## 1.2 System Controller Firmware (SCFW) Requirements

The i.MX 8 and 8X families require a minimum SCFW release version for correct operation and to prevent potential reliability issues.

The SCFW is released as part of a Board Support Package (e.g. Linux, Android) which may vary in version number for a specific BSP.

For example, NXP Yocto Linux release 4.14.98\_2.3.0 contains SCFW version 1.3.0, NXP Yocto Linux release 4.14.98\_2.0.0 GA contains SCFW version 1.2.10, whereas NXP Yocto Linux release 4.14.78\_1.0.0GA contains SCFW version 1.1.10.

The released SCFW version associated within each BSP is the minimum version required to correctly support the wider BSP functionality.

Customers should always check that they are using the specific SCFW binary delivered within their chosen BSP release. Customers should not mix newer BSP versions with older revisions of the SCFW.

#### CAUTION

Stresses beyond those listed under [Table 6](#) may affect reliability or cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions beyond those indicated in the “[Operating ranges](#)” or other parameter tables is not implied. Exposure to absolute-maximum-rated conditions for extended periods will affect device reliability.

<sup>3</sup> During low power state (see [Section 4.1.6, "Low power mode supply currents"](#)), this voltage can be dropped to 0.8 V +/- 3% for retention.

#### 4.1.4 External clock sources

Each processor has two external input system clocks: a low frequency (RTC\_XTALI) and a high frequency (XTALI).

The RTC\_XTALI is used for real time functions. It supplies the clock for real time clock operation and for slow-system and watchdog counters. The clock input can be connected to either an external oscillator or a crystal using the internal oscillator amplifier.

The system clock input XTALI is used to generate the main system clock. It supplies the PLLs and other peripherals. The system clock input requires a crystal using the internal oscillator amplifier.

The PCIe oscillator can be sourced internally or input to the chip. In both cases, it is a 100 MHz nominal clock using HCSL signaling to provide the PCIe reference clock.

The following table shows the interface frequency requirements.

Table 9. External Input Clock Frequency

Parameter Description	Symbol	Min	Typ	Max	Unit
RTC_XTALI Oscillator <sup>1,2</sup>	f <sub>ckil</sub>	—	32.768 <sup>3</sup> /32.0	—	kHz
XTALI Oscillator <sup>4,2</sup>	f <sub>xtal</sub>	—	24	—	MHz

Table 9. External Input Clock Frequency (continued)

Parameter Description	Symbol	Min	Typ	Max	Unit
PCIe oscillator <sup>5</sup>	f <sub>100M</sub>	—	100	—	MHz
Frequency accuracy	—	—	—	±300	ppm

<sup>1</sup> External oscillator or a crystal with internal oscillator amplifier.

<sup>2</sup> The required frequency stability of this clock source is application dependent. For recommendations, see the hardware development guide for this device.

<sup>3</sup> Recommended nominal frequency 32.768 kHz.

<sup>4</sup> Fundamental frequency crystal with internal oscillator amplifier.

<sup>5</sup> If using an external clock instead of the internal clock source, an HCSL-compatible clock is required.

The typical values shown in Table 9 are required for use with NXP board support packages (BSPs) to ensure precise time keeping and USB operations.

### 4.1.7 USB 2.0 PHY typical current consumption in Power-Down mode

In power down mode, everything is powered down, including the VBUS valid detectors, typical condition. The following table shows the USB interface typical current consumption in Power-Down mode.

**Table 12. USB 2.0 PHY typical current consumption in Power-Down Mode**

	VDD_USB_3P3 (3.3 V)	VDD_USB_1P8 (1.8 V)	VDD_USB_OTG_1P0 (1.0 V)
Current	1 $\mu$ A	0.06 $\mu$ A	0.5 $\mu$ A

## 4.2 Power supplies requirements and restrictions

The system design must comply with power-up sequence, power-down sequence, and steady state guidelines as described in this section to ensure the reliable operation of the device. Any deviation from these sequences may result in the following situations:

- Excessive current during power-up phase
- Prevention of the device from booting
- Irreversible damage to the processor

### 4.2.1 Power-up sequence

The device has the following power-up sequence requirements:

- Supply group 0 (SNVS) must be powered first. It is expected that group 0 will typically remain always on after the first power-on.
- Supply group 1 (MAIN and SCU) and group 0 must both be powered to their nominal values prior to boot. They must power up after or simultaneously with group 0.
- Supply group 2 (I/O's and DDR interface) consists of those modules required to start the boot process by accessing external storage devices. These must be fully powered prior to POR release if booting from one of these supplies interfaces. They must power up after or simultaneously with group 1.
- Supply group 3 consists of the remaining portions of the SoC. This includes nonboot I/O voltages and supplies for the major computational units. These can be sequenced in any order and as required to perform the desired functions for the intended application. They must power up after or simultaneously with group 2.

