Dual Universal Switched-Capacitor Filters

General Description

The MAX7490/MAX7491 consist of two identical low-power, low-voltage, wide dynamic range, rail-to-rail, 2nd-order switched-capacitor building blocks. Each of the two filter sections, together with two to four external resistors, can generate all standard 2nd-order functions: bandpass, lowpass, highpass, and notch (band reject). Three of these functions are simultaneously available. Fourth-order filters can be obtained by cascading the two 2nd-order filter sections. Similarly, higher order filters can easily be created by cascading multiple MAX7490/MAX7491s.

Two clocking options are available: self-clocking (through the use of an external capacitor) or external clocking for tighter cutoff frequency control. The clock-to-center frequency ratio is 100:1. Sampling is done at twice the clock frequency, further separating the cutoff frequency and Nyquist frequency.

The MAX7490/MAX7491 have an internal rail splitter that establishes a precise common voltage needed for single-supply operation. The MAX7490 operates from a single +5V supply and the MAX7491 operates from a single +3V supply. Both devices feature a low-power shutdown mode and come in a 16-pin QSOP package.

Applications

Tunable Active Filters

Multipole Filters

ADC Anti-Aliasing

Post-DAC Filtering

Adaptive Filtering

Phase-Locked Loops (PLLs)

Set-Top Boxes

Typical Application Circuit appears at end of data sheet.

Features

- **Dual 2nd-Order Filter in a 16-Pin QSOP Package**
- **High Accuracy**
  Q Accuracy: ±0.2%
  Clock-to-Center Frequency Error: ±0.2%
- **Rail-to-Rail Input and Output Operation**
- **Single-Supply Operation: +5V (MAX7490) or +3V (MAX7491)**
- **Internal or External Clock**
- **Highpass, Lowpass, Bandpass, and Notch Filters**
- **Clock-to-Center Frequency Ratio of 100:1**
- **Internal Sampling-to-Center Frequency Ratio of 200:1**
- **Center Frequency up to 40kHz**
- **Easily Cascaded for Multipole Filters**
- **Low-Power Shutdown: < 1µA Supply Current**

Ordering Information

ABSOLUTE MAXIMUM RATINGS

V_{DD} to GND .....-0.3V to +6V
EXTCLK, $\overline{SHDN}$ to GND .....-0.3V to +6V
INV_, LP_, BP_, N_/HP_, S_, COM,
CLK to GND.....-0.3V to (V_{DD} + 0.3V)
Maximum Current into Any Pin 50mA
Continuous Power Dissipation (T_A = +70°C)
16-Pin QSOP (derate 8.30mW/°C above +70°C).....667mW
Operating Temperature Range
MAX749_CEE .....0°C to +70°C
MAX749_EEE .....-40°C to +85°C
Die Temperature .....+150°C
Storage Temperature.....-65°C to +150°C
Lead Temperature (soldering, 10s) .....+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Dual Universal Switched-Capacitor Filters

Pin Description

PIN	NAME		FUNCTION
	FILTER A	FILTER B	
LP_	1	16	2nd-Order Lowpass Filter Output
BP_	2	15	2nd-Order Bandpass Filter Output
N_/HP_	3	14	2nd-Order Notch/Highpass Filter Output
INV_	4	13	Inverting Input of Filter Summing Op Amp
S_	5	12	Summing Input. The connection of the summing input, along with the other resistor connections, determine the circuit topology (mode) of each 2nd-order section. S_ must never be left unconnected.
$\overline{SHDN}$	6		Shutdown Input. Drive $\overline{SHDN}$ low to enable shutdown mode; drive $\overline{SHDN}$ high or connect to V_{DD} for normal operation.
GND	7		Ground Pin
V_{DD}	8		Positive Supply. Bypass V_{DD} with a 0.1µF capacitor to GND. A low-noise supply is recommended. Input +5V for MAX7490 or +3V for MAX7491.
CLK	9		Clock Input. Connect CLK to an external capacitor (C_{OSC}) between CLK and ground to set the internal oscillator frequency. For external clock operation, drive CLK with a CMOS-level clock. The duty cycle of the external clock should be between 45% and 55% for best performance.
EXTCLK	10		External/Internal Clock Select Input. Connect EXTCLK to V_{DD} when driving CLK externally. Connect EXTCLK to GND when using the internal oscillator.
COM	11		Common Pin. Biased internally at $V_{DD}/2$. Bypass externally to GND with 0.1µF capacitor. To override the internal biasing, drive COM with an external low-impedance source.

