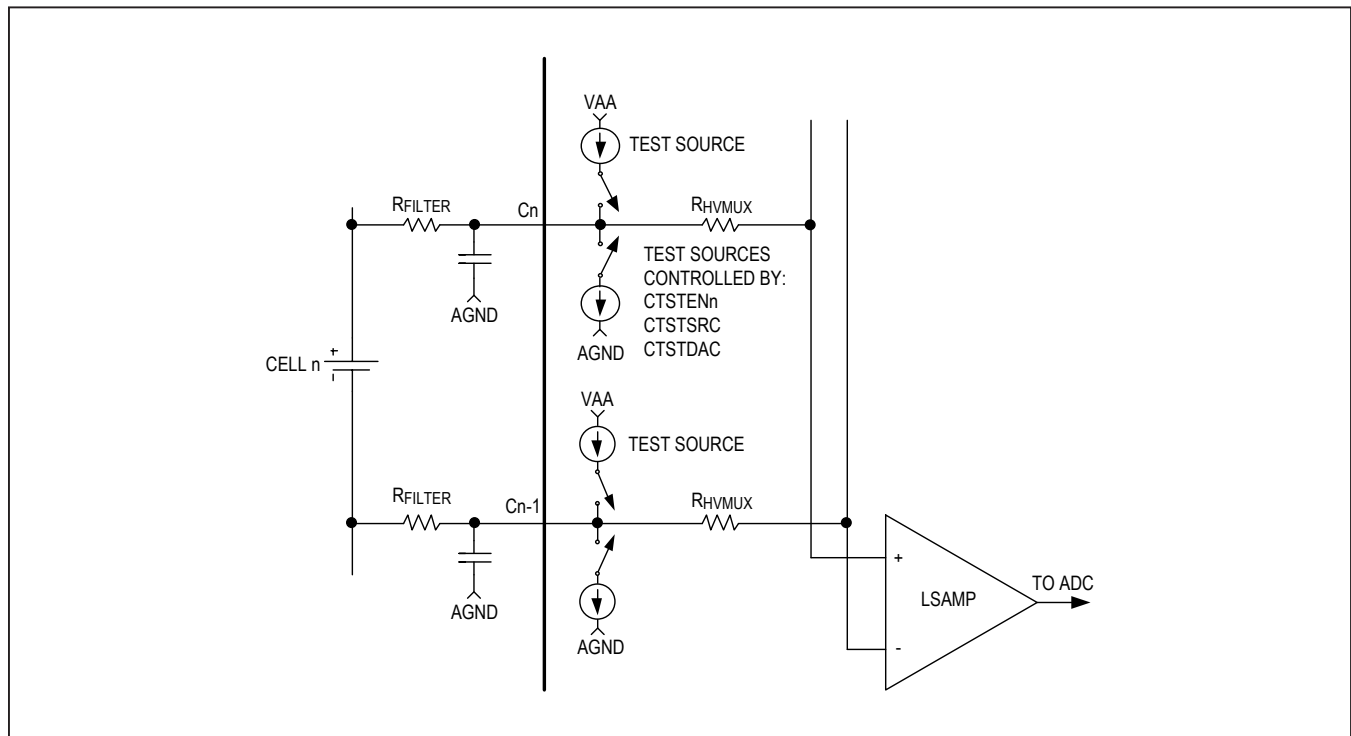

Figure 48. HVMUX Sequencer Diagnostic

Figure 49. HVMUX Sequencer Diagnostic

**ALU Diagnostic**

The ALU diagnostic utilizes the ADC test mode (ADCTSTEN = 1) to feed data from specific test registers directly into the ALU instead of from the ADC conversion. The host can write different data combinations to the test registers in this mode to provide test coverage for all ALU and data registers (CELLn, VBLKP, DIAG, and AUXINn) as well as all alerts that are based on the measurement data and the corresponding thresholds (e.g., overvoltage alerts).

The ADCTEST1x registers are used for all odd-numbered samples in oversampling mode as well as in single-sample acquisitions. The ADCTEST2x registers are used for all even-numbered samples (in oversampling mode). The A registers are used in lieu of the first conversion of each measurement and the B registers are used in lieu of the second conversion. After the acquisition, the host can read the measurement data registers and the alert registers and compare the data to expected values to verify the ALU functionality.

Figure 50. ALU Diagnostic

**AUXINn Open Diagnostic**

The AUXINn open diagnostic can be used to detect if the AUXINn pin is open circuit. The diagnostic procedure is shown in [Figure 51](#) and [Figure 52](#).

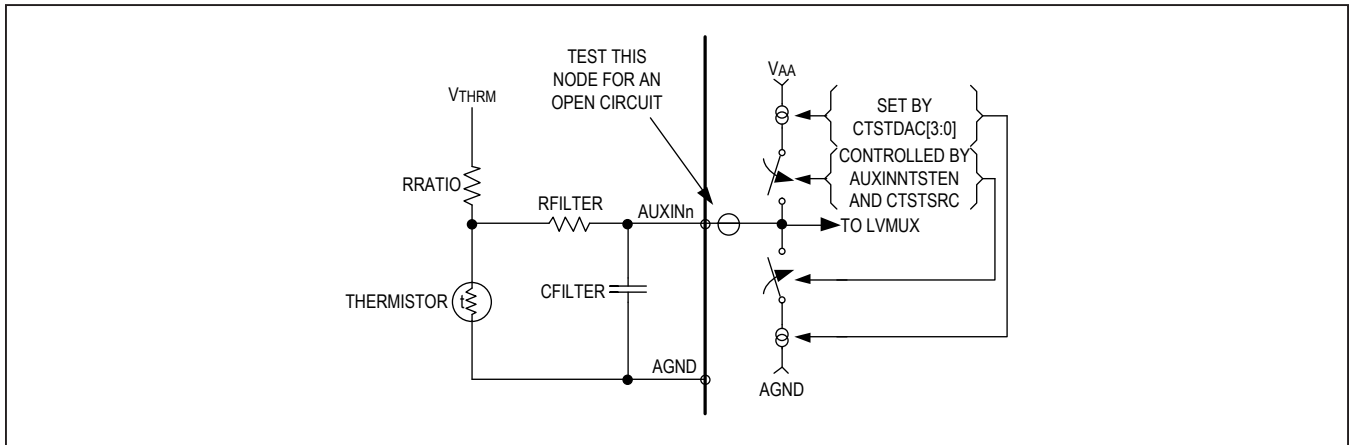

Figure 51. AUXINn Open Diagnostic

Figure 52. AUXINn Open Diagnostic

**Calibration ROM Diagnostic**

The CRC for the calibration ROM can be independently computed by the host. Any mismatch between the calculated CRC and the factory CRC indicates that the measurement accuracy may be compromised. The factory CRC, ROMCRC[7:0], is stored in the ID2 register.

The CRC for the calibration ROM uses the same polynomial as the CRC-8 PEC byte and is performed on addresses C0h to CAh, CFh, ID1, and ID2 and processed in the order shown in [Table 42](#), least-significant bit first. Registers CAL11, CAL12, CAL13, and CAL14 are excluded from the calculation. Also, certain ROM bits must be zeroed prior to performing the calculation using the bit-wise AND masks in [Table 42](#).

**Table 42. CRC Bit Mask**

ORDER	ADDRESS	NAME	BIT-WISE AND MASK
1	0xC0	CAL0	0x003F
2	0xC1	CAL1	0x007F
3	0xC2	CAL2	0x3FFF

**Applications Information**

**Vehicle Applications**

Battery cells can use various chemistries such as NiMH, Li-ion, SuperCap, or Lead-Acid. SuperCap cells are used in fast-charge applications such as energy storage for regenerative braking. An electric vehicle system may require a high-voltage battery pack containing up to 200 Li-ion cells or up to 500 NiMH cells.

A battery module is a number of cells connected in series that can be connected with other modules to build a high-voltage battery pack (see [Figure 53](#)). The modularity allows for economy, configurability, quick assembly, and serviceability. The minimum number of cells connected to any one device is limited by the device’s minimum operating voltage. The 9V minimum for  $V_{DCIN}$  usually requires at least two Li-ion, six NiMH, or six SuperCap cells per module.

