

MC9S12ZVM-Family Reference Manual and Datasheet

***S12 MagniV
Microcontrollers***

Rev. 2.11
28 OCT 2016
MC9S12ZVMRM

nxp.com

The ZVMC256, ZVML31, ZVM32 and ZVM16 devices are targeted for safety relevant systems and have been developed using an ISO26262 compliant development system under the NXP SafeAssure program. For details of device usage in safety relevant systems refer to the MC9S12ZVMB Safety Manual.

The document revision on the Internet is the most current. To verify this is the latest revision, refer to: nxp.com.

This document contains information for all modules except the CPU. For CPU information please refer to the CPU S12Z Reference Manual. This revision history table summarizes changes to this document. The individual module sections contain revision history tables with more detailed information.

NOTE

This reference manual documents the S12ZVM-Family.

It contains a superset of features within the family.

Some module versions differ from one part to another within the family.

Section 1.2.1 MC9S12ZVM-Family Member Comparison provides support to access the correct information for a particular part within the family.

NXP reserves the right to make changes without further notice to any products herein. NXP makes no warranty, representation, or guarantee regarding the suitability of its products for any particular purpose, nor does NXP assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in NXP data sheets and/or specifications can and do vary in different applications, and actual performance may vary over time. All operating parameters, including "typicals," must be validated for each customer application by customer's technical experts. NXP does not convey any license under its patent rights nor the rights of others. NXP Semiconductors products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the NXP Semiconductors product could create a situation where personal injury or death may occur. Should Buyer purchase or use NXP Semiconductors products for any such unintended or unauthorized application, Buyer shall indemnify and hold NXP Semiconductors and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that NXP Semiconductors was negligent regarding the design or manufacture of the part.

Table 0-1. Revision History

Date	Revision	Description
22 MAY2014	1.4	Updated family derivative table for S12ZVML32, S12ZVM32 and S12ZVM16 devices Added 64KB, 32KB and 16KB derivative information to flash module chapter Added pin routing options for S12ZVM32 and S12ZVM16 devices Added HV Phy information for the S12ZVM32 and S12ZVM16 derivatives Updated Part ID assignment table and ordering information for S12ZVM32 and S12ZVM16 Corrected PLL VCO maximum frequency specification Changed V_{LVLSA} maximum from 7V to 6.9V Added electrical parameter for HD division ratio through the phase multiplexer Corrected preferred VRL reference from VRL_1 to VRL_0 Included NVM timing parameters for the S12ZVM32 and S12ZVM16 devices Added GDU S12ZVM32 and S12ZVM16 specific differences and electrical specifications Added references to f_{WSTAT} Added VDDX short circuit fall back current and temperature/input dependency specs.
22 SEP 2014	1.5	Removed incorrect references to PACLK in TIM chapter Improved clarity of routing options in PIM chapter. Updated S12ZVM- Family derivative table. Added 48LQFP thermal package parameters Extended LINPHY specification range minimum to 5V Updated BKGD pin I/O specification Specified ADC accuracy for a range of VDDA and VREF.
20 MAR 2015	2.0	Added ZVMC256 information Added mask set 2N95G information Added more detailed PTU minimum trigger spacing description Updated CPMU, PIM and GDU chapters for ZVMC256 Improved CPMU specification clarity (see CPMU revision history) Removed electrical parameter classification Added reset startup timing parameter Updated BATS parameters Extended BKGD V_{IL} condition from 3.15V to 3.13V Extended GDU operating range from 26V to 26.6V Temperature sensor output at 150C changed from 2.25V to 2.33V. Added GDU VBS current parameter Updated package thermal information for ZVM32 and ZVM16 parts Added VBG temperature and voltage dependency parameters Added device stop current at 105C.
22 APR 2015	2.1	Updated Stop and Wait current parameter values (I_{SUPS} , I_{SUPW}) Corrected 80LQFP-EP pin name from VSS2 to VSS1 Updated ZVMC256 VDDS regulator parameters. Changed PL0 ESD specification Minor corrections to PIM, PMF, SRAM and ADC chapters (see module revision histories)
27 APR 2015	2.2	Updated Stop current parameter values (I_{SUPS}) Updated LINPHY parameter range limit to 5.5V Added more information about VDDS1, VDDS2, SNPS1, SNPS2 to CPMU chapter. Reintroduced EPRES bit for GDU V4 Added 80LQFP-EP mechanical package information

Table 0-1. Revision History

Date	Revision	Description
20 NOV 2015	2.3	<p>Added devices to Part ID list Table 1-6 Added explanation of GSUF dependency on xN14N mask set Table 1-19 Minor corrections to reset source and interrupt vector tables Table 1-15 Added device level POR information Figure 1-8 Minor correction to PIM chapter Added constraints to EXTCON, SCS2 and SCS1 bits in CPMU chapter Added PMF version difference table Table 15-3 Corrected footnotes and parameter spelling in GDU register summary Noted GDU sense amplifier dependence on GFDE bit Documented that flash option (FOPT) register can be written in special mode Added pulsed absolute maximum rating for HSx pins Table A-2 Extended VDDS1 and VDDS2 maximum ratings Table A-2 Added thermal resistance parameter values for 80LQFP-EP package Added VREG configuration to Run/Wait/Stop current measurement configuration Table A-16 Removed de-saturation thresholds from electrical spec. tables Added footnote for GDU tdelon/tdeloff electrical parameters Added max. and min. values for GDU HD signal division through phase mux. Removed incorrect limit from BATS electrical parameter table headers Extended CANPHY maximum ratings to 175°C Updated SRAM_ECC chapter to cover ZVMC256 Minor correction to PMF chapter Updated typical Stop IDD and Pseudo Stop IDD values for ZVMC256 based on validation data Added ZVMC256 parameter for Stop IDD with CANPHY and API enabled Table A-19 Renamed bit GSLEWMOD to TDEL (GDU V6). Removed GSLEWMOD bit (GDU V5) Noted temperature sensor slope is subject to further characterization</p>
14 DEC 2015	2.4	<p>Added T1IC0RR to PIM MODRR2 register Updated temperature sensor electrical specification, Table B-1 Added GDU current sense amp unity bandwidth parameter Table E-1, Table E-2 Added GDU current sense input resistance footnote Table E-1, Table E-2</p>
14 JAN 2016	2.5	<p>Clarified non production mask sets Table 1-4, Table 1-6 Updated ordering information in Appendix L Changed RESET pin input pulse passed parameter minimum specification value. Table A-13 Replaced Freescale with NXP in logo and page footers Added maximum value for GDU parameter VBSx current whilst high side inactive Table E-2</p>
07 MAR 2016	2.6	<p>Added 3N95G mask set information Table 1-19, Table 1-4, Table 1-6 Added list of ISO26262 compliant devices Moved GDU mask set dependent features to device overview section Table 1-19 Added new 64LQFP-EP package diagrams Table K.2 Added minimum value for GDU parameter VBSx current whilst high side inactive Table E-2 Updated V_{CSAoff} parameter limits for GDU V5 and GDU V6 Table E-1, Table E-2 Added ADCCMD1[7:6] device dependencies in register listing Section M.13, Section M.14 Simplified GDU device dependencies in register listing Section M.15 Corrected High Temperature Interrupt spec. (cannot wake up from STOP) Table 1-16 Added footnote to Table A-14 ZVMC256: added typical Run/Wait IDD values, updated 85°C Stop IDD Table A-18, Table A-19 Added bootstrap diode resistance parameter Table E-2 Updated GDU boost coil current limit specification Table E-2, Table E-1 Reverted to original current sense amp. offset values Table E-2, Table E-1 Added package to mask set mapping table Table K-1</p>
08 MAR 2016	2.7	<p>Changed maximum value of V_{BSTOFF} Table E-2, Table E-1 Updated 48LQFP-EP Mechanical Information Diagram Section K.1</p>

Table 0-1. Revision History

Date	Revision	Description
19 APR 2016	2.8	Added PAD pin leakage specification at 125°C Table A-12 Updated t_{HGON} , t_{HGOFF} parameter values Table E-1 Specified VRH drop when using VDDS1 or VDDS2 as VRH on ZVMC256 Section C.1.1.5 Added min. and max. desaturation comparator filter times to electrical spec. Table E-1 Updated 64LQFP-EP thermal parameters Table A-9 , Table A-10
06 JUN 2016	2.9	Fixed corrupted symbol fonts Table A-3 , Table A-5 Corrected wrong IFR reference Section 20.3.2.10 Clarified PAD8 leakage better Table A-12 Added I_{SUPR} and I_{SUPW} maximum values at $T_J = 175^\circ\text{C}$ for ZVMC256 Table A-18 Added Pseudo STOP maximum current for ZVMC256 Table A-20 Removed bandgap temperature dependency footnote, Table B-1 Changed ZVMC256 SNPS monitor threshold min/max values Table B-2 Changed VLS current limit threshold to 112mA Table E-1 , Table E-2 Removed desaturation comparator filter times from GDU chapter. Added desaturation comparator levels to Table E-1 , Table E-2 Added low side desaturation comparator functional range as footnote Table E-1 , Table E-2
29 JUN 2016	2.10	Updated GDU VBS filter Figure 18-20 Removed incorrect reference to temperature sensor influencing GDU outputs Section 1.13.3.4 Changed Stop IDD (ISUPS) specifications for ZVMC256 Table A-19
28 OCT 2016	2.11	Added IOC0 signal mapping to 48LQFP package Figure 1-6 Fixed corrupted symbol fonts in PIM chapter Added diode to VDDC pin Figure 1-18 Updated Stop mode current ISUPS maximum values Table A-19 Updated t_{delon} , t_{deloff} values Table E-1

Chapter 1

Device Overview MC9S12ZVM-Family

1.1	Introduction	25
1.2	Features	26
1.2.1	MC9S12ZVM-Family Member Comparison	26
1.2.2	Module Version Differences Within The S12ZVM Family	27
1.2.3	Functional Differences Between Masksets	28
1.3	Chip-Level Features	28
1.4	Module Features	29
1.4.1	S12Z Central Processor Unit (CPU)	29
1.4.2	Embedded Memory	30
1.4.3	Clocks, Reset & Power Management Unit (CPMU)	31
1.4.4	Main External Oscillator (XOSCLCP)	32
1.4.5	Timer (TIM0)	32
1.4.6	Timer (TIM1) (ZVMC256 only)	32
1.4.7	Pulse width Modulator with Fault protection (PMF)	32
1.4.8	Programmable Trigger Unit (PTU)	32
1.4.9	LIN physical layer transceiver (ZVML devices only)	33
1.4.10	Serial Communication Interface Module (SCI)	33
1.4.11	Multi-Scalable Controller Area Network (MSCAN)	33
1.4.12	Serial Peripheral Interface Module (SPI)	34
1.4.13	Analog-to-Digital Converter Module (ADC)	34
1.4.14	Supply Voltage Sensor (BATS)	34
1.4.15	On-Chip Voltage Regulator system (VREG)	34
1.4.16	Gate Drive Unit (GDU)	35
1.4.17	Current Sense	35
1.4.18	High Voltage Physical Interface (ZVM32, ZVM16)	35
1.4.19	CAN Physical Layer Module (ZVMC256 only)	35
1.4.20	Pulse Width Modulation Module (PWM) (ZVMC256 only)	36
1.5	Block Diagram	37
1.6	Device Memory Map	38
1.6.1	Flash Module	39
1.6.2	Part ID Assignments	41
1.7	Signal Description and Device Pinouts	41
1.7.1	Pin Assignment Overview	42
1.7.2	Detailed External Signal Descriptions	42
1.7.3	Power Supply And Voltage Regulator Related Pins	50
1.7.4	Package and Pinouts	51
1.8	Internal Signal Mapping	63
1.8.1	ADC Connectivity	63
1.8.2	Motor Control Loop Signals	64
1.8.3	Device Level PMF Connectivity	65
1.8.4	BDC Clock Source Connectivity	65
1.8.5	LINPHY Connectivity	65
1.8.6	HVPHY Connectivity	65

1.8.7	FTMRZ Connectivity	66
1.8.8	CPMU Connectivity	66
1.9	Modes of Operation	66
1.9.1	Chip Configuration Modes	66
1.9.2	Debugging Modes	67
1.9.3	Low Power Modes	67
1.10	Security	68
1.10.1	Features	68
1.10.2	Securing the Microcontroller	68
1.10.3	Operation of the Secured Microcontroller	69
1.10.4	Unsecuring the Microcontroller	69
1.10.5	Reprogramming the Security Bits	70
1.10.6	Complete Memory Erase	70
1.11	Resets and Interrupts	71
1.11.1	Reset	71
1.11.2	Interrupt Vectors	71
1.11.3	Effects of Reset	74
1.12	Module device level dependencies	75
1.12.1	CPMU COP and GDU Configuration	75
1.12.2	CPMU High Temperature Trimming	76
1.12.3	CPMU VDDC enable	77
1.12.4	Flash IFR Mapping	77
1.13	Application Information	77
1.13.1	ADC Calibration	77
1.13.2	SCI Baud Rate Detection	78
1.13.3	Motor Control Application Overview	78
1.13.4	BDCM Complementary Mode Operation	86
1.13.5	BLDC Six-Step Commutation	90
1.13.6	PMSM Control	92
1.13.7	Power Domain Overview (All devices except ZVMC256)	96
1.13.8	Power Domain Overview (ZVMC256)	98