#### NOTE

The definition of “power-up” refers to a stable voltage operating within the range defined in [Table 8](#). This should be taken into consideration, along with the different capacitive loading on each rail, if considering simultaneous switch-on of the different supply groups.

### 4.2.2 Power-down sequence

The device processor has the following power-down sequence requirements:

- Supply group 0 must be turned off last, after all other supplies.
- Supply group 1 can be turned off just prior to group 0.

All remaining supplies can be turned off prior to group 1.

**NOTE**

When switching off supply group 0 (SNVS), VDD\_SNVS\_4P2 must be discharged below 2.4 V before starting the next power-up sequence to ensure correct operation. This will generate a full SNVS reset, allowing correct operation on the next power-up sequence. This would also be a requirement to clear any security related flag as a result of an SNVS voltage drop, when tamper features are enabled.

### 4.2.3 Power Supplies Usage

The following table shows the power supplies usage by group.

**Table 13. Power supplies usage**

Supply Groups	Voltage

<sup>2</sup> VDD\_A35 and VDD\_GPU can be combined with one power supply.

## 4.3 PLL electrical characteristics

### 4.3.1 PLLs of subsystems

i.MX 8DualX embeds a large number of PLLs to address clocking requirements of the various subsystems. These PLLs are controlled through the SCU and not directly by Cortex-A or Cortex-M4F processors. A software API shall be used by those processors to access the PLL settings. Additional PLLs are specific to high-performance interfaces. These are described in the following sections.

This table summarizes the PLLs controlled by the SCU.

**Table 14. PLLs controlled by SCU**

## 4.4 On-chip oscillators

### 4.4.1 OSC24M

This block integrates trimmable internal loading capacitors and driving circuitry. When combined with a suitable 24 MHz external quartz element, it can generate a low-jitter clock. The oscillator is powered from VDD\_ANA1\_1P8. The internal loading capacitors are trimmable to provide fine adjustment of the 24 MHz oscillation frequency. It is expected that customers burn appropriate trim values for the selected crystal and board parasitics.

**Figure 2. Normal Crystal Oscillation mode**

Table 21. Crystal specifications

Parameter description	Min	Typ	Max	Unit
Frequency <sup>1</sup>	—	24	—	MHz
Cload <sup>2</sup>	—	18	—	pF
Maximum drive level	200	—	—	μW
ESR	—	—	60	Ω

<sup>1</sup> The required frequency accuracy is set by the serial interfaces utilized for a specific application and is detailed in the respective standard documents.

<sup>2</sup> Cload is the specification of the quartz element, not for the capacitors coupled to the quartz element.

#### 4.4.2 OSC32K

This block implements an internal amplifier, trimmable load capacitors and a bias network that when combined with a suitable quartz crystal implements a low power oscillator.

Additionally, if the clock monitor determines that the 32KHz oscillation is not present, then the source of the 32 KHz clock will automatically switch to the internal relaxation oscillator of lesser frequency accuracy.

#### CAUTION

The internal ring oscillator is not meant to be used in customer applications, due to gross frequency variation over wafer processing, temperature, and supply voltage. These variations will cause timing issues to many different circuits that use the internal ring oscillator for reference; and, if this timing is critical, application issues will occur. To prevent application issues, it is recommended to only use an external crystal or an accurate external clock. If this recommendation is not followed, NXP cannot guarantee full compliance of any circuit using this clock. The OSC32K runs from VDD\_SNVS\_LDO\_1P8\_CAP, which is regulated from VDD\_SNVS. The target battery/voltage range is 2.8 to 4.2 V for VDD\_SNVS, with a regulated output of approximately 1.75 V.

Table 22. OSC32K main characteristics

Parameter	Min	Typ	Max	Comments
Fosc	—	32.768 kHz	—	This frequency is nominal and determined mainly by the crystal selected. 32.0 KHz is also supported.
Current consumption	—	<ul style="list-style-type: none"> <li>• xtal oscillator mode: 5 μA</li> <li>• 32K internal oscillator mode: 10 μA</li> </ul>	—	These values are for typical process and room temperature. Values will be updated after silicon characterization.

Table 22. OSC32K main characteristics (continued)

Parameter	Min	Typ	Max	Comments
Bias resistor	—	200 M $\Omega$	—	This the integrated bias resistor that sets the amplifier into a high gain state. Any leakage through the ESD network, external board leakage, or even a scope probe that is significant relative to this value will debias the amplifier. The debiasing will result in low gain, and will impact the circuit's ability to start up and maintain oscillations.
<b>Target Crystal Properties</b>				
Cload	—	10 pF	—	Usually crystals can be purchased tuned for different Cloads. This Cload value is typically 1/2 of the capacitances realized on the PCB on either side of the quartz. A higher Cload will decrease oscillation margin, but increases current oscillating through the crystal.
ESR	—	50 k $\Omega$	100 k $\Omega$	Equivalent series resistance of the crystal. Choosing a crystal with a higher value will decrease the oscillating margin.