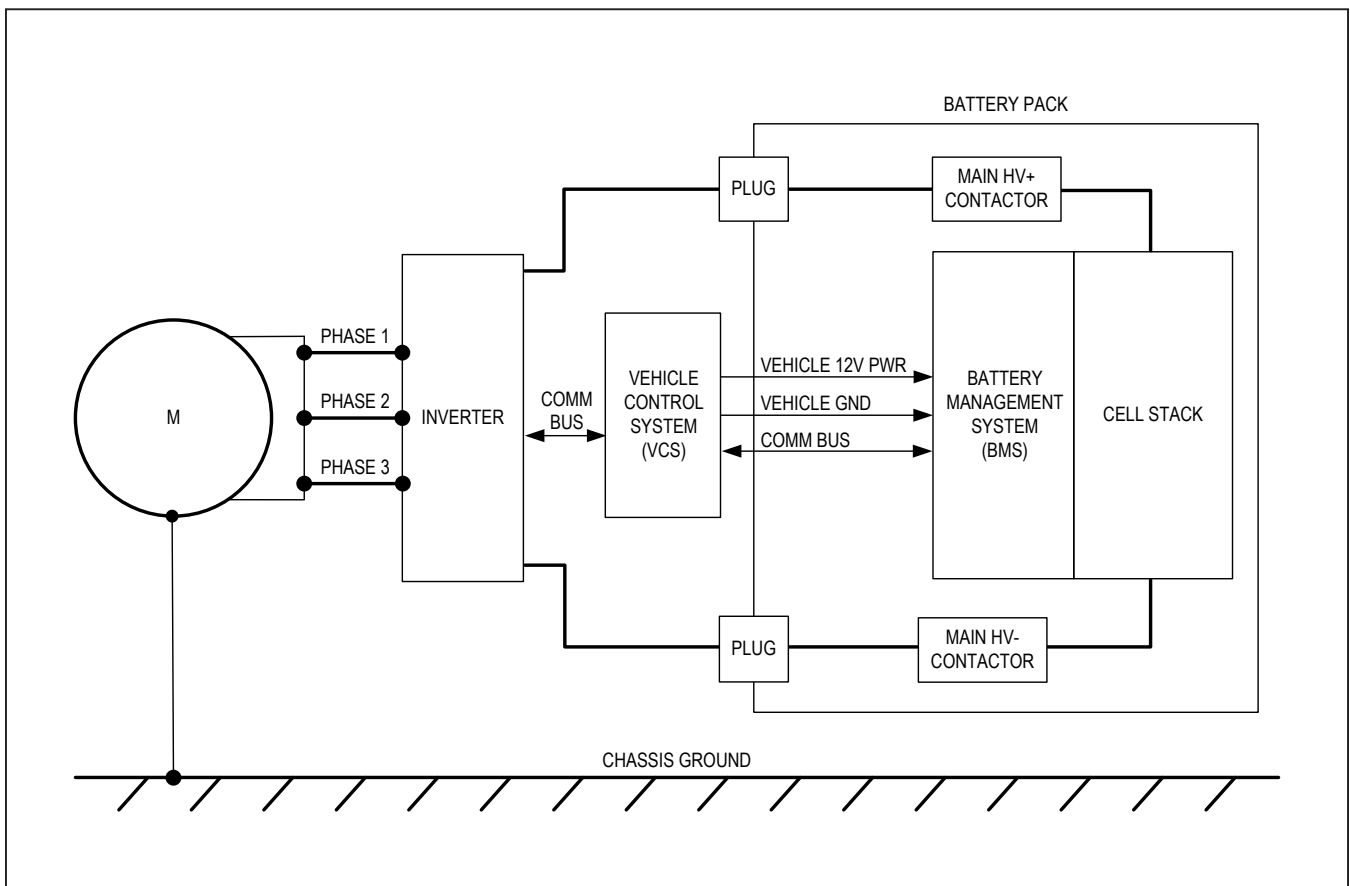

Figure 53. Electric Vehicle System

### Battery Management Systems

#### Daisy-Chain System

A daisy-chain system employs a single data link between the host and all the battery modules. The daisy-chain method reduces cost and requires only a single isolator between the lowest module and the host.

Figure 54. Daisy-Chain System

**Distributed-Module Communication**

A distributed-module system employs a separate data link and isolator between each battery module and the host with an associated increase in cost.

Figure 55. Distributed System

### Combining MAX17823H and MAX17880 Devices

The MAX17823H can be used stand-alone or in conjunction with the MAX17880. For systems containing both types of devices, the simplest implementation is to segregate them into two separate daisy chains. The separate daisy-chains increase the reliability and simplify device addressing.

However, if the system employs only a single daisy-chain, the companion devices must coexist in the same daisy-chain. To mitigate any potential addressing conflicts, the battery-management UART protocol allows the host to create a separate address space for each type of device. The host creates the separate address spaces during initialization of the daisy-chain. The host issues separate HELLOALL commands for each type of device using 57h for MAX17823H and A7h for MAX17880. Each type of device will ignore the HELLOALL command intended for the other type. While it does not matter which HELLOALL command is issued first, the host must ascertain the address returned from the first HELLOALL command, which is the last device address incremented by one. That value can then be used as the first address sent with the second HELLOALL command. In this manner, separate address spaces are created for each type of device.

### Acquisition Latency for Daisy-Chain Systems

A maximum 3-bit delay (1.5 $\mu$ s) is incurred as any command propagates through each daisy-chained device. For example, for an 8-device stack, a maximum 12 $\mu$ s delay is incurred. This allows all eight acquisitions to occur within 12 $\mu$ s of each other.

### Power-Supply Connection

Both internal and external protection circuits permit the device to derive its supply directly from the battery module voltage. The circuits protect against transients such as those that occur when the battery voltage is first connected to the device, when the vehicle inverter is connected to the battery stack, or during charge/discharge transitions such as regenerative braking. The internal circuits include 72V-tolerant battery inputs and a high noise rejection ratio (PSRR) for the internal low-voltage regulator.

The external protection circuit shown in [Figure 56](#) filters and clamps the DCIN input. During negative voltage transients, the filter capacitor maintains power to the device through the transient.

For maximum measurement accuracy, dedicated wires separate from the cell-sense wires should be used for the power-supply connection (Kelvin sense). This is to eliminate voltage drops in the sense wires induced by supply current. If the application can tolerate the induced error, the supply wires can serve as the sense wires to reduce the wire count.

### Connecting Cell Inputs

If the battery stack contains less than 12 cells, the lowest-order inputs (e.g., C1 and C0) should be utilized first and connected to the lowest common-mode signals. Any unused cell inputs should be shorted together and any unused switch inputs should be shorted together. The TOPCELL register must also be configured for stacks with less than 12 cells to mask out any false alerts corresponding to the unused channels.

### External Cell Balancing

The cell-balancing current can be switched by external transistors if more power dissipation is required. The internal switches can be used to switch the external transistors; the power is limited by external current-limiting resistors.

Figure 56. Power-Supply Connection

**External Cell-Balancing Using FET Switches**

An application circuit for cell-balancing that employs FET switches is shown in [Figure 57](#).  $Q_{BALANCE}$  is selected for low  $V_T$  that meets the minimum  $V_{CELLn}$  requirements of the application during balancing.  $D_{GATE}$  protects  $Q_{BALANCE}$  from reverse  $V_{GS}$  voltage during a hot-plug event.  $R_{GATE}$  protects the device by limiting the hot-plug inrush current.  $C_{GATE}$  can be added to attenuate transient noise coupled from the drain to the gate to maintain the transistor bias. The cell-balancing current is limited by  $R_{BALANCE}$ . A list of FET balancing components is shown in [Table 43](#).

Figure 57. External Balancing (FET)

**Table 43. FET Balancing Components**

COMPONENT NAME	TYPICAL VALUE OR PART	FUNCTION
$R_{BIAS}$	1k $\Omega$	Voltage-divider for transistor bias
$R_{GATE}$	100 $\Omega$	Hot-plug current-limiting resistor
$D_{GATE}$	S1B	Reverse-voltage gate protection
$C_{GATE}$	1nF	Transient $V_{GS}$ suppression
$R_{BALANCE}$	per application	Balancing current-limiting resistor
$Q_{BALANCE}$	SQ2310ES	External switch

**External Cell Balancing Using BJT Switches**

An application circuit for cell balancing that employs BJT switches is shown in [Figure 58](#). Q<sub>BALANCE</sub> is selected for power dissipation based on the I<sub>B</sub> drive current available and the cell-balancing current. D<sub>BASE</sub> protects Q<sub>BALANCE</sub> from negative V<sub>GS</sub> during hot-plug events. R<sub>BASE</sub> protects the device by limiting the hot-plug inrush current. The cell-balancing current is limited by R<sub>BALANCE</sub>. A list of BJT balancing components is shown in [Table 44](#).