Chapter 2

Port Integration Module (S12ZVMPIMV3)

2.1	Introduction	104
2.1.1	Overview	104
2.1.2	Features	107
2.2	External Signal Description	108
2.3	Memory Map and Register Definition	115
2.3.1	Register Map	116
2.3.2	PIM Registers 0x0200-0x020F	122
2.3.3	PIM Generic Registers	133
2.3.4	PIM Generic Register Exceptions	140
2.4	Functional Description	147
2.4.1	General	147

2.4.2	Registers	147
2.4.3	Pin I/O Control	149
2.4.4	Pin interrupts and Key-Wakeup (KWU)	151
2.4.5	Over-Current Interrupt	152
2.4.6	High-Voltage Input	152
2.5	Initialization and Application Information	154
2.5.1	Port Data and Data Direction Register writes	154
2.5.2	Open Input Detection on HVI	154
2.5.3	Over-Current Protection on EVDD1	156

Chapter 3 Memory Mapping Control (S12ZMMCV1)

3.1	Introduction	157
3.1.1	Glossary	158
3.1.2	Overview	158
3.1.3	Features	158
3.1.4	Modes of Operation	159
3.1.5	Block Diagram	159
3.2	External Signal Description	159
3.3	Memory Map and Register Definition	160
3.3.1	Memory Map	160
3.3.2	Register Descriptions	160
3.4	Functional Description	165
3.4.1	Global Memory Map	165
3.4.2	Illegal Accesses	167
3.4.3	Uncorrectable ECC Faults	168

Chapter 4 Interrupt (S12ZINTV0)

4.1	Introduction	169
4.1.1	Glossary	170
4.1.2	Features	170
4.1.3	Modes of Operation	171
4.1.4	Block Diagram	171
4.2	External Signal Description	172
4.3	Memory Map and Register Definition	172
4.3.1	Module Memory Map	172
4.3.2	Register Descriptions	173
4.4	Functional Description	178
4.4.1	S12Z Exception Requests	178
4.4.2	Interrupt Prioritization	178
4.4.3	Priority Decoder	179
4.4.4	Reset Exception Requests	179
4.4.5	Exception Priority	180

4.4.6	Interrupt Vector Table Layout	180
4.5	Initialization/Application Information	180
4.5.1	Initialization	180
4.5.2	Interrupt Nesting	181
4.5.3	Wake Up from Stop or Wait Mode	182

Chapter 5 Background Debug Controller (S12ZBDCV2)

5.1	Introduction	183
5.1.1	Glossary	183
5.1.2	Features	184
5.1.3	Modes of Operation	184
5.1.4	Block Diagram	186
5.2	External Signal Description	187
5.3	Memory Map and Register Definition	187
5.3.1	Module Memory Map	187
5.3.2	Register Descriptions	188
5.4	Functional Description	192
5.4.1	Security	192
5.4.2	Enabling BDC And Entering Active BDM	192
5.4.3	Clock Source	193
5.4.4	BDC Commands	193
5.4.5	BDC Access Of Internal Resources	210
5.4.6	BDC Serial Interface	213
5.4.7	Serial Interface Hardware Handshake (ACK Pulse) Protocol	216
5.4.8	Hardware Handshake Abort Procedure	218
5.4.9	Hardware Handshake Disabled (ACK Pulse Disabled)	219
5.4.10	Single Stepping	220
5.4.11	Serial Communication Timeout	220
5.5	Application Information	221
5.5.1	Clock Frequency Considerations	221

Chapter 6 S12Z Debug (S12ZDBG) Module

6.1	Introduction	223
6.1.1	Glossary	224
6.1.2	Overview	224
6.1.3	Features	224
6.1.4	Modes of Operation	225
6.1.5	Block Diagram	226
6.2	External Signal Description	226
6.2.1	External Event Input	226
6.2.2	Profiling Output	227
6.3	Memory Map and Registers	227

6.3.1	Module Memory Map	227
6.3.2	Register Descriptions	230
6.4	Functional Description	251
6.4.1	DBG Operation	251
6.4.2	Comparator Modes	251
6.4.3	Events	255
6.4.4	State Sequence Control	257
6.4.5	Trace Buffer Operation	258
6.4.6	Code Profiling	267
6.4.7	Breakpoints	271
6.5	Application Information	272
6.5.1	Avoiding Unintended Breakpoint Re-triggering	272
6.5.2	Debugging Through Reset	272
6.5.3	Breakpoints from other S12Z sources	273
6.5.4	Code Profiling	273

Chapter 7

ECC Generation Module (SRAM_ECCV1)

7.1	Introduction	275
7.1.1	Features	275
7.2	Memory Map and Register Definition	276
7.2.1	Register Summary	276
7.2.2	Register Descriptions	278
7.3	Functional Description	282
7.3.1	Non-aligned Memory Write Access	283
7.3.2	Aligned 2 and 4 Byte Memory Write Access	284
7.3.3	Memory Read Access	284
7.3.4	Memory Initialization	284
7.3.5	Interrupt Handling	285
7.3.6	ECC Algorithm	285
7.3.7	ECC Debug Behavior	285

Chapter 8

S12 Clock, Reset and Power Management Unit (V10 and V6)

8.1	Introduction	288
8.1.1	Differences between S12CPMU_UHV_V10 and S12CPMU_UHV_V6	289
8.1.2	Features	290
8.1.3	Modes of Operation	292
8.1.4	S12CPMU_UHV_V10_V6 Block Diagram	295
8.2	Signal Description	297
8.2.1	$\overline{\text{RESET}}$	297
8.2.2	EXTAL and XTAL	297
8.2.3	VSUP — Regulator Power Input Pin	297
8.2.4	VDDA, VSSA — Regulator Reference Supply Pins	297

8.2.5	VDDX, VSSX— Pad Supply Pins	297
8.2.6	VDDC— CAN Supply Pin	298
8.2.7	VDDS1— Sensor Supply1 Pin	298
8.2.8	VDDS2— Sensor Supply2 Pin	298
8.2.9	BCTL— Base Control Pin for external PNP	298
8.2.10	BCTLC — Base Control Pin for external PNP for VDDC power domain	299
8.2.11	BCTLS1 — Base Control Pin for external PNP for VDDS1 power domain	299
8.2.12	BCTLS2 — Base Control Pin for external PNP for VDDS2 power domain	300
8.2.13	SNPS1 — Sense Pin for VDDS1 power domain	300
8.2.14	SNPS2 — Sense Pin for VDDS2 power domain	300
8.2.15	VSS1,2 — Core Ground Pins	300
8.2.16	VDD— Core Logic Supply Pin	301
8.2.17	VDDF— NVM Logic Supply Pin	301
8.2.18	API_EXTCLK — API external clock output pin	301
8.2.19	TEMPSENSE — Internal Temperature Sensor Output Voltage	301
8.3	Memory Map and Registers	302
8.3.1	Module Memory Map	302
8.3.2	Register Descriptions	304
8.4	Functional Description	345
8.4.1	Phase Locked Loop with Internal Filter (PLL)	345
8.4.2	Startup from Reset	347
8.4.3	Stop Mode using PLLCLK as source of the Bus Clock	348
8.4.4	Full Stop Mode using Oscillator Clock as source of the Bus Clock	348
8.4.5	External Oscillator	350
8.4.6	System Clock Configurations	351
8.5	Resets	352
8.5.1	General	352
8.5.2	Description of Reset Operation	353
8.5.3	Oscillator Clock Monitor Reset	353
8.5.4	PLL Clock Monitor Reset	354
8.5.5	Computer Operating Properly Watchdog (COP) Reset	354
8.5.6	Power-On Reset (POR)	355
8.5.7	Low-Voltage Reset (LVR)	355
8.6	Interrupts	356
8.6.1	Description of Interrupt Operation	356
8.7	Initialization/Application Information	358
8.7.1	General Initialization Information	358
8.7.2	Application information for COP and API usage	358
8.7.3	Application Information for PLL and Oscillator Startup	359

Chapter 9

Analog-to-Digital Converter (ADC12B_LBA)

9.1	Differences ADC12B_LBA V1 vs V2 vs V3	361
9.2	Introduction	362

9.3	Key Features	363
9.3.1	Modes of Operation	364
9.3.2	Block Diagram	367
9.4	Signal Description	368
9.4.1	Detailed Signal Descriptions	368
9.5	Memory Map and Register Definition	369
9.5.1	Module Memory Map	369
9.5.2	Register Descriptions	372
9.6	Functional Description	406
9.6.1	Overview	406
9.6.2	Analog Sub-Block	406
9.6.3	Digital Sub-Block	407
9.7	Resets	420
9.8	Interrupts	420
9.8.1	ADC Conversion Interrupt	420
9.8.2	ADC Sequence Abort Done Interrupt	420
9.8.3	ADC Error and Conversion Flow Control Issue Interrupt	421
9.9	Use Cases and Application Information	422
9.9.1	List Usage — CSL single buffer mode and RVL single buffer mode	422
9.9.2	List Usage — CSL single buffer mode and RVL double buffer mode	422
9.9.3	List Usage — CSL double buffer mode and RVL double buffer mode	423
9.9.4	List Usage — CSL double buffer mode and RVL single buffer mode	423
9.9.5	List Usage — CSL double buffer mode and RVL double buffer mode	424
9.9.6	RVL swapping in RVL double buffer mode and related registers ADCIMDRI and ADCEOLRI	424
9.9.7	Conversion flow control application information	426
9.9.8	Continuous Conversion	428
9.9.9	Triggered Conversion — Single CSL	429
9.9.10	Fully Timing Controlled Conversion	430

Chapter 10 Supply Voltage Sensor - (BATSV3)

10.1	Introduction	431
10.1.1	Features	431
10.1.2	Modes of Operation	431
10.1.3	Block Diagram	432
10.2	External Signal Description	432
10.2.1	VSUP — Voltage Supply Pin	432
10.3	Memory Map and Register Definition	433
10.3.1	Register Summary	433
10.3.2	Register Descriptions	433
10.4	Functional Description	437
10.4.1	General	437
10.4.2	Interrupts	437

Chapter 11

Timer Module (TIM16B4CV3) Block Description

11.1	Introduction	441
11.1.1	Features	441
11.1.2	Modes of Operation	441
11.1.3	Block Diagrams	442
11.2	External Signal Description	443
11.2.1	IOC3 - IOC0 — Input Capture and Output Compare Channel 3-0	443
11.3	Memory Map and Register Definition	443
11.3.1	Module Memory Map	443
11.3.2	Register Descriptions	443
11.4	Functional Description	455
11.4.1	Prescaler	456
11.4.2	Input Capture	457
11.4.3	Output Compare	457
11.5	Resets	458
11.6	Interrupts	458
11.6.1	Channel [3:0] Interrupt (C[3:0]F)	458
11.6.2	Timer Overflow Interrupt (TOF)	458

Chapter 12

Timer Module (TIM16B2CV3) Block Description

12.1	Introduction	459
12.1.1	Features	459
12.1.2	Modes of Operation	459
12.1.3	Block Diagrams	460
12.2	External Signal Description	460
12.2.1	IOC1 - IOC0 — Input Capture and Output Compare Channel 1-0	461
12.3	Memory Map and Register Definition	461
12.3.1	Module Memory Map	461
12.3.2	Register Descriptions	461
12.4	Functional Description	473
12.4.1	Prescaler	474
12.4.2	Input Capture	475
12.4.3	Output Compare	475
12.5	Resets	476
12.6	Interrupts	476
12.6.1	Channel [1:0] Interrupt (C[1:0]F)	476
12.6.2	Timer Overflow Interrupt (TOF)	476

Chapter 13

Scalable Controller Area Network (S12MSCANV3)

Device Overview MC9S12ZVM-Family

Table 1-1. Revision History

Version Number	Revision Date	Sections Affected	Description of Changes
1.8	04.Sep.2014	Section 1.2.1	<ul style="list-style-type: none"> Added S12ZVML31 information to derivative table
2.0	10.Oct.2014	General	<ul style="list-style-type: none"> Added ZVMC256 information
2.01	06.Feb.2015	General	<ul style="list-style-type: none"> Added 2N95G maskset information. Added TIM1 for ZVMC256
2.02	25.Aug.2016	Figure 1-6 , Table 1-8 Section 1.13.3.6	<ul style="list-style-type: none"> Clarified IOC0 device pin mapping dependencies Clarified IOC0 device pin mapping dependencies Removed Temperature Sensor from list of Dynamic motor control fault inputs

1.1 Introduction

The MC9S12ZVM-Family is an automotive 16-bit microcontroller family using the NVM + UHV technology that offers the capability to integrate 40 V analog components. This family reuses many features from the existing S12/S12X portfolio. The particular differentiating features of this family are the enhanced S12Z core, the combination of dual-ADC synchronized with PWM generation and the integration of “high-voltage” analog modules, including the voltage regulator (VREG), Gate Drive Unit (GDU), and either Local Interconnect Network (LIN) physical layer or CAN Physical layer. These features enable a fully integrated single chip solution to drive up to 6 external power MOSFETs for BLDC or PMSM motor drive applications.

