## • Input Capacitor C<sub>IN</sub>

Input Capacitor C<sub>IN</sub> is required to prevent oscillation and reduce power supply ripple for applications when high power supply impedance or a long power supply line.

Therefore, use the recommended C<sub>IN</sub> value (refer to conditions of ELECTRIC CHARACTERISTIC) or larger and should connect between GND and V<sub>IN</sub> as shortest path as possible to avoid the problem.

## • Output Capacitor C<sub>O</sub>

Output capacitor (C<sub>O</sub>) will be required for a phase compensation of the internal error amplifier.

The capacitance and the equivalent series resistance (ESR) influence to stable operation of the regulator.

Use of a smaller C<sub>O</sub> may cause excess output noise or oscillation of the regulator due to lack of the phase compensation.

On the other hand, Use of a larger C<sub>O</sub> reduces output noise and ripple output, and also improves output transient response when rapid load change.

Therefore, use the recommended C<sub>O</sub> value (refer to conditions of ELECTRIC CHARACTERISTIC) or larger and should connect between GND and V<sub>OUT</sub> as shortest path as possible for stable operation.

In addition, you should consider varied characteristics of capacitor (a frequency characteristic, a temperature characteristic, a DC bias characteristic and so on) and unevenness peculiar to a capacitor supplier enough.

When selecting C<sub>O</sub>, recommend that have withstand voltage margin against output voltage and superior temperature characteristic though this product is designed stability works with wide range ESR of capacitor including low ESR products.