Figure 58. External Cell Balancing (BJT)

**Table 44. BJT Balancing Components**

COMPONENT NAME	TYPICAL VALUE OR PART	FUNCTION
R <sub>BIAS</sub>	22Ω	Voltage-divider for transistor bias
R <sub>BASE</sub>	15Ω	Hot-plug current-limiting resistor
D <sub>BASE</sub>	S1B	Reverse emitter-base voltage protection
C <sub>BASE</sub>	1nF	Transient V <sub>BE</sub> suppression
R <sub>BALANCE</sub>	per balancing current requirements	Balancing current-limiting resistor
Q <sub>BALANCE</sub>	NST489AMT1	External switch

**External Cell-Balancing Short-Circuit Detection**

A short-circuit fault in the external balancing path results in continuous current flow through  $R_{BALANCE}$  and  $Q_{BALANCE}$ . To detect this fault, the voltage drop across the sense-wire parasitic resistance must be measurable. A very small series resistor can added for this purpose.

**UART Interface**

The UART pins also employ both internal and external circuits to protect against noise. The recommended external filters are shown in [Figure 59](#). ESD protection is shown in [Figure 59](#) and [Figure 60](#).

Figure 59. UART Connection

**High-Z Idle Mode**

The high-Z idle mode lowers radiated emissions from wire harnesses by minimizing the charging and discharging of the AC-coupling capacitors when entering and exiting the idle mode. The application circuit shown in [Figure 61](#) uses a weak resistor-divider to bias the TX lines to  $V_{DDL}$  during the high-Z idle period and pnp transistor clamps to limit the maximum voltage at the TX pins during high noise injection. The resistor-divider and pnp clamps are not needed for applications utilizing only the low-Z mode. The low-Z and high-Z idle modes both exhibit a similar immunity to noise injection. Low-Z mode may be pre-

ferred for ports driving inductive loads to minimize ringing. See [Figure 60](#) for a high-Z idle mode application circuit.

**UART Supplemental ESD Protection**

The UART ports may require supplemental protection to meet IEC 61000-4-2 requirements for contact discharge. The recommended circuits to meet  $\pm 8\text{kV}$  protection levels are shown in [Figure 61](#) and [Figure 62](#). The protection components should be placed as near as possible to the signal's entry point on the PCB.

Figure 60. High-Z Idle Mode Application Circuit

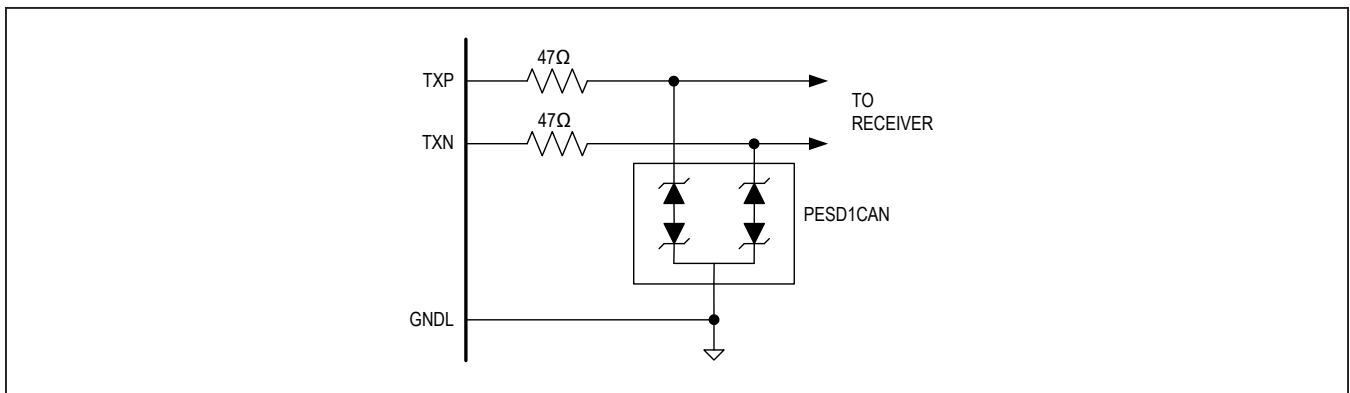

Figure 61. External ESD Protection for UART TX Ports

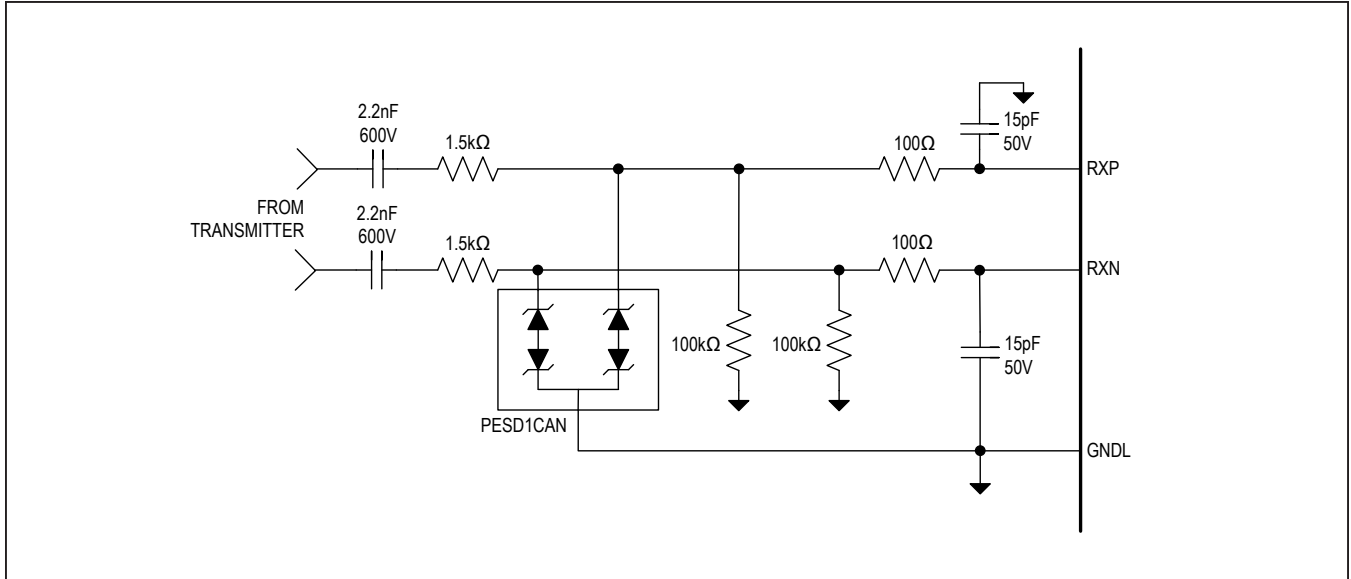

Figure 62. External ESD Protection for UART RX Ports

### Single-Ended RX Mode

To configure the lower port for single-ended RX mode, the RXLP input is connected to digital ground and the RXLN input receives the inverted signal, just as it does for differential mode. If the host cannot transmit inverted data then the signal must be inverted as shown in [Figure 63](#). Transmitter operation is not affected. If the upstack device is single-ended then only the TXUN signal is required. **Note:** In single-ended mode, SHDNL must be driven externally.

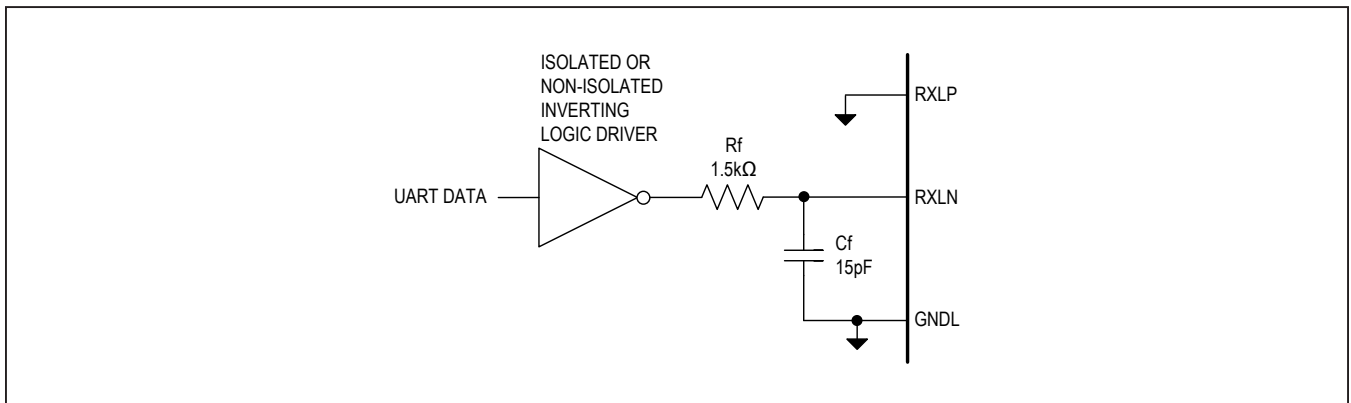

Figure 63. Application Circuit for Single-Ended Mode

**UART Isolation**

The UART is expected to communicate reliably in noisy high-power battery environments where both high dV/dt supply noise and common-mode current injection induced by electromagnetic fields are prevalent. Common-mode currents can also be induced by parasitic coupling of the system to a reference node such as a battery or vehicle chassis. The daisy-chain physical layer is designed for maximum noise immunity.

