## General Description

The MAX77826 is a subpower management IC for the latest 3G/4G smartphones and tablets. The MAX77826 contains a high-efficiency BUCK regulator, a BUCK BOOST regulator and 15 LDOs to power up peripherals. The MAX77826 also provides power on/off control logic and an I ${ }^{2}$ C serial interface to program individual regulator output voltages and on/off control for complete flexibility.
The linear regulators support a remote cap feature and provide greater than 70dB PSRR and less than $45 \mu \mathrm{~V}_{\mathrm{RMS}}$ noise.
The MAX77826 features ${ }^{2}$ ² -compatible, 2-wire serial interface that comprises a bidirectional serial data line (SDA) and a serial clock line (SCL). The MAX77826 supports SCL clock rates up to 3.4 MHz .

## Applications

- GSM, GPRS, EDGE, CDMA WCDMA, and LTE Smartphones and Tablets

## Ordering Information appears at end of data sheet.

## Benefits and Features

- Compact Total Solution Size Allows More Peripheral Devices in Smartphones and Tablets
- 3A High-Efficiency BUCK Regulator
- DVS (Dynamic Voltage Scaling) Through HS I2C
- $\pm 1 \%$ (typ) Output Voltage DC Accuracy
- Low Power Mode
- 2A BUCK BOOST Regulator
- 15 Linear Regulators with Remote Cap
- 3 NMOS LDOs (VOUT Range: 0.6V to 2.1875 V with 12.5 mV Step)
- $1 \times 150 \mathrm{~mA}$
- $1 \times 450 \mathrm{~mA}$
- $1 \times 600 \mathrm{~mA}$
- 6 PMOSLV LDOs (VoUT Range: 0.8 V to 3.975 V with 25 mV Step)
- $3 \times 150 \mathrm{~mA}$
- $3 \times 300 \mathrm{~mA}$
- 6 PMOSLS LDOs (Vout Range: 0.8 V to 3.975 V with 25 mV Step)
- $3 \times 150 \mathrm{~mA}$
- $3 \times 300 \mathrm{~mA}$
- $\pm 1.5 \%$ Typical Output Voltage DC Accuracy
- 70dB PSRR at 1 kHz
- Low Power Mode with $2 \mu \mathrm{~A}$ (typ) for all LDOs
- Simple Management of Power-Up/Down Sequence, Output Voltage Setting, and Fault Detection
- High-Speed (Up to 3.4 MHz ) $\mathrm{I}^{2} \mathrm{C}$ Serial Interface

## Absolute Maximum Ratings

|  |  |

Note 1: LX_ node has internal clamp diodes to PGND_ and INB_. Applications that give forward bias to these diodes should ensure that the total power loss does not exceed IC's package power dissipation limits.

## Package Thermal Characteristics (Note 2)

WLP
Junction-to-Ambient Thermal Resistance ( $\theta_{\mathrm{JA}}$ ) .......... $37^{\circ} \mathrm{C} / \mathrm{W}$
Note 2: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

## General Electrical Characteristics

| Output POK Trip Level | Rising edge, $\mathrm{V}_{\text {OUT }}$ when $\mathrm{V}_{\text {POK }}$ switches |  | 87.5 |  | \% |
| Output POK Hysteresis | $\mathrm{V}_{\text {OUT }}$ when $\mathrm{V}_{\text {POK }}$ switches |  | 3 |  | \% |

Note 3: Guaranteed by design. Not production tested.
Note 4: $100 \%$ production tested at $T_{A}=+25^{\circ} \mathrm{C}$, limits over the operating range are guaranteed by design.
Note 5: Limits are $100 \%$ production tested at $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$. Limits over the operating temperature range are guaranteed through correlation using statistical quality control methods.
Note 6: The maximum output current spec is not directly tested. Instead, it is guaranteed by LX NMOS current limit test.
Note 7: For NMOS LDOs, $\mathrm{V}_{\text {SYS }}$ must be at least 1.5 V above $\mathrm{V}_{\text {OUT }}\left(\mathrm{V}_{\text {SYS }} \geq \mathrm{V}_{\text {OUT }}+1.5 \mathrm{~V}\right)$.
Note 8: The maximum output current is guaranteed by the output voltage accuracy tests.
Note 9: For stability, guaranteed by design and not production tested.
Note 10: There is an n-channel MOSFET in series with the output active discharge resistance. This NMOS requires $\mathrm{V}_{\mathrm{SYS}}>1.2 \mathrm{~V}$ to be enhanced.

| A6 | LDO7 |  |
| B6 | LDO8 | LDO8 (150mA PMOSLV) Output. Bypass to GND with a $2.2 \mu \mathrm{~F}$ capacitor. |
| D6 | LDO9 | LDO9 (150mA PMOSLV) Output. Bypass to GND with a $2.2 \mu \mathrm{~F}$ capacitor. |
| G1 | LDO10 |  |
| G2 | LDO11 | LDO11 (150mA PMOSLS) Output. Bypass to GND with a $2.2 \mu \mathrm{~F}$ capacitor. |
| D1 | LDO12 |  |
| E1 | LDO13 |  |
| E2 | LDO14 | LDO14 (150mA PMOSLS) Output. Bypass to GND with a $2.2 \mu \mathrm{~F}$ capacitor. |
| D2 | LDO15 | LDO15 (150mA PMOSLS) Output. Bypass to GND with a $2.2 \mu \mathrm{~F}$ capacitor. |
| F3, G3 | OUTBB | BUCK BOOST Output |
| C1, C2 | PGNDB | BUCK Power GND |
| F5, G5 | PGNDBB | BUCK BOOST Power GND |
| C5 | REFBYP | LDO Reference Bypass Node. Connect a $0.1 \mu \mathrm{~F}$ Cap to GND. |
| D4 | SCL | ${ }^{2}{ }^{2} \mathrm{C}$ Clock Input. High Impedance in Off State. <br> A $1.5 \mathrm{k} \Omega \sim 2.2 \mathrm{k} \Omega$ of pullup resistor to VIO is required. |
| D3 | SDA | ${ }^{2} \mathrm{C}$ Data I/O. High Impedance in Off State. A $1.5 \mathrm{k} \Omega-2.2 \mathrm{k} \Omega$ of pullup resistor to $\mathrm{V}_{\mathrm{IO}}$ is required. |
| A3 | SYS | System (Battery) Voltage Input. Bypass to GND with a $1 \mu \mathrm{~F}$ capacitor. |
| C3 | $\mathrm{V}_{\mathrm{IO}}$ | IO Supply Voltage Input. Bypass to GND with a $0.1 \mu \mathrm{~F}$ capacitor. |