Detailed Description

The MAX7490/MAX7491 are universal switched-capacitor filters designed with a fixed internal f_{CLK}/f_O ratio of 100:1. Operating modes use external resistors connected in different arrangements to realize different filter functions (highpass, lowpass, bandpass, notch) in all of the classical filter topologies (Butterworth, Bessel, elliptic, Chebyshev). Figure 1 shows a block diagram.

Clock Signal

External Clock

The MAX7490/MAX7491 switched-capacitor filters are designed for use with external clocks that have a 50% ±5% duty cycle. When using an external clock, drive the EXTCLK pin high or connect to V_{DD}. Drive CLK with CMOS logic levels (GND and V_{DD}). Varying the rate of the external clock adjusts the center frequency of the filter:

$$f_O = f_{CLK} / 100$$

Internal Clock

When using the internal oscillator, drive the EXTCLK pin low or connect to GND and connect a capacitor (C_{OSC}) between CLK and GND. The value of the capacitor (C_{OSC}) determines the oscillator frequency as follows:

$$f_{OSC}\ (kHz) = 135 \times 10^3 / C_{OSC}\ (pF)$$

Since C_{OSC} is in the low picofarads, minimize the stray capacitance at CLK so that it does not affect the internal oscillator frequency. Varying the frequency of the internal oscillator adjusts the filter's center frequency by a 100:1 clock-to-center frequency ratio. For example, an internal oscillator frequency of 135kHz produces a nominal center frequency of 1.35kHz.

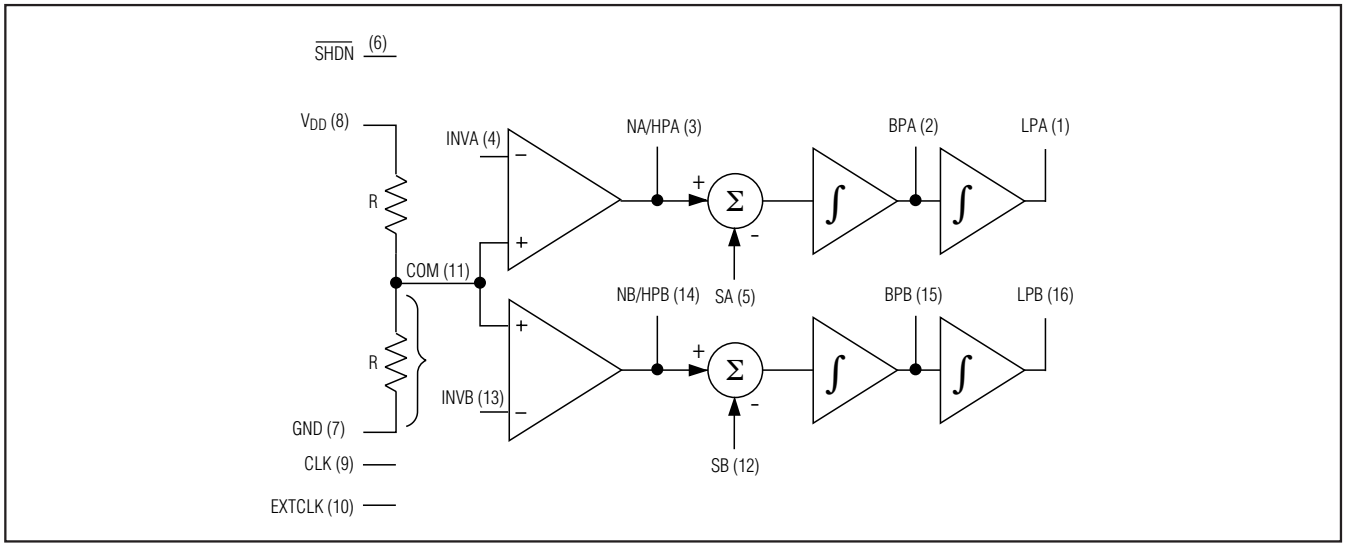

Figure 1. Block Diagram

2nd-Order Filter Stage

The MAX7490/MAX7491 are dual biquad filters. The biquad topology allows the use of standard filter tables and equations to implement simultaneous lowpass, bandpass, and notch or highpass filters. Topologies such as Butterworth, Chebyshev, Bessel, elliptic, as well as custom algorithms are possible.