The AC-coupled differential communication architecture has a ±30V common-mode range and +6V differential swing. This range is in addition to the static common-mode voltage across the AC-coupling capacitors between modules. Transmitter drivers have low internal impedance and are source-terminated by the application circuit so that impedances are well-matched in the high- and low-driver states. This architecture minimizes differential noise induced by common-mode current injection. The receiver inputs are filtered above the fundamental communication frequency to prevent high-frequency noise from entering the device. The system is designed for use with isolation transformers or optocouplers to provide an even higher degree of common-mode noise rejection in

circuit locations where extremely large common-mode noise is present, such as between vehicle chassis and the high-voltage battery pack terminals.

Since a mid-pack service-disconnect safety switch is present in many battery packs, the device is designed to communicate with the entire daisy-chain whether the service-disconnect switch is engaged or open. This is possible with daisy-chains that employ capacitor isolation.

**UART Transformer Isolation**

The UART ports can be transformer-coupled because of their DC-balanced differential design (see [Figure 64](#)). Transformer coupling between the MAX17841B interface and the MAX17823H provide excellent isolation and common-mode noise rejection. The center-tap of a signal transformer can be used to enhance common-mode rejection by AC-coupling the node to local ground. Common-mode currents that are able to pass through the parasitic coupling of the primary and secondary are shunted to ground to make a very effective common-mode noise filter.

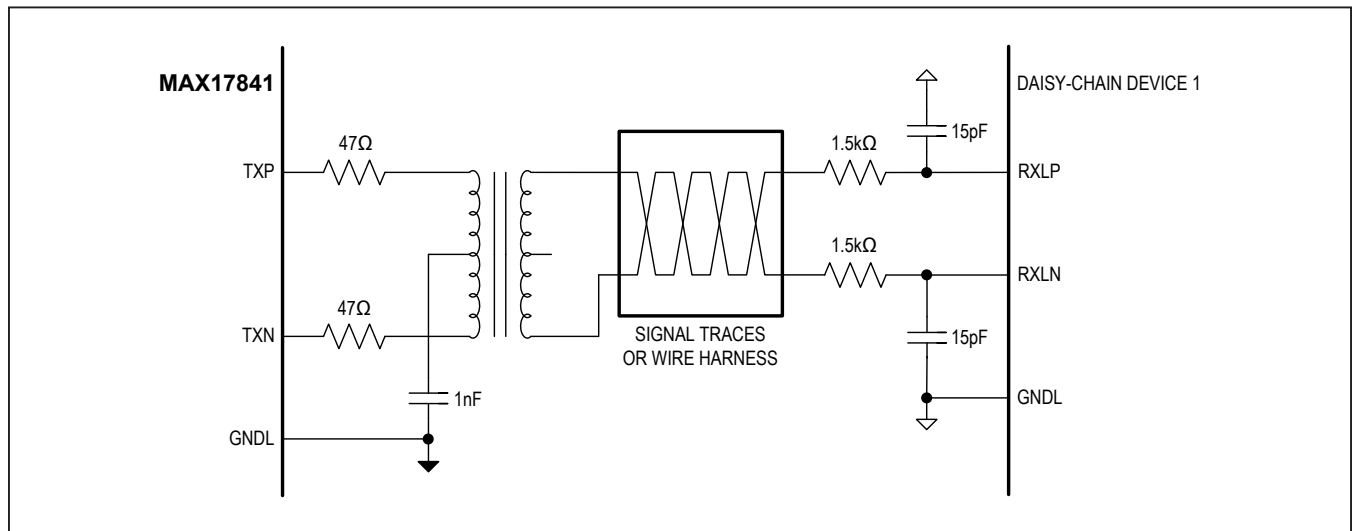

Figure 64. UART Transformer Isolation

**UART Optical Isolation**

The daisy-chain can use optical isolation instead of transformer or capacitor isolation (see [Figure 65](#)).

**Device Initialization Sequence**

Immediately after reset, all device addresses are set to 0x00 and the UART baud rate and receive modes have not been auto-detected; therefore, the following initialization sequence is recommended after every reset or after any change to the hardware configuration (see [Figure 66](#)):

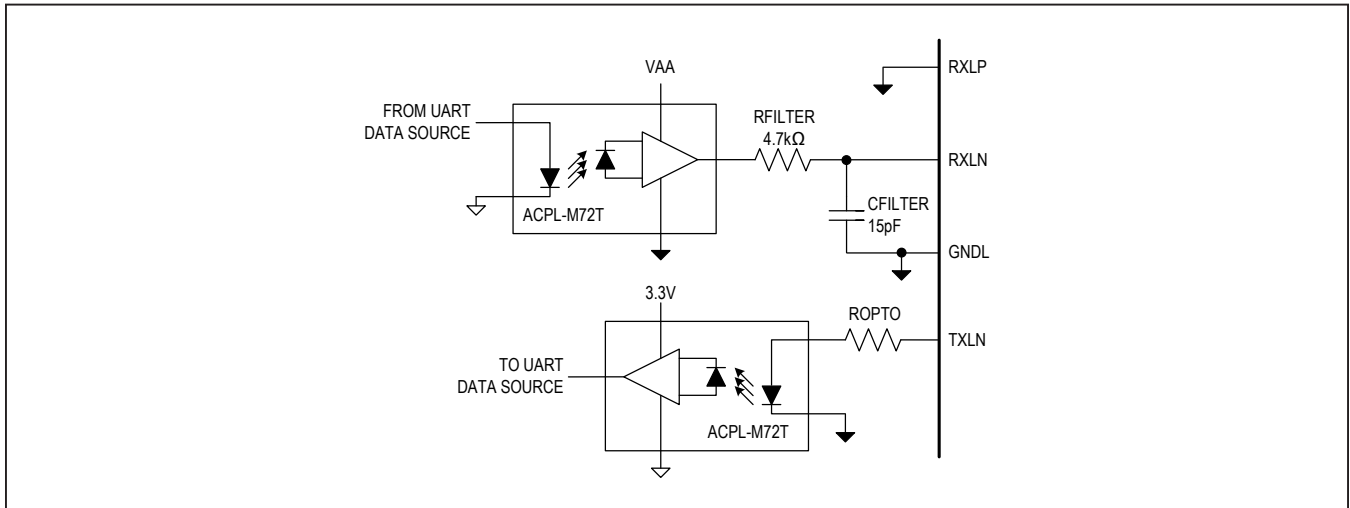

Figure 65. UART Optical Isolation

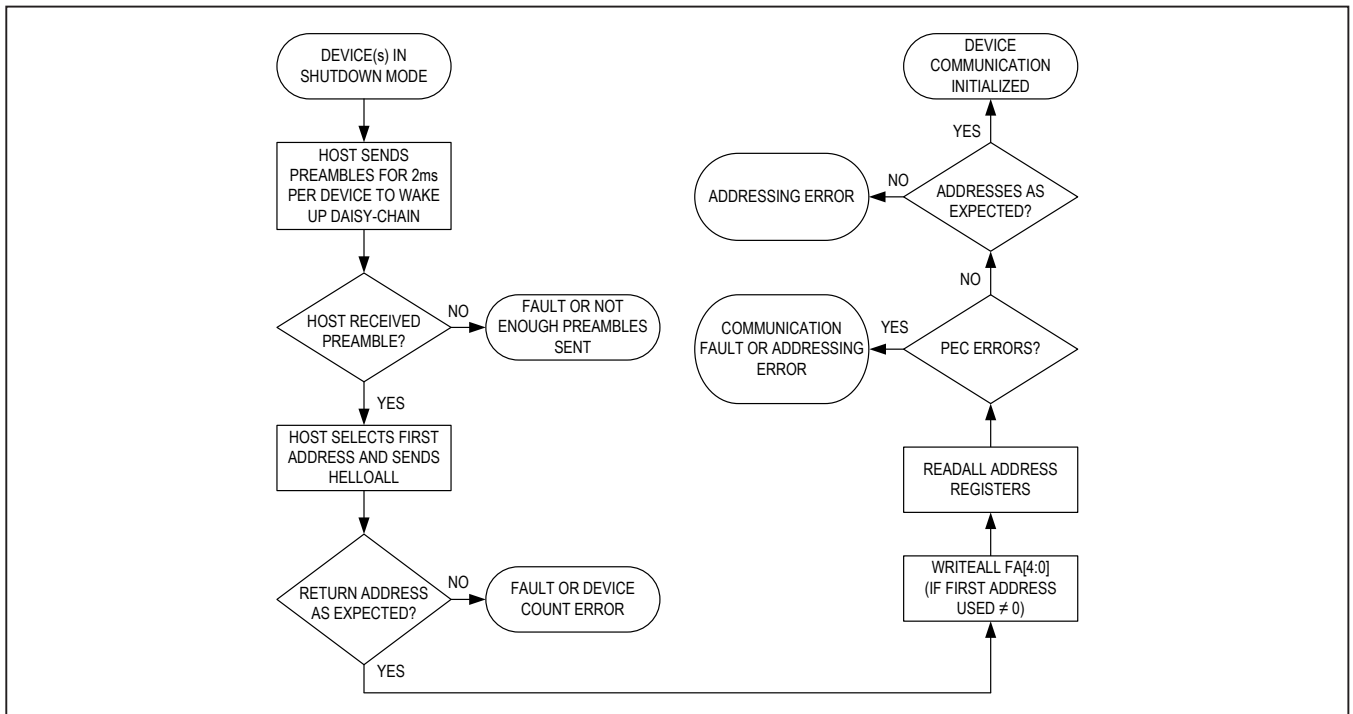

Figure 66. Device Initialization Sequence

After the daisy-chain is initialized, each device should be configured for operation as follows:

