# MIC2560 

## General Description

The MIC2560 V Cc and $\mathrm{V}_{\mathrm{PP}}$ Matrix controls PCMCIA (Personal Computer Memory Card International Association) memory card power supply pins, both $\mathrm{V}_{\mathrm{cc}}$ and $\mathrm{V}_{\text {pp }}$. The MIC2560 switches voltages from the system power supply to $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\text {PP }}$. The MIC2560 switches between the three $\mathrm{V}_{\mathrm{CC}}$ voltages (OFF, 3.3 V and 5.0 V ) and the $\mathrm{V}_{\mathrm{PP}}$ voltages (OFF, $0 \mathrm{~V}, 3.3 \mathrm{~V}, 5 \mathrm{~V}$, or 12.0 V ) required by PCMCIA cards. Output voltage is selected by two digital inputs for each output and output current ranges up to 1 A for $\mathrm{V}_{\mathrm{Cc}}$ and 200 mA for $\mathrm{V}_{\text {PP }}$.
The MIC2560 provides power management capability under the control of the PC Card controller and features over current and thermal protection of the power outputs, zero current "sleep" mode, suspend mode, low power dynamic mode, and on-off control of the PCMCIA socket power.
The MIC2560 is designed for efficient operation. In standby (sleep) mode the device draws very little quiescent current, typically $0.01 \mu \mathrm{~A}$. The device and PCMCIA ports are protected by current limiting and overtemperature shutdown. Full cross-conduction lockout protects the system power supply.
Data sheets and support documentation can be found on Micrel's web site at www.micrel.com.

## Features

- Complete PCMCIA VCC and VPP switch matrix in a single IC
- No external components required
- Logic compatible with industry standard PCMCIA controllers
- No voltage overshoot or switching transients
- Break-before-make switching
- Output current limit and overtemperature shutdown
- Digital flag for error condition indication
- Ultra-low power consumption
- Digital selection of VCC and VPP voltages
- Over 1A VCC output current
- 200mA VPP (12V) output current
- Options for direct compatibility with industry standard PCMCIA controllers
- 16-Pin SOIC package

## Applications

- PCMCIA power supply pin voltage switch
- Font cards for printers and scanners
- Data-collection systems
- Machine control data input systems
- Wireless communications
- Bar code data collection systems
- Instrumentation configuration/data-logging
- Docking stations (portable and desktop)
- Power supply management
- Power analog switching

## Typical Application

Micrel Inc. • 2180 Fortune Drive • San Jose, CA 95131 • USA• tel +1 (408) 944-0800 • fax + 1 (408) 474-1000 • http://www.micrel.com

## Ordering Information

| Part Number |  |  |  |
| :---: | :---: | :---: | :---: |
| Standard | Pb-Free | Temperature Range |  |

## Notes:

1. Functional operation above the absolute maximum stress ratings is not implied.
2. Static-sensitive device. Store only in conductive containers. Handling personnel and equipment should be grounded to prevent damage from static discharge.
3. Leakage current after 1,000 hours at $125^{\circ} \mathrm{C}$ may increase up to five times the initial limit.
4. Suspend mode is a pseudo-power-down mode the MIC2560 automatically allows when $V_{\text {PP IN }}=0 \mathrm{~V}$, $\mathrm{V}_{\text {PP out }}$ is deselected, and $\mathrm{V}_{\text {cc out }}=3.3 \mathrm{~V}$ is selected. Under these conditions, the MIC2560 functions in a reduced capacity mode where $\mathrm{V}_{\mathrm{cc}}$ output of 3.3 V is allowed, but at lower current levels (higher switch on-resistance).

