

The Future of Analog IC Technology ${ }^{\ominus}$

## DESCRIPTION

The MP8869 is a high-frequency, synchronous, rectified, step-down, switch-mode converter with an $I^{2} \mathrm{C}$ control interface. It offers a fully integrated solution that achieves 12A of continuous and 15A of peak output current with excellent load and line regulation over a wide input supply range.

In the $I^{2} \mathrm{C}$ control loop, the output voltage level can be controlled on-the-fly through an $1^{2} C$ serial interface. The voltage range can be adjusted from 0.6 V to 1.87 V in 10 mV steps. Voltage slew rate, frequency, current limit, hiccup/latch-off protection, enable, and power saving mode are also selectable through the $I^{2} \mathrm{C}$ interface.

Constant-on-time (COT) control operation provides fast transient response. An open-drain power good (PG) pin indicates that the output voltage is in the nominal range. Full protection features include over-voltage protection (OVP), over-current protection (OCP), and thermal shutdown.

The MP8869 is available in a QFN-14 (3mmx4mm) package.

## FEATURES

- Wide 4.5 V to 17 V Operating Input Range
- 12A Continuous/15A Peak Output Current
- 1\% Internal Reference Accuracy
- $I^{2} \mathrm{C}$ Programmable Output Range from 0.6 V to 1.87 V in 10 mV Steps with Slew Rate Control
- 5\% Accuracy Output Voltage and Output Current Readback via $1^{2} \mathrm{C}$
- Selectable PFM/PWM Mode, Adjustable Frequency and Current Limit through $I^{2} \mathrm{C}$
- 4 Different Selectable $I^{2} \mathrm{C}$ Addresses
- External Soft Start
- Open-Drain Power Good Indication
- Output Over-Voltage Protection (OVP)
- Hiccup/Latch-Off OCP
- Available in a QFN-14 ( $3 \mathrm{~mm} \times 4 \mathrm{~mm}$ ) Package

## APPLICATIONS

- Solid-State Drives (SSDs)
- Flat-Panel Television and Monitors
- Digital Set-Top Boxes
- Distributed Power Systems
- Networking/Servers

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

TYPICAL APPLICATION

## ORDERING INFORMATION

| Part Number* | Package | Top Marking |
| :---: | :---: | :---: |
| MP8869GL | QFN-14 $(3 \mathrm{mmx4mm})$ | See Below |

* For Tape \& Reel, add suffix -Z (e.g. MP8869GL-Z)

## TOP MARKING

MP: Product code of MP8869GL
Y: Year code
W: Lot number
8869: First four digits of the part number
LLL: Lot number

PACKAGE REFERENCE

Thermal Resistance ${ }^{(4)} \quad \boldsymbol{\theta}_{J A} \quad \boldsymbol{\theta}_{J C}$<br>QFN-14 (3mmx4mm).............48....... $11 \ldots{ }^{\circ} \mathrm{C} / \mathrm{W}$

## NOTES:

1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature $\mathrm{T}_{\mathrm{J}}(\mathrm{MAX})$, the junction-toambient thermal resistance $\theta_{\mathrm{JA}}$, and the ambient temperature $\mathrm{T}_{\mathrm{A}}$. The maximum allowable continuous power dissipation at any ambient temperature is calculated by $P_{D}(M A X)=\left(T_{J}\right.$ (MAX)-TA)/ $\theta_{\mathrm{JA}}$. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7, 4-layer PCB.

## ELECTRICAL CHARACTERISTICS

$\mathrm{V}_{\text {IN }}=12 \mathrm{~V}, \mathrm{~T}_{J}=-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}^{(5)}$, typical value is tested at $\mathrm{T}_{J}=+25^{\circ} \mathrm{C}$, unless otherwise noted.

## PIN FUNCTIONS

| QFN-14 <br> Pin\# | Name | Description |
| :---: | :---: | :---: |
| 1 | BST | Bootstrap. A capacitor is required between SW and BST to form a floating supply across the high-side switch driver. |
| 2 | SW | Switch output. Connect SW using a wide PCB trace. |
| 3 | SCL | $\mathrm{I}^{2} \mathrm{C}$ serial clock. |
| 4 | SDA | $\mathrm{I}^{2} \mathrm{C}$ serial data. |
| 5 | EN | Enable. Set EN high to enable the MP8869. EN has a $1.5 \mathrm{M} \Omega$ internal pull-down resistor to GND. EN is a high-voltage pin, so it can be connected to VIN directly for auto start-up. |
| 6 | A0 | $I^{2} \mathrm{C}$ address set-up. Connect a resistor divider from VCC to AO to set different $\mathrm{I}^{2} \mathrm{C}$ addresses. |
| 7 | PG | Power good indication. PG is an open-drain structure. PG is de-asserted if the output voltage is out of the regulation window. |
| 8 | PGND | System power ground. PGND is the reference ground of the regulated output voltage and requires special consideration during PCB layout. Connect PGND to the ground plane with copper traces and vias. |
| 9 | VIN | Supply voltage. The MP8869 operates from a 4.5V-to-17V input rail. Decouple the input rail with a ceramic capacitor. Connect VIN using a wide PCB trace. |
| 10 | VOUT | Output voltage sense. Connect VOUT to the positive terminal of the load. |
| 11 | FB | Feedback. Connect FB to the tap of an external resistor divider from the output to GND to set the output voltage before the $\mathrm{I}^{2} \mathrm{C}$ takes control. |
| 12 | SS | Soft-start set-up. Connect a capacitor from SS to ground to set the soft-start time. |
| 13 | VCC | Internal LDO regulator output. Decouple VCC with a $0.47 \mu \mathrm{~F}$ capacitor. |
| 14 | AGND | Signal ground. If AGND is not connected to PGND internally, ensure that AGND is connected to PGND during the PCB layout. |

## BLOCK DIAGRAM

Figure 1: Functional Block Diagram

## OPERATION

## PWM Operation

The MP8869 is a fully integrated, synchronous, rectified, step-down, switch-mode converter. The MP9969 uses constant-on-time (COT) control to provide fast transient response and easy loop stabilization. Figure 2 shows the simplified ramp compensation block. At the beginning of each cycle, the high-side MOSFET (HS-FET) turns on whenever the ramp voltage ( $V_{\text {Ramp }}$ ) is lower than the error amplifier output voltage ( $V_{\text {EAO }}$ ), which indicates an insufficient output voltage. The on period is determined by both the output voltage and input voltage to make the switching frequency fairly constant over the input voltage range.
After the on period elapses, the HS-FET enters the off state. By cycling the HS-FET between the on and off states, the converter regulates the output voltage. The integrated low-side MOSFET (LS-FET) turns on when the HS-FET is in its off state to minimize conduction loss.
Shoot-through occurs when both the HS-FET and LS-FET are turned on at the same time, causing a dead short between input and GND and reducing efficiency dramatically. The MP8869 prevents this by generating a deadtime (DT) internally between when the HS-FET is off and the LS-FET is on, and when the LSFET is off and the HS-FET is on. The device enters either heavy-load operation or light-load operation depending on the amplitude of the output current.