The MC9S12ZVM-Family includes error correction code (ECC) on RAM and flash memory, EEPROM for diagnostic or data storage, a fast analog-to-digital converter (ADC) and a frequency modulated phase locked loop (IPLL) that improves the EMC performance. The MC9S12ZVM-Family allows the integration of several key system components into a single device, optimizing system architecture and achieving significant space savings. The MC9S12ZVM-Family delivers all the advantages and efficiencies of a 16-bit MCU while retaining the low cost, power consumption, EMC, and code-size efficiency advantages currently enjoyed by users of existing S12(X) families. The MC9S12ZVM-Family is available in different pin-out options, using 80-pin, 64-pin and 48-pin LQFP-EP packages to accommodate LIN, CAN and external PWM based application interfaces. In addition to the I/O ports available in each module, further I/O ports are available with interrupt capability allowing wake-up from stop or wait modes.

The MC9S12ZVM-Family is a general-purpose family of devices suitable for a range of applications, including:

- 3-phase sensorless BLDC motor control for
 - Fuel pump

- Water pump
- Oil pump
- A/C compressor
- HVAC blower
- Engine cooling fan
- Electric vehicle battery cooling fan
- Brush DC motor control requiring driving in 2 directions, along with PWM control for
 - Reversible wiper
 - Trunk opener

1.2 Features

This section describes the key features of the MC9S12ZVM-Family. It documents the superset of features within the family. Some module versions differ from one part to another within the family. Section 1.2.1 MC9S12ZVM-Family Member Comparison provides information to help access the correct information for a particular part within the family.

1.2.1 MC9S12ZVM-Family Member Comparison

Table 1-2 provides a summary of feature set differences within the MC9S12ZVM-Family.

1. Mask set differences listed in Section 1.2.3

1.2.3 Functional Differences Between Masksets

The parts ZVML128, ZVMC128, ZVML64, ZVMC64 and ZVML32 have the following mask set options.

CAUTION

The maskset 2N95G uses the VSUP pin as the LINPHY supply. Thus the BST function must not be used on this maskset because enabling it could cause a LINPHY supply voltage offset with respect to other devices on the LIN bus.

Further GDU configuration mask set dependencies are specified in Table 1-19.

Table 1-4. N95G Option Table

Feature	0N95G ⁽¹⁾	1N95G	2N95G	3N95G
LINPHY supply pin	HD	HD	VSUP	HD
BST pin function available	Yes	Yes	No	Yes
GDU low side driver state in HD over-voltage case	on	GOCA1	GOCA1	GOCA1

1. 0N95G is not a production mask set

1.3 Chip-Level Features

On-chip modules available within the family include the following features:

- S12Z CPU core
- 256, 128, 64, 32 or 16KB on-chip flash with ECC
- 1K, 512 or 128 byte EEPROM with ECC
- 32, 8, 4 or 2 KB on-chip SRAM with ECC
- Phase locked loop (IPLL) frequency multiplier with internal filter
- 1 MHz internal RC oscillator with +/-1.3% accuracy over rated temperature range
- 4-20MHz amplitude controlled pierce oscillator
- Internal COP (watchdog) module
- 6-channel, 15-bit pulse width modulator with fault protection (PMF)
- Low side and high side FET pre-drivers for each phase
 - Gate drive pre-regulator
 - LDO (Low Dropout Voltage Regulator) (typically 11V)
 - High side gate supply generated using bootstrap circuit with external diode and capacitor
 - Sustaining charge pump with two external capacitors and diodes
 - High side drain (HD) monitoring on internal ADC channel using HD/5 voltage
- Two parallel analog-to-digital converters (ADC) with 12-bit resolution and up to 16 channels available on external pins
- Programmable Trigger Unit (PTU) for synchronization of PMF and ADC
- One serial peripheral interface (SPI) module
- One serial communication interface (SCI) module with interface to internal LIN physical layer transceiver (with RX connected to a timer channel for frequency calibration purposes, if desired)

- Up to one additional SCI (not connected to LIN physical layer)
- On-chip LIN physical layer transceiver fully compliant with the LIN 2.2 standard (S12ZVML versions)
- One High Voltage physical interface. (ZVM32, ZVM16 versions only)
- 4-channel timer module (TIM0) with input capture/output compare
- 2-channel timer module (TIM1) with input capture/output compare (ZVMC256 version only)
- One 8-bit, 8-channel pulse width modulator (PWM) module. (ZVMC256 version only)
- MSCAN (1 Mbit/s, CAN 2.0 A, B software compatible) module
- On-chip voltage regulator (VREG) for regulation of input supply and all internal voltages
 - Optional VREG ballast control output to supply an external CAN physical layer
- CAN Physical Layer, ISO 11898-2 and ISO 11898-5 compliant. (ZVMC256 version only)
- Two voltage regulator outputs to supply external loads. (ZVMC256 version only)
- Two current sense circuits for overcurrent detection or torque measurement
- Autonomous periodic interrupt (API)
- 20mA high-current output for use as Hall sensor supply
- Supply voltage sense with low battery warning
- Chip temperature sensor
- One High Voltage Input (ZVMC256 version only)

1.4 Module Features

The following sections provide more details of the integrated modules.

1.4.1 S12Z Central Processor Unit (CPU)

The S12Z CPU is a revolutionary high-speed core, with code size and execution efficiencies over the S12X CPU. The S12Z CPU also provides a linear memory map eliminating the inconvenience and performance impact of page swapping.

- Harvard Architecture - parallel data and code access
- 3 stage pipeline
- 32-Bit wide instruction and databus
- 32-Bit ALU
- 24-bit addressing, of 16MB linear address space
- Instructions and Addressing modes optimized for C-Programming & Compiler
 - MAC unit 32bit += 32bit*32bit
 - Hardware divider
 - Single cycle multi-bit shifts (Barrel shifter)
 - Special instructions for fixed point math
- Unimplemented opcode traps

- Unprogrammed byte value (0xFF) defaults to SWI instruction

1.4.1.1 Background Debug Controller (BDC)

- Background debug controller (BDC) with single-wire interface
 - Non-intrusive memory access commands
 - Supports in-circuit programming of on-chip nonvolatile memory

1.4.1.2 Debugger (DBG) ZVML31, ZVM32, ZVM16 feature subset listed in S12ZDBG chapter

- Enhanced DBG module including:
 - Four comparators (A, B, C and D) each configurable to monitor PC addresses or addresses of data accesses
 - A and C compare full address bus and full 32-bit data bus with data bus mask register
 - B and D compare full address bus only
 - Three modes: simple address/data match, inside address range, or outside address range
 - Tag-type or force-type hardware breakpoint requests
- State sequencer control
- 64 x 64-bit circular trace buffer to capture change-of-flow addresses or address and data of every access
 - Begin, End and Mid alignment of tracing to trigger
- Profiling mode for external visibility of internal program flow

1.4.2 Embedded Memory

1.4.2.1 Memory Access Integrity

- Illegal address detection
- ECC support on embedded NVM and system RAM

1.4.2.2 Flash

On-chip flash memory on the MC9S12ZVM-family on the features the following:

- Up to 256KB of program flash memory
 - 32 data bits plus 7 syndrome ECC (error correction code) bits allow single bit fault correction and double fault detection
 - Erase sector size 512 bytes
 - Automated program and erase algorithm
 - User margin level setting for reads
 - Protection scheme to prevent accidental program or erase

1.4.2.3 EEPROM

- Up to 1K byte EEPROM
 - 16 data bits plus 6 syndrome ECC (error correction code) bits allow single bit error correction and double fault detection
 - Erase sector size 4 bytes
 - Automated program and erase algorithm
 - User margin level setting for reads

1.4.2.4 SRAM

- Up to 32 KB of general-purpose RAM with ECC
 - Single bit error correction and double bit error detection

1.4.3 Clocks, Reset & Power Management Unit (CPMU)

- Real time interrupt (RTI)
- Clock monitor, supervising the correct function of the oscillator (CM)
- Computer operating properly (COP) watchdog
 - Configurable as window COP for enhanced failure detection
 - Can be initialized out of reset using option bits located in flash memory
- System reset generation
- Autonomous periodic interrupt (API) (combination with cyclic, watchdog)
- Low Power Operation
 - RUN mode is the main full performance operating mode with the entire device clocked.
 - WAIT mode when the internal CPU clock is switched off, so the CPU does not execute instructions.
 - Pseudo STOP - system clocks are stopped but the oscillator the RTI, the COP, and API modules can be enabled
 - STOP - the oscillator is stopped in this mode, all clocks are switched off and all counters and dividers remain frozen, with the exception of the COP and API which can optionally run from ACLK.

1.4.3.1 Internal Phase-Locked Loop (IPLL)

- Phase-locked-loop clock frequency multiplier
 - No external components required
 - Reference divider and multiplier allow large variety of clock rates
 - Automatic bandwidth control mode for low-jitter operation
 - Automatic frequency lock detector
 - Configurable option to spread spectrum for reduced EMC radiation (frequency modulation)
 - Reference clock sources:

- Internal 1 MHz RC oscillator (IRC)
- External 4-20 MHz crystal oscillator/resonator

1.4.3.2 Internal RC Oscillator (IRC)

- Trimmable internal 1MHz reference clock.
 - Trimmed accuracy over -40°C to 150°C junction temperature range: $\pm 1.3\%$ max.

1.4.4 Main External Oscillator (XOSCLCP)

- Amplitude controlled Pierce oscillator using 4 MHz to 20 MHz crystal
 - Current gain control on amplitude output
 - Signal with low harmonic distortion
 - Low power
 - Good noise immunity
 - Eliminates need for external current limiting resistor
 - Trans conductance sized for optimum start-up margin for typical crystals
 - Oscillator pins shared with GPIO functionality

1.4.5 Timer (TIM0)

- 4 x 16-bit channels Timer module for input capture or output compare
- 16-bit free-running counter with 8-bit precision prescaler

1.4.6 Timer (TIM1) (ZVMC256 only)

- 2 x 16-bit channels Timer module for input capture or output compare
- 16-bit free-running counter with 8-bit precision prescaler

1.4.7 Pulse width Modulator with Fault protection (PMF)

- 6 x 15-bit channel PWM resolution
- Each pair of channels can be combined to generate a PWM signal (with independent control of edges of PWM signal)
- Dead time insertion available for each complementary pair
- Center-aligned or edge-aligned outputs
- Programmable clock select logic with a wide range of frequencies
- Programmable fault detection

1.4.8 Programmable Trigger Unit (PTU)

- Enables synchronization between PMF and ADC

- 2 trigger input sources and software trigger source
- 2 trigger outputs
- One 16-bit delay register pre-trigger output
- Operation in One-Shot or Continuous modes

1.4.9 LIN physical layer transceiver (ZVML devices only)

- Compliant with LIN Physical Layer 2.2 specification.
- Compliant with the SAE J2602-2 LIN standard.
- Standby mode with glitch-filtered wake-up.
- Slew rate selection optimized for the baud rates: 10.4kBit/s, 20kBit/s and Fast Mode (up to 250kBit/s).
- Switchable 34k Ω /330k Ω pull-ups (in shutdown mode, 330k Ω only)
- Current limitation for LIN Bus pin falling edge.
- Over-current protection.
- LIN TxD-dominant timeout feature monitoring the LPTxD signal.
- Automatic transmitter shutdown in case of an over-current or TxD-dominant timeout.
- Fulfills the OEM “Hardware Requirements for LIN (CAN and FlexRay) Interfaces in Automotive Applications” v1.3.