- 1) Perform a READALL of the status registers.
  - The ALRTRST bit should be set in all devices to signify that a reset occurred.
  - Check for other unexpected alerts.
- 2) Clear the ALRTRST bit on each device so that future unintended resets can be detected.
- 3) Change configuration registers as necessary with WRITEALL commands:
  - Configure the alert enables and alert thresholds as required by the application.
  - Configure the acquisition mode.
- 4) Perform all necessary key-on diagnostics.
- 5) Start the acquisition cycle.
- 6) Continuously monitor diagnostic and alert status bits.
- 7) Periodically perform additional diagnostics, as required by the application.

**Error Checking**

Data integrity is provided by Manchester encoding, parity, character framing, and packet-error checking (PEC). The combination of these features verify stage-to-stage communication both in the write and read directions with a hamming distance(HD) value of 6 for commands with a length up to 247 bits (counted prior to Manchester encoding and character framing). This is equivalent to the longest possible command packet for a daisy-chain of up to 13 devices. The data-check byte is present in the READALL and READDEVICE commands to verify the entire command propagated without errors. Using the

data-check and PEC bytes, complete transaction integrity for READALL and READDEVICE command packets can be verified.

**PEC Errors**

If the device receiver receives an invalid PEC byte, the ALRTPEC bit is set in the STATUS register. A device does not execute any write command unless the received PEC matches the calculated PEC, so to verify the write command execution, the host should perform a READALL to verify the contents of the written register.

For returned read packets, the host should store the received data, perform the PEC calculation, and compare the results to the received PEC byte before considering the data to be valid. To support PEC, the host must implement a CRC-8 (8-bit cyclic redundancy check) encoding and decoding algorithm based on the following polynomial:

$$P(x) = x^8 + x^6 + x^3 + x^2 + 1$$

The host uses the algorithm to process all bytes received in the command packet prior to the PEC byte itself. Neither the PEC nor the alive-counter bytes are part of the calculation. The bits are processed in the order they are received, LSB first. A byte-wise pseudocode algorithm is shown in [Figure 68](#), but lookup table solutions are also possible to reduce host calculation time.

For commonly issued command packets, the host can pre-calculate (hard-code) the PEC byte. For commonly used partial packets, the CRC value of a partial calculation can be used as the initial value for a subsequent run-time calculation (see [Figure 67](#)).

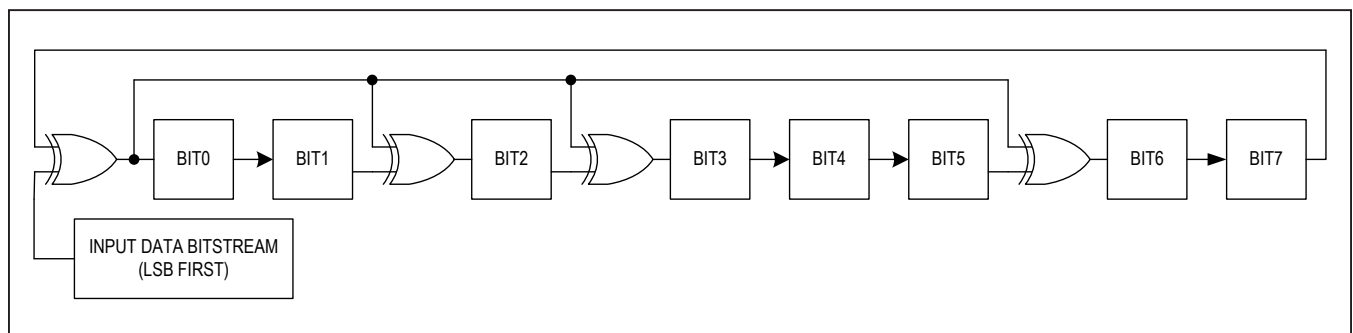

Figure 67. CRC Calculation

```

Function PEC_Calculation(ByteList(), NumberOfBytes, CRCByte)
{
    // CRCByte is initialized to 0 for each ByteList in this implementation, where
    // ByteList contains all bytes of a single command. It is passed into the
    // function in case a partial ByteList calculation is needed.

    // Data is transmitted and calculated in LSb first format
    // Polynomial = x^8+x^6+x^3+x^2+1
    POLY = &HB2 // 10110010b for LSb first

    //Loop once for each byte in the ByteList
    For ByteCounter = 0 to (NumberOfBytes - 1)
    (
        //Bitwise XOR the current CRC value with the ByteList byte
        CRCByte = CRCByte XOR ByteList(Counter1)

        //Process each of the 8 CRCByte remainder bits
        For BitCounter = 1 To 8
        (
            // The LSb should be shifted toward the highest order polynomial
            // coefficient. This is a right shift for data stored LSb to the right
            // and POLY having high order coefficients stored to the right.

            // Determine if LSb = 1 prior to right shift
            If (CRCByte AND &H01) = 1 Then
                // When LSb = 1, right shift and XOR CRCByte value with 8 LSbs
                // of the polynomial coefficient constant. "/ 2" must be a true right
                // shift in the target CPU to avoid rounding problems.
                CRCByte = ((CRCByte / 2) XOR POLY)
            Else
                //When LSb = 0, right shift by 1 bit. "/ 2" must be a true right
                // shift in the target CPU to avoid rounding problems.
                CRCByte = (CRCByte / 2)
            End If

            //Truncate the CRC value to 8 bits if necessary
            CRCByte = CRCByte AND &HFF

            //Proceed to the next bit
            Next BitCounter
        )

        //Operate on the next data byte in the ByteList
        Next ByteCounter
    )

    // All calculations done; CRCByte value is the CRC byte for ByteList() and
    // the initial CRCByte value
    Return CRCByte
}

```

0x27	0000h	CELL8	Cell 8 measurement result
0x28	0000h	CELL9	Cell 9 measurement result
0x29	0000h	CELL10	Cell 10 measurement result
0x2A	0000h	CELL11	Cell 11 measurement result
0x2B	0000h	CELL12	Cell 12 measurement result
0x2C	0000h	BLOCK	Block-measurement result
0x2D	0000h	AIN1	AUXIN1 measurement result
0x2E	0000h	AIN2	AUXIN2 measurement result
0x2F	0000h	TOTAL	Sum of all cell measurements
0x40	FFFCh	OVTHCLR	Cell overvoltage-clear threshold
0x42	FFFCh	OVTHSET	Cell overvoltage-set threshold
0x44	0000h	UVTHCLR	Cell undervoltage-clear threshold
0x46	0000h	UVTHSET	Cell undervoltage-set threshold
0x48	FFFCh	MSMTCH	Cell-mismatch threshold
0x49	0000h	AINOT	AUXIN overtemperature threshold
0x4A	FFF0h	AINUT	AUXIN undertemperature threshold
0x4B	0000h	BALSHRTTHR	Balancing switch diagnostic, short-circuit threshold
0x4C	0000h	BALLOWTHR	Balancing switch diagnostic, on-state low threshold
0x4D	0000h	BALHIGHTHR	Balancing switch diagnostic, on-state high threshold
0x50	0000h	DIAG	Diagnostic measurement result
0x51	0000h	DIAGCFG	Diagnostic configuration
0x52	0000h	CTSTCFG	Test-source configuration
0x57	0000h	ADCTEST1A	User-specified data for ALU diagnostic
0x58	0000h	ADCTEST1B	User-specified data for ALU diagnostic
0x59	0000h	ADCTEST2A	User-specified data for ALU diagnostic
0x5A	0000h	ADCTEST2B	User-specified data for ALU diagnostic