V <sub>PP</sub> RTC_XTALI	700	—	VDD_SNVLS_LDO_1P8_CAP	mV	1,2,3
Rise/fall time	—	—	—	ns	4

<sup>1</sup> The external clock is fed into the chip from the RTC\_XTALI pin; the RTC\_XTALO pin should be left floating.

<sup>2</sup> The parameter specified here is a peak-to-peak value and V<sub>IH</sub>/V<sub>IL</sub> specifications do not apply.

<sup>3</sup> The voltage applied on RTC\_XTALI must be within the range of VSS to VDD\_SNVLS\_LDO\_1P8\_CAP.

<sup>4</sup> The rise/fall time of the applied clock are not strictly confined.

## 4.5 I/O DC Parameters

This section includes the DC parameters of the following I/O types:

- XTALI and RTC\_XTALI (clock inputs) DC parameters
- General Purpose I/O (GPIO) DC parameters

### NOTE

The term 'OVDD' in this section refers to the associated supply rail of an input or output.

Figure 3. Circuit for Parameters Voh and Vol for I/O Cells

### 4.5.1 XTALI and RTC\_XTALI (Clock Inputs) DC Parameters

For RTC\_XTALI,  $V_{IH}/V_{IL}$  specifications do not apply. The high and low levels of the applied clock on this pin are not strictly defined, as long as the input's peak-to-peak amplitude meet the requirements and the input's voltage value does not exceed the limits.

<sup>1</sup> As programmed in the associated IOMUX (DSE field) register.

<sup>2</sup> Overshoot and undershoot conditions (transitions above OVDD and below GND) on switching pads must be held below 0.3 V, and the duration of the overshoot/undershoot must not exceed 10% of the system clock cycle. Overshoot/undershoot must be controlled through printed circuit board layout, transmission line impedance matching, signal line termination, or other methods. Noncompliance to this specification may affect device reliability or cause permanent damage to the device. (OVDD is the IO supply.)

<sup>3</sup> To maintain a valid level, the transition edge of the input must sustain a constant slew rate (monotonic) from the current DC level through to the target DC level,  $V_{IL}$  or  $V_{IH}$ . Monotonic input transition time is from 0.1 ns to 1 ns.

## 4.7 Output Buffer Impedance Parameters

This section defines the I/O impedance parameters for the following I/O types:

- General Purpose I/O (GPIO) output buffer impedance
- Double Data Rate I/O (DDR) output buffer impedance for LPDDR4 and DDR3L modes

### NOTE

GPIO and DDR I/O output driver impedance is measured with “long” transmission line of impedance  $Z_{tl}$  attached to I/O pad and incident wave launched into transmission line.  $R_{pu}/R_{pd}$  and  $Z_{tl}$  form a voltage divider that defines specific voltage of incident wave relative to OVDD. Output driver impedance is calculated from this voltage divider (see [Figure 6](#)).

## 4.7.2 DDR I/O output buffer impedance

The following tables show DDR3L and LPDDR4 I/O output buffer impedance of the device.

The ZQ Calibration cell uses a single register (ZQnPR0) to determine the target output buffer impedances of the pull-up driver and the pull-down driver, as well as the target on-die termination impedance. The resulting calibration setting is then applied to all DDR pads within the PHY complex.

Table 42 and Table 44 show, respectively, the recommended ZQnPR0 field settings for the DDR3L and LPDDR4 I/Os to achieve the desired output buffer impedances. ### 4.8.3 DDR SDRAM–specific parameters (LPDDR4 and DDR3L)

The i.MX 8x Family of processors have been designed and tested to work with JEDEC JESD209-4A–compliant LPDDR4 memory and with JEDEC JESD79-3-1 DDR3L compliant with DDR3L memory. Timing diagrams and tolerances required to work with these memories are specified in the respective documents and are not reprinted here.

Meeting the necessary timing requirements for a DDR memory system is highly dependent on the components chosen and the design layout of the system as a whole. NXP cannot cover in this document all the requirements needed to achieve a design that meets full system performance over temperature, voltage, and part variation; PCB trace routing, PCB dielectric material, number of routing layers used, placement of bulk/decoupling capacitors on critical power rails, VIA placement, GND and Supply planes layout, and DDR controller/PHY register settings all are factors affecting the performance of the memory system. Consult the hardware user guide for this device and NXP validated design layouts for information on how to properly design a PCB for best DDR performance. NXP strongly recommends duplicating an NXP validated design as much as possible in the design of critical power rails, placement of bulk/decoupling capacitors and DDR trace routing between the processor and the selected DDR memory. All supporting material is readily available on the device web page on

<https://www.nxp.com/products/processors-and-microcontrollers/applications-processors/i.mx-applications-processors/i.mx-8-processors:IMX8-SERIES> .