Figure 2: Simplified Compensation Block

## Switching Frequency

The MP8869 uses constant-on-time (COT) control, so there is no dedicated oscillator in the IC. The input voltage is fed into the on-time one-shot timer through the internal frequency resistor. The duty ratio is VOUT/VIN, and the switching frequency is fairly constant over the input voltage range.

The MP8869's switching frequency can be adjusted by setting the two bits $D[5: 4]$ in register 02 through $I^{2} \mathrm{C}$ communication. When the output voltage setting is low and the input voltage is high, the switching on-time may be limited by the internal minimum on-time limit, and switching frequency decreases. Table 1 shows the maximum switching frequency vs. the output voltage when VIN $=12 \mathrm{~V}$ and $\mathrm{VIN}=$ 5 V .

Table 1: Maximum Frequency Selection vs. Output Voltage

|  | Maximum Frequency Selecting |  |
| :---: | :---: | :---: |
| Vo $(\mathrm{V})$ | VIN $=12 \mathrm{~V}$ | VIN $=5 \mathrm{~V}$ |
| 5 | 1.25 MHz | $/$ |
| 3.3 | 1.25 MHz | 1.25 MHz |
| 2.5 | 1.25 MHz | 1.25 MHz |
| 1.8 | 1.25 MHz | 1.25 MHz |
| 1.5 | 1.25 MHz | 1.25 MHz |
| 1.2 | 1 MHz | 1.25 MHz |
| 1 | 750 kHz | 1.25 MHz |
| 0.9 | 750 kHz | 1.25 MHz |
| 0.6 | 500 kHz | 1.25 MHz |

## Forced PWM Operation

When the MP8869 works in forced PWM mode, the MP8869 enters continuous conduction mode (CCM), where the HS-FET and LS-FET repeat the on/off operation, even if the inductor current is zero or a negative value. The switching frequency ( $F_{s w}$ ) is fairly constant. Figure 3 shows the timing diagram during this operation.

Figure 3: Forced PWM Operation

## Light-Load Operation

When the MP8869 works in auto PFM/PWM mode or light-load operation, the MP8869 reduces the switching frequency automatically to maintain high efficiency, and the inductor current drops almost to zero. When the inductor current reaches zero, the LS-FET driver goes into tri-state (high-Z) (see Figure 4). The output capacitors discharge slowly to GND through R1 and R2. This operation improves efficiency greatly when the output current is low.

Figure 4: Light-Load Operation
Light-load operation is also called skip mode because the HS-FET does not turn on as frequently during heavy-load condition. The frequency at which the HS-FET turns on is a function of the output current. As the output current increases, the time period that the current modulator regulates becomes shorter, the HS-FET turns on more frequently, and the switching frequency increases. The output current reaches critical levels when the current modulator time is zero and can be determined with Equation (1):

$$
\begin{equation*}
\mathrm{I}_{\text {OUT }}=\frac{\left(\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {OUT }}\right) \times \mathrm{V}_{\text {OUT }}}{2 \times \mathrm{L} \times \mathrm{F}_{\text {SW }} \times \mathrm{V}_{\text {IN }}} \tag{1}
\end{equation*}
$$

The device reverts to PWM mode once the output current exceeds the critical level. Afterward, the switching frequency remains fairly constant over the output current range.
The MP8869 can operate in pulse frequency modulation (PFM) mode under light load to improve efficiency (low-power mode). The MP8869 can also operate in forced PWM mode at any load condition. This mode is selectable through the $I^{2} \mathrm{C}$ control. To enable low-power mode, set the mode bit to 0 . To disable low power mode, set the Mode bit to 1, and the converter will work in forced PWM mode. The Mode bit is set to 0 (PFM) by default.

## Operating without an External Ramp

The traditional constant-on-time control scheme is intrinsically unstable if the output capacitor's ESR is not large enough to be an effective current-sense resistor. Ceramic capacitors cannot be used as output capacitors, usually. The MP8869 has built-in, internal ramp compensation to ensure that the system is stable, even without the help of the output capacitor's ESR. The pure ceramic capacitor solution can reduce the output ripple, total BOM cost, and board area significantly.

## VCC Regulator

A 3.5 V internal regulator powers most of the internal circuitries. A 470nF decoupling capacitor is needed to stabilize the regulator and reduce ripple. This regulator takes the VIN input and operates in the full VIN range. After EN is pulled high, and VIN is greater than 3.5 V , the output of the regulator is in full regulation. When VIN is lower than 3.5 V , the output voltage decreases and follows the input voltage. A $0.47 \mu \mathrm{~F}$ ceramic capacitor is required for decoupling.

## Error Amplifier (EA)

The error amplifier (EA) compares the FB voltage against the internal 0.6 V reference (REF) for non- ${ }^{2}{ }^{2}$ mode and outputs a PWM signal. In $I^{2} \mathrm{C}$ mode, FB is opened, and VOUT is connected to the EA non-inverter input. The reference voltage can be programmed from 0.6 V to 1.87 V in the $\mathrm{I}^{2} \mathrm{C}$ control loop. The optimized internal ramp compensation minimizes the external component count and simplifies the control loop design.

## Enable (EN)

EN is a digital control pin that turns the regulator, including the $1^{2} \mathrm{C}$ block, on and off. Drive EN high to turn on the regulator; drive EN low to turn off the regulator. An internal $1.5 \mathrm{M} \Omega$ resistor is connected from EN to ground. EN can operate with an 18 V input voltage, which allows EN to be directly connected to VIN for automatic start-up. When the external EN is high, set the EN bit to 0 in register 01 to stop the HS-FET and LS-FET from switching. The MP8869 resumes switching by setting the EN bit to 1 .