1.4.10 Serial Communication Interface Module (SCI)

- Full-duplex or single-wire operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse widths
- 16-bit baud rate selection
- Programmable character length
- Programmable polarity for transmitter and receiver
- Active edge receive wakeup
- Break detect and transmit collision detect supporting LIN

1.4.11 Multi-Scalable Controller Area Network (MSCAN)

- Implementation of the CAN protocol — Version 2.0A/B
- Five receive buffers with FIFO storage scheme
- Three transmit buffers with internal prioritization using a “local priority” concept
- Flexible maskable identifier filter supports two full-size (32-bit) extended identifier filters, or four 16-bit filters, or either 8-bit filters
- Programmable wake-up functionality with integrated low-pass filter

1.4.12 Serial Peripheral Interface Module (SPI)

- Configurable 8- or 16-bit data size
- Full-duplex or single-wire bidirectional
- Double-buffered transmit and receive
- Master or slave mode
- MSB-first or LSB-first shifting
- Serial clock phase and polarity options

1.4.13 Analog-to-Digital Converter Module (ADC)

- Dual ADC
 - 12-bit resolution
 - Up to 16 external channels & 8 internal channels
 - 2.5us for single 12-bit resolution conversion
 - Left or right aligned result data
 - Continuous conversion mode
- Programmers model with list based command and result storage architecture
ADC directly writes results to RAM, preventing stall of further conversions
- Internal signals monitored with the ADC module
 - VRH, VRL, $(VRL+VRH)/2$, Vsup monitor, Vbg, TempSense, GDU phase, GDU DC-link
- External pins can also be used as digital I/O

1.4.14 Supply Voltage Sensor (BATS)

- Monitoring of supply (VSUP) voltage
- Internal ADC interface from an internal resistive divider
- Generation of low or high voltage interrupts

1.4.15 On-Chip Voltage Regulator system (VREG)

- Voltage regulator
 - Linear voltage regulator directly supplied by VSUP
 - Low-voltage detect on VSUP
 - Power-on reset (POR)
 - Low-voltage reset (LVR) for VDDX domain
 - External ballast device support to reduce internal power dissipation
 - Capable of supplying both the MCU internally plus external components
 - Over-temperature interrupt
- Internal voltage regulator
 - Linear voltage regulator with bandgap reference

- Low-voltage detect on VDDA
- Power-on reset (POR) circuit
- Low-voltage reset for VDD domain
- Package option for VREG ballast control output to supply external CANPHY
- Option for 2 further VREG ballast control outputs to supply external components (ZVMC256)

1.4.16 Gate Drive Unit (GDU)

- Low side and high side FET pre-drivers for each phase
- Gate drive pre-regulator LDO (Low Dropout Voltage Regulator)
- High side gate supply done via bootstrap circuit
- External bootstrap diode replaced by internal circuit (GDUV5 only)
- Sustaining charge pump with two external capacitors and diodes
- Optional boost converter configuration with voltage feedback
- FET-Predriver desaturation and error recognition
- Monitoring of FET High Side drain (HD) voltage
- Diagnostic failure management
- Low side drain pins for monitoring desaturation of switch reluctance motor drivers (ZVMC256)

1.4.17 Current Sense

- 2 channel, integrated op-amp functionality

1.4.18 High Voltage Physical Interface (ZVM32, ZVM16)

- Single pin high voltage interface signal operating in the VSUP voltage range
- Internal interface mapped to internal timer channel.
- Compliant with the ISO9141 (K-line) standard.
- Standby mode with glitch-filtered wake-up.
- Slew rate selection optimized for: 5.2 kHz, 10 kHz and Fast Mode (up to 125 kHz).
- Switchable 34 k Ω /330 k Ω pullup resistors (in shutdown mode, 330 k Ω only).
- Current limitation for pin falling edge.
- Overcurrent protection.

1.4.19 CAN Physical Layer Module (ZVMC256 only)

- High speed CAN interface for baud rates of up to 1 Mbit/s
- ISO 11898-2 and ISO 11898-5 compliant for 12 V battery systems
- SPLIT pin driver for bus recessive level stabilization
- Low power mode with remote CAN wake-up handled by MSCAN module

- Configurable wake-up pulse filtering
- Over-current shutdown for CANH and CANL
- Voltage monitoring on CANH and CANL
- CPTXD-dominant timeout feature monitoring the CPTXD signal
- Fulfills the OEM “Hardware Requirements for (LIN,) CAN (and FlexRay) Interfaces in Automotive Applications” v1.3

1.4.20 Pulse Width Modulation Module (PWM) (ZVMC256 only)

- Configurable as 8 channels x 8-bit or 4 channels x 16-bit
- Programmable period and duty cycle per channel
- Center-aligned or edge-aligned outputs
- Programmable clock select logic with a wide range of frequencies

1.5 Block Diagram

Block Diagram shows the maximum configuration
 Not all pins or all peripherals are available on all devices and packages. Red highlighted features are ZVMC256 specific.
 Rerouting options are not shown.

Figure 1-1. MC9S12ZVM-Family Block Diagram

1.6 Device Memory Map

Table 1-5 shows the device register memory map. All modules that can be instantiated more than once on S12 devices are listed with an index number, even if they are only instantiated once on this device family.

Table 1-5. Module Register Address Ranges

Address	Module	Size (Bytes)
0x0000–0x0003	Part ID Register Section 1.6.2	4
0x0004–0x000F	Reserved	12
0x0010–0x001F	INT	16

0x0998–0x0FFF	Reserved	1640

1. Reading from the first 16 locations in this reserved range returns undefined data
2. Address range = 0x0690-0x069F on Maskset N06E

NOTE

Reserved register space shown above is not allocated to any module. This register space is reserved for future use. Writing to these locations has no effect. Read access to these locations returns zero.

1.6.1 Flash Module

This device family instantiates different flash modules, depending on derivative. The flash documentation for the all devices is featured in the FTMRZ section.

Figure 1-2. MC9S12ZVM-Family Global Memory Map. (See Table 1-3 for individual device details)

1.6.2 Part ID Assignments

The part ID is located in four 8-bit registers at addresses 0x0000-0x0003. The read-only value is a unique part ID for each revision of the chip. [Table 1-6](#) shows the assigned part ID number and mask set number. The shaded part ID numbers are not production mask sets.

Table 1-6. Assigned Part ID Numbers

Device	Mask Set Number	Part ID	Option
MC9S12ZVMC256	0N00R	0x00180000	CAN
MC9S12ZVMC256	1N00R	0x00180100	CAN

1.7 Signal Description and Device Pinouts

This section describes signals that connect off-chip. It includes pin out diagrams a table of signal properties, and detailed discussion of signals. Internal inter module signal mapping at device level is described in [1.8 Internal Signal Mapping](#).

1.7.1 Pin Assignment Overview

Table 1-7 provides a summary of which ports are available.

Table 1-7. Port Availability by Option

Port	80 LQFP	64 LQFP	48LQFP
Port AD	PAD[15:0]	PAD[8:0]	PAD[8],PAD[2:0]
Port E	PE[1:0]	PE[1:0]	PE[1:0]
Port L	PL[0]	—	—
Port P	PP[1:0]	PP[2:0]	PP[0]
Port S	PS[3:0]	PS[5:0]	PS[1:0]
Port T	PT[3:0]	PT[3:0]	PT[0]
sum of ports	29	24	10

NOTE

To avoid current drawn from floating inputs, all non-bonded pins should be configured as output or configured as input with a pull up or pull down device enabled

1.7.2 Detailed External Signal Descriptions

This section describes the properties of signals available at device pins. Signal names associated with modules that can be instantiated more than once on an S12 are indexed, even if the module is only instantiated once on the **MC9S12ZVM-Family**. If a signal already includes a channel number, then the index is inserted before the channel number. Thus AN_x_y corresponds to AN instance x, channel number y.

1.7.2.1 $\overline{\text{RESET}}$ — External Reset Signal

The $\overline{\text{RESET}}$ signal is an active low bidirectional control signal. It acts as an input to initialize the MCU to a known start-up state, and an output when an internal MCU function causes a reset. The $\overline{\text{RESET}}$ pin has an internal pull-up device.

1.7.2.2 TEST — Test Pin

This input only pin is reserved for factory test. This pin has an internal pull-down device.

NOTE

The TEST pin must be tied to ground in all applications.

1.7.2.3 MODC — Mode C Signal

The MODC signal is used as an MCU operating mode select during reset. The state of this signal is latched to the MODC bit at the rising edge of RESET. The signal has an internal pull-up device.

1.7.2.4 PAD[15:0] / KWAD[15:0] — Port AD, Input Pins of ADC

These are general-purpose input or output signals. The signals can be configured on per signal basis as interrupt inputs with wake-up capability (KWAD). These signals can have a pull-up or pull-down device selected and enabled on per signal basis. During and out of reset the pull devices are disabled.

1.7.2.5 PE[1:0] — Port E I/O Signals

PE[1:0] are general-purpose input or output signals. The signals can have a pull-down device, enabled by on a per pin basis. Out of reset the pull-down devices are enabled.

1.7.2.6 PL[0] — Port L Input Signal

PL[0] is a high voltage input port. The port can be configured as interrupt input with wake-up capability (KWL[0]). The input voltage is also scaled and mapped to an internal ADC channel.

1.7.2.7 PP[2:0] / KWP[2:0] — Port P I/O Signals

PP[2:0] are general-purpose input or output signals. The signals can be configured on per signal basis as interrupt inputs with wake-up capability (KWP[2:0]). They can have a pull-up or pull-down device selected and enabled on per signal basis. During and out of reset the pull devices are disabled.

1.7.2.8 PS[5:0] / KWS[5:0] — Port S I/O Signals

PS[5:0] are general-purpose input or output signals. The signals can be configured on per signal basis as interrupt inputs with wake-up capability (KWS[5:0]). They can have a pull-up or pull-down device selected and enabled on per signal basis. During and out of reset the pull-up devices are enabled.

1.7.2.9 PT[3:0] — Port T I/O Signals

PT[3:0] are general-purpose input or output signals. They can have a pull-up or pull-down device selected and enabled on per signal basis. During and out of reset the pull devices are disabled.

1.7.2.10 AN0_[7:0], AN1_[7:0]— ADC Input Signals

These are the analog inputs of the Analog-to-Digital Converters. These are mapped to PAD port pins. The number of analog input channels connected to PAD port pins is package option dependent.

1.7.2.11 VRH0_[2:0], VRL0_[1:0] — ADC0 Reference Signals

VRH0_[2:0] and VRL0_[1:0] are the reference voltage signals for the analog-to-digital converter ADC0.

1.7.2.12 VRH1_[2:0], VRL1_[1:0] — ADC1 Reference Signals

VRH1_[2:0] and VRL1_[1:0] are the reference voltage signals for the analog-to-digital converter ADC1.

1.7.2.13 SPI0 Signals

1.7.2.13.1 $\overline{SS0}$ Signal

This signal is associated with the slave select SS functionality of the serial peripheral interface SPI0.

1.7.2.13.2 SCK0 Signal

This signal is associated with the serial clock SCK functionality of the serial peripheral interface SPI0.

1.7.2.13.3 MISO0 Signal

This signal is associated with the MISO functionality of the serial peripheral interface SPI0. This signal acts as master input during master mode or as slave output during slave mode.

1.7.2.13.4 MOSI0 Signal

This signal is associated with the MOSI functionality of the serial peripheral interface SPI0. This signal acts as master output during master mode or as slave input during slave mode.

1.7.2.14 SCI[1:0] Signals

1.7.2.14.1 RXD[1:0] Signals

These signals are associated with the receive functionality of the serial communication interfaces (SCI[1:0]).

1.7.2.14.2 TXD[1:0] Signals

These signals are associated with the transmit functionality of the serial communication interfaces (SCI[1:0]).

1.7.2.15 CAN0 Signals

1.7.2.15.1 RXCAN0 Signal

This signal is associated with the receive functionality of the scalable controller area network controller (MSCAN0).

1.7.2.15.2 TXCAN0 Signal

This signal is associated with the transmit functionality of the scalable controller area network controller (MSCAN0).

1.7.2.16 Timer IOC0_[3:0] Signals

The signals IOC0_[3:0] are associated with the input capture or output compare functionality of the timer (TIM0) module.

1.7.2.17 Timer IOC1_[1:0] Signals (ZVMC256 only)

The signals IOC1_[1:0] are associated with the input capture or output compare functionality of the timer (TIM1) module.

1.7.2.18 PWM1_[5:0] Signals

The signals PWM1_[5:0] are associated with the PMF module digital channel outputs.

1.7.2.19 PWM0_[7,5,3,1] Signals (ZVMC256 only)

The PWM0 signals are associated with the PWM0 module digital channel outputs.

1.7.2.20 PTU Signals

1.7.2.20.1 PTUT[1:0] Signals

These signals are the PTU trigger output signals. These signals are routed to pins for debugging purposes.

1.7.2.20.2 PTURE Signal

This signal is the PTU reload enable output signal. This signal is routed to a pin for debugging purposes.

1.7.2.21 Interrupt Signals — $\overline{\text{IRQ}}$ and $\overline{\text{XIRQ}}$

$\overline{\text{IRQ}}$ is a maskable level or falling edge sensitive input. $\overline{\text{XIRQ}}$ is a non-maskable level-sensitive interrupt.

1.7.2.22 Oscillator and Clock Signals

1.7.2.22.1 Oscillator Pins — EXTAL and XTAL

EXTAL and XTAL are the crystal driver and external clock pins. On reset all the device clocks are derived from the internal PLLCLK, independent of EXTAL and XTAL. XTAL is the oscillator output.