Processors that demonstrate full DDR performance on NXP validated designs, but do not function on customer designs, are not considered marginal parts. A report detailing how the returned part behaved on an NXP validated system will be provided to the customer as closure to a customer's reported DDR issue. Customers bear the responsibility of properly designing the Printed Circuit Board, correctly simulating and modeling the designed DDR system, and validating the system under all expected operating conditions (temperatures, voltages) prior to releasing their product to market.

## 4.9 General-Purpose Media Interface (GPMI) Timing

The GPMI controller is a flexible interface NAND Flash controller with 8-bit data width, up to 400 MB/s I/O speed, and individual chip select. It supports Asynchronous Timing mode, Source Synchronous Timing mode, and Toggle Timing mode, as described in the following subsections.

### 4.9.1 GPMI Asynchronous mode AC timing (ONFI 1.0 compatible)

Asynchronous mode AC timings are provided as multiplications of the clock cycle and fixed delay. The Maximum I/O speed of GPMI in Asynchronous mode is about 50 MB/s. Figure 9 through Figure 12 depict the relative timing between GPMI signals at the module level for different operations under Asynchronous mode. Table 51 describes the timing parameters (NF1–NF17) that are shown in the figures.

NF17	Data hold on read	tDHR	0.82/11.83 [see <sup>5,6</sup> ] ]	—	ns

<sup>1</sup> The GPMI asynchronous mode output timing can be controlled by the module's internal registers HW\_GPMI\_TIMING0\_ADDRESS\_SETUP, HW\_GPMI\_TIMING0\_DATA\_SETUP, and HW\_GPMI\_TIMING0\_DATA\_HOLD. This AC timing depends on these registers settings. In the table, AS/DS/DH represents each of these settings.

<sup>2</sup> AS minimum value can be 0, while DS/DH minimum value is 1.

<sup>3</sup> T = GPMI clock period - 0.075ns (half of maximum p-p jitter).

<sup>4</sup> NF12 is met automatically by the design.

<sup>5</sup> Non-EDO mode.

<sup>6</sup> EDO mode, GPMI clock  $\approx$  100 MHz  
(AS=DS=DH=1, GPMI\_CTL1 [RDN\_DELAY] = 8, GPMI\_CTL1 [HALF\_PERIOD] = 0).

In EDO mode (Figure 13), NF16/NF17 are different from the definition in non-EDO mode (Figure 12). They are called tREA/tRHOH (NAND\_RE\_B access time/NAND\_RE\_B HIGH to output hold). The typical value for them are 16 ns (max for tREA)/15 ns (min for tRHOH) at 50 MB/s EDO mode. In EDO mode, GPMI will sample NAND\_DATAxx at rising edge of delayed NAND\_RE\_B provided by an internal DPLL. The delay value can be controlled by GPMI\_CTRL1.RDN\_DELAY (see the GPMI chapter of the device reference manual. The typical value of this control register is 0x8 at 50 MT/s EDO mode. However, if the board delay is large enough and cannot be ignored, the delay value should be made larger to compensate the board delay.