## Under-Voltage Lockout (UVLO)

Under-voltage lockout (UVLO) protects the chip from operating at an insufficient supply voltage. The MP8869 UVLO comparator monitors the input voltage, VIN, and output voltage of the VCC regulator. The MP8869 is active when the voltages exceed the UVLO rising threshold.

## Soft-Start (SS) and Pre-Bias Start-Up

The soft start (SS) prevents the converter output voltage from overshooting during startup. When the chip starts up, the internal circuitry generates a soft-start voltage that ramps up from OV to VCC. When SS is lower than REF, the error amplifier uses $S S$ as the reference. When SS is higher than REF, the error amplifier uses REF as the reference.

The approximate typical soft-start time can be calculated with Equation (2):

$$
\begin{equation*}
t_{s s}(m s)=\frac{V_{r e f}(V) \times C_{s s}(n F)}{7 \mu A} \tag{2}
\end{equation*}
$$

Where $\mathrm{V}_{\text {ref }}$ is reference voltage of the FB loop or $I^{2} \mathrm{C}$ loop.
If the output of the MP8869 is pre-biased to a certain voltage during start-up, the IC disables the switching of both the HS-FET and LS-FET until the voltage on the internal SS capacitor exceeds the sensed output voltage at FB or VOUT ${ }^{(7)}$.
NOTE:
7) $\mathrm{V}_{-}$BOOT $=1$, sense FB voltage. $\mathrm{V}_{-}$BOOT $=0$, sense VOUT voltage.
The MP8869 also provides a selectable softstop function which defines the output discharge behavior after EN shutdown. By default, the output is not controlled after EN shutdown. If setting the soft-stop control bit D[3] to 1 in register 02 via the $1^{2} \mathrm{C}$, the output is discharged linearly to zero in a quarter of the soft-start time.

## Over-Current-Protection (OCP)

The MP8869 has a default, hiccup, cycle-bycycle, over-current limiting control. The currentlimit circuit employs both high-side current limit and a low-side "valley" current-sensing algorithm. The MP8869 uses the $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ of the LS-FET as a current-sensing element for the valley current limit. If the magnitude of the highside current-sense signal is above the current-
limit threshold, the PWM on pulse is terminated, and the LS-FET is turned on. Afterward, the inductor current is monitored by the voltage between GND and SW. GND is used as the positive current sensing node, so GND should be connected to the source terminal of the bottom MOSFET. PWM is not allowed to initiate a new cycle before the inductor current falls to the valley threshold.

After the cycle-by-cycle over-current limit occurs, the output voltage drops until VOUT is below the under-voltage (UV) threshold, typically $60 \%$ below the reference. Once UV is triggered, the MP8869 enters hiccup mode to restart the part periodically. This protection mode is especially useful when the output is dead shorted to ground. The average shortcircuit current is greatly reduced to alleviate thermal issues and protect the regulator. The MP8869 exits hiccup mode once the overcurrent condition is removed.
Short the output to ground first, and then power on the part. The MP8869's ${ }^{2} \mathrm{C}$ is disabled in this condition. The $1^{2} \mathrm{C}$ resumes operation after the short circuit is removed. When hiccup OCP bit $\mathrm{D}[1]$ in register 01 is set to 0 by the $\mathrm{I}^{2} \mathrm{C}$, a latch-off occurs if OCP is triggered, and FB UVP is triggered.

## Power Good (PG)

The power good (PG) indicates whether the output voltage is in the normal range compared to the internal reference voltage. PG is an open-drain structure. An external pull-up supply is required. During power-up, the PG output is pulled low. This indicates to the system to remain off and keep the load on the output to a minimum. This helps reduce in-rush current at start-up.
When the output voltage is higher than $90 \%$ and lower than $115 \%$ of the internal reference voltage, and the soft start is finished, then the PG signal is pulled high. When the output voltage is lower than $85 \%$ after the soft start finishes, the PG signal remains low. When the output voltage is higher than $115 \%$ of the internal reference, PG is switched low. The PG signal rises high again the after output voltage drops below $105 \%$ of the internal reference voltage.

PG implements an adjustable deglitch time via the $I^{2} \mathrm{C}$ whenever VOUT crosses the UV/OV rising and falling threshold. This guarantees the correct indication when the output voltage is scaled through the $\mathrm{I}^{2} \mathrm{C}$.
The PG output is pulled low immediately when either EN UVLO, input UVLO, OCP, or OTP are triggered.

## Input Over-Voltage Protection (VIN OVP)

The MP8869 monitors VIN to detect an input over-voltage event. This function is active only when the output is in OV or soft-stop condition. When the output is in OVP state, or soft stop is enabled, output discharge is enabled to charge the input voltage high. When the input voltage exceeds the input OVP threshold, both the HSFET and LS-FET stop switching.

## Output Over-Voltage Protection (OVP)

The MP8869 monitors both FB and VOUT to detect an over-voltage event. When setting the V_BOOT bit to 1, an internal comparator monitors FB. When setting the V_BOOT bit to 0 , the internal comparator monitors VOUT. When the FB or VOUT voltage becomes higher than $125 \%$ of the internal reference voltage, the controller enters dynamic regulation mode, and the input voltage may be charged up during this time. When input OVP is triggered, the IC stops switching. If OVP mode is set to "Auto Retry" in the $I^{2} C$, the IC begins switching once the input voltage drops below the VIN OVP recover threshold. Otherwise, the MP8869 latches off. OVP auto-retry mode or latch-off mode occurs only if the soft start has finished.
Dynamic regulation mode can be operated by turning on the low side until the low-side negative current limit is triggered. Then the body diode of the HS-FET free-wheels the current.

The output power charges the input, which may trigger the VIN OVP function. In VIN OVP, neither the HS-FET or LS-FET turn on and stop charging VIN. If the output is still over-voltage and the input voltage drops below the VIN OVP threshold, repeat the operation. If the output voltage is below 110\% of the internal reference voltage, then output OVP is exited.