Internal Common Voltage

The COM pin sets the common-mode input voltage and is internally biased to $V_{DD}/2$ with a resistor-divider. The resistors used are typically 250kΩ for the MAX7490, and typically 80kΩ for the MAX7491. The common-mode voltage is easily overdriven by an external voltage supply if desired. Bypass COM to the analog ground with at least a 0.1µF capacitor.

Inverting Inputs

Locate resistors that are connected to INV_ as close as possible to INV_ to reduce stray capacitance and noise pickup. INV_ are inverting inputs to continuous-time op amps, and behave like a virtual ground. There is no sampling energy present on these inputs.

Outputs

Each switched-capacitor section, together with two to four external resistors, can generate all standard 2nd-order functions: bandpass, lowpass, highpass, and notch (band-reject) functions. Three of these functions are simultaneously available. The maximum signal swing is limited by the power-supply voltages used. The amplifiers' outputs in the MAX7490/MAX7491 are able to swing to within approximately 0.2V of either supply.

Driving coaxial cable, large capacitive loads, or total resistive loads less than 10kΩ will degrade the total harmonic distortion (THD) performance. Note that the effective resistive load at the output must include both the feedback resistors and any external load resistors.

Low-Power Shutdown Mode

The MAX7490/MAX7491 have a shutdown mode that is activated by driving $\overline{SHDN}$ low. In shutdown mode, the filter supply current reduces to < 1µA (max), and the filter outputs become high impedance. The COM input also becomes high impedance during shutdown. For normal operation, drive $\overline{SHDN}$ high or connect to V_{DD}.

Applications Information

Designing with the MAX7490/MAX7491 begins by selecting the mode that best fits the desired circuit requirements. Table 1 lists the available modes and their relative advantages and disadvantages. Table 2 lists the different nomenclature used in the explanations that follow.

Dual Universal Switched-Capacitor Filters

Table 1. Filter Operating Modes

MODE	LP	HP	BP	N	LP-N*	HP-N*	COMMENTS
1	•		•	•			f_{CLK}/f_O ratio is the nominal value. Good for bandpass filters with identical sections cascaded, higher order Butterworth filters, high-Q bandpass, low-Q notches.
1B	•		•	•			Same as Mode 1 with f_{CLK}/f_O ratios greater than the nominal value.
2	•		•	•			Combination of Mode 1 and Mode 3; f_{CLK}/f_O ratios always less than the nominal value. Less sensitivity to resistor tolerances than Mode 3.
2N					•		Extension of Mode 2 that allows higher frequencies. Highpass and lowpass outputs are summed with external op amp and two resistors. Good for lowpass elliptic filters.
3	•	•	•				Adjustable f_O above and below the nominal frequency. Commonly used for multiple-pole Chebyshev filters, all-pole higher order bandpass, lowpass, and highpass filters.
3A	•	•	•		•	•	Extension of Mode 3 that needs an external op amp and two additional resistors. Commonly used for lowpass or higher elliptic or Cauer filters.

**LP-N = lowpass notch, HP-N = highpass notch. Both require an external op amp. See Definition of Terms (Table 2).*

Table 2. Definition of Terms

TERM	DEFINITION
f_{CLK}	The clock frequency applied to the switched-capacitor filter.
f_O	The center frequency of the 2nd-order complex pole pair, f_O, is determined by measuring the peak response frequency at the bandpass output.
f_{NOTCH}	The frequency of minimum amplitude response at the notch output.
Q	Quality factor, or Q, is the ratio of f_O to the -3dB bandwidth of the 2nd-order bandpass filter. Q also determines the amount of amplitude peaking at the lowpass and highpass outputs, but is not measured at these outputs.
H_{OBP}	The gain in V/V of the bandpass output at $f = f_O$.
H_{OLP}	The gain in V/V of the lowpass output at $f \rightarrow 0Hz$.
H_{OHP}	The gain in V/V of the highpass output at $f \rightarrow f_{CLK}/2$.
H_{ON1}	The notch output gain as $f \rightarrow 0Hz$.
H_{ON2}	The notch output gain at $f = f_{CLK}/2$.
LP-N	A notch output with $H_{ON1} > H_{ON2}$.
HP-N	A notch output with $H_{ON1} < H_{ON2}$.