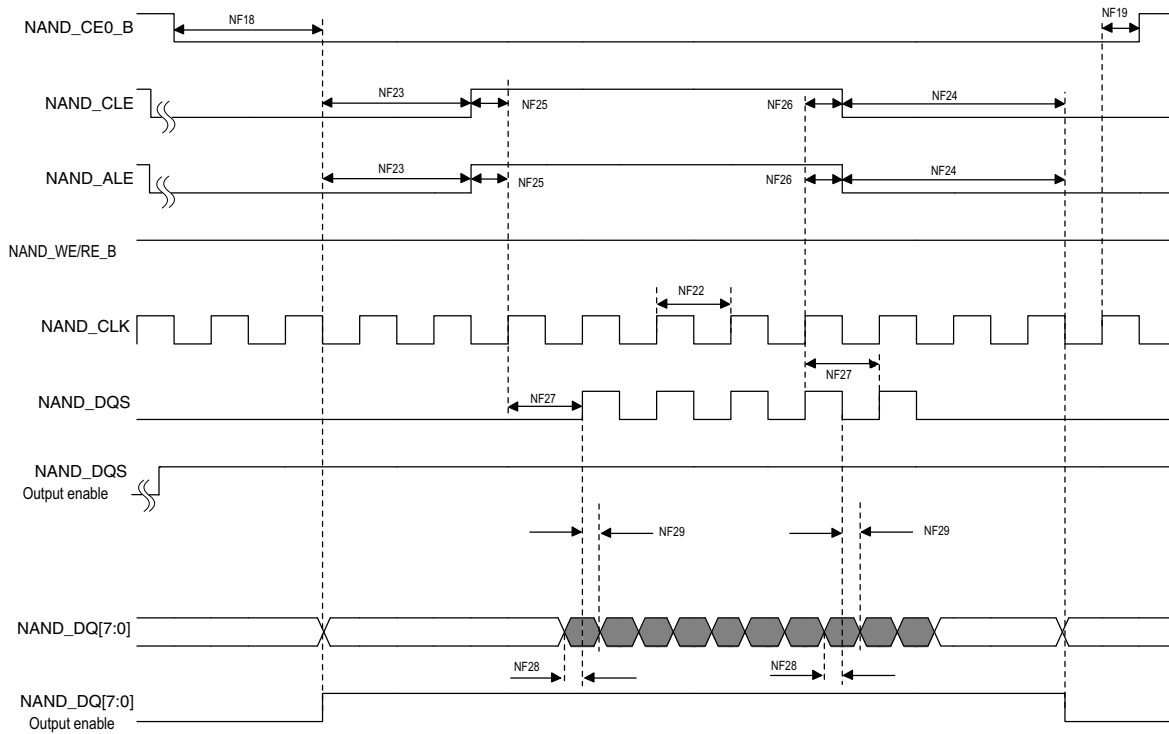

### 4.9.2 GPMI Source Synchronous mode AC timing (ONFI 2.x compatible)

The following figure shows the write and read timing of Source Synchronous mode.

NF31	NAND_DQS/NAND_DQ read hold skew	tQHS	—	1.95	—

<sup>1</sup> The GPMI source synchronous mode output timing can be controlled by the module's internal registers GPMI\_TIMING2\_CE\_DELAY, GPMI\_TIMING2\_PREAMBLE\_DELAY, GPMI\_TIMING2\_POST\_DELAY. This AC timing depends on these registers settings. In the table, CE\_DELAY/PRE\_DELAY/POST\_DELAY represents each of these settings.

<sup>2</sup> T = tCK (GPMI clock period) - 0.075ns (half of maximum p-p jitter).

Figure 17 shows the timing diagram of NAND\_DQS/NAND\_DATAxx read valid window. For Source Synchronous mode, the typical value of tDQSQ is 0.85 ns (max) and 1 ns (max) for tQHS at 200 MB/s. GPMI will sample NAND\_DATA[7:0] at both rising and falling edge of a delayed NAND\_DQS signal, which can be provided by an internal DPLL. The delay value can be controlled by GPMI register GPMI\_READ\_DDR\_DLL\_CTRL.SLV\_DLY\_TARGET (see the GPMI chapter of the device reference manual. Generally, the typical delay value of this register is equal to 0x7 which means 1/4 clock cycle delay expected. However, if the board delay is large enough and cannot be ignored, the delay value should be made larger to compensate the board delay.

### 4.9.3 ONFI NV-DDR2 mode (ONFI 3.2 compatible)

#### 4.9.3.2 Read and write timing

ONFI 3.2 mode read and write timing is the same as Toggle mode AC timing. See [Section 4.9.4, “Toggle mode AC Timing”](#), for details.

<sup>1</sup> The GPMI toggle mode output timing can be controlled by the module's internal registers HW\_GPMI\_TIMING0\_ADDRESS\_SETUP, HW\_GPMI\_TIMING0\_DATA\_SETUP, and HW\_GPMI\_TIMING0\_DATA\_HOLD. This AC timing depends on these registers settings. In the table, AS/DS/DH represents each of these settings.

<sup>2</sup> AS minimum value can be 0, while DS/DH minimum value is 1.

<sup>3</sup> T = tCK (GPMI clock period) - 0.075 ns (half of maximum p-p jitter).

<sup>4</sup> CE\_DELAY represents HW\_GPMI\_TIMING2[CE\_DELAY]. NF18 is guaranteed by the design. Read/Write operation is started with enough time of ALE/CLE assertion to low level.

<sup>5</sup> PRE\_DELAY+1) ≥ (AS+DS)

<sup>6</sup> Shown in [Figure 18](#).

<sup>7</sup> Shown in [Figure 19](#).

For DDR Toggle mode, [Figure 19](#) shows the timing diagram of NAND\_DQS/NAND\_DATA<sub>xx</sub> read valid window. The typical value of tDQSQ is 1.4 ns (max) and 1.4 ns (max) for tQHS at 133 MB/s. GPMI will sample NAND\_DATA[7:0] at both rising and falling edge of an delayed NAND\_DQS signal, which is provided by an internal DPLL. The delay value of this register can be controlled by GPMI register GPMI\_READ\_DDR\_DLL\_CTRL.SLV\_DLY\_TARGET (see the GPMI chapter of the device reference manual. Generally, the typical delay value is equal to 0x7 which means 1/4 clock cycle delay expected. But if the board delay is big enough and cannot be ignored, the delay value should be made larger to compensate the board delay.