## Output Absolute Over-Voltage Protection (OVP_ABS)

The MP8869 monitors the VOUT voltage to detect absolute over-voltage protection. When VOUT is larger than 6.5 V , the controller enters dynamic regulation mode if the OVP retry bit is set to 1 in the $I^{2} \mathrm{C}$ register 01 . Otherwise, the MP8869 latches off when output OVP and input OVP are both triggered. Absolute OVP works once both the input voltage and EN are higher than their rising thresholds. This means that this function can work even during a soft start.

## Thermal Shutdown

Thermal shutdown prevents the chip from operating at exceedingly high temperatures. When the silicon die reaches temperatures that exceed $160^{\circ} \mathrm{C}$, the entire chip shuts down. When the temperature is less than its lower threshold (typically $140^{\circ} \mathrm{C}$ ), the chip is enabled again.
The $D[1]$ and $D[2]$ bits can be monitored in register 06 for more information about the IC silicon temperature.

## Floating Driver and Bootstrap Charging

An external bootstrap capacitor powers the floating power MOSFET driver. This floating driver has its own UVLO protection. This UVLO's rising threshold is 2.4 V with a 150 mV hysteresis. The bootstrap capacitor voltage is regulated by VIN internally through D1, M1, C4, L 1 and C 2 (see Figure 5). If $\mathrm{V}_{\mathrm{BST}}-\mathrm{V}_{\mathrm{SW}}$ exceeds $3.3 \mathrm{~V}, \mathrm{U} 1$ regulates M 1 to maintain a 3.3 V BST voltage across C4.

Figure 5: Internal Bootstrap Charging Circuit

## Start-Up and Shutdown

If VIN, VCC, and EN exceed their respective thresholds, the chip starts up. The reference block starts first, generating stable reference voltages and currents, and then the internal regulator is enabled. The regulator provides a stable supply for the remaining circuitries.

Several events can shut down the chip: EN low, VIN low, VCC low, thermal shutdown, OVP latch, and OCP latch. In the shutdown procedure, the signaling path is blocked first to avoid any fault triggering. $\mathrm{V}_{\text {EAO }}$ and the internal supply rail are then pulled down.

## $I^{2} C$ Control and Default Output Voltage

When the MP8869 is enabled, the output voltage is determined by the FB resistors with a programmed soft-start time. Afterward, the $1^{2} \mathrm{C}$ bus can communicate with the master. If the chip does not receive an $I^{2} \mathrm{C}$ communication signal continuously, it can work through FB and performs behavior similar to a traditional non${ }^{2}{ }^{2} \mathrm{C}$ part. The output voltage is determined by the resistor dividers R1, R2, and FB reference voltage. Vout can be calculated by Equation (3):

$$
\begin{equation*}
\operatorname{Vout}(\mathrm{V})=0.6 \times\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right) \tag{3}
\end{equation*}
$$

The FB loop $\mathrm{V}_{\text {REF }}$ is 0.6 V . The FB loop reference voltage is a fixed value that cannot be adjusted by the $\mathrm{I}^{2} \mathrm{C}$.

## Loop Switch

There is no output slew rate control during the FB loop to the $1^{2} \mathrm{C}$ loop. When the output voltage setting is much larger or smaller than the present voltage, it is recommended to take two steps to finish the loop switch and output voltage setting.

During the FB loop to the $I^{2} \mathrm{C}$ loop, first set the output voltage in the $I^{2} \mathrm{C}$ loop to the present output voltage, and then set V_BOOT $=0$ to switch the FB loop to the $I^{2} \mathrm{C}$ loop. Second, change the output voltage to the target with slew-rate control in the $I^{2} \mathrm{C}$ loop. Please refer to the Output Voltage Dynamic Scaling section on page 30 for details.

In the $1^{2} \mathrm{C}$ control loop, the output voltage is determined by the $1^{2} \mathrm{C}$ control, and the FB feedback loop is disabled. After the MP8869 receives a valid data byte of the output voltage setting, the MP8869 adjusts the DAC output as the reference voltage with a controlled slew rate. The slew rate is determined by three bits $\mathrm{D}[5: 3]$ in register 01.

## $1^{2} \mathrm{C}$ Slave Address

To support multiple devices used on the same ${ }^{12} \mathrm{C}$ bus, A0 can be used to select four different addresses. A resistor divider from VCC to GND can achieve an accurate reference voltage. Connect AO to this reference voltage to set a different $I^{2} \mathrm{C}$ slave address (see Figure 6). The internal circuit changes the $I^{2} \mathrm{C}$ address accordingly. When the master sends an 8 -bit address value, the 7 -bit $I^{2} \mathrm{C}$ address should be followed by $0 / 1$ to indicate a write/read operation. Table 2 shows the recommended $I^{2} \mathrm{C}$ address selection by the A0 voltage.

Figure 6: ${ }^{1} \mathbf{C}$ C Slave Address Selection Set-Up
Table 2: Recommended $I^{2} C$ Slave Address Selection by A0 Resistor Divider

| A0 Upper Resistor Rao_up $(k \Omega)$ | A0 LowerResistorRAO_down (k $\Omega$ ) | $1^{2} \mathrm{C}$ Slave Address |  |
| :---: | :---: | :---: | :---: |
|  |  | Binary | Hex |
| No connect | No connect | 1100000 | 60 H |
| 500 | 300 | 1100010 | 62H |
| 300 | 500 | 1100100 | 64H |
| 100 | No connect | 1100110 | 66H |

## $I^{2}$ C INTERFACE

## $I^{2} C$ Serial Interface Description

The $I^{2} \mathrm{C}$ is a 2 -wire, bidirectional, serial interface consisting of a data line (SDA) and a clock line (SCL). The lines are pulled to a bus voltage externally when they are idle. When connecting to the line, a master device generates an SCL signal and device address and arranges the communication sequence. The MP8869 interface is an $I^{2} \mathrm{C}$ slave. The $I^{2} \mathrm{C}$ interface adds flexibility to the power supply solution. The output voltage, transition slew rate, and other parameters can be controlled by the $1^{2} \mathrm{C}$ interface instantaneously.

## Data Validity

One clock pulse is generated for each data bit transferred. The data on the SDA line must be stable during the high period of the clock. The high or low state of the data line can only change when the clock signal on the SCL line is low (see Figure 7).