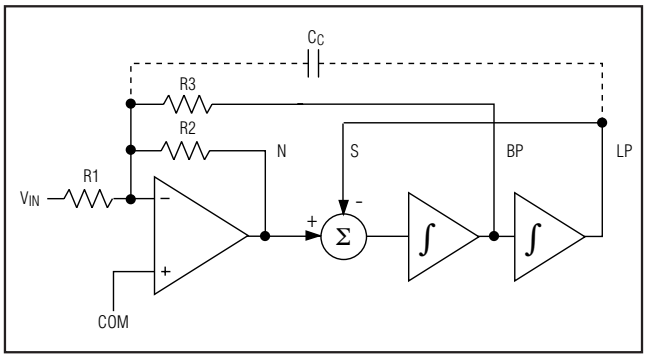

Figure 2. Mode 1, 2nd-Order Filter Providing Notch, Bandpass, and Lowpass Outputs

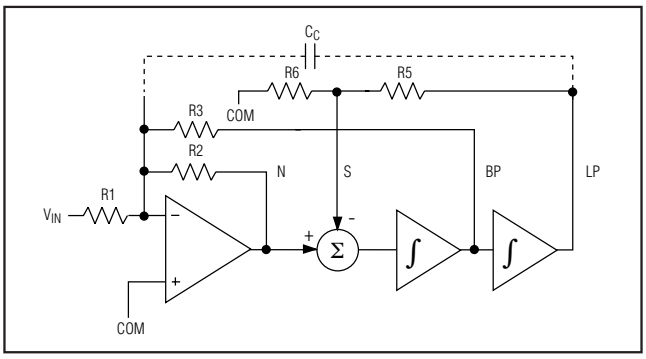

Figure 3. Mode 1B, 2nd-Order Filter Providing Notch, Bandpass, and Lowpass Outputs

Mode 1

Figure 2 shows the MAX7490/MAX7491s' configuration of Mode 1. This mode provides 2nd-order notch, lowpass, and bandpass filter functions. The gain at all three outputs is inversely proportional to the value of R1. The center frequency, f_O, is fixed at $f_{CLK}/100$. High-Q bandpass filters can be built without exceeding the bandpass amplifier's output swing (i.e., H_{OBP} does not have to track Q). The notch and bandpass center frequencies are identical. The notch output gain is the same above and below the notch center frequency. Mode 1 can also be used to make high-order Butterworth lowpass filters, low Q notches, and multiple-order bandpass filters obtained by cascading identical switched-capacitor sections.

Mode 1 Design Equations

$$f_O = \frac{f_{CLK}}{100}$$

$$f_{notch} = f_O$$

$$Q = \frac{R3}{R2}$$

$$H_{OLP} = \frac{-R2}{R1}$$

$$H_{OBP} = \frac{-R3}{R1}$$

$$H_{ON1}(\text{as } f \rightarrow 0\text{Hz}) = \frac{-R2}{R1}$$

$$H_{ON2}(\text{at } f = f_{CLK}/2) = \frac{-R2}{R1}$$

Mode 1B

Figure 3 shows the configuration of Mode 1B. R5 and R6 are added to lower the feedback voltage from the lowpass output to the summing input. This allows the clock-to-center frequency to be adjusted beyond the nominal value. This mode essentially has the same functions and speed as Mode 1 while providing a high-Q with f_{CLK}/f_O ratios greater than the nominal value.

Mode 1B Design Equations

$$f_O = \frac{f_{CLK}}{100}\sqrt{\frac{R6}{R6+R5}}$$

$$f_n = f_O$$

$$Q = \frac{R3}{R2}\sqrt{\frac{R6}{R6+R5}}$$

$$H_{OLP} = \frac{-R2}{R1}\frac{R6+R5}{R6}$$

$$H_{OBP} = \frac{-R3}{R1}$$

$$H_{ON1}(\text{as } f \rightarrow 0\text{Hz}) = \frac{-R2}{R1}$$

$$H_{ON2}(\text{at } f = f_{CLK}/2) = \frac{-R2}{R1}$$

Mode 2

Figure 4 shows the configuration of Mode 2. Mode 2 is a combination of Mode 1 and Mode 3. In this mode, f_{CLK}/f_O is always less than the part's nominal ratio. However, it provides less sensitivity to resistor tolerances than does Mode 3. It has a highpass notch output where the notch frequency depends solely on the clock frequency.