## 4.10 External Peripheral Interface Parameters

The following subsections provide information on external peripheral interfaces.

### 4.10.1 LPSPI timing parameters

All LPSPI interfaces do not have the same maximum serial clock frequency. There are two groups. LPSPI interfaces which can operate at 60 MHz in Master mode and 40 MHz in Slave mode and the other group where interfaces operate at 40 MHz in Master mode and 20 MHz in Slave mode. The same performance is achieved at 1.8 V and 3.3 V unless otherwise stated.

Below are the LPSPI interfaces and their respective chip selects:

**Table 54. LPSPI interfaces and chip selects**

### 4.10.2 Serial audio interface (SAI) timing parameters

The timings and figures in this section are valid for noninverted clock polarity (I2S\_TCR2.BCP = 0b0, I2S\_RCR2.BCP = 0b0) and non-inverted frame sync polarity (I2S\_TCR4.FSP = 0b0, I2S\_RCR4.FSP = 0b0). If the polarity of the clock and/or the frame sync have been inverted, all the timings remain valid by inverting the clock signal (SAI\_TXC / SAI\_RXC) and/or the frame sync (SAI\_TXFS / SAI\_RXFS) shown in the figures below.

The same performance is achieved at both 1.8 V and 3.3 V unless otherwise stated.

#### NOTE

SAI0 and SAI1 are transmit/receive capable. SAI2 and SAI3 are receive only.

#### 4.10.2.1 SAI Master Synchronous mode

In this mode, transmitter clock and frame sync are used by both transmitter and receiver (I2S\_TCR2.SYNC=0b00, I2S\_RCR2.SYNC=0b01). In that case, SAI interface requires only 4 signals to be routed: SAI\_TXC, SAI\_TXFS, SAI\_TXD and SAI\_RXD. SAI\_RXC and SAI\_RXFS can be left unconnected. I2S\_RCR2.BCI shall be set to 0b1 to get setup and hold times provided in Table 59.

ID	Parameters	Min	Max	Unit
—	SAI TXC clock frequency	—	49.152	MHz

t3	SAI TXD output valid	—	2	ns
t4	SAI RXD input setup	1	—	ns
t5	SAI RXD input hold	4	—	ns

#### 4.10.2.2 SAI Master mode

In this mode, transmitter and/or receiver part are set to bring out transmit and/or receive clock. Frame sync can be either input or output.

Figure 23. SAI Master mode

Table 60. SAI timings—Master mode

ID	Parameters	Min	Max	Unit
—	SAI TXC / RXC clock frequency <sup>1</sup>	—	49.152	MHz

t3	SAI TXD output valid	—	2	ns
t4	SAI RXD/RXFS/TXFS input setup	6	—	ns
t5	SAI RXD/RXFS/TXFS input hold	0	—	ns

<sup>1</sup> Given the high setup time requirement on inputs, receiver and transmitter, when using frame sync in input, are likely to run at a lower frequency. This frequency will be driven by characteristics of the external component connected to the interface.

### 4.10.2.3 SAI Slave mode

In this mode, transmitter and/or receiver parts are set to receive transmit and/or receive clock from external world. Frame sync can be either input or output.

### 4.10.5.1 RGMII

#### 4.10.5.1.1 No-Internal-Delay mode

This mode corresponds to the RGMIIv1.3 specification.

Figure 33. RGMII timing diagram—No-Internal-Delay mode

ID	Parameter	Min	Typ	Max	Unit

t2	Data to clock output skew	-500	—	500	ps
t3	Data to clock input skew <sup>1(1)</sup>	1	—	2.6	ns

<sup>1</sup> This implies that PC board design requires clocks to be routed such that an additional trace delay of greater than 1.5 ns and less than 2.0 ns is added to the associated clock signal.

#### 4.10.6 CAN network AC Electrical Specifications

The Flexible Controller Area Network (FlexCAN) module is a communication controller implementing the CAN protocol according to the CAN with Flexible Data rate (CAN FD) protocol and the CAN 2.0B protocol specification. The processor has three CAN modules available for systems design. Tx and Rx ports for both modules are multiplexed with other I/O pins. See the IOMUXC chapter of the device reference manual to see which pins expose Tx and Rx pins; these ports are named FLEXCAN\_TX and FLEXCAN\_RX, respectively.

### 4.10.7 I<sup>2</sup>C Module Timing Parameters

This section describes the timing parameters of the I<sup>2</sup>C module. The following figure depicts the timing of the I<sup>2</sup>C module, and Table 73 lists the I<sup>2</sup>C module timing characteristics.

