General Description

The MAX5302 combines a low-power, voltage-output, 12-bit digital-to-analog converter (DAC) and a precision output amplifier in an 8-pin μ MAX package. It operates from a single +5V supply, drawing less than 280 μ A of supply current.

The output amplifier's inverting input is available to the user, allowing specific gain configurations, remote sensing, and high output current capability. This makes the MAX5302 ideal for a wide range of applications, including industrial process control. Other features include a software shutdown and power-on reset.

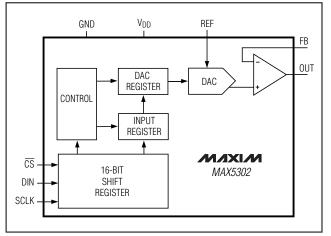

The serial interface is SPI™/QSPI™/MICROWIRE™ compatible. The DAC has a double-buffered input, organized as an input register followed by a DAC register. A 16-bit serial word loads data into the input register. The DAC register can be updated independently or simultaneously with the input register. All logic inputs are TTL/CMOSlogic compatible and buffered with Schmitt triggers to allow direct interfacing to optocouplers.

Features

- ♦ 12-Bit DAC with Configurable Output Amplifier
- +5V Single-Supply Operation
- ♦ Low Supply Current: 0.28mA Normal Operation 2µA Shutdown Mode
- Available in 8-Pin µMAX
- Power-On Reset Clears DAC Output to Zero
- ♦ SPI/QSPI/MICROWIRE Compatible
- Schmitt-Trigger Digital Inputs for Direct Optocoupler Interface

MAX5302

Pin Description

PIN	NAME	FUNCTION
1	OUT	DAC Output Voltage
2	CS	Chip-Select Input. Active low.
3	DIN	Serial-Data Input
4	SCLK	Serial-Clock Input
5	FB	DAC Output Amplifier Feedback
6	REF	Reference Voltage Input
7	GND	Ground
8	V _{DD}	Positive Power Supply

Detailed Description

The MAX5302 contains a voltage-output digital-to-analog converter (DAC) that is easily addressed using a simple 3-wire serial interface. The IC includes a 16-bit shift register, and has a double-buffered input composed of an input register and a DAC register (see *Functional Diagram*). In addition to the voltage output, the amplifier's negative input is available to the user.

The DAC is an inverted R-2R ladder network that converts a digital input (12 data bits plus 1 sub-bit) into an equivalent analog output voltage in proportion to the applied reference voltage. Figure 1 shows a simplified circuit diagram of the DAC.

Reference Inputs

The reference input accepts positive DC and AC signals. The voltage at the reference input sets the full-scale output voltage for the DAC. The reference input voltage range is 0 to (V_{DD} - 1.4V). The output voltage (V_{OUT}) is represented by a digitally programmable voltage source, as expressed in the following equation:

$V_{OUT} = (V_{REF} \cdot NB / 4096)$ Gain

where NB is the numeric value of the DAC's binary input code (0 to 4095), V_{REF} is the reference voltage, and Gain is the externally set voltage gain.

The impedance at the reference input is code dependent, ranging from a low value of $14k\Omega$ when the DAC has an input code of 1554 hex, to a high value exceeding several gigaohms (leakage currents) with an input code of 0000 hex. Because the input impedance at the reference pin is code dependent, load regulation of the reference source is important.

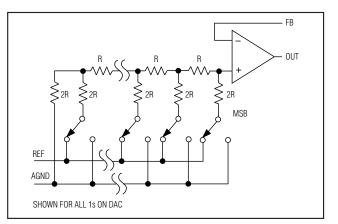

Figure 1. Simplified DAC Circuit Diagram

In shutdown mode, the MAX5302's REF input enters a high-impedance state with a typical input leakage current of $0.001 \mu A.$

The reference input capacitance is also code dependent and typically ranges from 15pF (with an input code of all 0s) to 50pF (at full scale).

The MAX873 +2.5V reference is recommended for the MAX5302.

Output Amplifier

The MAX5302's DAC output is internally buffered by a precision amplifier with a typical slew rate of 0.6V/µs. Access to the output amplifier's inverting input provides the user greater flexibility in output gain setting/signal conditioning (see the *Applications Information* section).

With a full-scale transition at the MAX5302 output, the typical settling time to $\pm 1/2LSB$ is 14µs when loaded with 5k Ω in parallel with 100pF (loads less than 2k Ω degrade performance).

The amplifier's output dynamic responses and settling performances are shown in the *Typical Operating Characteristics*.

Shutdown Mode

The MAX5302 features a software-programmable shutdown that reduces supply current to a typical value of 4 μ A. Writing 111X XXXX XXXX XXXX as the input control word puts the device in shutdown mode (Table 1).