1.7.2.22.2 ECLK

This signal is associated with the output of the bus clock (ECLK).

NOTE

This feature is only intended for debug purposes at room temperature. It must not be used for clocking external devices in an application.

1.7.2.23 BDC and Debug Signals

1.7.2.23.1 BKGD — Background Debug signal

The BKGD signal is used as a pseudo-open-drain signal for the background debug communication. The BKGD signal has an internal pull-up device.

1.7.2.23.2 PDO — Profiling Data Output

This is the profiling data output signal used when the DBG module profiling feature is enabled. This signal is output only and provides a serial, encoded data stream that can be used by external development tools to reconstruct the internal CPU code flow.

1.7.2.23.3 PDOCLK — Profiling Data Output Clock

This is the PDO clock signal used when the DBG module profiling feature is enabled. This signal is output only. During code profiling this is the clock signal that can be used by external development tools to sample the PDO signal.

1.7.2.23.4 DBGEEV — External Event Input

This signal is the DBG external event input. It is input only. Within the DBG module, it allows an external event to force a state sequencer transition, or trace buffer entry, or to gate trace buffer entries. A falling edge at the external event signal constitutes an event. Rising edges have no effect. The maximum frequency of events is half the internal core bus frequency.

1.7.2.24 FAULT5 — External Fault Input

This is the PMF fault input signal, with configurable polarity, that can be used to disable PMF operation when asserted. Asynchronous shutdown of the GDU outputs HG[2:0] and LG[2:0] is not supported. Select QSMPm[1:0] > 0 in PMF.

1.7.2.25 LIN Physical Layer Signals (Not Available On ZVMC256)

1.7.2.25.1 LIN0

On S12ZVML derivatives this pad is connected to the single-wire LIN data bus.

On the S12ZVM32 and S12ZVM16 derivatives this is a single pin bidirectional high voltage physical interface. It operates in the VSUP voltage range. It can be connected to an external single-wire data bus.

1.7.2.25.2 LP0TXD

This is the LIN physical layer (or HV physical interface) transmitter input signal.

1.7.2.25.3 LP0RXD

This is the LIN physical layer (or HV physical interface) receiver output signal.

1.7.2.25.4 LP0DR1

This is the LIN (or HV physical interface) LP0DR1 register bit, visible at the designated pin for debug purposes.

1.7.2.25.5 LGND — LINPHY Ground Pin

On S12ZVM(L) parts LGND is the ground pin for the LIN physical layer LINPHY. This signal must be connected to board ground, even if the LINPHY is not used.

On S12ZVM32 and S12ZVM16 parts this the ground pin for the HV physical interface. It must be connected to board ground even when the HV physical interface is not used.

1.7.2.26 CAN Physical Layer Signals (ZVMC256 Only)**1.7.2.26.1 CANH0 — CAN Bus High Pin0**

The CANH0 signal either connects directly to CAN bus high line or through an optional external common mode choke.

1.7.2.26.2 CANL0 — CAN Bus Low Pin0

The CANL0 signal either connects directly to CAN bus low line or through an optional external common mode choke.

1.7.2.26.3 SPLIT0 — CAN Bus Termination Pin0

The SPLIT0 pin can drive a 2.5 V bias for bus termination purpose (CAN bus middle point). Usage of this pin is optional and depends on bus termination strategy for a given bus network.

1.7.2.26.4 CPTXD0

This is the CAN physical layer transmitter input signal.

1.7.2.26.5 CPRXD0

This is the CAN physical layer receiver output signal.

1.7.2.26.6 CPDR0

This is the CAN physical layer direct control output signal.

1.7.2.26.7 BCTLC

BCTLC provides the base current of an external bipolar that supplies an external CAN physical interface. This signal is only available on S12ZVMC versions. If not used BCTLC should be left unconnected.

1.7.2.26.8 VDDC (Only Available On S12ZVMC Versions)

VDDC is the CANPHY supply. This is the output voltage of the external bipolar, whose base current is supplied by BCTL. It is fed back to the MCU for regulation. On the ZVMC128 a diode is recommended between VDDA and VDDC, whereby the anode is connected to VDDC.

1.7.2.26.9 VSSC (Only Available On ZVMC256)

VSSC is the CANPHY ground.

1.7.2.27 Gate Drive Unit (GDU) Signals

These are associated with driving the external FETs.

1.7.2.27.1 HD — FET Predriver High side Drain Input

This is the drain connection of the external high-side FETs. The voltage present at this input is scaled down by an internal voltage divider, and can be routed to the internal ADC via an analog multiplexer.

1.7.2.27.2 VBS[2:0] - Bootstrap Capacitor Connections

These signals are the bootstrap capacitor connections for phases HS[2:0]. The capacitor connected between HS[2:0] and these signals provides the gate voltage and current to drive the external FET.

1.7.2.27.3 HG[2:0] - High-Side Gate signals

The pins are the gate drives for the three high-side power FETs. The drivers provide a high current with low impedance to turn on and off the high-side power FETs.

1.7.2.27.4 HS[2:0] - High-Side Source signals

The pins are the source connection for the high-side power FETs and the drain connection for the low-side power FETs. The low voltage end of the bootstrap capacitor is also connected to this pin.

1.7.2.27.5 VLS[2:0] - Voltage Supply for Low -Side Drivers

The pins are the voltage supply pins for the three low-side FET pre-drivers. These pins should be connected to the voltage regulator output pin VLS_OUT.

1.7.2.27.6 LG[2:0] - Low-Side Gate signals

The pins are the gate drives for the low-side power FETs. The drivers provide a high current with low impedance to turn on and off the low-side power FETs.

1.7.2.27.7 LS[2:0] - Low-Side Source Signals

The pins are the low-side source connections for the low-side power FETs. The pins are the power ground pins used to return the gate currents from the low-side power FETs.

1.7.2.27.8 LD[2:0] - Low-Side Drain Signals (ZVMC256 Only)

The pins are the low-side drain connections for the low-side power FETs. The pins can be used to monitor the low-side power FETs for desaturation conditions.

1.7.2.27.9 CP - Charge Pump Output Signal

This pin is the switching node of the charge pump circuit. The supply voltage for charge pump driver is the output of the voltage regulator VLS_OUT. The output voltage of this pin switches typically between 0V and 11V. Must be left unconnected if not used.

1.7.2.27.10 VCP - Charge Pump Input For High-Side Driver Supply

This is the charge pump input for the FET high-side gate drive supply circuit. The pin must be left unconnected if not used.

1.7.2.27.11 BST - Boost Signal

This pin provides the basic switching elements required to implement a boost converter for low battery voltage conditions. This requires external diodes, capacitors and a coil. This pin must be left unconnected if not used.

The boost function must not be used on devices of the maskset 2N95G, because these devices use the VSUP pin as the LINPHY supply. Thus boosting the VSUP voltage can cause LIN supply voltage offsets to other devices on the LIN bus.

1.7.2.27.12 VSSB - Boost Ground Signal

This pin is a separate ground pin for the on chip boost converter switching device.

1.7.2.27.13 VLS_OUT - 11V Voltage Regulator Output

This pin is the output of the integrated voltage regulator. The output voltage is typically $V_{VLS}=11V$. The input voltage to the voltage regulator is the VSUP pin.

1.7.2.27.14 AMPP[1:0] - Current Sense Amplifier Non-Inverting Input

These are the current sense amplifier non-inverting inputs.

1.7.2.27.15 AMPM[1:0] - Current Sense Amplifier Inverting Input

These are the current sense amplifier inverting inputs.

1.7.2.27.16 AMP[1:0] - Current Sense Amplifier Output

These are the current sense amplifier outputs.

1.7.2.28 High Current Output — EVDD1

This is a high current, low voltage drop output intended for supplying external devices in a range of up to 20mA. Configuring the pin direction as output automatically enables the high current capability.

1.7.3 Power Supply And Voltage Regulator Related Pins

The power and ground pins are described below. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible.

NOTE

All ground pins must be connected together in the application.

1.7.3.1 VDDX1, VDDX2, VSSX1 — Digital I/O Power and Ground Pins

VDDX1, VDDX2 are voltage regulator outputs to supply the digital I/O drivers.

The VSSX1 pin is the ground pin for the digital I/O drivers.

Bypass requirements on VDDX2, VDDX1, VSSX1 depend on how heavily the MCU pins are loaded.

1.7.3.2 BCTL

BCTL is the ballast connection for the on chip voltage regulator. It provides the base current of an external bipolar for the VDDX and VDDA supplies. If not used BCTL should be left unconnected.

1.7.3.3 VDDA, VSSA — Power Supply Pins For ADC

These are the power supply and ground pins for the analog-to-digital converter and the voltage regulator.

1.7.3.4 VDD, VSS2 — Core Power And Ground Pins

The VDD voltage supply of nominally 1.8V is generated by the internal voltage regulator. The return current path is through the VSS1 pin on ZVMC256, or VSS2 pin on other devices.

1.7.3.5 VDDF, VSS1— NVM Power And Ground Pins

The VDDF voltage supply of nominally 2.8V is generated by the internal voltage regulator. The return path is through the VSS1 pin. On ZVMC256, the return current path is through the VSS1 and VSSX pins.

1.7.3.6 VSUP — Voltage Supply Pin for Voltage Regulator

VSUP is the main supply pin typically coming from the car battery/alternator in the 12V supply voltage range. This is the voltage supply input from which the voltage regulator generates the on chip voltage supplies. It must be protected externally against a reverse battery connection.

1.7.3.7 VDDS1 — 5V Supply Pin For External Devices (ZVMC256 Only)

This provides a regulated, short circuit protected, 5V supply for external devices. This is the output voltage of the external bipolar, whose base current is supplied by BCTLS1. It is fed back to the MCU for regulation.

1.7.3.8 BCTLS1 (ZVMC256 Only)

BCTLS1 provides the base current of an external bipolar that supplies VDDS1. If not used BCTLS1 should be left unconnected.

1.7.3.9 SNPS1 (ZVMC256 Only)

SNPS1 is the sense input associated with the VDDS1 regulator. The voltage regulator uses it to detect a short circuit or over current condition.

1.7.3.10 VDDS2 — 5V Supply Pin For External Devices (ZVMC256 Only)

This provides a regulated, short circuit protected, 5V supply for external devices. This is the output voltage of the external bipolar, whose base current is supplied by BCTLS2. It is fed back to the MCU for regulation.

1.7.3.11 BCTLS2 (ZVMC256 Only)

BCTLS2 provides the base current of an external bipolar that supplies VDDS2. If not used BCTLS2 should be left unconnected.

1.7.3.12 SNPS2 (ZVMC256 Only)

SNPS2 is the sense input associated with the VDDS2 regulator. The voltage regulator uses it to detect a short circuit or over current condition.

1.7.4 Package and Pinouts

The following package options are offered.

- 80LQFP-EP (exposed pad) with internal CANPHY and CAN VREG.
- 64LQFP-EP (exposed pad) with internal LINPHY or HV physical interface.
- 64LQFP-EP (exposed pad) with CAN VREG to support a low cost external CANPHY.
- 48LQFP-EP (exposed pad) with internal LINPHY or HV physical interface

The exposed pad must be connected to a grounded contact pad on the PCB.

The exposed pad has an electrical connection within the package to VSSFLAG (VSSX die connection).

The pin out details are shown in the following diagrams. Signals in brackets denote routing options.

The exposed pad on the package bottom must be connected to a grounded contact pad on the PCB.

Figure 1-3. S12ZVMC256 80-pin LQFP pin out

The exposed pad on the package bottom must be connected to a grounded contact pad on the PCB.

On MC9S12ZVM options the LIN0 pin is mapped to the HV physical interface function

IOC0_1 and IOC0_2 can be routed to Port S on the ZVMC256, ZVML31, ZVM32 and ZVM16 devices but not on other devices.