Figure 37. I<sup>2</sup>C bus timing

Table 73. I<sup>2</sup>C Module Timing Parameters

IC3	Set-up time for STOP condition	4.0	—	0.6	—	µs
IC4	Data hold time	0 <sup>1</sup>	3.45 <sup>2</sup>	0 <sup>1</sup>	0.9 <sup>2</sup>	µs
IC5	HIGH Period of I2Cx_SCL Clock	4.0	—	0.6	—	µs
IC6	LOW Period of the I2Cx_SCL Clock	4.7	—	1.3	—	µs
IC7	Set-up time for a repeated START condition	4.7	—	0.6	—	µs
IC8	Data set-up time	250	—	100 <sup>3</sup>	—	ns
IC9	Bus free time between a STOP and START condition	4.7	—	1.3	—	µs

IC11/IC11b	Fall time of both I2Cx_SDA and I2Cx_SCL signals	—	300	20 + 0.1C <sub>b</sub> <sup>4</sup>	300	ns
IC12	Capacitive load for each bus line (C <sub>b</sub> )	—	400	—	400	pF

<sup>1</sup> A device must internally provide a hold time of at least 300 ns for I2Cx\_SDA signal in order to bridge the undefined region of the falling edge of I2Cx\_SCL.

<sup>2</sup> The maximum hold time has only to be met if the device does not stretch the LOW period (ID no IC5) of the I2Cx\_SCL signal.

<sup>3</sup> A Fast-mode I2C-bus device can be used in a Standard-mode I2C-bus system, but the requirement of Set-up time (ID No IC7) of 250 ns must be met. This automatically is the case if the device does not stretch the LOW period of the I2Cx\_SCL signal. If such a device does stretch the LOW period of the I2Cx\_SCL signal, it must output the next data bit to the I2Cx\_SDA line max\_rise\_time (IC9) + data\_setup\_time (IC7) = 1000 + 250 = 1250 ns (according to the Standard-mode I2C-bus specification) before the I2Cx\_SCL line is released.

<sup>4</sup> C<sub>b</sub> = total capacitance of one bus line in pF.

<sup>1</sup> High-speed mode is only available for I2C modules in DMA, SCU and Cortex-M4 subsystems.

	Slew Rate @ $C_{LOAD}= 20$ pF	30	—	150	mV/ns
	Slew Rate @ $C_{LOAD}= 70$ pF	30	—	100	mV/ns
$C_{LOAD}$	Load Capacitance	0	—	70	pF

<sup>1</sup>  $C_{LOAD}$  includes the low equivalent transmission line capacitance. The capacitance of TX and RX are assumed to always be < 10 pF. The distributed line capacitance can be up to 50 pF for a transmission line with 2 ns delay.

<sup>2</sup> The rise-time of TREOT starts from the HS common-level at the moment of the differential amplitude drops below 70 mV, due to stopping the differential drive.

<sup>3</sup> With an additional load capacitance CCM between 0 to 60 pF on the termination center tap at RX side of the lane.

<sup>4</sup> This parameter value can be lower than TLPX due to differences in rise vs. fall signal slopes and trip levels and mismatches between Dp and Dn LP transmitters. Any LP exclusive-OR pulse observed during HS EoT (transition from HS level to LP-11) is glitch behavior as described in Low-Power Receiver section.

<sup>5</sup> When the output voltage is between 15% and below 85% of the fully settled LP signal levels.

<sup>6</sup> Measured as average across any 50 mV segment of the output signal transition.

<sup>7</sup> This value represents a corner point in a piecewise linear curve.

<sup>1</sup> When the pad voltage is within the signal voltage range between  $V_{GNDSH(min)}$  to  $VOH + V_{GNDSH(max)}$  and the Lane Module is in LP receive mode.

<sup>2</sup> This value includes ground shift.

<sup>3</sup> The voltage overshoot and undershoot beyond the  $V_{PIN}$  is only allowed during a single 20 ns window after any LP-0 to LP-1 transition or vice versa. For all other situations it must stay within the  $V_{PIN}$  range.

<sup>1</sup> When the output is transitioning between logic 0 and logic 1, or logic 1 and logic 0, and driving a terminated transmission line, the outputs monotonically transition between VOL and VOH, VOH, and VOL respectively. Target rise and fall times observed at the receiver and are primarily set by board trace impedance and Load capacitance. Rise and fall times are defined by 25% and 75% crossing points.

<sup>2</sup> Calculated as:  $2 \times (T_R - T_F) / (T_R + T_F)$

<sup>3</sup>  $I_R$  is proportional to the reference current. Measured across RT. The primary contributor to output voltage spread is VDD spread, and so a VDD tighter than  $\pm 10\%$  may be required to achieve this spread.

<sup>4</sup> Higher output voltages may occur depending on load, power supply, and selected output drive. Higher output voltages may transiently occur during initialization period following TXENA assertion.