Block Diagram

## Detailed Description

## Top System Management

## System Faults

The MAX77826 monitors the system for the following faults: global thermal, local thermal shutdown, and undervoltage lockout.

## Global Thermal Fault

The MAX77826 has a centralized thermal protection circuit which monitors temperature on the die. If the die temperature exceeds $+165^{\circ} \mathrm{C}$ (TSHDN), a thermal shutdown event initiates, and the MAX77826 enters its global shutdown state.
In addition to the $+165^{\circ} \mathrm{C}$ threshold, there are two additional comparators that trip at $+120^{\circ} \mathrm{C}$ and $+140^{\circ} \mathrm{C}$. Interrupts are generated in the event the die temperature reaches $+120^{\circ} \mathrm{C}$ or $+140^{\circ} \mathrm{C}$.
There is a $15^{\circ} \mathrm{C}$ thermal hysteresis. After the thermal shutdown, if the die temperature reduces by $15^{\circ} \mathrm{C}$, the thermal shutdown bus deasserts.

## Local Thermal Shutdown

If any of the BUCK BOOST or LDOs reach the thermal shutdown threshold, the MAX77826 shuts down the corresponding block locally. If the temperature goes below a threshold, that block goes back to normal operation.

## Undervoltage Lockout

When $V_{\text {SYs }}$ falls below VUVLO_F (typ 2.05V), the MAX77826 enters its undervoltage lockout (UVLO) mode. UVLO forces the MAX77826 to a dormant state until the source voltage is high enough to allow the MAX77826 to be securely functional. $1^{2} \mathrm{C}$ does not function and the Type-O register contents are reset to their default values in UVLO mode. UVLO rising threshold is set to 2.5 V by an OTP option.
Chip Enable (CE)
A logic-high on CE pin puts the MAX77826 into standby mode (enabled). In standby mode, all user registers are accessible through ${ }^{2} \mathrm{C}$ so that the host processor can
overwrite the default output voltages of regulators and each regulator can be enabled by either $\mathrm{I}^{2} \mathrm{C}$ or the GPIO input if applicable.
When the CE pin goes high, the MAX77826 turns on the top-level bias circuitry, and it takes typically $85 \mu \mathrm{~s}$ to settle. As soon as the top-level bias is ready, BUCK BOOST is ready to be turned on. However, BUCK and LDOs require additional $85 \mu \mathrm{~s}$ (typ) for REFBYP to settle. Total, it takes $170 \mu \mathrm{~s}(85 \mu \mathrm{~s}+85 \mu \mathrm{~s})$ for REFBYP to settle from CE $=$ high. In the worst-case scenario, it can take up to $230 \mu \mathrm{~s}$. Once REFBYP is ready, all the regulators are allowed to be tuned on through $I^{2} \mathrm{C}$ or the ENx pins. In case the regulars are enabled before the bias circuitry is ready, the regulators require longer time to startup.
When CE pin is pulled low, the MAX77826 goes into shutdown mode (disabled) and turns off all the regulators regardless of ENx pins. This event also resets all Type-O registers to their POR default values.

## Immediate Shutdown Events

The following events initiate immediate shutdown: thermal protection ( $\mathrm{TJ}_{\mathrm{J}}>+165^{\circ} \mathrm{C}$ ), $\mathrm{V}_{\mathrm{SYS}}<\mathrm{V}_{\mathrm{SYS}}$ UVLO falling threshold (VUVLO_F), $\mathrm{V}_{\mathrm{IO}}<\mathrm{V}_{\mathrm{IO}}$ OK threshold ( $\mathrm{V}_{\text {TH_VIO_OK }}$ )
The events in this category are associated with potentially hazardous system states. Powering down the host processor and resetting all Type-O registers help mitigate any issues that can occur due to these potentially hazardous conditions. Note that the MAX77826 cannot be enabled until the junction temperature drops below $+150^{\circ} \mathrm{C}$ in case thermal protection caused the immediate shutdown.

## Operating Mode (OPMD)

Each regulator (BUCK, BUCK BOOST, and LDO) has independent register bits to control its operating mode. These bits determines on/off operation during initial startup, output enable control, and sleep mode operation based on the enable control logic of each regulator. The POR default values of output enable bits (x_EN) are 0 (output off).

## Enable Control Logic1

BUCK, BUCK BOOST, and LDO12 have independent ${ }^{12} \mathrm{C}$ enable bits and dedicated GPIO enable pins (ENB, ENBB, and ENL12). As shown in Table 1, regulators can be turned on/off by ENx or ${ }^{2}{ }^{2} \mathrm{C}$ control bits.