Dual Universal Switched-Capacitor Filters

Mode 2 Design Equations

$$f_O = \frac{f_{CLK}}{100}\sqrt{1+\frac{R2}{R4}}$$

$$f_n = \frac{f_{CLK}}{100}$$

$$Q = \frac{R3}{R2}\sqrt{1+\frac{R2}{R4}}$$

$$H_{OLP} = \frac{-R2}{R1}\left(\frac{R4}{R4+R2}\right)$$

$$H_{OBP} = \frac{-R3}{R1}$$

$$H_{ON1}(f \rightarrow 0Hz) = \frac{-R2}{R1}\left(\frac{R4}{R4+R2}\right)$$

$$H_{ON2}(\text{at } f = f_{CLK}/2) = \frac{-R2}{R1}$$

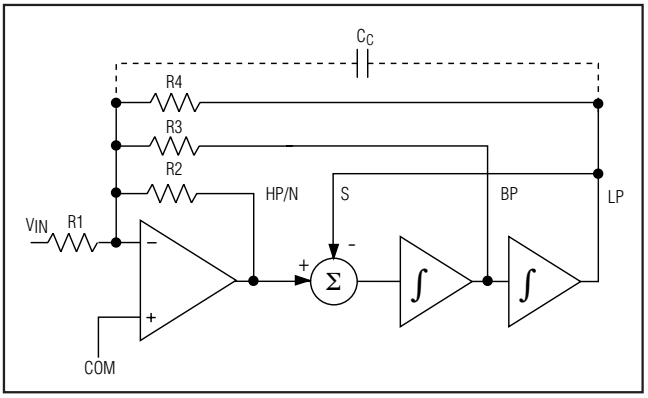

Figure 4. Mode 2, 2nd-Order Filter Providing a Highpass Notch, Bandpass, and Lowpass Outputs

Mode 2N Design Equations

$$f_O = \frac{f_{CLK}}{100}\sqrt{1+\frac{R2}{R4}}$$

$$f_n = \frac{f_{CLK}}{100}\sqrt{1+\frac{R_H}{R_L}}$$

$$Q = \frac{R3}{R2}\sqrt{1+\frac{R2}{R4}}$$

$$H_{ON1}(f \rightarrow 0Hz) = \left(\frac{R_G}{R_H}+\frac{R_G}{R_L}\right)\left(\frac{R2}{R1}\right)\left(\frac{R4}{R4+R2}\right)$$

Mode 2N

Figure 5 shows the configuration of Mode 2N. This mode extends the topology of Mode 3A to Mode 2, where the highpass and lowpass outputs are summed through two external resistors, R_H and R_L, to create a lowpass notch filter that has higher frequency than the one in Mode 2. Mode 2 is most useful in lowpass elliptic designs. When cascading the sections of the MAX7490/MAX7491, the highpass and lowpass outputs can be summed directly into the inverting input of the next section. Only one external op amp is needed.