In shutdown mode, the amplifier's output and the reference input enter a high-impedance state. The serial interface remains active. Data in the input registers is retained in shutdown, allowing the MAX5302 to recall the output state prior to entering shutdown. Exit shutdown mode by either recalling the previous configuration or

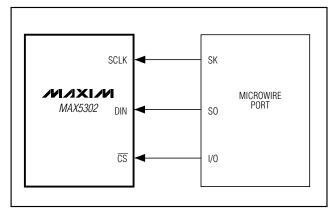

Figure 2. Connections for MICROWIRE

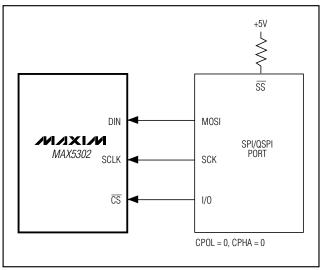

Figure 3. Connections for SPI/QSPI

by updating the DAC with new data. When powering up the device or bringing it out of shutdown, allow 20µs for the output to stabilize.

Serial-Interface Configurations

The MAX5302's 3-wire serial interface is compatible with both MICROWIRE (Figure 2) and SPI/QSPI (Figure 3). The serial-input word consists of 3 control bits followed by 12+1 data bits (MSB first), as shown in Figure 4. The 3-bit control code determines the MAX5302's response outlined in Table 1.

The MAX5302's digital inputs are double buffered. Depending on the command issued through the serial interface, the input register can be loaded without affecting the DAC register, the DAC register can be loaded directly, or the DAC register can be updated from the input register (Table 1).

Serial-Interface Description

The MAX5302 requires 16 bits of serial data. Table 1 lists the serial-interface programming commands. For certain commands, the 12+1 data bits are "don't cares." Data is sent MSB first and can be sent in two 8-bit packets or one 16-bit word (\overline{CS} must remain low until 16 bits are transferred). The serial data is composed of 3 control

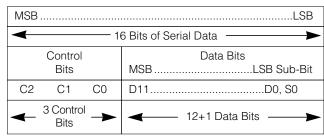

Figure 4. Serial-Data Format

Table 1. Serial-Interface Programming Commands

	16-BIT SERIAL WORD				
C2	C1	C0	D11D0 MSB LSB	S0	FUNCTION
Х	0	0	12 bits of data	0	Load input register; DAC register immediately updated (also exit shutdown).
Х	0	1	12 bits of data	0	Load input register; DAC register unchanged.
х	1	0	xxxxxxxxxxxx	Х	Update DAC register from input register (also exit shutdown; recall previous state).
1	1	1	XXXXXXXXXXXXX	Х	Shutdown
0	1	1	XXXXXXXXXXXXX	Х	No operation (NOP)

X = Don't care

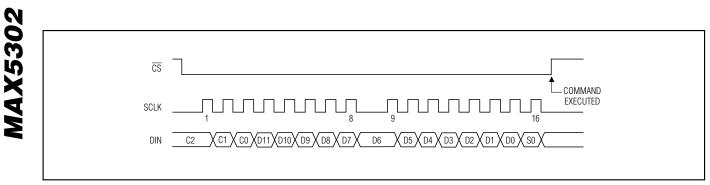

Figure 5. Serial-Interface Timing Diagram

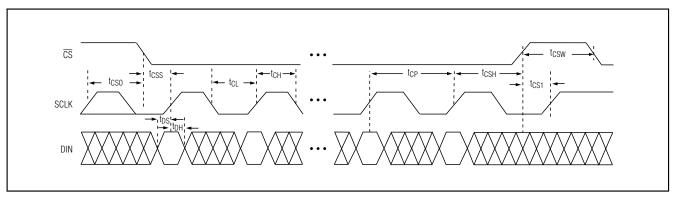

Figure 6. Detailed Serial-Interface Timing Diagram

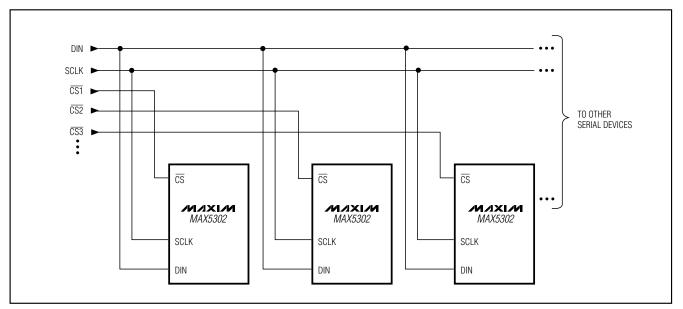

Figure 7. Multiple MAX5302s Sharing Common DIN and SCLK Lines

bits (C2, C1, C0), followed by the 12+1 data bits D11...D0, S0 (Figure 4). Set the sub-bit (S0) to zero. The 3-bit control code determines the register to be updated and the configuration when exiting shutdown.