<sup>5</sup> Peak change in output differential voltage when driving a logic 0 and when driving a logic 1 under DC conditions.

<sup>6</sup> Peak change in output differential voltage when driving a logic 0 and when driving a logic 1 under AC conditions.

<sup>7</sup> Measured under "clean power supply and ground" conditions, and after de-embedding the jitter of the input, measured over a time span of 1000 cycles

<sup>8</sup> Power supply induced jitter is included under this category, and the power supply variation is to be less than 8mVpp. Note that customer has to be uncommonly careful with power supply fidelity due to the small jitter numbers.

<sup>9</sup> Power consumption is simulated under the following conditions:

Typ: TT, VDD=1.0 V, VD18=1.8 V, 25 °C

Max: FF, VDD=1.1 V, VD18=1.98 V, 125 °C

Dynamic: TXENA=1, TXOE=1

Static: TXENA=0, TXOE=1

## 4.10.12 FlexSPI (Quad SPI/Octal SPI) timing parameters

The FlexSPI interface can work in SDR or DDR modes. It can operate up to 60 MHz at 3.3 V, 166 MHz at 1.8 V SDR mode or 200 MHz at 1.8 V DDR mode. It supports single-ended and differential DQS signaling.

FlexSPI supports the following clocking scheme for a read data path:

- Dummy read strobe generated by FlexSPI controller and looped back internally (FlexSPIn\_MCR0[RXCLKSRC] = 0x0)
- Dummy read strobe generated by FlexSPI controller and looped back through the DQS pad (FlexSPIn\_MCR0[RXCLKSRC] = 0x1). It means the I/O cannot be used for another feature.
- Read strobe provided by memory device and input from DQS pad (FlexSPIn\_MCR0[RXCLKSRC] = 0x3)

I <sub>in,ext,leak</sub>	External Channel Leakage Current	—	30	500	nA	—
E <sub>IL</sub>	Input leakage error	RAS * I <sub>in</sub>			mV	—

<sup>1</sup> Typical values assume VDD\_ADC\_1P8 = 1.8 V, Temp = 25 °C, f<sub>ACLK</sub> = Max, unless otherwise stated. Typical values are for reference only. All values, including Min and Max, are derived from lab characterization and are not tested in production.

<sup>2</sup> This resistance is external to the input pad. To achieve the best results, the analog source resistance must be kept as low as possible. The results in this data sheet were derived from a system that had < 15 Ω analog source resistance. The RAS/CAS (analog source capacitance) time constant should be kept to < 1 ns.

<sup>3</sup> See Figure 57.

<sup>4</sup> ADC conversion clock at max frequency and using linear histogram.

<sup>5</sup> Input data used for test was 1 kHz sine wave.

<sup>6</sup> Measured at VREFH = 1.8 V and pwrsel = 2.

<sup>7</sup> ENOB can be lower than shown, if an ADC channel corrupts other ADC channels through capacitive coupling. This coupling may be dominated by board parasitics. Care must be taken not to corrupt the desired channel being measured. This coupling becomes worse at higher analog frequencies and with switching waveforms due to the harmonic content.

<sup>8</sup> Error measured at fullscale at 1.8 V.

<sup>9</sup> Error measured at zero scale at 0 V.

<sup>10</sup> Power Configuration Select, PWRSEL, is set to 10 binary.

The following table shows the ADC electrical specifications for 1V ≤ VREFH < VDD\_ADC\_1P8.

## 5 Boot mode configuration

This section provides information on boot mode configuration pins allocation and boot devices interfaces allocation.

### 5.1 Boot mode configuration pins

The following table provides boot options, functionality, fuse values, and associated pins. Several input pins are also sampled at reset and can be used to override fuse values, depending on the value of FORCE\_BOOT\_FROM\_FUSE. After it is blown, the Boot mode pin is ignored by ROM; ROM receives 'boot mode' from the BT\_MODE\_FUSES fuse. The boot option pins are in effect when BT\_FUSE\_SEL fuse is '0' (cleared, which is the case for an unblown fuse). For detailed boot mode options configured by the Boot mode pins, see the “System Boot, Fusemap, and eFuse” chapter of the device reference manual for more details.

**Table 113. Fuse and associated pins used for Boot**

### 5.2 Boot devices interfaces allocation

The following table lists the interfaces that can be used by the boot process in accordance with the specific Boot mode configuration. The table also describes the interface’s specific modes and IOMUXC allocation, which are configured during boot when appropriate.

<sup>1</sup> FASTD are GPIO balls configured for high speed operation using the FASTRZ control.

<sup>2</sup> Reset condition shown is before boot code execution. For pad changes after boot code execution, see the System Boot chapter of the device reference manual.

<sup>3</sup> SCU\_WDOG\_OUT was previously named JTAG\_TRST\_B; it has been renamed because its functionality has changed.