## Enable Control Logic 2

LDO1-LDO11 and LDO13-LDO15 have independent ${ }^{2}$ C enable bits. As shown in Table 2, regulators can be turned on/off by the ${ }^{2} \mathrm{C}$ control bits.

## Reset Conditions

## System Reset

When $\mathrm{V}_{\text {SYS }}$ voltage drops below its POR threshold ( $\approx 1.55 \mathrm{~V}$ ), all Type-S1 registers are reset to their POR default values.

## Off Reset

Off reset occurs by any power-off events. This condition resets all Type-O registers to their POR default values.

## Table 1. Enable Control <br> Logic 1 Truth Table

| CE | ENx | B_EN <br> BB_EN <br> L12_EN | B_LPM <br> L12_LPM | OPERATING <br> MODE |

| :---: | :---: | :---: | :--- |
| Low | x | x | Device off |
| High | 0 | x | Output off |
| High | 1 | 1 | Output on <br> (low power mode) |
| High | 1 | 0 | Output on |

## Interrupt and Mask

IRQB pin is used to indicate to the host processor that the status on the MAX77826 has changed. IRQB signal is asserted whenever one or more interrupts are triggered. The host processor reads the interrupt source register (ADDR 0x00) and the interrupt registers as indicated by the interrupt source register in order to see the cause of interrupt event.
Each interrupt register can be read at a time. IRQB pin goes high (cleared) as soon as the read sequence finishes. If an interrupt is captured during the read sequence, IRQB pin is held low. Note that the interrupt source register is cleared when the corresponding interrupt registers are read by the host processor.
Each interrupt can be masked (disabled) by setting the corresponding interrupt mask register bit. In case an interrupt mask bit is set (masked), the corresponding interrupt bit is not supposed to be set even when the interrupt condition is met. As a result, the IRQB pin stays high for this event. If the mask bit is cleared for an active interrupt, the corresponding interrupt bit is set to pull the IRQB pin low.

Figure 1. Enable Control Logic 1

Figure 2. Enable Control Logic 2

## BUCK Regulator

The MAX77826 includes a 3A current-mode BUCK regulator. In normal operation, BUCK consumes only $22 \mu \mathrm{~A}$ quiescent current. In low power mode, the quiescent current is decreased to $8 \mu \mathrm{~A}$ with reduced load capability.

The summary of features is:

- 3A of maximum output current rating
- 2.6 V to 5.5 V input voltage range
- Output voltage range from 0.50 V to 1.80 V in 6.25 mV steps
- $\pm 1 \%$ (typ) output voltage DC accuracy
- 2 MHz (typ) switching frequency
- Automatic SKIP/PWM or forced PWM modes
- > 90\% peak efficiency
- Programmable slew rate for increasing output voltage settings

## Operating Mode Control

The operating mode bit resides in the top level that controls the enable/disable state of BUCK through the B_EN register and also controls the operating mode (low power or normal mode) through the B_LPM register.

## SKIP/Forced PWM Operation

In normal operating mode, BUCK automatically transitions from SKIP mode to fixed frequency operation as load current increases. For operating modes where lowest output ripple is required, forced PWM switching behavior can be enabled by writing 1 to B_FPWM bit.

## Low Power Mode Operation

In low power mode, the quiescent current is reduced from $22 \mu \mathrm{~A}$ to $8 \mu \mathrm{~A}$. The output current is limited to 10 mA . It is not recommended to adjust the output voltage in low power mode. The regulator does not automatically enter/ exit low power mode. The host processor needs to control low power mode operation in times of known low power states through the $\mathrm{I}^{2} \mathrm{C}$ serial interface.

## Startup and Soft-Start

When starting up BUCK regulator, the bias circuitry must be enabled and provided with adequate time to settle. The bias circuitry is guaranteed to settle within $250 \mu \mathrm{~s}$, at which time, the BUCK regulators' power-up sequences can commence. Note that attempting to implement a powerup sequence before BIASOK signal is generated results in all enabled regulators starting up at the same time.

The BUCK regulator supports starting into a prebiased output. For example, if the output capacitor has an initial voltage of 0.4 V when the regulator is enabled, the regulator gradually increases the capacitor voltage to the required target voltage such as 1.0 V . This is unlike other regulators without the start into prebias feature in which they can force the output capacitor voltage to OV before the soft-start ramp begins.
The BUCK regulator has a soft-start rate of $14 \mathrm{mV} / \mu \mathrm{s}$. The controlled soft-start rate and BUCK regulator current limit (ILIMP) limit the input inrush current to the output capacitor ( $l_{\text {INRUSH }}$ ). $I_{\text {INRUSH }}=\min \left(l_{\text {LIMP }}\right.$ and COUT $\left.x d v / d t\right)$. Note that the input current of BUCK regulator is lower than the inrush current to the output capacitor by the ratio of output to input voltage.

## Output Voltage Setting

The output voltage is programmable from 0.50 V to 1.80 V in 6.25 mV steps to allow fine adjustment to the processor supply voltage under light load conditions to minimize power loss within the processor. The default output voltage is set by an OTP option at the factory. The default output voltage can be overwritten by changing the contents in B_VOUT[7:0] register prior to enabling the regulator. The output voltage can also be adjusted during normal operation.