## Application Information

PCMCIA $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{PP}}$ control is easily accomplished using the MIC2560 voltage selector/switch IC. Four control bits determine $\mathrm{V}_{\mathrm{CC}}$ out and $\mathrm{V}_{\text {PP OUT }}$ voltage and standby/operate mode condition. $\mathrm{V}_{\text {PP OUT }}$ output voltages of $\mathrm{V}_{\mathrm{CC}}(3.3 \mathrm{~V}$ or 5 V$)$, $\mathrm{V}_{\mathrm{PP}}$, or a high impedance state are available. When the $\mathrm{V}_{\mathrm{Cc}}$ high impedance condition is selected, the device switches into "sleep" mode and draws only nano-amperes of leakage current. An error flag falls low if the output is improper, because of overtemperature or overcurrent faults. Full protection from hot switching is provided which prevents feedback from the $\mathrm{V}_{\text {PP }}$ out to the $\mathrm{V}_{\mathrm{CC}}$ inputs (from 12 V to 5 V , for example) by locking out the low voltage switch until $\mathrm{V}_{\text {PP out }}$ drops below $\mathrm{V}_{\text {cc }}$. The $\mathrm{V}_{\mathrm{cc}}$ output is similarly protected against 5 V to 3.3 V shoot through.
The MIC2560 is a low-resistance power MOSFET switching matrix that operates from the computer system main power supply. Device logic power is obtained from $\mathrm{V}_{\mathrm{CC} 3}$ and internal MOSFET drive is obtained from the $\mathrm{V}_{\mathrm{PP}}$ in pin (usually +12 V ) during normal operation. If +12 V is not available, the MIC2560 automatically switches into "suspend" mode, where $\mathrm{V}_{\text {cc out }}$ can be switched to 3.3 V , but at higher switch resistance. Internal break-before-make switches determine the output voltage and device mode.

## Supply Bypassing

External capacitors are not required for operation. The MIC2560 is a switch and has no stability problems. For best results however, bypass $\mathrm{V}_{\mathrm{CC3} \operatorname{IN},}, \mathrm{~V}_{\mathrm{CC5} \text { IN }}$, and $\mathrm{V}_{\mathrm{PP} \text { in }}$ inputs with filter capacitors to improve output ripple. As all internal device logic and voltage/current comparison functions are powered from the $\mathrm{V}_{\mathrm{CC3}}$ in line, supply bypass of this line is the most critical, and may be necessary in some cases. In the most stubborn layouts, up to $0.47 \mu \mathrm{~F}$ may be necessary. Both $\mathrm{V}_{\mathrm{Cc}}$ out and $V_{\text {PP out }}$ pins may have $0.01 \mu \mathrm{~F}$ to $0.1 \mu \mathrm{~F}$ capacitors for noise reduction and electrostatic discharge (ESD) damage prevention. Larger values of output capacitor might create current spikes during transitions, requiring larger bypass capacitors on the $\mathrm{V}_{\mathrm{CC3} \text { IN }}, \mathrm{V}_{\mathrm{CC} 5}$ IN , and $\mathrm{V}_{\mathrm{PP} \text { IN }}$ pins.

## PCMCIA Implementation

The MIC2560 is designed for compatibility with the Personal Computer Memory Card International Association's (PCMCIA) Specification, revision 2.1 as well as the PC Card Specification, (March 1995), including the CardBus option.
The Personal Computer Memory Card International Association (PCMCIA) specification requires two $\mathrm{V}_{\mathrm{PP}}$ supply pins per PCMCIA slot. $\mathrm{V}_{\mathrm{PP}}$ is primarily used for programming Flash (EEPROM) memory cards. The two $V_{\text {PP }}$ supply pins may be programmed to different voltages. Fully implementing PCMCIA specifications requires a MIC2560, a MIC2557 PCMCIA VPP Switching

Matrix, and a controller. Figure 3 shows this full configuration, supporting both 5.0 V and $3.3 \mathrm{~V} \mathrm{~V}_{\mathrm{CC}}$ operation.

Figure 3. MIC2560 Typical PCMCIA Memory Card Application with Dual $\mathrm{V}_{\mathrm{cc}}(5.0 \mathrm{~V}$ or 3.3 V$)$ and separate $\mathrm{V}_{\mathrm{PP} 1}$ and $\mathrm{V}_{\mathrm{PP} 2}$.