Figure 7: Bit Transfer on the $\mathrm{I}^{2} \mathrm{C}$ Bus
Start and stop are signaled by the master device, which signifies the beginning and the end of the $I^{2} \mathrm{C}$ transfer. The start condition is defined as the SDA signal transitioning from high to low while the SCL is high. The stop condition is defined as the SDA signal transitioning from low to high while the SCL is high (see Figure 8).

Figure 8: Start and Stop Conditions

Start and stop conditions are always generated by the master. The bus is considered to be busy after the start condition, and is considered to be free again after a minimum of $4.7 \mu \mathrm{~s}$ after the stop condition. The bus remains busy if a repeated start ( Sr ) is generated instead of a stop condition. The start ( S ) and repeated start ( Sr ) conditions are functionally identical.

## Transfer Data

Every byte put on the SDA line must be eight bits long. Each byte must be followed by an acknowledge bit. The acknowledge-related clock pulse is generated by the master. The transmitter releases the SDA line (high) during the acknowledge clock pulse. The receiver must pull down the SDA line during the acknowledge clock pulse so that it remains stable low during the high period of this clock pulse.

Data transfers follow the format shown in Figure 9. After the start condition (S), a slave address is sent. This address is 7 bits long followed by an eighth data direction bit (R/W). A zero indicates a transmission (write), and a one indicates a request for data (read). A data transfer is always terminated by a stop condition (P) generated by the master. However, if a master still wishes to communicate on the bus, it can generate a repeated start condition $(\mathrm{Sr})$ and address another slave without first generating a stop condition.

Figure 9: Complete Data Transfer
The MP8869 requires a start condition, a valid ${ }^{2} \mathrm{C}$ address, a register address byte, and a data byte for a single data update. After receiving each byte, the MP8869 acknowledges by pulling the SDA line low during the high period of a single clock pulse. A valid $I^{2} \mathrm{C}$ address selects the MP8869. The MP8869 performs an update on the falling edge of the LSB byte.

## REGISER DESCRIPTION

## Register Map

The MP8869 contains six write or read registers. Register 00 is the output voltage selection register. Register 01 is the first system control register, and users can use it to set the slew rate, hiccup OCP, etc. Register 02 is the second system control register, and users can use to set the switching frequency, current limit, etc.

Register 03 and register 04 are output current and output voltage indicating registers. Register 05 is the IC ID register. Register 06 is the IC status indication register, and users can use it to check if the IC is in an over-current protection, over-temperature protection status, etc. The register map is shown below.

## Register Description

## 1) Reg00 VSEL

Register 00 is the output voltage selection register. The MP8869 default output voltage is determined by the FB resistor divider after the MP8869 power start-up or EN start-up. The reference voltage in the FB control loop is fixed at 0.6 V .

After the MP8869 starts up, the output voltage can be controlled by the $I^{2} \mathrm{C}$ through setting the highest bit V_BOOT $=0$. Before adjusting the output reference voltage, the bit GO_BIT of the first system control register 01 should be set to 1 ,
and then the output reference voltage can be adjusted by the lower seven bits of register 00 in the $I^{2} \mathrm{C}$ loop. When the output reference voltage setting command is finished, GO_BIT auto-resets to 0 to prevent false operation of the VOUT scaling. GO_BIT should be set to 1 before adjusting the output reference voltage in the $I^{2} \mathrm{C}$ loop.
Table 3 shows the output voltage selection chart from 0.6 V to 1.87 V in the $1^{2} \mathrm{C}$ control loop.

| NAME | BITS | DEFAULT | DESCRIPTION |
| :---: | :---: | :---: | :---: |
| V_BOOT | D[7] | 1 | FB control loop enable bit. V_BOOT $=1$ means the output voltage is determined by the resistor divider connecting to FB. The FB reference voltage is fixed at 0.6 V . V_BOOT $=0$ means the output voltage is controlled by the $I^{2} \mathrm{C}$ through VOUT. This bit is helpful for the default output voltage setting before the $I^{2} \mathrm{C}$ signal is active. If the $I^{2} \mathrm{C}$ is not used, the part works well with FB. |
| Output reference | D[6:0] | 0011110 | Set the output voltage from 0.6 V to 1.87 V (see Table 3). The default value is 0.9 V . |

Table 3: Output Voltage Selection Chart

| $\mathbf{D}[6: 0]$ | VOUT(V) | $\mathbf{D}[6: 0]$ | $\mathbf{V O U T}(\mathbf{V})$ | $\mathbf{D}[6: 0]$ | VOUT(V) | $\mathbf{D}[6: 0]$ | VOUT(V) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 0011111 | 0.91 | 0111111 | 1.23 | 1011111 | 1.55 | 1111111 | 1.87 |

## 2) Reg01 SysCntIreg1

Register 01 is the first system control register.
The highest bit, EN, can be used to turn the part on or off when the external EN is high. When the external EN is high, the part shuts down by setting the EN bit to 0 , and then the HS-FET and LS-FET stop switching. The part resumes switching by setting the EN bit to 1 again. When the external EN is low, the converter is off, and the $I^{2} \mathrm{C}$ shuts down.
The bit GO_BIT is only used for output reference setting in the $I^{2} \mathrm{C}$ loop. Set GO_BIT to 1 to enable the $I^{2} C$ authority of writing the output reference. When the command is finished, GO_BIT auto-resets to 0 to prevent false operation of the VOUT scaling.

The IC switches to forced PWM mode when the GO_BIT is set to 1 to achieve a smooth output waveform during the output dynamic scaling. After the output scaling is complete, GO_BIT is set to 0 automatically, and the IC operation mode switches to the original mode set by the Mode bit.

The 3-bit slew rate $\mathrm{D}[5: 3]$ is used for slew rate selection during the output voltage dynamic scaling when the output voltage is controlled by the $I^{2} \mathrm{C}$ loop. A proper slew rate reduces the inrush current, as well as voltage overshoot and undershoot. Eight different slew rate levels can be selected.

The bit Retry OVP defines the protection mode when OVP is triggered. When Retry OVP is set to 1 , the part enters auto-recovery when OVP is removed. When Retry OVP is set to 0 , the part latches off once output OVP occurs, and VIN OVP is triggered until VIN or EN are toggled.
The bit Hiccup OCP defines the over-current protection mode. When Hiccup OCP is set to 1 , the part enters hiccup mode when OCP and UVP are both triggered. When Hiccup OCP is set to 0 , the part enters latch-off when OCP and UVP are both triggered.