## Changing Output Voltage While Operating

In a typical smartphone or tablet application, there are several power domains in which the operating frequency of the processor increases or decreases (DVFS). When the operating frequency needs to be changed, it is expected that BUCK regulator responds to a command to change the output voltages to new target values quickly. The high peak current limit, coupled with low inductance and small output capacitance, allows the BUCK regulator to respond to a positive step change in output voltage and settle to the new target value quickly. The BUCK regulator provides programmable ramp-up slew rates to accommodate different requirements.
For a negative step change in output voltage, the settling time is not critical. In forced PWM mode (either B_FPWM bit or B_FSRAD bit is enabled), the negative inductor current through NMOS discharges energy from the output capacitor to help the output voltage decrease to the new target value faster. In skip mode, negative inductor current is not allowed so that the output voltage settling time is dependent on the load current and the output capacitance.

## Output Voltage Slew Rate Control

The BUCK regulator supports programmable slew rate control feature when increasing and decreasing the output voltage. The ramp-up slew rate can be set to $12.5 \mathrm{mV} / \mu \mathrm{s}$, $25 \mathrm{mV} / \mu \mathrm{s}, 50 \mathrm{mV} / \mu \mathrm{s}$ or $100 \mathrm{mV} / \mu \mathrm{s}$ independently through the B_RAMP[1:0] bits, while the ramp-down slew rate is fixed to $6.25 \mathrm{mV} / \mu \mathrm{s}$.

## Output Active Discharge Resistance

BUCK provides an internal $100 \Omega$ resistor for output active discharge function. If the active discharge function is enabled ( $B \_A D=1$ ), the internal resistor discharges the energy stored in the output capacitor to GND whenever the regulator is disabled.
Either the regulator remains enabled or the active discharge function is disabled ( $B \_A D=0$ ), the internal resistor is disconnected from the output. If the active discharge function is disabled, the output voltage decays at a rate that is determined by the output capacitance and the load current when the regulator is turned off.

## Inductor Selection

BUCK is optimized for a $0.47 \mu \mathrm{H}$ inductor. The lower the inductor DCR, the higher BUCK efficiency is. Users need to trade off inductor size with DCR value and choose a suitable inductor for BUCK.

## Input Capacitor Selection

The input capacitor, $\mathrm{C}_{\mathrm{IN}}$, reduces the current peaks drawn from the battery or input power source and reduces switching noise in the IC. The impedance of $\mathrm{C}_{\mathrm{IN}}$ at the switching frequency should be kept very low. Ceramic capacitors with X5R or X7R dielectrics are highly rec-
ommended due to their small size, low ESR, and small temperature coefficients. For most applications, a $10 \mu \mathrm{~F}$ capacitor is sufficient.

## Output Capacitor Selection

The output capacitor, COUT, is required to keep the output voltage ripple small and to ensure regulation loop stability. COUT must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. Due to the unique feedback network, the output capacitance can be very low. The recommended minimum output capacitance for BUCK is $22 \mu \mathrm{~F}$.

## BUCK BOOST Regulator

The MAX77826 BUCK BOOST regulator utilizes a fourswitch H-bridge configuration to realize BUCK, BUCK BOOST, and BOOST operating modes. In this way, this topology maintains output voltage regulation when the input voltage is greater than, equal to, or less than the output voltage. The MAX77826 BUCK BOOST is ideal in Li-ion battery powered applications, providing 2.6 V to 4.1875 V output voltage and up to 2 A output current across the input voltage range. High switching frequency and a unique control algorithm allow the smallest solution size, low output noise, and highest efficiency across a wide input voltage and output current range.
The MAX77826 BUCK BOOST regulator typically generates a 3.50 V output voltage. The input current limit is set to 3.5 A (typ) to guarantee delivery of 2 A at 3.50 V from 3.0V input. Internal soft-start limits the inrush current at startup.

Figure 3. BUCK BOOST Block Diagram

## H-Bridge Controller

The H-bridge architecture operates at 3 MHz fixed frequency with a pulse width modulated (PWM), current mode control scheme. This topology is in a cascade of a BOOST regulator and a BUCK regulator using a single inductor and output capacitor. BUCK, BUCK BOOST, and BOOST stages are 100\% synchronous for highest efficiency in portable applications.
There are three phases implemented with the H-bridge switch topology, as shown in Figure 4:
Ф1 switch period (Phase 1: P1 = on, N2 = on) stores energy in the inductor, ramping up the inductor current at a rate proportional to the input voltage divided by inductance; VINBB/L.
Ф2 switch period (Phase 2: P1 = on, N3 = on) ramps the inductor current up or down, depending on the differential voltage across the inductor, divided by inductance; $\pm\left(\mathrm{V}_{\text {INBB }}-\mathrm{V}_{\text {OUTBB }}\right) / \mathrm{L}$.
Ф3 switch period (Phase 3: N1 = on, N3 = on) ramps down the inductor current at a rate proportional to the output voltage divided by inductance, $-\mathrm{V}_{\text {OUTBB }} / \mathrm{L}$.

Figure 4. BUCK BOOST Switching Intervals

2-Phase BUCK topology is utilized when $\mathrm{V}_{\text {INBB }}>\mathrm{V}_{\text {OUTBB }}$. A switching cycle is completed in one clock periods. Switch period $\Phi 2$ is followed by switch period $\Phi 3$, resulting in an inductor current waveform similar to Figure 5.
3-Phase BUCK topology is utilized when $\mathrm{V}_{\text {INBB }}>\mathrm{V}_{\text {OUTBB }}$ and 2-Phase BUCK cannot support $\mathrm{V}_{\mathrm{O}}$. Switch period is: $\Phi 1 \rightarrow \Phi 2 \rightarrow \Phi 3$. Switch period $\Phi 1$ is fixed. This results in an inductor current waveform similar to Figure 6.
2-Phase BOOST topology is utilized when $\mathrm{V}_{\text {INBB }}$ < VOUTBB. A switching cycle is completed in one clock periods. Switch period $\Phi 1$ is followed by switch period $\Phi 2$, resulting in an inductor current waveform similar to Figure 7.
3-Phase BOOST topology is utilized when $\mathrm{V}_{\text {INBB }}<$ $V_{\text {OUTBB }}$ and 2-Phase BOOST cannot support $\mathrm{V}_{\mathrm{O}}$. Switch period is: $\Phi 1 \rightarrow \Phi 2 \rightarrow \Phi 3$. Switch period $\Phi 3$ is fixed. This results in an inductor current waveform similar to Figure 8.