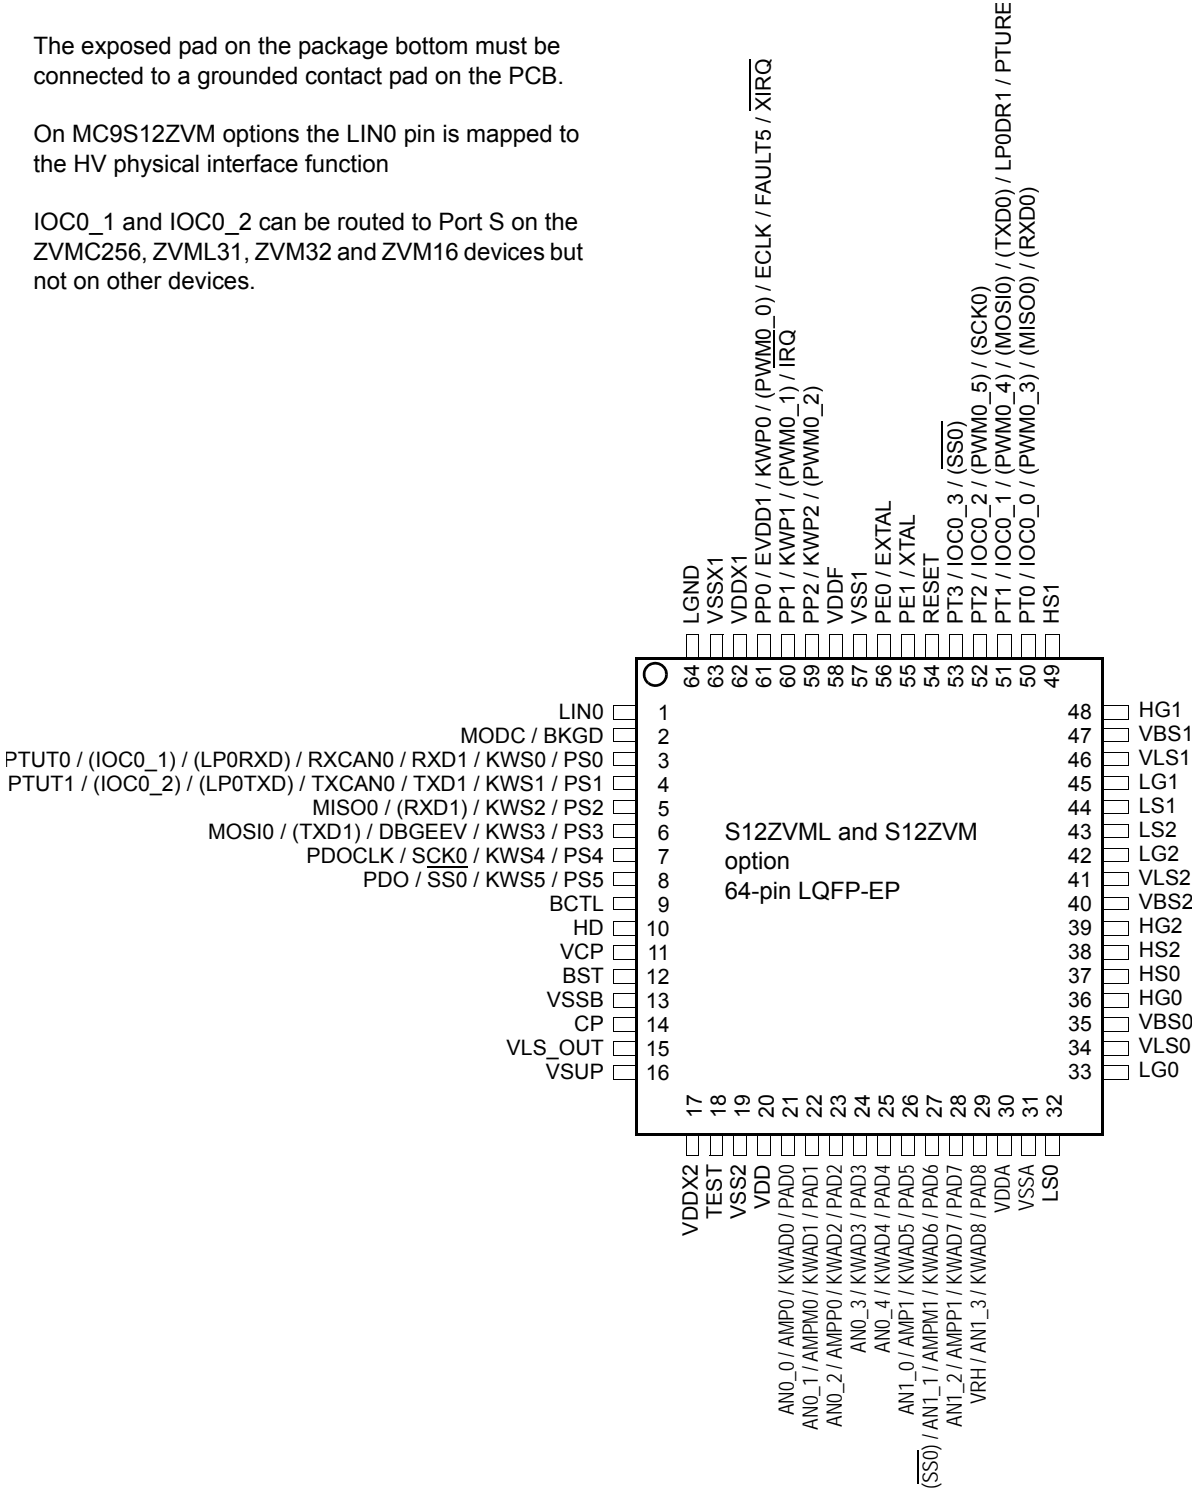

Figure 1-4. S12ZVM and S12ZVM option 64-pin LQFP pin out

The exposed pad on the package bottom must be connected to a grounded contact pad on the PCB.

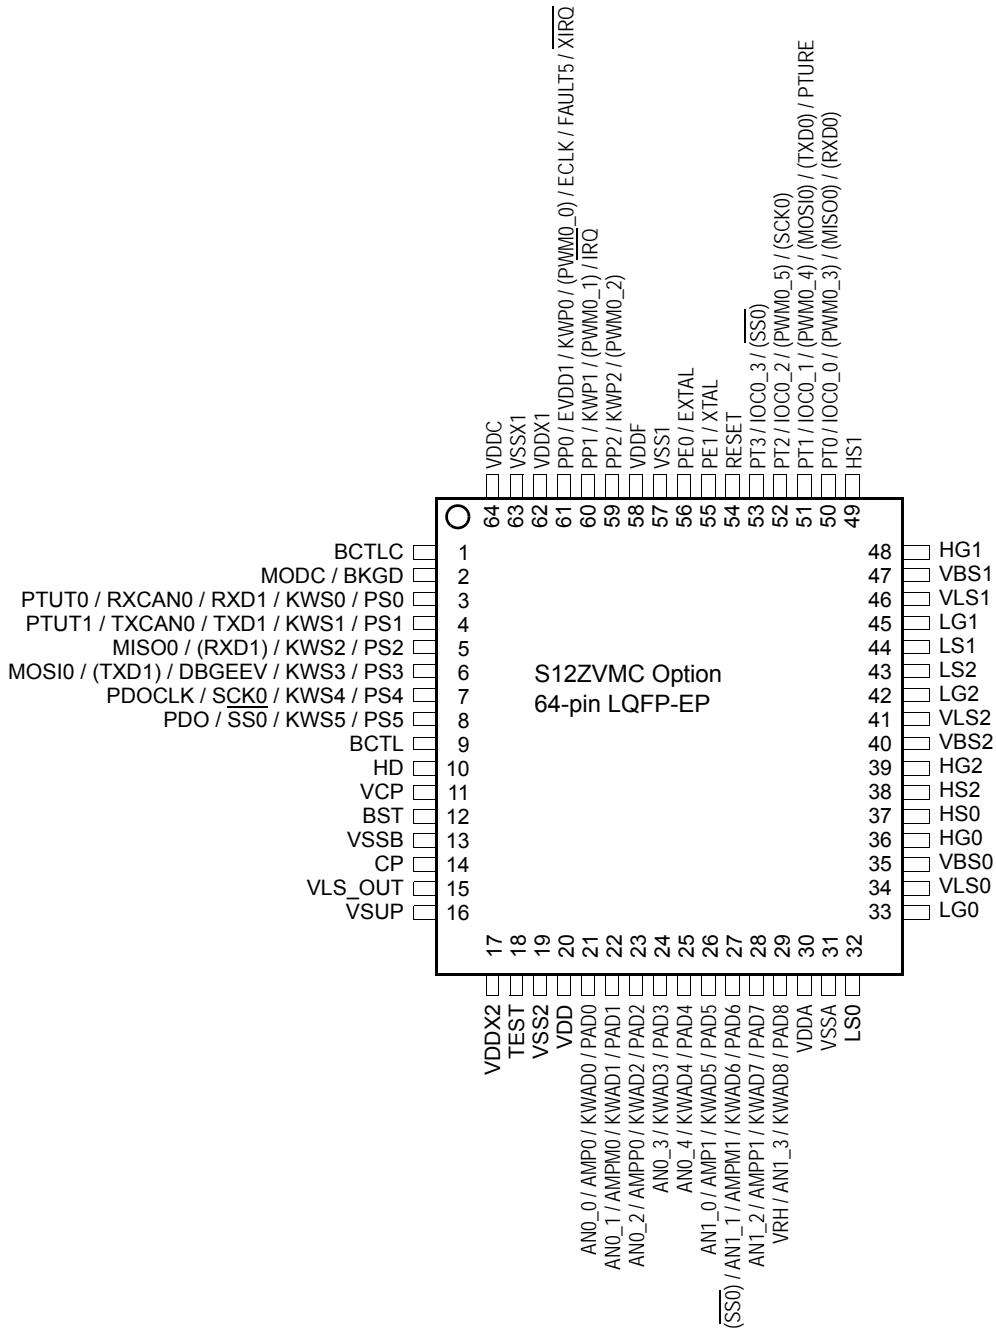

Figure 1-5. S12ZVMC Option 64-pin LQFP pin out

The exposed pad on the package bottom must be connected to a grounded contact pad on the PCB.

The LIN0 pin is mapped to the HV physical interface

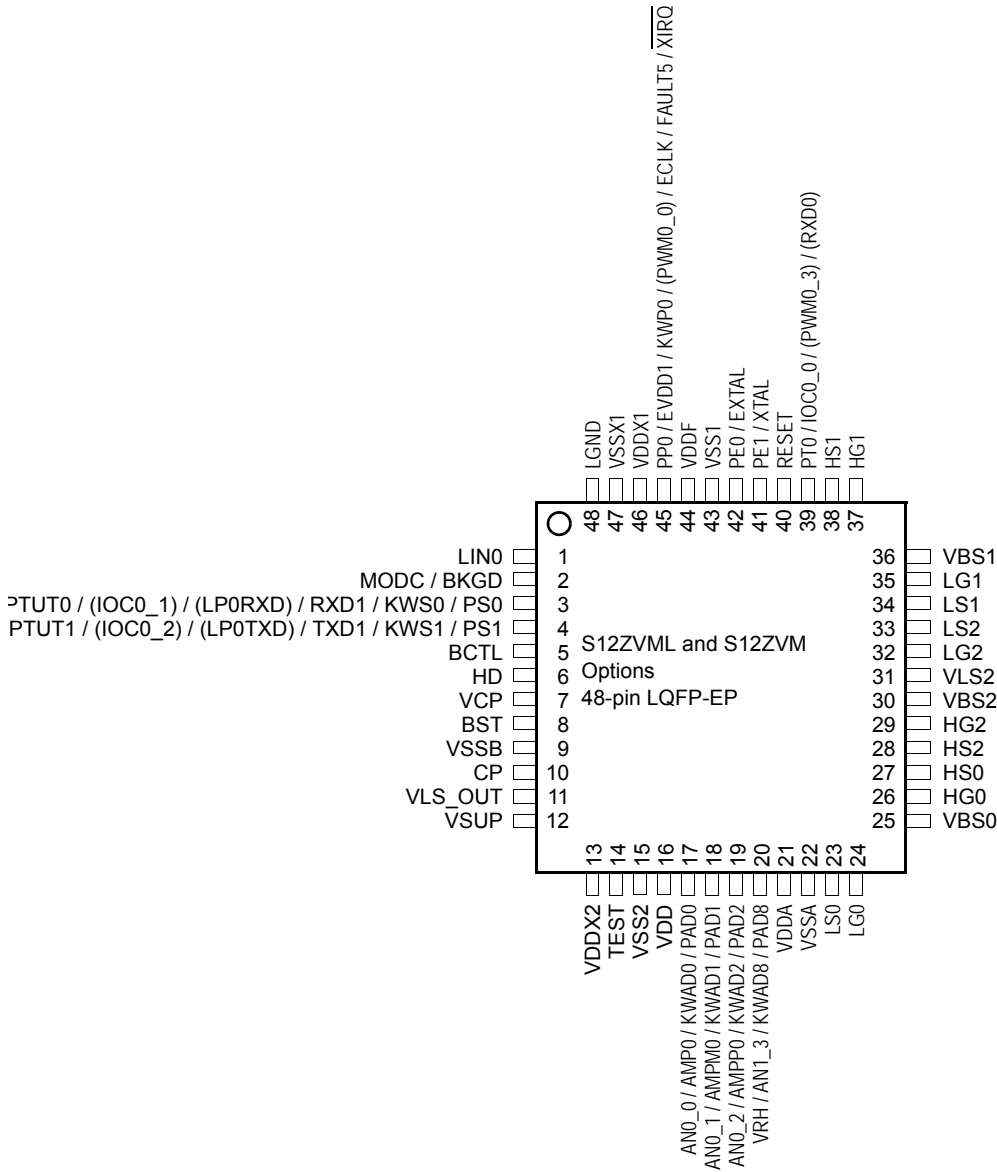

Figure 1-6. S12ZVM, S12ZVML Option 48-pin LQFP

1.8 Internal Signal Mapping

This section specifies the mapping of inter-module signals at device level.