The lowest bit, Mode, is used for selecting forced PWM or auto PFM/PWM mode at light load. When Mode is set to 0 , auto-PFM/PWM mode is enabled at light load. When Mode is set to 1, forced PWM mode is enabled at light load.

| NAME | BITS | DEFAULT | DESCRIPTION |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| EN | D[7] | 1 | $1^{2} \mathrm{C}$ controlled turn-on or turn-off of the part. When the external EN is low, the converter is off and $I^{2} \mathrm{C}$ shuts down. When EN is high, the EN bit takes over. The default EN bit is 1 . |  |  |  |
| GO_BIT | D[6] | 0 | Switch bit of the $1^{2} \mathrm{C}$ writing authority for output reference command only. Set GO_BIT = 1 to enable the $I^{2} \mathrm{C}$ authority of writing the output reference. When the command is finished, GO_BIT auto-resets to 0 to prevent false operation of the VOUT scaling. Write the GO_BIT = 1 first, then write the output reference voltage and change the V _BOOT status. <br> Voltage scaling examples: <br> 1) Set GO_BIT $=1$. <br> 2) Write register 00 : set $\mathrm{V} \_B O O T=0$ and set the output reference. <br> 3) Read back the GO_BIT value to see if the output scaling is finished. If GO_BIT $=0$, the voltage scaling is done. Otherwise, VOUT is still in adjustment. <br> 4) Set GO_BIT = 1 if output voltage scaling is needed a second time. <br> 5) Write register 00: set V _BOOT $=0$ and set the output reference. |  |  |  |
| Slew rate | D[5:3] | 100 | The slew rate during the $1^{2} \mathrm{C}$-controlled voltage changing is defined by three bits. The output voltage changes linearly from the previous voltage to the new set voltage with a below slew rate. This helps to reduce the inrush current, voltage overshoot, and voltage undershoot greatly. |  |  |  |
|  |  |  | D[5:3] | Slew Rate | D[5:3] | Slew Rate |
|  |  |  | 000 | $40 \mathrm{mV} / \mu \mathrm{s}$ | 100 | $5 \mathrm{mV} / \mathrm{\mu s}$ |
|  |  |  | 001 | $30 \mathrm{mV} / \mu \mathrm{s}$ | 101 | $2.5 \mathrm{mV} / \mathrm{\mu s}$ |
|  |  |  | 010 | $20 \mathrm{mV} / \mathrm{\mu s}$ | 110 | $1.25 \mathrm{mV} / \mathrm{\mu s}$ |
|  |  |  | 011 | $10 \mathrm{mV} / \mathrm{\mu s}$ | 111 | $0.625 \mathrm{mV} / \mathrm{\mu s}$ |
| Retry | D[2] | 1 | FB or VOUT over-voltage protection mode selection bit. 1 means the part auto-recovers when OVP is removed. 0 means the part latches off once output OVP and VIN OVP are both triggered until VIN or EN is power reset. |  |  |  |
| $\begin{aligned} & \text { Hiccup } \\ & \text { OCP } \end{aligned}$ | D[1] | 1 | Over-current protection mode selection. 1 means hiccup mode OCP. 0 means latch-off type OCP. |  |  |  |
| Mode | D[0] | 0 | Set Mode to 0 to enable PFM mode; set Mode to 1 to disable autoPFM/PWM mode. Default is auto-PFM/PWM mode for light load. |  |  |  |

## 3) Reg02 SysCntlreg2

Register 02 is the second system control register.
The highest two bits of the PG deglitch time $\mathrm{D}[7: 6]$ defines the power good signal rising and falling edge delay times. When output OVP or UVP is triggered, the PG signal turns low or high after a delay time. There are four levels of PG delay time that can be programmed by the $1^{2} \mathrm{C}$ in different conditions.

The two switching frequency bits $D[5: 4]$ are used for switching frequency selection. The MP8869 supports up to 1.25 MHz of switching frequency by setting the two bits to 11 . The MP8869 maximum programmable switching frequency is limited by the internal minimum on-time (see Table 1).

The bit Soft Stop defines the output voltage discharge behavior after EN shutdown. When Soft Stop is set to 0 , the output voltage is not controlled after EN shutdown. When Soft Stop is set to 1, the output voltage is discharged linearly to zero with the set soft-stop time.

The lowest three bits, Current Limit Adjust $\mathrm{D}[2: 0]$, are used for peak and valley current-limit selection. There are eight levels of current limit that can be selected for different application conditions.

| NAME | BITS | DEFAULT | DESCRIPTION |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| PG deglitch time | D[7:6] | 11 | Power good signal rising and falling edges' delay time. When FB or VOUT is out of the regulation window, the PG comparator is triggered, but needs a delay time before the PG signal can turn high or low. |  |  |  |
|  |  |  | D[7:6] | PG deglitch | D[7:6] | PG deglitch |
|  |  |  | 00 | $<1 \mu \mathrm{~s}$ | 10 | $12 \mu \mathrm{~s}$ |
|  |  |  | 01 | $6 \mu \mathrm{~s}$ | 11 | $30 \mu \mathrm{~s}$ |
| Switching frequency | D[5:4] | 00 | Switching frequency set bit. There is no dedicated frequency oscillator inside the part. The switching frequency is fairly fixed by controlling the Ton timer. |  |  |  |
|  |  |  | D[5:4] | Frequency | D[5:4] | Frequency |
|  |  |  | 00 | 500 kHz | 10 | 1 MHz |
|  |  |  | 01 | 750 kHz | 11 | 1.25 MHz |
| Soft stop | D[3] | 0 | This bit defines the VOUT discharge behavior after EN shutdown. " 0 " means VOUT is not controlled after EN shutdown; "1" means VOUT is discharged linearly to zero with the set soft-stop time. |  |  |  |
| Current limit adjust | D[2:0] | 001 | D[2:0] | Valley current limit (A) | D[2:0] V | rrent limit (A) |
|  |  |  | 000 | 16 | 100 | 8.5 |
|  |  |  | 001 | 14 | 101 | 7 |
|  |  |  | 010 | 12 | 110 | 6 |
|  |  |  | 011 | 10 | 111 | 5 |

## 4) Reg03 Output Current

Register 03 is an output current-indicating register. After the part starts up, the DC output current information can be read through the $I^{2} C$ communication.
When the inductor current is in DCM, the output current sense is not very accurate. The Mode bit can be set to 1 (PWM mode) for good
current sensing accuracy at light load. When the inductor current enters CCM, the output current sense accuracy is excellent (typical accuracy is 5\% when the output current is higher than 2A).
Table 4 shows the output current chart from 0 A to 12.75

## 6) Reg05 ID1

Register 05 is the IC information indicating register. The highest four bits, Vendor ID $D[7: 4]$, are set to 1000 internally.