## Inductor Selection

BUCK BOOST is optimized for a $1 \mu \mathrm{H}$ inductor. The lower the inductor DCR, the higher BUCK BOOST efficiency is.

Users need to trade off inductor size with DCR value and choose a suitable inductor for BUCK BOOST.

The input capacitor, $\mathrm{C}_{\mathrm{IN}}$, reduces the current peaks drawn from the battery or input power source and reduces switching noise in the IC. The impedance of $\mathrm{C}_{I N}$ at the switching frequency should be kept very low. Ceramic capacitors with X5R or X7R dielectrics are highly recommended due to their small size, low ESR, and small temperature coefficients. For most applications, a $10 \mu \mathrm{~F}$ capacitor is sufficient.

## Output Capacitor Selection

The output capacitor, COUT, is required to keep the output voltage ripple small and to ensure regulation loop stability. COUT must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. Due to the unique feedback network, the output capacitance can be very low. The recommended minimum output capacitance for BUCK BOOST is $47 \mu \mathrm{~F}$.

## Linear Regulators

The MAX77826 provides 15 low dropout linear regulators including 3 NMOS LDOs, 6 PMOSLV LDOs, and 6 PMOSLS LDOs. Each of these regulators draws $27 \mu \mathrm{~A} / 18 \mu \mathrm{~A}$ (NMOS/PMOS) of quiescent current in normal operating mode and $<5 \mu \mathrm{~A}$ in low power mode. PMOSLV LDOs allow input voltages as low as 1.7 V for optimized system efficiency.
All regulators can be operated in low power mode that supports up to 5 mA of maximum load current.
The summary of features is:

- 3 NMOS LDOs (Vout range: 0.6 V to 2.1875 V with 12.5 mV step)
- $1 \times 150 \mathrm{~mA}$
- $1 \times 450 \mathrm{~mA}$
- $1 \times 600 \mathrm{~mA}$
- 6 PMOSLV LDOs (VOUT range: 0.8 V to 3.975 V with 25 mV step)
- $3 \times 150 \mathrm{~mA}$
- $3 \times 300 \mathrm{~mA}$
- 6 PMOSLS LDOs (Vout range: 0.8 V to 3.975 V with 25 mV step)
- $3 \times 150 \mathrm{~mA}$
- $3 \times 300 \mathrm{~mA}$
- $\pm 1.5 \%$ typical Output Voltage DC Accuracy
- 70 dB PSRR at 1 kHz

## LDO Reference

The MAX77826 has a single LDOREF bias rail. LDOREF is enabled or disabled along with the central bias block (SBIA) so that LDOREF is ready whenever any LDO turns on. It has a very low quiescent current of $2 \mu \mathrm{~A}$ typical.

## Operating Mode Control

The operation mode bits for each LDO reside in the top level that controls the enable/disable state for each LDO through the Lx_EN signal and also controls the operation modes (low power or normal mode) for each LDO through the Lx_LPM signal.

## Low Power Mode

In low power mode, the quiescent current of each LDO is reduced from $27 \mu \mathrm{~A} / 18 \mu \mathrm{~A}$ (NMOS/PMOS) to less than $5 \mu \mathrm{~A}$. The output current of each LDO is limited to 5 mA if operating in low power mode. Each LDO can be individually enabled to operate in low power mode.

## Soft-Start and Dynamic Voltage Change

When a regulator is enabled, the output voltage ramps to the final voltage at the slew rate of $30 \mathrm{mV} / \mu \mathrm{s}$. The $30 \mathrm{mV} /$ $\mu \mathrm{s}$ ramp rate results in around 30 mA inrush current with a $1.0 \mu \mathrm{~F}$ output capacitor under no load condition. For a 1.8 V LDO ramping from OV , the output voltage regulation is achieved within $60 \mu \mathrm{~s}$. The soft-start ramp rate is also the rate of change at the output when switching dynamically between two output voltages without disabling. The soft-start circuitry of LDOs supports starting into a prebiased output.

## Output Active Discharge

Each LDO provides an internal $100 \Omega$ resistor for output active discharge function. If the active discharge function is enabled ( $L x \_A D=1$ ), the internal resistor discharges the energy stored in the output capacitor to GND whenever the regulator is disabled.
Either the regulator remains enabled or the active discharge function is disabled ( $L x \_A D=0$ ), the internal resistor is disconnected from the output. If the active discharge function is disabled, the output voltage decays at a rate that is determined by the output capacitance and the load current when the regulator is turned off.