1.8.1 ADC Connectivity

1.8.1.1 ADC Reference Voltages

The ZVMC256 includes ADC12B_LBA V3 which features VRH_2, VRH_1, VRH_0 and VRL_0. On these devices for each ADC instance VRH_0 is mapped to VDDA, VRH_1 is mapped to VDDS1 and VRH_2 is mapped to VDDS2. VRL_0 is mapped to VSSA. Both VDDS1 and VDDS2 must be enabled by bits in the CPMUVREGCTL register before they can be used as references. When using VDDS1 or VDDS2 as VRH reference, the reference is impacted by a voltage drop across the internal short circuit protection switch. This is specified in [Section C.1.1.5](#).

All other devices in the family include ADC12B_LBA V1, which features VRH_1, VRH_0, VRL_1 and VRL_0. On these devices, for both ADC instances, VRL_0 and VRL_1 are mapped to VSSA, whereby VRL_0 is the preferred reference for low noise. For both ADC instances VRH_1 is mapped to VDDA and VRH_0 is mapped to PAD8.

1.8.1.2 ADC Internal Channels

The ADC0 and ADC1 internal channel mapping is shown in [Table 1-10](#) and [Table 1-11](#) respectively.

The GDU current sense amplifier outputs are mapped to pins with ADC input functionality. Thus configuring the ADC to convert these pin channels automatically converts the current sense outputs.

The ADC internal temperature sensors must be calibrated by the user. No electrical parameters are specified for these sensors. The VREG temperature sensor electrical parameters are given in the appendices.

Table 1-10. Usage of ADC0 Internal Channels

ADCCMD_1 CH_SEL[5:0]						ADC Channel	Usage
0	0	1	0	0	0	Internal_0	ADC0 temperature sensor
0	0	1	0	0	1	Internal_1	VREG temperature sensor or bandgap (V_{BG}) ⁽¹⁾
0	0	1	0	1	0	Internal_2	GDU phase multiplexer voltage
0	0	1	0	1	1	Internal_3	GDU DC link voltage monitor
0	0	1	1	0	0	Internal_4	BATS VSUP sense voltage
0	0	1	1	0	1	Internal_5	HVI[0] ⁽²⁾
0	0	1	1	1	0	Internal_6	Reserved
0	0	1	1	1	1	Internal_7	Reserved

1. Selectable in CPMU

2. ZVMC256 only. On other devices this channel is reserved.

Table 1-11. Usage of ADC1 Internal Channels

ADCCMD_1 CH_SEL[5:0]						ADC Channel	Usage
0	0	1	0	0	0	Internal_0	ADC1 temperature sensor
0	0	1	0	0	1	Internal_1	VREG temperature sensor or bandgap (V_{BG}) ⁽¹⁾
0	0	1	0	1	0	Internal_2	GDU phase multiplexer voltage
0	0	1	0	1	1	Internal_3	GDU DC link voltage monitor
0	0	1	1	0	0	Internal_4	Reserved
0	0	1	1	0	1	Internal_5	Reserved
0	0	1	1	1	0	Internal_6	Reserved
0	0	1	1	1	1	Internal_7	Reserved

1. Selectable in CPMU

1.8.2 Motor Control Loop Signals

The motor control loop signals are described in [1.13.3.1 Motor Control Loop Overview](#)

1.8.3 Device Level PMF Connectivity

Table 1-12. Mapping of PMF signals

PMF Connection	Usage
Channel0	High-Side Gate and Source Pins HG[0], HS[0]
Channel1	Low-Side Gate and Source Pins LG[0], LS[0]
Channel2	High-Side Gate and Source Pins HG[1], HS[1]
Channel3	Low-Side Gate and Source Pins LG[1], LS[1]
Channel4	High-Side Gate and Source Pins HG[2], HS[2]
Channel5	Low-Side Gate and Source Pins LG[2], LS[2]
FAULT5	External FAULT5 pin
FAULT4	HD Over voltage or GDU over current
FAULT3	VLS under voltage
FAULT2	GDU Desaturation[2] or GDU over current
FAULT1	GDU Desaturation[1] or GDU over current
FAULT0	GDU Desaturation[0] or GDU over current
IS2	GDU Phase Status[2]
IS1	GDU Phase Status[1]
IS0	GDU Phase Status[0]
async_event_edge_sel[1:0]	Tied to b11 (both edges active)

1.8.4 BDC Clock Source Connectivity

The BDC clock, BDCCLK, is mapped to the IRCCLK generated in the CPMU module.

The BDC clock, BDCFCLK is mapped to the device bus clock, generated in the CPMU module.

1.8.5 LINPHY Connectivity

The VLINSUP supply is device dependent.

On ZVML128, ZVMC128, ZVML64, ZVMC64 and ZVML32 devices with the maskset number 2N95G it is connected to VSUP

On all other devices it is connected to the device HD pin.

The LINPHY0 signals are mapped internally to SCI0. The receiver can be routed to TIM0 input capture channel3. These routing options are described in detail in the PIM section.

1.8.6 HVPHY Connectivity

The HVPHY signals (S12ZVM32 and S12ZVM16 derivatives only) are mapped internally to SCI0. The receiver can be routed to TIM0 input capture channel3.

1.8.7 FTMRZ Connectivity

The soc_erase_all_req input to the flash module is driven directly by a BDC erase flash request resulting from the BDC ERASE_FLASH command.

The FTMRZ FCLKDIV register is forced to 0x05 by the BDC ERASE_FLASH command. This configures the clock frequency correctly for the initial bus frequency on leaving reset. The bus frequency must not be changed before launching the ERASE_FLASH command.

The device bus frequency, below which the flash wait states can be disabled, is specified in the device operating conditions table in [Table A-6](#).

1.8.8 CPMU Connectivity

The API clock generated in the CPMU is not mapped to a device pin in the MC9S12ZVM-Family.

1.9 Modes of Operation

The MCU can operate in different modes. These are described in [1.9.1 Chip Configuration Modes](#).

The MCU can operate in different power modes to facilitate power saving when full system performance is not required. These are described in [1.9.3 Low Power Modes](#).

Some modules feature a software programmable option to freeze the module status whilst the background debug module is active to facilitate debugging. This is referred to as freeze mode at module level.

1.9.1 Chip Configuration Modes

The different modes and the security state of the MCU affect the debug features (enabled or disabled).

The operating mode out of reset is determined by the state of the MODC signal during reset ([Table 1-13](#)). The MODC bit in the MODE register shows the current operating mode and provides limited mode switching during operation. The state of the MODC signal is latched into this bit on the rising edge of $\overline{\text{RESET}}$.

Table 1-13. Chip Modes

Chip Modes	MODC
Normal single chip	1
Special single chip	0

1.9.1.1 Normal Single-Chip Mode

This mode is intended for normal device operation. The opcode from the on-chip memory is being executed after reset (requires the reset vector to be programmed correctly). The processor program is executed from internal memory.

1.9.1.2 Special Single-Chip Mode

This mode is used for debugging operation, boot-strapping, or security related operations. The background debug mode (BDM) is active on leaving reset in this mode

1.9.2 Debugging Modes

The background debug mode (BDM) can be activated by the BDC module or directly when resetting into Special Single-Chip mode. Detailed information can be found in the BDC module section.

Writing to internal memory locations using the debugger, whilst code is running or at a breakpoint, can change the flow of application code.

The MC9S12ZVM-Family supports BDC communication throughout the device Stop mode. During Stop mode, writes to control registers can alter the operation and lead to unexpected results. It is thus recommended not to reconfigure the peripherals during STOP using the debugger.

On the S12ZVML and S12ZVMC versions, the DBG module supports breakpoint, tracing and profiling features. At board level the profiling pins can use the same 6-pin connector typically used for the BDC BKGD pin. The connector pin mapping shown in [Figure 1-7](#) is supported by device evaluation boards and leading development tool vendors.

GND	2	1	BKGD
RST	4	3	PDO
VDDX	6	5	PDOCLK

Figure 1-7. Standard Debug Connector Pin Mapping

1.9.3 Low Power Modes

The device has two dynamic-power modes (run and wait) and two static low-power modes (stop and pseudo stop). For a detailed description refer to the CPMU section.

- Dynamic power mode: Run
 - Run mode is the main full performance operating mode with the entire device clocked. The user can configure the device operating speed through selection of the clock source and the phase locked loop (PLL) frequency. To save power, unused peripherals must not be enabled.
- Dynamic power mode: Wait
 - This mode is entered when the CPU executes the WAI instruction. In this mode the CPU does not execute instructions. The internal CPU clock is switched off. All peripherals can be active in system wait mode. For further power consumption the peripherals can individually turn off their local clocks. Asserting `RESET`, `XIRQ`, `IRQ`, or any other interrupt that is not masked, either locally or globally by a CCR bit, ends system wait mode.
- Static power modes:
 - Static power (Stop) modes are entered following the CPU STOP instruction unless an NVM command is active. When no NVM commands are active, the Stop request is acknowledged and

the device enters either Stop or Pseudo Stop mode. Further to the general system aspects of Stop mode discussed here, the motor control loop specific considerations are described in [Section 1.13.3.10](#).

- Pseudo-stop: In this mode the system clocks are stopped but the oscillator is still running and the real time interrupt (RTI), watchdog (COP) and Autonomous Periodic Interrupt (API) may be enabled. Other peripherals are turned off. This mode consumes more current than system STOP mode but, as the oscillator continues to run, the full speed wake up time from this mode is significantly shorter.
- Stop: In this mode the oscillator is stopped and clocks are switched off. The counters and dividers remain frozen. The autonomous periodic interrupt (API) may remain active but has a very low power consumption. The key pad, SCI and MSCAN transceiver modules can be configured to wake the device, whereby current consumption is negligible.
If the BDC is enabled in Stop mode, the VREG remains in full performance mode and the CPMU continues operation as in run mode. With BDC enabled and BDCCIS bit set, then all clocks remain active to allow BDC access to internal peripherals. If the BDC is enabled and BDCCIS is clear, then the BDCSI clock remains active, but bus and core clocks are disabled. With the BDC enabled during Stop, the VREG full performance mode and clock activity lead to higher current consumption than with BDC disabled. If the BDC is enabled in Stop mode, then the BATS voltage monitoring remains enabled.

1.10 Security

The MCU security mechanism prevents unauthorized access to the flash memory. It must be emphasized that part of the security must lie with the application code. An extreme example would be application code that dumps the contents of the internal memory. This would defeat the purpose of security. Also, if an application has the capability of downloading code through a serial port and then executing that code (e.g. an application containing bootloader code), then this capability could potentially be used to read the EEPROM and Flash memory contents even when the microcontroller is in the secure state. In this example, the security of the application could be enhanced by requiring a response authentication before any code can be downloaded.

Device security details are also described in the flash block description.

1.10.1 Features

The security features of the S12Z chip family are:

- Prevent external access of the non-volatile memories (Flash, EEPROM) content
- Restrict execution of NVM commands

1.10.2 Securing the Microcontroller

The chip can be secured by programming the security bits located in the options/security byte in the Flash memory array. These non-volatile bits keep the device secured through reset and power-down.

This byte can be erased and programmed like any other Flash location. Two bits of this byte are used for security (SEC[1:0]). The contents of this byte are copied into the Flash security register (FSEC) during a reset sequence.

The meaning of the security bits SEC[1:0] is shown in Table 1-14. For security reasons, the state of device security is controlled by two bits. To put the device in unsecured mode, these bits must be programmed to SEC[1:0] = '10'. All other combinations put the device in a secured mode. The recommended value to put the device in secured state is the inverse of the unsecured state, i.e. SEC[1:0] = '01'.

Table 1-14. Security Bits

SEC[1:0]	Security State
00	1 (secured)
01	1 (secured)
10	0 (unsecured)
11	1 (secured)

NOTE

Please refer to the Flash block description for more security byte details.

1.10.3 Operation of the Secured Microcontroller

By securing the device, unauthorized access to the EEPROM and Flash memory contents is prevented. Secured operation has the following effects on the microcontroller:

1.10.3.1 Normal Single Chip Mode (NS)

- Background debug controller (BDC) operation is completely disabled.
- Execution of Flash and EEPROM commands is restricted (described in flash block description).

1.10.3.2 Special Single Chip Mode (SS)

- Background debug controller (BDC) commands are restricted
- Execution of Flash and EEPROM commands is restricted (described in flash block description).

In special single chip mode the device is in active BDM after reset. In special single chip mode on a secure device, only the BDC mass erase and BDC control and status register commands are possible. BDC access to memory mapped resources is disabled. The BDC can only be used to erase the EEPROM and Flash memory without giving access to their contents.