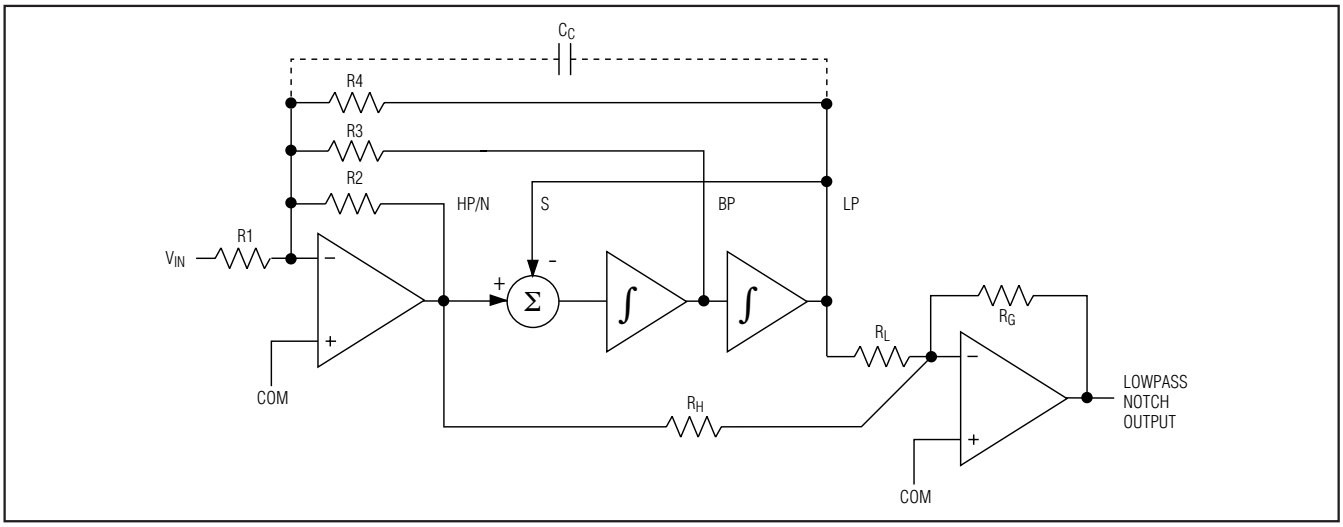

Figure 5. Mode 2N, 2nd-Order Filter Providing a Lowpass Notch Output

Mode 3

Figure 6 shows the configuration of Mode 3. This mode is a sampled time (Z transform) equivalent of the classical 2nd-order state variable filter. In this versatile mode, the ratio of resistors R2 and R4 can move the center frequency both above and below the nominal ratio. Mode 3 is commonly used to make multiple-pole Chebyshev filters with a single clock frequency. This mode can also be used to make high-order all-pole bandpass, lowpass, and highpass filters.

Mode 3 Design Equations

$$f_O = \frac{f_{CLK}}{100}\sqrt{\frac{R2}{R4}}$$

$$Q = \frac{R3}{R2}\sqrt{\frac{R2}{R4}}$$

$$H_{OHP} = \frac{-R2}{R1}$$

$$H_{OLP} = \frac{-R4}{R1}$$

$$H_{OBP} = \frac{-R3}{R1}$$

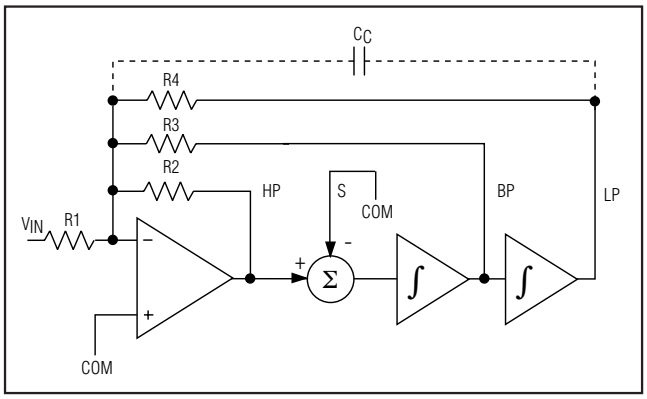

Figure 6. Mode 3, 2nd-Order Section Providing Highpass, Bandpass, and Lowpass Outputs

Mode 3A

Figure 7 shows the configuration of Mode 3A. Similar to Mode 2, this mode adds an external op amp. See Table 3 for op amp selection ideas. This op amp creates a highpass notch and lowpass notch by summing the highpass and lowpass outputs through two external resistors, R_H and R_L. The ratio of resistors R_H and R_L adjusts the notch frequency, while R2 and R4 adjust the bandpass center frequency, since the notch (zero pair) frequency can be adjusted to both above and below f_O. Mode 3A is suitable for both lowpass and highpass elliptic or Cauer filters. In multipole elliptic filters, only one external op amp is needed. Use the inverting input of the internal op amp as the summing node for all but the final section of the filter.

Dual Universal Switched-Capacitor Filters

Table 3. Suggested External Op Amps

PART	GBW (MHz)	SLEW RATE (V/µs)	$I_{SUPPLY/AMP}$ (mA)	PIN-PACKAGE
MAX4281	2	0.7	0.5	5 SOT23
MAX4322	5	2.0	1.1	5 SOT23
MAX4130	10	4.0	1.15	5 SOT23
MAX4490	10	10.0	2.0	5 SOT23

Mode 3A Design Equations

$$f_O = \frac{f_{CLK}}{100}\sqrt{\frac{R2}{R4}}$$

$$f_n = \frac{f_{CLK}}{100}\sqrt{\frac{R_H}{R_L}}$$

$$Q = \frac{R3}{R2}\sqrt{\frac{R2}{R4}}$$

$$H_{OHP} = \frac{-R2}{R1}$$

$$H_{OLP} = \frac{-R4}{R1}$$

$$H_{OBP} = \frac{-R3}{R1}$$

$$H_{ON1}(f \rightarrow 0Hz) = \frac{R_G}{R_L}\left(\frac{R4}{R1}\right)$$

$$H_{ON2}(\text{at } f = f_{CLK}/2) = \frac{R_G}{R_H}\left(\frac{R2}{R1}\right)$$

Note: When the passband gain error exceeds 1dB, the use of capacitor C_C between the lowpass output and the inverting input will reduce the gain error. The value can best be determined experimentally. Typically, it should be about 5pF/dB ($C_{C\text{-}MAX}$ = 15pF).