**Version Register (address 0x00)**

BIT	POR	NAME	DESCRIPTION	
D15	823h	MOD[11:0]	Model number. Always reads 823h.	
D14				
D13				
D12				
D11				
D10				
D9				
D8				
D7				
D6				
D5				
D4				
D3	7h	VER[3:0]	Die version per table below:	
D2			<b>VERSION</b>	<b>VER[3:0]</b>
D1			MAX17823H	7h
D0			MAX17823B	6h
			MAX17823A	5h
			MAX17823A	4h
			MAX17823	3h
			MAX17823	2h
	MAX17823	1h		

**ADDRESS Register (address 0x01)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12	0	FA[4:0]	Address of the device connected to the host (first address). If the host uses a first address other than 0x00 in the HELLOALL command, then the host must write that first address to all devices in the daisy-chain with a WRITEALL command. READALL commands require that FA[4:0] and DA[4:0] be correct in order for the data check and PEC features to function as intended.
D11			
D10			
D9			
D8			
D7	0	Reserved	Always reads logic-zero.
D6			
D5			
D4	0	DA[4:0]	Device address written by the HELLOALL command as it propagates up the daisy-chain and is automatically incremented for each device. The host must choose a first address so that the last device address will not exceed the maximum address of 0x1F during the HELLOALL command. Writing has no effect except with a HELLOALL command while ADDRUNLOCK = 1.
D3			
D2			
D1			
D0			

**STATUS Register (address 0x02)**

BIT	POR	NAME	DESCRIPTION
D15	1	ALRTRST	Indicates a power-on-reset event occurred. Clear after power-on and after a successful HELLOALL to detect future resets. Writing to a logic-one has no effect.
D14	0	ALRTOV	Bit-wise logical OR of ALRTOVCELL[15:0]. Read-only.
D13	0	ALRTUV	Bit-wise logical OR of ALRTUVCELL[15:0]. Read-only.
D12	0	ALRTSHDNL	Indicates $V_{SHDNL} < V_{IL}$ . Read during shutdown diagnostic when $V_{AA} > V_{PORFALL}$ . Cleared by writing to logic-zero or POR. Writing to a logic-one has no effect.
D11	0	ALRTSHDNLRT	Indicates $V_{SHDNL} < V_{IL}$ . Read during shutdown diagnostic when $V_{AA} > V_{PORFALL}$ . Read-only.
D10	0	ALRTMSMTCH	Indicates $V_{MAX} - V_{MIN} > V_{MSMTCH}$ . Cleared at next acquisition if the condition is false. Read-only.
D9	0	ALRTTCOLD	Logical OR of ALRTOVAIN0 and ALRTOVAIN1. Read-only.
D8	0	ALRTTHOT	Logical OR of ALRTUVAIN0 and ALRTUVAIN1. Read-only.
D7	0	ALRTPEC	Indicates a received character contained a PEC error. Cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D6	0	Reserved	Always reads logic-zero.
D5			
D4	0	ALRTMAN	Indicates that a character received by the lower UART contained a Manchester error. Cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D3	0	0	Write ignored, Read back '0'.
D2	0	ALRTPAR	Indicates that a character received by the lower UART contained a parity error. Cleared only by writing to logic-zero. Writing to logic-one has no effect.
D1	0	ALRTFMEA2	Bit-wise logical OR of FMEA2[15:0]. Read-only.
D0	0	ALRTFMEA1	Bit-wise logical OR of FMEA1[15:0]. Read-only.

**FMEA1 Register (address 0x03)**

BIT	POR	NAME	DESCRIPTION
D15	0	ALRTOSC1	Indicates that the 32kHz oscillator frequency is not within $\pm 5\%$ of its expected value. The status is updated every two cycles (32kHz). Cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D14	0	ALRTOSC2	Same as ALRTOSC1 (redundant alert). Cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D13	0	0	Always reads logic-zero.
D12	0	ALRTCOMMSEU1	Indicates that the UART has placed the upper-port receiver in single-ended mode based on the first preamble received after POR. This bit is not set until the ALRTRST bit is cleared. Read-only.
D11	0	ALRTCOMMSEL1	Indicates that the UART has placed the lower-port receiver in single-ended mode based on the first preamble received after POR. This bit is not set until the ALRTRST bit is cleared. Read-only.
D10	0	ALRTCOMMSEU2	Same as ALRTCOMMSEU1 (redundant alert) except that it sets before ALRTRST is cleared. Read-only.
D9	0	ALRTCOMMSEL2	Same as ALRTCOMMSEL2 (redundant alert) except that it sets before ALRTRST is cleared. Read-only.
D8	0	ALRTVDDL3	Indicates $V_{DDL3} < V_{VDDL\_OC}$ . This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D7	0	ALRTVDDL2	Indicates $V_{DDL2} < V_{VDDL\_OC}$ . This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D6	0	ALRTGNDL2	Indicates an open circuit on the GNDL2 pin. This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D5	0	ALRTBALSW	Bit-wise logical OR of ALRTBALSW[15:0]. Read-only.
D4	0	ALRTTEMP	Indicates that $T_{DIE} > 115^{\circ}\text{C}$ ( $120^{\circ}\text{C}$ typical) or that the diagnostic measurement did not have sufficient settling time ( $< 50\mu\text{s}$ ) and therefore may not be accurate. Cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D3	0	ALRTHVUV	Indicates $V_{HV} < V_{HVUV}$ . This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to logic-one has no effect.
D2	0	ALRTGNDL3	Indicates an open circuit on the GNDL3 pin. This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D1	0	ALRTVDDL1	Indicates $V_{DDL1} < V_{VDDL\_OC}$ . This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D0	0	ALRTGNDL1	Indicates an open circuit on the GNDL1 pin. This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.

**ALRTCELL Register (address 0x04)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13	0	ALRTAIN1	Logical OR of ALRTOVAIN1 and ALRTUVAIN1. Read-only.
D12	0	ALRTAIN0	Logical OR of ALRTOVAIN0 and ALRTUVAIN0. Read-only.
D11	0	ALRTCELL [12:1]	ALRTCELL[n] is the logical OR of ALROVCELL[n] and ALRTUVCELL[n]. Read-Only.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**ALRTOVCELL Register (address 0x05)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13	0	ALRTOVAIN1	Indicates $V_{AIN1} > AINUT$ (cold). Cleared at next acquisition if the condition is false. Read-only.
D12	0	ALRTOVAIN0	Indicates $V_{AIN0} > AINUT$ (cold). Cleared at next acquisition if the condition is false. Read-only.
D11	0	ALRTOV[12:1]	ALRTOV[n] indicates $V_{CELLN} > V_{OV}$ (OVTHRSET threshold) if ALRTOVEN[n] = 1. Cleared at next acquisition if the condition is false. Read-only.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**ALRTUVCELL Register (address 0x07)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13	0	ALRTUVAIN1	Indicates $V_{AIN1} < AINOT$ (hot). Cleared at next acquisition if the condition is false. Read-only.
D12	0	ALRTUVAIN0	Indicates $V_{AIN0} < AINOT$ (hot). Cleared at next acquisition if the condition is false. Read-only.
D11	0	ALRTUV[12:1]	ALRTUV[n] indicates $V_{CELLn} < V_{UV}$ (UVTHRSET threshold) if ALRTUVEN[n] = 1. Cleared at next acquisition if the condition is false. Read-only.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**ALRTBALS Register (address 0x08)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12			
D11	0	ALRTBALS [11:0]	ALRTBALS[n] indicates the corresponding measurement result exceeds the threshold specified by BALSWDIAG[2:0]. Cleared at next acquisition if the condition is false. Read-only.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**MINMAXCELL Register (address 0x0A)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12			
D11	Fh	MAXCELL[3:0]	Cell number of the maximum cell voltage currently in the measurement registers. If multiple cells have the same maximum value, this field contains the highest cell number with that measurement. Read-only.
D10			
D9			
D8			
D7	0	Reserved	Always reads logic-zero.
D6			
D5			
D4			
D3	Fh	MINCELL[3:0]	Cell number of the minimum cell voltage currently in the measurement registers. If multiple cells have the same minimum value, this field contains the highest cell number with that measurement. Read-only.
D2			
D1			
D0			

**FMEA2 Register (address 0x0B)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12			
D11			
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2	0	ALRTHVHDRM	Indicates that $V_{HV} - V_{C12}$ was too low during the acquisition for an accurate measurement. Cleared only by writing to logic-zero. Writing to a logic-one has no effect.
D1	0	Reserved	Always reads logic-zero.
D0	0	ALRTHVOV	Indicates that $V_{HV} - V_{DCIN} > V_{HVOV}$ . This bit is not set until the ALRTRST bit is cleared and cleared only by writing to logic-zero. Writing to a logic-one has no effect.