## Thermal Considerations

In most applications, the MAX77826 does not dissipate much heat because of its high efficiency. However, in applications where the MAX77826 runs with heavy loads at high ambient temperature, the junction temperature can exceed the maximum operating temperature. In case the junction temperature reaches approximately $+165^{\circ} \mathrm{C}$, the thermal overload protection triggers. The maximum power dissipation of the MAX77826 depends on the thermal resistance of the IC package and PCB. The power dissipated in the device is:

$$
P_{D}=\text { POUT } \times(1 / \eta-1)
$$

where $\eta$ is the efficiency of the regulator and POUT is the output power delivered to the load.
The maximum allowed power dissipation is:

$$
P_{\text {MAX }}=\left(T_{J M A X}-T_{A}\right) / \theta_{J A}
$$

$T_{\text {JMAX }}-T_{A}$ is the temperature difference between the maximum rated junction temperature and the ambient temperature, $\theta_{\mathrm{JA}}$ is the thermal resistance between the junction and the ambient.

## Serial Interface

The ${ }^{12}$ C-compatible, 2 -wire serial interface is used for regulator on/off control, setting output voltages, and other functions. See the Register Map for details.
The I2C serial bus consists of a bidirectional serial-data line (SDA) and a serial clock (SCL). ${ }^{2}$ C is an open-drain bus. SDA and SCL require pullup resistors ( $500 \Omega$ or greater). Optional $24 \Omega$ resistors in series with SDA and SCL help to protect the device inputs from high voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus lines.

## System Configuration

${ }^{2} \mathrm{C}$ bus is a multimaster bus. The maximum number of devices that can attach to the bus is only limited by bus capacitance.
The figure above shows an example of a typical ${ }^{2}{ }^{2} \mathrm{C}$ system. A device on $I^{2} \mathrm{C}$ bus that sends data to the bus in called a transmitter. A device that receives data from the bus is called a receiver. The device that initiates a data transfer and generates SCL clock signals to control the data transfer is a master. Any device that is addressed by the master is considered a slave. When the MAX77826 ${ }^{2}{ }^{2} \mathrm{C}$-compatible interface is operating in normal mode, it is a slave on $I^{2} \mathrm{C}$ bus, and it can be both a transmitter and a receiver.

## Bit Transfer

One data bit transfers for each SCL clock cycle. The data on SDA must remain stable during the high portion of SCL clock pulse. Changes in SDA while SCL is high are control signals (START and STOP conditions).

## START and STOP Conditions

When the $I^{2} \mathrm{C}$ serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA, while SCL is high.
A START condition from the master signals the beginning of a transmission to the MAX77826. The master terminates transmission by issuing a NOT ACKNOWLEDGE followed by a STOP condition.
A STOP condition frees the bus. To issue a series of commands to the slave, the master can issue REPEATED START (Sr) commands instead of a STOP command to maintain control of the bus. In general, a REPEATED START command is functionally equivalent to a regular START command.
When a STOP condition or incorrect address is detected, the MAX77826 internally disconnects SCL from the ${ }^{2}{ }^{2} \mathrm{C}$ serial interface until the next START condition, minimizing digital noise and feedthrough.

Figure 10. $I^{2} \mathrm{C}$ Bit Transfer

Figure 11. START and STOP Conditions

## Acknowledge

Both the I2C bus master and MAX77826 (slave) generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each 9-bit data packet. To generate an ACKNOWLEDGE (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse. To generate a NOT-ACKNOWLEDGE (nA), the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high period of the clock pulse.
Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

## Slave Address

The $I^{2}$ C slave address of the MAX77826 is shown in Table 5.
In general, the clock signal generation for the ${ }^{2} \mathrm{C}$ bus is the responsibility of the master device. The ${ }^{2} \mathrm{C}$ specification allows slow slave devices to alter the clock signal by holding down the clock line. The process in which a slave device holds down the clock line is typically called clock stretching. The MAX77826 does not use any form of clock stretching to hold down the clock line.

## General Call Address

The MAX77826 does not implement ${ }^{2} \mathrm{C}$ specification general call address. If the MAX77826 sees the general call address (00000000b), it does not issue an ACKNOWLEDGE (A).

## Table 5. Power Management Slave

Address

| SLAVE <br> ADDRESS <br> (7 bit) | SLAVE <br> ADDRESS <br> (Write) | SLAVE <br> ADDRESS <br> (Read) |
| :---: | :---: | :---: |
| 1100000 | $0 \times C 0(11000000)$ | $0 \times C 1(11000001)$ |

## Communication Speed

The MAX77826 provides an ${ }^{2} \mathrm{C}$ 3.0 -compatible ( 3.4 MHz ) serial interface.

- ${ }^{2} \mathrm{C}$ revision 3-compatible serial communications channel
- 0 Hz to 100 kHz (standard mode)
- 0 Hz to 400 kHz (fast mode)
- OHz to 1 MHz (fast mode plus)
- OHz to 3.4 MHz (high-speed mode)
- Does not utilize $\mathrm{I}^{2} \mathrm{C}$ clock stretching

Operating in standard mode, fast mode and fast mode plus do not require any special protocols. The main consideration when changing the bus speed through this range is the combination of the bus capacitance and pullup resistors. Higher time constants created by the bus capacitance and pullup resistance ( $C \times R$ ) slow the bus operation. Therefore, when increasing bus speeds the pullup resistance must be decreased to maintain a reasonable time constant. Refer to the Pullup Resistor Sizing section of ${ }^{2} \mathrm{C}$ revision 3.0 specification for detailed guidance on the pullup resistor selection. In general for bus capacitances of 200 pF , a 100 kHz bus needs $5.6 \mathrm{k} \Omega$ pullup resistors, a 400 kHz bus needs about a $1.5 \mathrm{k} \Omega$ pullup resistors, and a 1 MHz bus needs $680 \Omega$ pullup resistors. Note that the pullup resistor dissipates power when the opendrain bus is low. The lower the value of the pullup resistor, the higher the power dissipation is (V2/R).
Operating in high-speed mode requires some special considerations. For the full list of considerations, refer to the I2C 3.0 specification. The major considerations with respect to the MAX77826 are:

- The ${ }^{2} \mathrm{C}$ bus master uses current source pullups to shorten the signal rise times.
- The ${ }^{2}$ 2 slave must use a different set of input filters on its SDA and SCL lines to accommodate for the higher bus speed.
- The communication protocols need to utilize the highspeed master code.