Figure 4. MIC2560 Typical PCMCIA Memory Card Application with Dual $\mathrm{V}_{\mathrm{cc}}(5.0 \mathrm{~V}$ or 3.3 V$)$. Note that $\mathrm{V}_{\text {PP1 }}$ and $\mathrm{V}_{\text {PP2 }}$ are Driven Together.

However, many cost sensitive designs (especially notebook/palmtop computers) connect $\mathrm{V}_{\text {PP1 }}$ to $\mathrm{V}_{\text {PP2 }}$ and the MIC2557is not required. This circuit is shown in Figure 4.
When a memory card is initially inserted, it should receive $\mathrm{V}_{\mathrm{Cc}}-$ either $3.3 \mathrm{~V} \pm 0.3 \mathrm{~V}$ or $5.0 \mathrm{~V} \pm 5 \%$. The initial voltage is determined by a combination of mechanical socket "keys" and voltage sense pins. The card sends a handshaking data stream to the controller, which then determines whether or not this card requires $\mathrm{V}_{\mathrm{PP}}$ and if the card is designed for dual $\mathrm{V}_{\mathrm{CC}}$. If the card is
compatible with and desires a different $\mathrm{V}_{\mathrm{CC}}$ level, the controller commands this change by disabling $\mathrm{V}_{\mathrm{Cc}}$, waiting at least 100 ms , and then re-enabling the other $\mathrm{V}_{\mathrm{CC}}$ voltage.
If no card is inserted or the system is in sleep mode, the controller outputs a $\left(\mathrm{V}_{\mathrm{CC} 3}\right.$ in, $\mathrm{V}_{\mathrm{CC5}}$ in $)=(0,0)$ to the MIC2560, which shuts down $\mathrm{V}_{\mathrm{cc}}$. This also places the switch into a high impedance output shutdown (sleep) mode, where current consumption drops to nearly zero, with only tiny CMOS leakage currents flowing.
During Flash memory programming with standard $(+12 \mathrm{~V})$ Flash memories, the PCMCIA controller outputs a ( 1,0 ) to the ENO, EN1 control pins of the MIC2560, which connects $\mathrm{V}_{\text {PP in }}$ to $\mathrm{V}_{\text {PP out. }}$. The low ON resistance of the MIC2560 switches allow using small bypass capacitors (in some cases, none at all) on the $\mathrm{V}_{\mathrm{cc}}$ out and $\mathrm{V}_{\mathrm{PP} \text { out }}$ pins, with the main filtering action performed by a large filter capacitor on the input supply voltage to $\mathrm{V}_{\mathrm{PP} \text { IN }}$ (usually the main power supply filter capacitor is sufficient). The $\mathrm{V}_{\text {PP }}$ out transition from $\mathrm{V}_{\mathrm{CC}}$ to 12.0 V typically takes $250 \mu \mathrm{~s}$. After programming is completed, the controller outputs a (EN1, ENO) $=(0,1)$ to the MIC2560, which then reduces $\mathrm{V}_{\text {PP out }}$ to the $\mathrm{V}_{\mathrm{CC}}$ level for read verification. Break-before-make switching action reduces switching transients and lowers maximum current spikes through the switch from the output capacitor. The flag comparator prevents having high voltage on the $\mathrm{V}_{\text {PP OUT }}$ capacitor from contaminating the $V_{C C}$ inputs, by disabling the low voltage $V_{P P}$ switches until $\mathrm{V}_{\mathrm{PP}}$ out drops below the $\mathrm{V}_{\mathrm{Cc}}$ level selected. The lockout delay time varies with the load current and the capacitor on $\mathrm{V}_{\mathrm{PP}}$ out. With a $0.1 \mu \mathrm{~F}$ capacitor and nominal $l_{\text {PP out }}$, the delay is approximately $250 \mu \mathrm{~s}$.
Internal drive and bias voltage is derived from $\mathrm{V}_{\mathrm{PP}}$ IN. Internal device control logic is powered from $\mathrm{V}_{\mathrm{Cc} 3} \mathrm{in}$. Input logic threshold voltages are compatible with common PCMCIA controllers using either 3.3 V or 5 V supplies. No pull-up resistors are required at the control inputs of the MIC2560.