**ID1 Register (address 0x0D)**

BIT	POR	NAME	DESCRIPTION
D15	xxxxh	DEVID[15:0]	The two least-significant bytes of the 24-bit factory-programmed device ID. A valid device ID has two or more bits set to logic-one. Read-only.
D14			
D13			
D12			
D11			
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**ID2 Register (address 0x0E)**

BIT	POR	NAME	DESCRIPTION
D15	xxh	ROMCRC[7:0]	8-bit CRC value computed from the onboard read-only memory. Read-only.
D14			
D13			
D12			
D11			
D10			
D9			
D8			
D7	xxh	DEVID[23:16]	Most-significant byte of the 24-bit factory-programmed device ID. A valid device ID has two or more bits set to logic-one. Read-only.
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**DEVCFG1 Register (address 0x10)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Reads back the written value.
D14			
D13			
D12			
D11			
D10			
D9			
D8			
D7	0	FORCEPOR	Enables hard POR by pulling down SHDNL internally. If cleared before the POR occurs, it will disable the active pulldown on SHDNL.
D6	0	ALIVECNTEN	Enables inclusion of alive-counter byte at end of all write and read packets.
D5	0	ADCTSTEN	Enables the ALU test mode. This mode feeds 12-bit data from the ADCTEST registers directly into the ALU instead of from the ADC conversion.
D4	0	SCANTODIS	Disables the acquisition watchdog but does not clear the SCANTIMEOUT flag in the SCANCTRL register if it is set.
D3	0	DBLBUFEN	Enables the double-buffer mode. This mode automatically transfers data from the ALU to the data registers at the start of the next acquisition instead of at the end of the acquisition. This mode can be used in conjunction with the DATAMOVE bit so the host can start an acquisition and then start reading the previous acquisition (during the current acquisition), even if the read cycle takes longer than the acquisition.
D2	0	NOPEC	Disables packet-error checking (PEC).
D1	1	ADDRUNLOCK	Disables write-protection of device address DA[4:0]. Cleared only by HELLOALL command (write-protected).
D0	0	SPOR	Enables soft POR. Writing to a logic-zero has no effect. Always reads logic-zero.

**GPIO Register (address 0x11)**

BIT	POR	NAME	DESCRIPTION
D15	0	DIR[3:0]	Setting DIR[n] enables GPIO <sub>n</sub> as an output. Default state is high-impedance input.
D14			
D13			
D12			
D11	0	RD[3:0]	Indicates the current logic state of each GPIO <sub>n</sub> pin input buffer. The logic state is sampled at the end of the parity bit of the register address byte during a read of this register. Read-only.
D10			
D9			
D8			
D7	0	GPIO3TMR	Enables the GPIO3 timer mode. This mode overrides DIR[3] and DRV[3] and drives GPIO3 to logic-one when the timer is counting, and drives to logic-zero when the timer times out. Emergency-discharge mode (EMGCYDCHG=1) automatically enables the GPIO3 timer mode.
D6	0	Reserved	Always reads logic-zero.
D5			
D4			
D3	0	DRV[3:0]	Setting DRV[n] sets GPIO <sub>n</sub> to logic-one if DIR[n] is set.
D2			
D1			
D0			

**MEASUREEN Register (address 0x12)**

BIT	POR	NAME	DESCRIPTION
D15	0	BLKCONNECT	Connects the voltage-divider to the V <sub>BLKP</sub> pin. Must be enabled prior to the VBLOCK measurement.
D14	0	BLOCKEN	Enables measurement of the VBLKP input in the acquisition mode.
D13	0	AIN2EN	Enables measurement of the AUXIN2 input in the acquisition mode.
D12	0	AIN1EN	Enables measurement of the AUXIN1 input in the acquisition mode.
D11	0	CELLEN[12:1]	Enables measurement of the respective cell in the acquisition mode. Disabled channels result in a measurement value of 0000h.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**SCANCTRL Register (address 0x13)**

BIT	POR	NAME	DESCRIPTION			
D15	0	SCANDONE	Indicates the acquisition has completed. Cleared only by writing it to logic-zero to detect completion of the next acquisition. Writing to logic-one has no effect. A new acquisition will not commence if this bit is set.			
D14	0	SCANTIMEOUT	Indicates the acquisition did not complete in the expected period of time. The timeout depends on the oversampling configuration. Cleared only by writing it to logic-zero to allow detection of future timeout events. The acquisition watchdog can be disabled by setting SCANTOEN in the DEVCFG1 register.			
D13	0	DATARDY	Indicates the measurement data from the acquisition has been transferred from the ALU to the data registers and may now be read. Data for all measurement registers and MIN/MAX/TOTAL is transferred at the same time. Cleared by writing it to logic-zero to allow detection of the next data transfer. Writing to logic-one has no effect.			
D12	0	Reserved	Always reads logic-zero.			
D11						
D10	0	BALSWDIAG [2:0]	Configures the cell-balancing switch diagnostic modes per table below. When selected, these modes effectively override the BALSWEEN, MEASUREEN, ALTMUXSEL, and POLARITY configurations during the acquisition mode and update the ALRTBALSW register per the BALHIGHTHR and BALLOWTHR thresholds. Refer to Diagnostic section for details.			
D9						
D8				<b>BALSWDIAG[2:0]</b>		<b>DIAGNOSTIC TEST</b>
				000		None
				001		Balancing Switch Short
				010		Balancing Switch Open
				011		None
				100		None
				101		Cell Sense Open Odds
				110		Cell Sense Open Evens
111		None				
D7	0	POLARITY	Enables bipolar mode for ADC (input range is -2.5V to 2.5V). Default is unipolar mode (input range is 0 to 5V)			

**SCANCTRL Register (address 0x13) (continued)**

BIT	POR	NAME	DESCRIPTION	
D6	0	OVSAMPL[2:0]	Configures for the number oversamples in the acquisition per table below:	
D5				
D4			<b>OVSAMPL [2:0]</b>	<b>OVERSAMPLES</b>
			000	1
			001	4
			010	8
			011	16
			100	32
			101	64
			110	128
111	128			
D3	0	0	Always reads logic-zero.	
D2	0	SCANMODE	Enables top-down scan mode. Default is pyramid scan mode.	
D1	0	DATAMOVE	Initiates transfer of measurement data from ALU to data registers (manual transfer) and sets DATARDY. ALU data is preserved until a new acquisition is started. Always reads logic-zero. Ignored in acquisition mode.	
D0	0	SCAN	Enables the acquisition mode and (if in double-buffer mode) transfers previous acquisition data from ALU to data registers. Acts as a strobe bit and therefore does not need to be cleared. Always reads logic-zero. Ignored in acquisition mode.	

**ALRTOVEN Register (address 0x14)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13	0	AINOVALRTEN1	Enables the AIN1 overvoltage alert
D12	0	AINOVALRTEN0	Enables the AIN0 overvoltage alert
D11	0	OVALRTEN [12:1]	Enables the overvoltage alert for the respective cell. Clearing also clears the associated cell alert.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**ALRTUVEN Register (address 0x15)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13	0	AINUVALRTEN1	Enables the AIN1 undervoltage alert
D12	0	AINUVALRTEN0	Enables the AIN0 undervoltage alert
D11	0	UVALRTEN [12:1]	Enables the undervoltage alert for the respective cell. Clearing also clears the associated cell alert.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**WATCHDOG Register (address 0x18)**

BIT	POR	NAME	DESCRIPTION		
D15	0	Reserved	Always reads logic-zero.		
D14	0	CBPDIV[2:0]	Sets the step size of the cell-balancing timer LSB per table below:		
D13			<b>CBPDIV[2:0]</b>	<b>STEP SIZE</b>	<b>TIMEOUT RANGE</b>
D12			000	Disabled	No timeout
			001	1s	1–15s
			010	4s	4–60s
			011	16s	16–240s
			100	64s	64–960s
			101	128s	128–1920s
			110	256s	256–3840s
			111	256s	256–3840s
D11	0	CBTIMER[3:0]	Watchdog timer for the cell-balancing switches. The timer counts down at a rate set by CBPDIV. When the timer reaches 0, all cell-balancing switches are disabled by a signal separate from the BALSLEN bits. The timer should be periodically rewritten with a timeout value to keep the cell balancing switches enabled. When the timer value is read, the value reported is latched during the stop bit time following the ACQCFG UART register address of the READALL command. If the GPIO3TMR configuration is enabled, the GPIO3 pin is driven high while CBTIMER[3:0] is nonzero and is driven low when the timer value is zero. The cell-balancing timer is reset to zero when EMGCYDCHG = 1.		
D10					
D9					
D8					
D7	0	Reserved	Always reads logic-zero.		
D6					
D5					
D4					
D3					
D2					
D1					
D0					