The lowest four bits, IC Reversion ID D[3:0], indicates IC revision information.

| NAME | BITS | DESCRIPTION |
| :---: | :---: | :--- |
| Vendor ID | D[7:4] | 1000. |
| IC revision ID | D[3:0] | IC revision. |

## 7) Reg06 Status

Register 06 is a fault condition-indicating register. The highest four bits, $D[7: 4]$, are reserved for future use.

The bit OC is the output over-current indication. When the bit is set to 1 , the IC is in hiccup mode or OC latch-off.

| NAME | BITS | DESCRIPTION |
| :---: | :---: | :--- |
| Reserved | $\mathrm{D}[7: 4]$ | Reserved for future use. <br> OC |
| $\mathrm{D}[3]$ | Output over-current indication. When this bit is high, the IC is in hiccup mode or trips <br> OC latch-off. |  |
| OTEW | $\mathrm{D}[2]$ | Die temperature early warning bit. When the bit is high, the die temperature is higher <br> than 120 |
| OT | $\mathrm{D}[1]$ | Over-temperature indication. When the bit is high, the IC is in thermal shutdown. <br> PG$\mathrm{D[0]}$Output power good indication. When the bit is high, the VOUT power is normal. This <br> means VOUT is higher than 95\% and lower than 115\% of the designed regulation <br> voltage. PG compares FB/VOUT with REF. |

## APPLICATION INFORMATION

## Setting the Output Voltage in a FB Control Loop

The MP8869 can be controlled by the FB loop or $I^{2} \mathrm{C}$ loop. The FB loop is the default loop during power-up or EN on. In this case, the output voltage can be set by the external resistor dividers. The FB loop reference voltage is a fixed value $(0.6 \mathrm{~V})$ and cannot be programmed by the $\mathrm{I}^{2} \mathrm{C}$.
The FB loop network is shown in Figure 10.

Figure 10: FB Loop Network
Choose R1 and R2 with Equation (4):

$$
\begin{equation*}
R 2=\frac{R 1}{\frac{V_{\text {OUT }}}{0.6 V}-1} \tag{4}
\end{equation*}
$$

Table 6 lists the recommended feedback resistors value for common output voltages.

Table 6: Resistor Selection for Common Output Voltages ${ }^{(8)}$

| Vout (V) | R1 (kת) | R2 (kS) | Rt (kS) | L ( $\mu \mathrm{H}$ ) |
| :---: | :---: | :---: | :---: | :---: |
| 1.0 | 80.6 | 120 | 10 | 1.5 |
| 1.2 | 80.6 | 80.6 | 10 | 1.5 |
| 1.5 | 80.6 | 53.6 | 10 | 1.5 |
| 1.8 | 80.6 | 40.2 | 10 | 1.5 |
| 2.5 | 80.6 | 25.5 | 10 | 2.2 |
| 3.3 | 80.6 | 17.8 | 10 | 2.2 |
| 5 | 80.6 | 11 | 10 | 3.3 |

note:
8) The recommended parameters are based on a 12 V input voltage and $22 \mu \mathrm{Fx} 4$ output capacitor. Different input voltage and output capacitor values may affect the selection of R1 and R2. For other components' parameters, please refer to the Typical Application Circuits on page 34.

## Setting the Output Voltage in an $\mathrm{I}^{2} \mathrm{C}$ Control Loop

After the part powers up and EN turns on, the FB loop can be programmed to the $1^{2} \mathrm{C}$ loop sensing (VOUT) by setting V _BOOT $=0$. In this case, the output voltage can be set by the $I^{2} \mathrm{C}$ from 0.6 V to 1.87 V . Refer to Table 3 for more details about the output voltage setting.

## Output Voltage Dynamic Scale

The output voltage dynamic scaling can be done only in the $I^{2} \mathrm{C}$ control loop. Refer to Figure 11 and follow the steps below.

1. Write GO_BIT (Reg01[6]) to 1 .
2. Write Reg00 to select the feedback loop by setting V_BOOT (Reg00[7]) and setting the reference voltage by Output Reference (Reg00[6:0]) simultaneously. When the command is finished, GO_BIT auto-resets to 0 to prevent false operation of the VOUT scaling.
Repeat the above two steps if the output voltage needs to be changed to a different voltage.

Figure 11: Loop Switch and Output Voltage Dynamic Scale Flow Chart

## Selecting the Inductor

Use a $0.47 \mu \mathrm{H}$-to- $5 \mu \mathrm{H}$ inductor with a DC current rating at least $25 \%$ percent higher than the maximum load current for most applications. For highest efficiency, use an inductor with a DC resistance less than $5 \mathrm{~m} \Omega$. For most designs, the inductance value can be derived from Equation (5):

$$
\begin{equation*}
\mathrm{L}_{1}=\frac{\mathrm{V}_{\text {OUT }} \times\left(\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {OUT }}\right)}{\mathrm{V}_{\mathrm{IN}} \times \Delta \mathrm{I}_{\mathrm{L}} \times \mathrm{f}_{\text {OSC }}} \tag{5}
\end{equation*}
$$

Where $\Delta I_{L}$ is the inductor ripple current.
Choose the inductor ripple current to be approximately $30 \%$ of the maximum load current. The maximum inductor peak current can be calculated with Equation (6):

$$
\begin{equation*}
\mathrm{I}_{\mathrm{L}(\mathrm{MAX})}=\mathrm{I}_{\mathrm{LOAD}}+\frac{\Delta \mathrm{I}_{\mathrm{L}}}{2} \tag{6}
\end{equation*}
$$

Use a larger inductor for improved efficiency under light-load conditions below 100 mA .