Offset Voltage

Switched-capacitor integrators generally exhibit higher input offsets than discrete RC integrators. The larger offset is mainly due to the charge injection of the CMOS switches into the integrating capacitors. The internal op amp offset also adds to the overall offset value. Figure 8 shows the input offsets from a single 2nd-order section. Table 4 lists the formula for the output offset voltage for various modes and output pins.

Power Supplies

The MAX7490 operates from a single +5V supply, and the MAX7491 operates from a single +3V supply. Bypass V_{DD} to GND with at least a 0.1µF capacitor. V_{DD} should be isolated from other digital or high-voltage analog supplies. If dual supplies are required, connect the COM pin to the system ground and the GND pin to the negative supply. Figure 9 shows an example of dual-supply operation. Single-supply and dual-supply performances are equivalent. For dual-supply operation, drive CLK, $\overline{SHDN}$, and EXTCLK from GND (which is now V-) to V_{DD}. If using the internal oscillator in dual-supply mode, C_{OSC} can be returned to either GND or the actual ground voltage. Use the MAX7490 for ±2.5V and use the MAX7491 for ±1.5V.

For most applications, a 0.1µF bypass capacitor from COM to GND is sufficient. If the V_{DD} supply has significant 60Hz energy, increase this capacitor to 1µF or greater to provide better power-supply rejection.

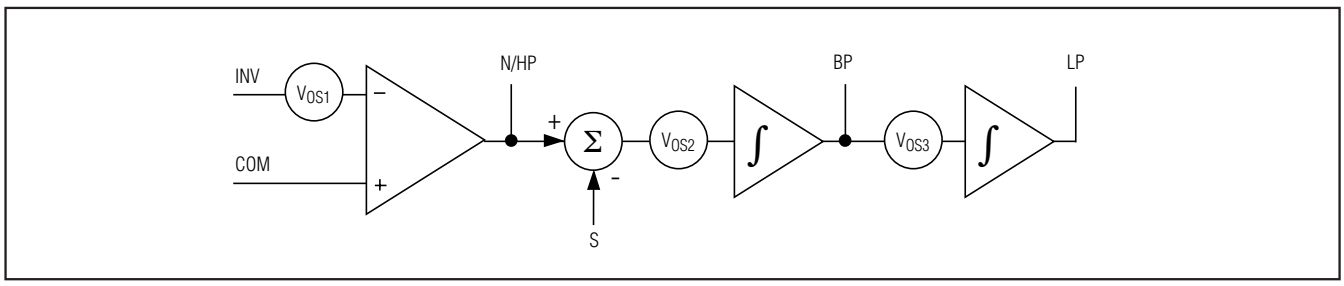

Figure 8. Block Diagram of a 2nd-Order Section Showing the Input Offsets

Table 4. Output DC Offsets for a 2nd-Order Section

MODE	$V_{OSN/HP}$	V_{OSBP}	V_{OSLP}
1	$V_{OS1}[1 + (R2 / R3) + (R2 / R1)] - (V_{OS3})(R2 / R3)$	V_{OS3}	$V_{OSN/HP} - V_{OS2}$
1b	$V_{OS1}[1 + (R2 / R3) + (R2 / R1)] - (V_{OS3})(R2 / R3)$	V_{OS3}	$(V_{OSN/HP} - V_{OS2})[1 + R5 / R6)]$
2	$V_{OS1}[1 + (R2 / R3) + (R2 / R1) + (R2 / R4) - (V_{OS3})(R2 / R3)][R4 / R2 + R4] + (V_{OS2})[R2 / R2 + R4]$	V_{OS3}	$V_{OSN/HP} - V_{OS2}$
3	V_{OS2}	V_{OS3}	$V_{OS1}[1 + (R4 / R1) + (R4 / R2) + (R4 / R3)] - (V_{OS2})(R4 / R2) - (V_{OS3})(R4 / R3)$