Figures 5 and 6 show the serial-interface timing requirements. The chip-select (\overline{CS}) pin must be low to enable the DAC's serial interface. When \overline{CS} is high, the interface control circuitry is disabled. \overline{CS} must go low at least t_{CSS} before the rising serial-clock (SCLK) edge to properly clock in the first bit. When \overline{CS} is low, data is clocked into the internal shift register through the serial-data input pin (DIN) on SCLK's rising edge. The maximum guaranteed clock frequency is 10MHz. Data is latched into the MAX5302 input/DAC register on \overline{CS} 's rising edge.

Figure 7 shows a method of connecting several MAX5302s. In this configuration, the clock and the data bus are common to all devices, and separate chip-select lines are used for each IC.

Applications Information

Unipolar Output

For a unipolar output, the output voltage and the reference input have the same polarity. Figure 8 shows the MAX5302 unipolar output circuit, which is also the typical operating circuit. Table 2 lists the unipolar output codes.

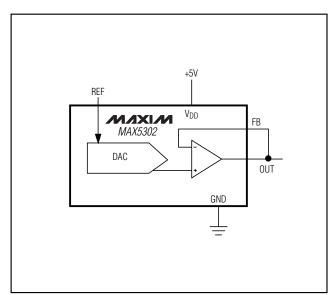

Figure 8. Unipolar Output Circuit

Rail-to-Rail is a registered trademark of Nippon Motorola, Ltd.

Figure 9 illustrates a Rail-to-Rail[®] output. This circuit shows the MAX5302 with the output amplifier configured with a closed-loop gain of +2 to provide a 0V to 5V full-scale range when a 2.5V reference is used.

Bipolar Output

The MAX5302 output can be configured for bipolar operation using Figure 10's circuit according to the following equation:

where NB is the numeric value of the DAC's binary input code. Table 3 shows digital codes (offset binary) and the corresponding output voltage for Figure 10's circuit.

Using an AC Reference

In applications where the reference has AC-signal components, the MAX5302 has multiplying capability within the reference input range specifications. Figure 11 shows a technique for applying a sine-wave signal to the reference input where the AC signal is offset before being applied to REF. The reference voltage must never be more negative than GND.

The MAX5302's total harmonic distortion plus noise (THD+N) is typically less than -77dB (full-scale code), given a 1Vp-p signal swing and input frequencies up to 25kHz. The typical -3dB frequency is 650kHz, as shown in the *Typical Operating Characteristics* graphs.

Table 2. Unipolar Code Table

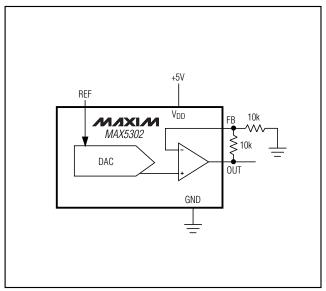

Figure 9. Unipolar Rail-to-Rail Output Circuit

Digitally Programmable Current Source

The circuit of Figure 12 places an NPN transistor (2N3904 or similar) within the op amp feedback loop to implement a digitally programmable, unidirectional current source. The output current is calculated with the following equation:

IOUT = (VREF / R) (NB / 4096)

where NB is the numeric value of the DAC's binary input code, and R is the sense resistor shown in Figure 12.

Power-Supply Considerations

On power-up, the input and DAC registers are cleared (set to zero code).

For rated MAX5302 performance, V_{REF} must be at least 1.4V below V_{DD} . Bypass V_{DD} with a 4.7µF capacitor in parallel with a 0.1µF capacitor to GND. Use short lead lengths and place the bypass capacitors as close to the supply pins as possible.

Grounding and Layout Considerations

Digital or AC transient signals on GND can create noise at the analog output. Connect GND to the highest-quality ground available.

Good PC board ground layout minimizes crosstalk between the DAC output, reference input, and digital input. Reduce crosstalk by keeping analog lines away from digital lines. Wire-wrapped boards are not recommended.

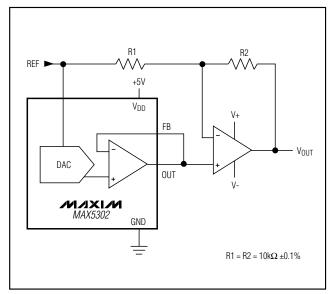

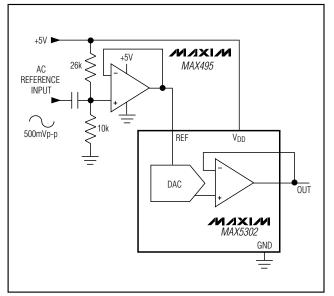

Figure 10. Bipolar Output Circuit