## Selecting the Input Capacitor

The input current to the step-down converter is discontinuous and therefore requires a capacitor to supply AC current to the step-down converter while maintaining the DC input voltage. Use low ESR capacitors for best performance. Ceramic capacitors with X5R or X7R dielectrics are recommended because of their low ESR and small temperature coefficients. For most applications, use two $22 \mu \mathrm{~F}$ capacitors.

Since C1 absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in the input capacitor can be estimated with Equation (7):

$$
\begin{equation*}
\mathrm{I}_{\mathrm{C} 1}=\mathrm{I}_{\mathrm{LOAD}} \times \sqrt{\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}} \times\left(1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}}\right)} \tag{7}
\end{equation*}
$$

The worst-case condition occurs at VIN = 2VOUT, shown in Equation (8):

$$
\begin{equation*}
\mathrm{I}_{\mathrm{C} 1}=\frac{\mathrm{I}_{\mathrm{LOAD}}}{2} \tag{8}
\end{equation*}
$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum, or ceramic. When using electrolytic or tantalum capacitors, add a small, high-quality, ceramic capacitor (e.g.: $0.1 \mu \mathrm{~F}$ ) placed as close to the IC as possible. When using ceramic capacitors, ensure that they have enough capacitance to provide a sufficient charge to prevent excessive voltage ripple at input. The input voltage ripple caused by the capacitance can be estimated with Equation (9):

$$
\begin{equation*}
\Delta \mathrm{V}_{\mathrm{IN}}=\frac{\mathrm{I}_{\mathrm{LOAD}}}{\mathrm{f}_{\mathrm{S}} \times \mathrm{C} 1} \times \frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}} \times\left(1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}}\right) \tag{9}
\end{equation*}
$$

## Selecting the Output Capacitor

The output capacitor (C2) maintains the DC output voltage. Use ceramic, tantalum, or lowESR electrolytic capacitors. For best results, use low ESR capacitors to keep the output voltage ripple low. The output voltage ripple can be estimated with Equation (10):

$$
\begin{equation*}
\Delta \mathrm{V}_{\mathrm{OUT}}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{f}_{\mathrm{S}} \times \mathrm{L}_{1}} \times\left(1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}}\right) \times\left(\mathrm{R}_{\mathrm{ESR}}+\frac{1}{8 \times \mathrm{f}_{\mathrm{S}} \times \mathrm{C} 2}\right) \tag{10}
\end{equation*}
$$

Where $L_{1}$ is the inductor value, and $R_{\text {ESR }}$ is the equivalent series resistance (ESR) value of the output capacitor.

For ceramic capacitors, the capacitance dominates the impedance at the switching frequency and causes the majority of the output voltage ripple. For simplification, the output voltage ripple can be estimated with Equation (11):

$$
\begin{equation*}
\Delta \mathrm{V}_{\text {OUT }}=\frac{\mathrm{V}_{\text {OUT }}}{8 \times \mathrm{f}_{\mathrm{S}}^{2} \times \mathrm{L}_{1} \times \mathrm{C} 2} \times\left(1-\frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\mathrm{IN}}}\right) \tag{11}
\end{equation*}
$$

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be approximated with Equation (12):

$$
\begin{equation*}
\Delta \mathrm{V}_{\mathrm{OUT}}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{f}_{\mathrm{S}} \times \mathrm{L}_{1}} \times\left(1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}}\right) \times \mathrm{R}_{\mathrm{ESR}} \tag{12}
\end{equation*}
$$

The characteristics of the output capacitor also affect the stability of the regulation system. The MP8869 can be optimized for a wide range of capacitance and ESR values.

## External Bootstrap Diode

An external bootstrap diode can enhance the efficiency of the regulator given the following conditions:

- VOUT is 5 V or 3.3 V
- Duty cycle is high: $\mathrm{D}>50 \%$

In these cases, add an external BST diode from VCC to BST (see Figure 12).

Figure 12: Optional External Bootstrap Diode to Enhance Efficiency
The recommended external BST diode is IN4148, and the recommended BST capacitor value is $0.1 \mu \mathrm{~F}$ to $1 \mu \mathrm{~F}$.

## PCB Layout Guidelines ${ }^{(9)}$

Efficient PCB layout is critical for stable operation. For best results, refer to Figure 13 and follow the guidelines below. A four-layer layout is strongly recommended to achieve better thermal performance.

1. Place the high-current paths (PGND, VIN, and SW) very close to the device with short, direct, and wide traces.
2. Keep the VIN and PGND pads connected with large copper planes.
3. Use at least two layers for the IN and PGND trace to achieve better thermal performance.
4. Add several vias close to the IN and PGND pads to help with thermal dissipation.
5. Place the input capacitors as close to VIN and PGND as possible.
6. Place the decoupling capacitor as close to VCC and PGND as possible.
7. Place the external feedback resistors next to FB.
8. Ensure that there is no via on the FB trace.
9. Keep the switching node SW short and away from the feedback network.
10. Keep the BST voltage path (BST, C3, and SW) as short as possible.

## note:

9) The recommended layout is based on the Typical Application circuit on page 34.

Figure 13: Recommend Layout

## Design Example

Table 7 is a design example following the application guidelines for the specifications below.

Table 7: Design Example

| $\mathbf{V}_{\text {IN }}$ | 12 V |
| :---: | :---: |
| V out $^{\text {out }}$ | 1 V |
| lo $^{2}$ | 12 A |

The detailed application schematics are shown in Figure 14 through Figure 20. The typical performance and circuit waveforms are shown in the Typical Performance Characteristics section. For more device applications, please refer to the related evaluation board datasheets.

## TYPICAL APPLICATION CIRCUITS ${ }^{(10)}$

Figure 14: $\mathrm{V}_{\mathrm{IN}}=12 \mathrm{~V}, \mathrm{~V}_{\text {OUt }}=1 \mathrm{~V}$, lout $=12 \mathrm{~A}$

Figure 15: $\mathrm{V}_{\mathrm{IN}}=12 \mathrm{~V}, \mathrm{~V}_{\text {out }}=1.2 \mathrm{~V}$, lout $=12 \mathrm{~A}$
