

SY75576L

267MHz 1:4 3.3V HCSL/LVDS Fanout Buffer

PrecisionEdge™

General Description

The SY75576L is a high-speed, fully differential 1:4 clock fanout buffer optimized to provide four identical output copies with 137fs phase jitter and maximum 50ps output-to-output skew. Designed to be used with PCI-Express applications, SY75576L accepts and outputs HCSL or LVDS logic levels.

The SY75576L operates from a 3.3V \pm 5% power supply and is guaranteed over the full industrial temperature range (-40°C to +85°C). It is available in a 20-pin TSSOP lead-free package.

The SY75576L is part of Micrel's high-speed, ultra-low jitter, PrecisionEdge™ product line.

Datasheets and support documentation are available on Micrel's web site at: <u>www.micrel.com</u>.

Functional Block Diagram

Features

- Four differential pairs of LVDS or HCSL outputs
- Two pairs of differential inputs accept LVDS or HCSL logic levels
- 267MHz max HCSL frequency
- 100MHz max LVDS frequency
- Ultra low phase jitter:
 - 137fs_{rms}, 200MHz (12kHz–20MHz)
 - 153fs_{rms}, 156.25MHz (12kHz–20MHz)
 - 212fs_{rms}, 100MHz (12kHz-20MHz)
- <2ps Total_Jitter_{pk-pk}, 200MHz (BER = 10⁻¹²)
- 50ps output-to-output skew
- 3.3V ±5% power supply operation
- -40°C to +85°C operating temperature
- Available in 20-pin TSSOP lead-free package

Applications

- Clock distribution
- PCI-Express
- Servers
- Switches
- Routers

Notes:

3. Permanent device damage may occur if absolute maximum ratings are exceeded. This is a stress rating only and functional operation is not implied at conditions other than those detailed in the operational sections of this datasheet. Exposure to absolute maximum ratings conditions for extended periods may affect device reliability.

- 4. The datasheet limits are not guaranteed if the device is operated beyond the operating ratings.
- 5. Package thermal resistance assumes that the exposed pad is soldered (or equivalent) to the device's most negative potential on the PCB. ψ_{JB} and θ_{JA} values are determined for a 4-layer board in still-air unless otherwise stated. The circuit is designed to meet the DC specifications shown in the above table after thermal equilibrium has been established.

Notes:

11. Measured from the differential input crossing point to the differential output crossing point.

12. Output-to-Output skew is the difference in time between outputs, receiving data from the same input, for the same temperature, voltage, and transition.

13. This parameter is defined in accordance with JEDEC Standard 65.

Jitter Analysis

Jitter is defined as the deviation of a signal from its ideal position. Phase noise is the presence of signal energy at frequencies other than the carrier. Random jitter has a Gaussian distribution and is specified as an rms unit, which is one standard deviation of the distribution. Since Gaussian distribution is unbounded in an infinite sample, no communication system can be completely error free. Instead, communication links are rated with a maximum bit error rate (BER), which is typically around 10^{-12} for high-speed communication equipment. Achieving a desired BER requires accounting for a number of standard deviations of random noise by using the appropriate value for *N* (see Table 1) in the formula in Equation 1.

$$Tj = N \times Rj + Dj$$

Where Tj is total jitter, Rj is random jitter, and Dj is deterministic jitter. If routing clock signals, the deterministic jitter is usually negligible and the Tj is dominated by the random jitter. Calculating Tj from Rj using Equation 1 gives the values in Table 1.

Table 1.	Standard	Deviations	of Random Noise
----------	----------	------------	-----------------

BER	N	R _j at 200MHz	T _j at 200MHz
10 ⁻¹⁰	12.723	137fs_rms	1.743ps
10 ⁻¹¹	13.412	137fs_rms	1.837ps
10 ⁻¹²	14.069	137fs_rms	1.927ps