Figure 12. Slave Address Byte Example for Power Block

At power-up and after each STOP condition, the MAX77826 inputs filters are set for standard mode, fast mode, or fast mode plus (i.e., 0 Hz to 1 MHz ). To switch the input filters for high-speed mode, use the high-speed master code protocols that are described in Communication Protocols section.

## Communication Protocols

The MAX77826 supports both writing and reading from its registers. Table TBD shows the $I^{2}$ C communication protocols for each functional block. The power block uses the same communications protocols.

## Writing to a Single Register

Figure 13 shows the protocol for the $\mathrm{I}^{2} \mathrm{C}$ master device to write one byte of data to the MAX77826. This protocol is the same as the SMBus specification's write byte protocol. The write byte protocol is as follows:

1) The master sends a START command (S).
2) The master sends the 7-bit slave address followed by a write bit ( $R / \bar{W}=0$ ).
3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
4) The master sends an 8-bit register pointer.
5) The slave acknowledges the register pointer.
6) The master sends a data byte.
7) The slave updates with the new data
8) The slave acknowledges or does not acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
9) The master sends a STOP condition ( P ) or a REPEATED START condition (Sr). Issuing a $P$ ensures that the bus input filters are set for 1 MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

## Writing to Sequential Registers

Figure 14 shows the protocol for writing to a sequential registers. This protocol is similar to the write byte protocol, except the master continues to write after it receives the first byte of data. When the master is done writing, it issues a STOP or REPEATED START. The writing to sequential registers protocol is as follows:

1) The master sends a START command (S).
2) The master sends the 7-bit slave address followed by a write bit ( $\mathrm{R} / \overline{\mathrm{W}}=0$ ).

Figure 13. Writing to a Single Register with Write Byte Protocol
3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA LOW.
4) The master sends an 8-bit register pointer.
5) The slave acknowledges the register pointer.
6) The master sends a data byte.
7) The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register, and the data becomes active.
8) Steps 6 and 7 are repeated as many times as the master requires.
9) During the last acknowledge related clock pulse, the master can issue an ACKNOWLEDGE (A) or a NOT ACKNOWLEDGE (nA).
10) The master sends a STOP condition (P) or a REPEATED START condition ( Sr ). Issuing a $P$ ensures that the bus input filters are set for 1 MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

Figure 14. Writing to Sequential Registers $X$ to $N$

## Writing Multiple Bytes using Register-Data Pairs

Figure 15 shows the protocol for $\mathrm{I}^{2} \mathrm{C}$ master device to write multiple bytes to the MAX77826 using register-data pairs. This protocol allows ${ }^{2}{ }^{2} \mathrm{C}$ master device to address the slave only once and then send data to multiple registers in a random order. Registers can be written continuously until the master issues a STOP condition. The multiple byte register-data pair protocol is as follows:

1) The master sends a START command.
2) The master sends the 7-bit slave address followed by a write bit.
3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
4) The master sends an 8-bit register pointer.
5) The slave acknowledges the register pointer.
6) The master sends a data byte.
7) The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
8) Steps 4 to 7 are repeated as many times as the master requires.
9) The master sends a STOP condition. During the rising edge of the stop related SDA edge, the data byte that was previously written is loaded into the target register and becomes active.

Figure 15. Writing to Multiple Registers with Multiple Byte Register-Data Pairs Protocol

## Reading from a Single Register

The $I^{2} \mathrm{C}$ master device reads one byte of data to the MAX77826. This protocol is the same as SMBus specification's read byte protocol. The read byte protocol is as follows:

1) The master sends a START command (S).
2) The master sends the 7-bit slave address followed by a write bit ( $R / \bar{W}=0$ ).
3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
4) The master sends an 8-bit register pointer.
5) The slave acknowledges the register pointer.
6) The master sends a REPEATED START command ( Sr ).
7) The master sends the 7-bit slave address followed by a read bit ( $R / \bar{W}=1$ ).
8) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
9) The addressed slave places 8 bit of data on the bus from the location specified by the register pointer.
10) The master issues a NOT ACKNOWLEDGE (nA).
11) The master sends a STOP condition ( $P$ ) or a REPEATED START condition (Sr). Issuing a $P$ ensures that the bus input filters are set for 1 MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.
Note that every time MAX77826 receives a STOP, its register pointer is set to $0 \times 00$. If reading register $0 \times 00$ after a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

## Reading from Sequential Registers

Figure 16 shows the protocol for reading from sequential registers. This protocol is similar to the read byte protocol except the master issues an ACKNOWLEDGE (A) to signal the slave that it wants more data. When the master has all the data it requires, it issues a NOT ACKNOWLEDGE ( $n A$ ) and a STOP (P) to end the transmission. The continuous read from sequential registers protocol is as follows:

1) The master sends a START command (S).
2) The master sends the 7-bit slave address followed by a write bit ( $\mathrm{R} / \overline{\mathrm{W}}=0$ ).
3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA LOW.
4) The master sends an 8-bit register pointer.
5) The slave acknowledges the register pointer.
6) The master sends a REPEATED START command ( Sr ).
7) The master sends the 7-bit slave address followed by a read bit ( $R / \bar{W}=1$ ).
8) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
9) The addressed slave places 8 bit of data on the bus from the location specified by the register pointer.
10) The master issues an ACKNOWLEDGE (A) signaling the slave that it wishes to receive more data.
11) Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a NOT ACKNOWLEDGE (nA) to signal that it wishes to stop receiving data.
12) The master sends a STOP condition ( P ) or a REPEATED START condition (Sr). Issuing a STOP (P) ensures that the bus input filters are set for 1 MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.
Note that every time the MAX77826 receives a STOP its register pointer is set to $0 x 00$. If reading register $0 \times 00$ after a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

## Engaging HS-Mode for Operation up to 3.4 MHz

Figure 17 shows the protocol for engaging HS mode operation. HS mode operation allows for a bus operating speed up to 3.4 MHz . The engaging HS mode protocol is as follows:

1) Begin the protocol while operating at a bus speed of 1 MHz or lower.
2) The master sends a START command (S).
3) The master sends the 8-bit master code of 00001xxxb where xxxb are don't care bits.
4) The addressed slave issues a NOT ACKNOWLEDGE (nA).
5) The master may now increase its bus speed up to 3.4 MHz and issue any read/write operation.
6) The master may continue to issue high-speed read/ write operations until a STOP $(P)$ is issued. Issuing a STOP $(P)$ ensures that the bus input filters are set for 1 MHz or slower operation. After a STOP has been issued, steps 1 to 6 in the above algorithm may be skipped.

| 1 | RSVD | 0 |  |  |
| 0 | B_FSRAD | 1 | Falling Slew Rate Active Discharge <br> 0: Disable Active Discharge <br> BUCK is allowed to operate in SKIP mode during the time the output voltage decreases (only if B3_FPWM = 0). In SKIP mode, BUCK cannot sink current from the output capacitor and the output voltage falling slew rate is a function of the external load. If the load is heavy, the output voltage falling slew rate is limited to $6.25 \mathrm{mV} / \mu \mathrm{s}$. If the load is light, the output voltage falling slew rate is a function of the output capacitance and the load. Note that the internal feedback string always imposes a $2 \mu \mathrm{~A}$ load on the output. <br> 1: Enable Active Discharge <br> BUCK operates in forced PWM mode during the time the output voltage decreases. In forced PWM mode, BUCK can sink current from the output capacitor to ensure that the output voltage falls at the rate of $6.25 \mathrm{mV} / \mathrm{\mu s}$. To ensure a smooth output voltage ramp-down, forced PMW mode remains engaged for $50 \mu \mathrm{~s}$ after the output voltage decreases to its target voltage. |  |

## BUCK_SS_FREQ

## BUCK Soft-Start and Switching Frequency Configuration Register

| ADDRESS | MODE |  | TYPE: 0 | RESET VALUE: 0x04 |
| :---: | :---: | :---: | :---: | :---: |
| 0x40 | R/W |  |  |  |
| BIT | NAME | POR | DESCRIPTION |  |
| 7:5 | RSVD | 000 | Write 0. |  |
| 4 | B_SS | 0 | BUCK Soft-Start Slew Rate <br> 0: $14 \mathrm{mV} / \mathrm{ms}$ <br> 1: $25 \mathrm{mV} / \mu \mathrm{s}$ |  |
| 3 | RSVD | 0 | Write 0. |  |
| 2:0 | B_FREQ[2:0] | 100 | Multiphase Current Mode BUCK Switching Frequency <br> 000b: 3.6 MHz <br> 001b: 3.2 MHz <br> 010b: 2.8 MHz <br> 011b: 2.4MHz <br> 100b: 2.0 MHz <br> 101b: 1.6 MHz <br> 110b: 1.2 MHz <br> 111b: 0.8 MHz |  |

## UVLO_FALL

VSYS UVLO Falling Threshold Program Register

| ADDRESS | MODE |  | TYPE: 0 | RESET VALUE: 0x01 |
| :---: | :---: | :---: | :---: | :---: |
| 0x41 | R/W |  |  |  |
| BIT | NAME | POR | DESCRIPTION |  |
| 7:2 | RSVD | 000000 | Write 000000. |  |
| 1:0 | UVLO_F[1:0] | 01 | VSYS UVLO Falling Threshold <br> 00b: Not used <br> 01b: 2.05V <br> 10b: 2.25 V <br> 11b: 2.45 V |  |

Note: 0x42-0xFF: RSVD.

## Typical Application Circuit

## Ordering Information

| PART | TEMP RANGE | PIN-PACKAGE |
| :---: | :---: | :---: |
| MAX $77826 \mathrm{EWJ}+$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | $49 \mathrm{Bumps}(7 \times 7)$ |
| 0.4 mm Pitch |  |  |

+Denotes a lead(Pb)-free/RoHS-compliant package.
Chip Information
PROCESS: S18B

## Package Information

For the latest package outline information and land patterns (footprints), go to www.maximintegrated.com/packages. Note that a "+", "\#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

| PACKAGE <br> TYPE | PACKAGE <br> CODE | OUTLINE <br> NO. | LAND <br> PATTERN NO. |
| :---: | :---: | :---: | :---: |
| 49 WLP | W493E3+1 | $21-0728$ | Refer to <br> Application <br> Note 1891 |

## Revision History

| REVISION <br> NUMBER | REVISION <br> DATE | DESCRIPTION | PAGES <br> CHANGED |
| :---: | :---: | :--- | :---: |
| 0 | $6 / 15$ | Initial release | - |
| 1 | $7 / 15$ | Corrected typos and updated notes in Electrical Characteristics table. | 4,7 |