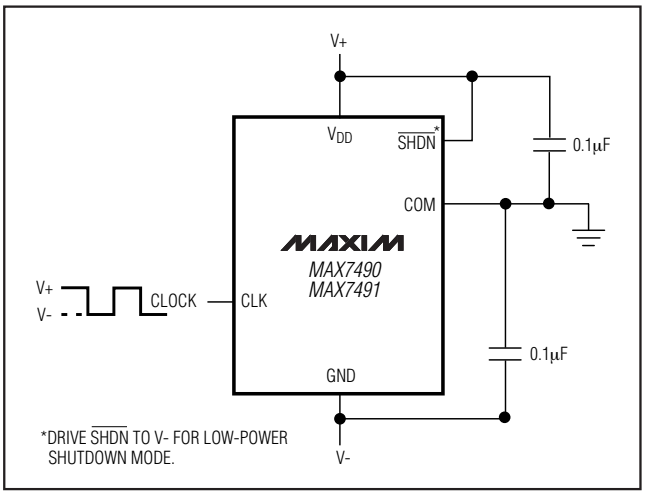

Figure 9. Dual-Supply Operation

Input Signal Amplitude Range

The optimal input signal range is determined by observing the voltage level at which the signal-to-noise plus distortion (SINAD) ratio is maximized for a given corner frequency. The *Typical Operating Characteristics* show the THD + Noise response as the input signal's peak-to-peak amplitude is varied. In most systems, the input signal should be kept as large as possible to maximize the signal-to-noise ratio (SNR). Allow sufficient headroom to ensure no signal clipping under expected operating conditions.

Anti-Aliasing and Post-DAC Filtering

When using the MAX7490/MAX7491 for anti-aliasing or post-DAC filtering, synchronize the DAC (or ADC) and the filter clocks. If the clocks are not synchronized, beat frequencies may alias into the desired passband.

Aliasing

Aliasing is an inherent phenomenon of most switched-capacitor filters. As with all sampled systems, frequency components of the input signal above one half the sampling rate will be aliased. The MAX7490/MAX7491 sample at twice the clock frequency, yielding a 200:1 sampling to cutoff frequency ratio.

In particular, input signal components (f_{IN}) near the sampling rate generate a difference frequency ($f_{SAMPLING} - f_{IN}$) that often falls within the passband of the filter. Such aliased signals, when they appear at the output, are indistinguishable from real input information. For example, the aliased output signal generated when a 99kHz waveform is applied to a filter sampling at 100kHz, (f_{CLK} = 50kHz) is 1kHz. This waveform is an attenuated version of the output that would result from a true 1kHz input. Since sampling is done at twice the clock frequency, the Nyquist frequency is the same as the clock frequency.

A simple passive RC lowpass input filter is usually sufficient to remove input frequencies that can be aliased. In many cases, the input signal itself may be band limited and require no special anti-alias filtering. Selecting a passive filter cutoff frequency equal to $f_C/2$ gives 12dB rejection at the Nyquist frequency.

Clock Feedthrough

Clock feedthrough is defined as the RMS value of the clock frequency and its harmonics that are present at the filter's output pins, even without input signal. The clock feedthrough can be greatly reduced by adding a simple RC lowpass network at the final filter output. Choose a cutoff frequency as low as possible to provide maximum noise attenuation. The attenuation and phase shift of the external filter will limit the actual frequency selected.

Dual Universal Switched-Capacitor Filters

Table 5. Cascading Identical Bandpass Filter Sections

TOTAL SECTIONS	TOTAL BW	TOTAL Q
1	1.000 B	1.00 Q
2	0.644 B	1.55 Q
3	0.510 B	1.96 Q
4	0.435 B	2.30 Q
5	0.386 B	2.60 Q

Wideband Noise

The wideband noise of the filter is the total RMS value of the device's noise spectral density and is used to determine the operating SNR. Most of its frequency contents lie within the filter's passband and cannot be reduced with postfiltering. The total noise depends mainly on the Q of each filter section and the cascade sequence. Therefore, in multistage filters, place the section with the highest Q first for lower output noise.

Multiple Filter Stages

In some designs, such as very narrow band filters, or in modes where f_O cannot be tuned with resistors, several 2nd-order sections with identical f_O may be cascaded without multiple feedback. The total Q of the resultant filter (Q_T) is:

$$\text{Total } Q_T = Q / \left(2^{1/N} - 1\right)^{1/2}$$

Q is the Q of each individual filter section, and N is the number of 2nd-order sections. In Table 5, the total Q and total bandwidth (BW) are listed for up to five identical 2nd-order sections. B is the bandwidth of each section.