**ACQCFG Register (address 0x19)**

BIT	POR	NAME	DESCRIPTION	
D15	0	Reserved	Always reads logic-zero.	
D14				
D13				
D12				
D11				
D10				
D9	0	THRMMODE [1:0]	Sets the step size of the cell-balancing timer LSB per table below:	
D8			<b>THRMMODE[1:0]</b>	<b>OPERATION</b>
			00	Auto mode (on in acquisition mode)
			01	Auto mode (on in acquisition mode)
			10	Manual mode, THRM switch off
	11	Manual mode, THRM switch on		
D7	0	Reserved	Always reads logic-zero.	
D6				
D5	0	AINTIME [5:0]	Configures the pre-conversion settling time for each enabled AUXIN input from 6 $\mu$ s (default) up to 384 $\mu$ s (6 $\mu$ s/bit). This is to allow extra settling time if the application circuit requires it since the THRM voltage is not driven out until the start of the acquisition (in auto mode).	
D4				
D3				
D2				
D1				
D0				

**BALSWEN Register (address 0x1A)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12			
D11	0	BALSWEN [11:0]	BALSWEN[n-1] enables the balancing switch (conducting) between SWn and SWn-1.
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3			
D2			
D1			
D0			

**DEVCFG2 Register (address 0x1B)**

BIT	POR	NAME	DESCRIPTION
D15	0	LASTLOOP	Enables UART loopback mode, which internally connects upper-port transmitter to upper-port receiver. The loopback mode allows the host to locate a break in daisy-chain communication whether or not the last daisy-chained device uses an external wire loopback wire or the internal loopback.
D14	0	Reserved	Always reads logic-zero.
D13			
D12	0	DBLBUFSEL	Enables alternate double-buffer mode. Contact Maxim Applications for details; otherwise, leave in default state.
D11	0	TXLIDLEHIZ	Enables High-Z idle mode, which causes the TX drivers of the lower UART to idle in the high-Z state instead of idling in the logic-zero state (default mode). Leave in default state for normal operation.
D10	0	TXUIDLEHIZ	Enables High-Z idle mode, which causes the TX drivers of the upper UART to idle in the high-Z state instead of idling in the logic-zero state (default mode). Leave in default state for normal operation.
D9	0	RESERVED	Reserved for future use. Reads the written value.
D8	0	EMGCYDCHG	Set to enable emergency-discharge mode (configured by BALSWDCHG).
D7	0	Reserved	Always reads logic-zero.
D6			
D5			
D4			
D3			
D2			
D1			
D0	0	HVCPDIS	Disables the HV charge pump. Used for ALRTHVUV diagnostic. If the HV charge pump is disabled in normal operation, measurement errors will result due to $V_{HV}$ undervoltage.

**BALDIAGCFG1 Register (address 0x1C)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13	0	ALTMUXSEL_M	Mirror for ALTMUXSEL bit.
D12	0	POLARITY_M	Mirror for POLARITY bit.
D11	0	CELLEN_M [12:1]	Mirror for CELLEN[12:1] in the MEASUREEN register. Writing to this field also updates CELLEN[12:1]. Reading this field reflects CELLEN[12:1].
D10			
D9			
D8			
D7

D0			

**BALSWDCHG Register (address 0x1D)**

BIT	POR	NAME	DESCRIPTION		
D15	0	DCHGWIN [2:0]	Configuration for emergency-discharge mode (EMGCYDCHG = 1). Sets the duty cycle for each discharge cycle (even or odd) per the table below:		
D14					
D13			<b>DCHGWIN[2:0] (LSb = 7.5s)</b>		<b>BEHAVIOR</b>
			0h		Switches on for 7.5s, off for 52.5s
			1h		Switches on for 15s, off for 45s
			...		...
7h		Switches on for 59.94s, off for 62.5ms			
D12	0	Reserved	Always reads logic-zero.		
D11	0	DCHGCNTR [3:0]	Discharge counter that can be read to verify operation of the emergency-discharge mode (EMGCYDCHG = 1). During the emergency-discharge mode, the discharge counter counts at 2Hz rolling over at Fh to 0h and continuing until the emergency-discharge mode terminates. Read-only.		
D10					
D9					
D8					
D7	0	DCHGTIME [7:0]	Write to set the timeout value of the emergency-discharge mode (EMGCYDCHG = 1) per the table below. Writing to 00h disables the timer and terminates the emergency-discharge mode. The timer starts when EMGCYDCHG = 1 (and DCHGTIME[7:0] ≠ 00h) and stops when it reaches the timeout. The timer is reset when EMGCYDCHG = 0.		
D6					
D5			<b>DCHGTIME[7:0] (LSb = 2 hours)</b>		<b>TIMEOUT</b>
D4			00h		Discharge mode disabled
D3			01h		Discharge mode disabled after 4 hours
D2			02h		Discharge mode disabled after 6 hours
D1			...		...
D0			FFh		Discharge mode disabled after 512 hours

**TOPCELL Register (address 0x1E)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12			
D11			
D10			
D9			
D8			
D7			
D6			
D5			
D4			
D3	Ch	TOPCELL[3:0]	Configures the top-cell position if less than 12 channels are used. This is to properly mask the ALRTBALS diagnostic alerts. TOPCELL[3:0] = 0h is not a valid configuration and is identical to the default, Ch (12d).
D2			
D1			
D0			

**CELLn Register (addresses 0x20 to 0x2B)**

BIT	POR	NAME	DESCRIPTION
D15	0	CELLn[15:0]	CELLn[15:2] contains the 14-bit measurement result for CELLn. CELLn[1:0] always reads logic-zero. Read-only.
D14			
D13			
D12			
D11			
D10			
D9			
D8

D11	0	CTSTSRC	Configures the cell-input test-current sources to either source current from V <sub>AA</sub> (logic-one), or sink current to AGND (logic-zero).																										
D10	0	Reserved	Always reads logic-zero.																										

**DIAGCFG Register (address 0x51) (continued)**

BIT	POR	NAME	DESCRIPTION		
D9	0	AUXINTSTEN [2:1]	Enables the test-current sources connected to the corresponding AUXIN input for diagnostic testing. The current level is configured by the CTSTDAC[3:0] and the current direction is configured by CTSTSRC.		
D8	0				
D7	0	MUXDIAGBUS	Selects the HVMUX output to which the HVMUX test-current source is connected, if MUXDIAGPAIR is enabled, as shown below:		
			<b>MUXDIAGBUS</b>	<b>HVMUX OUTPUT</b>	
			0	Output used for even cells, C0, and AGND	
			1	Output used for odd cells and REF, and ALTREF	
D6	0	MUXDIAGPAIR	Configures a single HVMUX test-current source to be connected to only one HVMUX output (as selected by MUXDIAGBUS). In the default configuration (MUXDIAGPAIR = 0), both HVMUX test-current sources are connected to both HVMUX outputs.		
D5	0	Reserved	Always reads logic-zero.		
D4	0	MUXDIAGEN	Enables the HVMUX test-current source(s). The current level is configured by CSTDAC[3:0] and the connectivity is configured by MUXDIAGPAIR, and MUXDIAGBUS		
D3	0	ALTMUXSEL	Enables cell measurements on the SWn inputs (ALTMUX data path) instead of the Cn inputs (HVMUX data path). Refer to the <a href="#">Diagnostics</a> section.		
D2	0	DIAGSEL [2:0]	Selects the diagnostic measurement for the acquisition per table below:		
D1			<b>DIAGSEL[2:0]</b>	<b>DIAGNOSTIC MEASUREMENT</b>	
D0				0b000	No measurement
				0b001	V <sub>ALTREF</sub>
				0b010	V <sub>AA</sub> (with ADC reference = V <sub>THRM</sub> )
				0b011	LSAMP Offset
				0b100	Zero-scale ADC output (000h)
				0b101	Full-scale ADC output (FFFh)
				0b110	Die temperature
		0b111	No measurement		

**CTSTEN Register (address 0x52)**

BIT	POR	NAME	DESCRIPTION
D15	0	Reserved	Always reads logic-zero.
D14			
D13			
D12	0	CTSTEN [12:0]	Enables the current sources connected to the corresponding cell input for diagnostic testing. The current level is configured by the CTSTDAC[3:0] and the current direction is configured by CTSTSRC in the DIAGCFG register.

## Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX17823HGCB/V+	-40°C to +105°C	64 LQFP

+Denotes a lead(Pb)-free/RoHS-compliant package.  
/V denotes an automotive-qualified part.

## Package Information

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](http://www.maximintegrated.com/packages). Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

PACKAGE TYPE	PACKAGE CODE	OUTLINE NO.	LAND PATTERN NO.