## Output Current and Protection

MIC2560 output switches are capable of more current than needed in PC Card applications (1A) and meet or exceed all PCMCIA specifications. For system and card protection, output currents are internally limited. For full system protection, long term (millisecond or longer) output short circuits invoke overtemperature shutdown, protecting the MIC2560, the system power supplies, the card socket pins, and the memory card. Overtemperature shutdown typically occurs at a die temperature of $115^{\circ} \mathrm{C}$.

## Single $\mathrm{V}_{\mathrm{cc}}$ Operation

For PC Card slots requiring only a single $\mathrm{V}_{\mathrm{cc}}$, connect $\mathrm{V}_{\mathrm{CC3} \text { in }}$ and $\mathrm{V}_{\mathrm{CC5} \text { in }}$ together and to the system $\mathrm{V}_{\mathrm{CC}}$ supply (i.e., Pins 1, 3, and 15 are all connected to system $\mathrm{V}_{\mathrm{cc}}$ ).

Either the $\mathrm{V}_{\mathrm{CC} 5}$ switch or the $\mathrm{V}_{\mathrm{CC}}$ switch may be used to enable the card slot $\mathrm{V}_{\mathrm{cc}}$; generally the $\mathrm{V}_{\mathrm{CC} 3}$ switch is preferred because of its lower ON resistance.

## Suspend Mode

An additional feature in the MIC2560 is a pseudo powerdown mode, Suspend Mode, which allows operation without a $\mathrm{V}_{\text {PP IN }}$ supply. In Suspend Mode, the MIC2560 supplies 3.3 V to $\mathrm{V}_{\text {cc }}$ out whenever a $\mathrm{V}_{\mathrm{Cc}}$ output of 3.3 V is enabled by the PCMCIA controller. This mode allows the system designer the ability to turn OFF the $\mathrm{V}_{\mathrm{PP}}$ supply generator to save power when it is not specifically required. The PCMCIA card receives $\mathrm{V}_{\mathrm{cc}}$ at reduced capacity during Suspend Mode, as the switch resistance rises to approximately $4.5 \Omega$.

Figure 5. Circuit for Generating Bias Drive for the $\mathrm{V}_{\mathrm{cc}}$ Switches when +12 V is Not Readily Available.

## High Current $\mathrm{V}_{\mathrm{cc}}$ Operation Without a +12V Supply

Figure 5 shows the MIC2560 with $\mathrm{V}_{\mathrm{CC}}$ switch bias provided by a simple charge pump. This enables the system designer to achieve full $\mathrm{V}_{c c}$ performance without a +12 V supply, which is often helpful in battery powered systems that only provide +12 V when it is needed. These on-demand +12 V supplies generally have a quiescent current draw of a few milli-amperes, which is far more than the microamperes used by the MIC2560. The charge pump of figure 5 provides this low current, using about $100 \mu \mathrm{~A}$ when enabled. When $\mathrm{V}_{\text {PP оut }}=12 \mathrm{~V}$ is selected, however, the on-demand $\mathrm{V}_{\mathrm{PP}}$ generator must be used, as this charge pump cannot deliver the current required for Flash memory programming. The Schottky diode may not be necessary, depending on the configuration of the on-demand +12 V generator and whether any other loads are on this line.

## Package Information

DETAIL "A"

## NDTES:

1. DIMENSIUNS ARE IN INCHES[MM].
2. CINTRDLLING DIMENSIUN: INCHES.

DIMENSIDN DDES NDT INCLUDE MDLD FLASH $\quad$ R
PROTRUSIONS, EITHER DF WHICH SHALL NDT
EXCEED $0.006[0.15]$ PER SIDE.