1.10.4 Unsecuring the Microcontroller

Unsecuring the microcontroller can be done using three different methods:

1. Backdoor key access
2. Reprogramming the security bits
3. Complete memory erase

1.10.4.1 Unsecuring the MCU Using the Backdoor Key Access

In normal single chip mode, security can be temporarily disabled using the backdoor key access method. This method requires that:

- The backdoor key has been programmed to a valid value
- The KEYEN[1:0] bits within the Flash options/security byte select 'enabled'.
- The application program programmed into the microcontroller has the capability to write to the backdoor key locations

The backdoor key values themselves would not normally be stored within the application data, which means the application program would have to be designed to receive the backdoor key values from an external source (e.g. through a serial port)

The backdoor key access method allows debugging of a secured microcontroller without having to erase the Flash. This is particularly useful for failure analysis.

NOTE

No backdoor key word is allowed to have the value 0x0000 or 0xFFFF.

1.10.5 Reprogramming the Security Bits

Security can also be disabled by erasing and reprogramming the security bits within the flash options/security byte to the unsecured value. Since the erase operation will erase the entire sector (0xFF_FE00–0xFF_FFFF) the backdoor key and the interrupt vectors will also be erased; this method is not recommended for normal single chip mode. The application software can only erase and program the Flash options/security byte if the Flash sector containing the Flash options/security byte is not protected (see Flash protection). Thus Flash protection is a useful means of preventing this method. The microcontroller enters the unsecured state after the next reset following the programming of the security bits to the unsecured value.

This method requires that:

- The application software previously programmed into the microcontroller has been designed to have the capability to erase and program the Flash options/security byte.
- The Flash sector containing the Flash options/security byte is not protected.

1.10.6 Complete Memory Erase

The microcontroller can be unsecured by erasing the entire EEPROM and Flash memory contents. If ERASE_FLASH is successfully completed, then the Flash unsecures the device and programs the security byte automatically.

1.11 Resets and Interrupts

1.11.1 Reset

Table 1-15. lists all reset sources and the vector locations. Resets are explained in detail in the [Chapter 8](#), “S12 Clock, Reset and Power Management Unit (V10 and V6)”.

Table 1-15. Reset Sources and Vector Locations

Vector Address	Reset Source	CCR Mask	Local Enable
0xFFFFFC	Power-On Reset (POR)	None	None
	Low Voltage Reset (LVR)	None	None
	External pin $\overline{\text{RESET}}$	None	None
	PLL clock monitor reset	None	None
	Oscillator Clock monitor reset	None	OSCE in CPMUOSC register OMRE in CPMUOSC2 register
	COP watchdog reset	None	CR[2:0] in CPMUCOP register

1.11.2 Interrupt Vectors

[Table 1-16](#) lists all interrupt sources and vectors in the default order of priority. The interrupt module description provides an interrupt vector base register (IVBR) to relocate the vectors.

Table 1-16. Interrupt Vector Locations

Vector Address ⁽¹⁾	Interrupt Source	CCR Mask	Local Enable	Wake up from STOP	Wake up from WAIT
Vector base + 0x1F8	Unimplemented page1 op-code trap (SPARE)	None	None	-	-
Vector base + 0x1F4	Unimplemented page2 op-code trap (TRAP)	None	None	-	-
Vector base + 0x1F0	Software interrupt instruction (SWI)	None	None	-	-
Vector base + 0x1EC	System call interrupt instruction (SYS)	None	None	-	-
Vector base + 0x1E8	Machine exception	None	None	-	-
Vector base + 0x1E4	Reserved				
Vector base + 0x1E0	Reserved				
Vector base + 0x1DC	Spurious interrupt	—	None	-	-
Vector base + 0x1D8	$\overline{\text{XIRQ}}$ interrupt request	X bit	None	Yes	Yes
Vector base + 0x1D4	$\overline{\text{IRQ}}$ interrupt request	I bit	IRQCR(IRQEN)	Yes	Yes
Vector base + 0x1D0	RTI time-out interrupt	I bit	CPMUINT (RTIE)	See CPMU section	Yes

Table 1-16. Interrupt Vector Locations

Vector Address ⁽¹⁾	Interrupt Source	CCR Mask	Local Enable	Wake up from STOP	Wake up from WAIT
Vector base + 0x1CC	TIM0 timer channel 0	I bit	TIM0TIE (C0I)	No	Yes
Vector base + 0x1C8	TIM0 timer channel 1	I bit	TIM0TIE (C1I)	No	Yes
Vector base + 0x1C4	TIM0 timer channel 2	I bit	TIM0TIE (C2I)	No	Yes
Vector base + 0x1C0	TIM0 timer channel 3	I bit	TIM0TIE (C3I)	No	Yes
Vector base + 0x1BC to Vector base + 0x1B0	Reserved				
Vector base + 0x1AC	TIM0 timer overflow	I bit	TIM0TSCR2(TOI)	No	Yes
Vector base + 0x1A8 to Vector base + 0x1A4	Reserved				
Vector base + 0x1A0	SPI0	I bit	SPI0CR1 (SPIE, SPTIE)	No	Yes
Vector base + 0x19C	SCI0	I bit	SCI0CR2 (TIE, TCIE, RIE, ILIE) SCI0ACR1 (RXEDGIE, BERRIE, BKDIE)	RXEDIF only	Yes
Vector base + 0x198	SCI1	I bit	SCI1CR2 (TIE, TCIE, RIE, ILIE) SCI1ACR1 (RXEDGIE, BERRIE, BKDIE)	RXEDIF only	Yes
Vector base + 0x194	Reserved				
Vector base + 0x190	Reserved				
Vector base + 0x18C	ADC0 Error	I bit	ADC0EIE (IA_EIE, CMD_EIE, EOL_EIE, TRIG_EIE, RSTAR_EIE, LDOK_EIE) ADC0IE(CONIF_OIE)	No	Yes
Vector base + 0x188	ADC0 conversion sequence abort	I bit	ADC0IE(SEQAD_IE)	No	Yes
Vector base + 0x184	ADC0 conversion complete	I bit	ADC0CONIE[15:0]	No	Yes
Vector base + 0x180	Oscillator status interrupt	I bit	CPMUINT (OSCIE)	No	Yes
Vector base + 0x17C	PLL lock interrupt	I bit	CPMUINT (LOCKIE)	No	Yes
Vector base + 0x178 to Vector base + 0x174	Reserved				
Vector base + 0x170	RAM error	I bit	EECIE (SBEEIE)	No	Yes
Vector base + 0x16C to Vector base + 0x168	Reserved				
Vector base + 0x164	FLASH error	I bit	FERCNFG (SFDIE)	No	Yes
Vector base + 0x160	FLASH command	I bit	FCNFG (CCIE)	No	Yes

Table 1-16. Interrupt Vector Locations

Vector Address ⁽¹⁾	Interrupt Source	CCR Mask	Local Enable	Wake up from STOP	Wake up from WAIT
Vector base + 0x15C	CAN0 wake-up	I bit	CAN0RIER (WUPIE)	Yes	Yes
Vector base + 0x158	CAN0 errors	I bit	CAN0RIER (CSCIE, OVRIE)	No	Yes
Vector base + 0x154	CAN0 receive	I bit	CAN0RIER (RXFIE)	No	Yes
Vector base + 0x150	CAN0 transmit	I bit	CAN0TIER (TXEIE[2:0])	No	Yes
Vector base + 0x14C to Vector base + 0x148	Reserved				
Vector base + 0x144	LINPHY over-current interrupt	I bit	LPPIE (LPDTIE, LPOCIE)	No	Yes
Vector base + 0x140	BATS supply voltage monitor interrupt	I bit	BATIE (BVHIE, BVLIE)	No	Yes
Vector base + 0x13C	GDU Desaturation Error	I bit	GDUIE (GDSEIE)	No	Yes
Vector base + 0x138	GDU Voltage Limit Detected	I bit	GDUIE (GOCIE, GHHDIE, GLVLSIE)	No	Yes
Vector base + 0x134 to Vector base + 0x12C	Reserved				
Vector base + 0x128	CAN Physical Layer (ZVMC256 Only)	I bit	CPIE (CPVFIE, CPOCIE, CPDTIE)	No	Yes

1.11.3 Effects of Reset

When a reset occurs, MCU registers are initialized. Refer to the respective block sections for register reset states. The initialization of I/O pins is specified in the PIM section.

On each reset, the Flash module executes a reset sequence to load Flash configuration registers. If double faults are detected in the reset phase, Flash module protection and security may be active on leaving reset. This is explained in more detail in the Flash module description. If a reset occurs while any Flash command

is in progress, that command will be immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed.

The system RAM arrays, including their ECC syndromes, are initialized following a power on reset. All other RAM arrays are not initialized out of any type of reset. With the exception of a power-on-reset the RAM content is unaltered by a reset occurrence.

The power on reset sequence including flash and SRAM initialization is shown in [Figure 1-8](#)

Figure 1-8. Device Power On Reset Sequence

1.12 Module device level dependencies

1.12.1 CPMU COP and GDU Configuration

The COP time-out rate bits CR[2:0] and the WCOP bit in the CPMUCOP register are loaded from the Flash configuration field byte at global address 0xFF_FE0E during the flash initialization phase of the

reset sequence. The GSUF bit in the GDUF register is also loaded during the reset sequence. See [Table 1-17](#), [Table 1-18](#) and [Table 1-19](#).

Table 1-17. Initial COP Rate Configuration

NV[2:0] in FOPT Register	CR[2:0] in CPMUCOP Register
000	111
001	110
010	101
011	100
100	011
101	010
110	001
111	000

Table 1-18. Initial WCOP Configuration

NV[3] in FOPT Register	WCOP in CPMUCOP Register
1	0
0	1

Table 1-19. GDU Configuration

Mask Set	GSUF (GDUF[7]) Initialization	EPRES (GDUE[5]) Inclusion	GDUCTR1 Available bits	HD nominal over-voltage time constant
0N95G, 1N95G	1	Not usable	None	300ns
2N95G	0	Not usable	None	2.7us
3N95G	FOPT:NV[6]	Not included	GDUCTR1[0]	2.7us
0N14N	1	Not included	None	2.7us
1N14N	$\overline{\text{FOPT:NV[7]}}$ ⁽¹⁾	Not included	None	2.7us
0N00R, 1N00R	$\overline{\text{FOPT:NV[7]}}$ ⁽¹⁾	Not included	GDUCTR1[7,6,0]	2.7us

1. Note bit inversion

The EPRES bit was only included in early mask sets but was not usable. The implementation of GDUCTR1 register bits is also mask set dependent as shown in [Table 1-19](#).

1.12.2 CPMU High Temperature Trimming

The value loaded from the flash into the CPMUHTTR register is a default value for the device family. There is no device specific trimming carried out during production. The specified V_{HT} value is a typical value that is part dependent and should thus be calibrated.

1.12.3 CPMU VDDC enable

On the ZVMC256 device, if the CANPHY is not used then the VDDC regulator can be disabled by clearing EXTCON. An external VDDC capacitor is however still required for power up.

1.12.4 Flash IFR Mapping

Table 1-20. Flash IFR Mapping

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	IFR Byte Address
					ADC0 reference conversion using VRH_1/VSSA											0x1F_C040 & 0x1F_C041
					ADC0 reference conversion using VRH_0/VSSA											0x1F_C042 & 0x1F_C043
					ADC1 reference conversion using VRH_1/VSSA											0x1F_C044 & 0x1F_C045
					ADC1 reference conversion using VRH_0/VSSA											0x1F_C046 & 0x1F_C047

1.13 Application Information

1.13.1 ADC Calibration

For applications that do not provide external ADC reference voltages, the VDDA/VSSA supplies can be used as sources for VRH/VRL respectively. Since the VDDA must be connected to VDDX at board level in the application, the accuracy of the VDDA reference is limited by the internal voltage regulator accuracy. In order to compensate for VDDA reference voltage variation in this case, the reference voltage is measured during production test using the internal reference voltage V_{BG} which has a narrow variation over temperature and external voltage supply. V_{BG} is mapped to an internal channel of each ADC module (Table 1-10, Table 1-11). The resulting 12-bit right justified ADC conversion results of V_{BG} are stored to the flash IFR for reference, as listed in Table 1-20.

The measurement conditions of the reference conversion are listed in the device electrical parameters appendix. By measuring the voltage V_{BG} in the application environment and comparing the result to the reference value in the IFR, it is possible to determine the current ADC reference voltage V_{RH} :

$$V_{RH} = \frac{\text{StoredReference}}{\text{ConvertedReference}} \cdot 5V$$

The exact absolute value of an analog conversion can be determined as follows:

$$\text{Result} = \text{ConvertedADInput} \cdot \frac{\text{StoredReference} \cdot 5V}{\text{ConvertedReference} \cdot 2^n}$$

With:

ConvertedADInput:	Result of the analog to digital conversion of the desired pin
ConvertedReference:	Result of internal channel conversion

StoredReference:	Value in IFR location
n:	ADC resolution (12 bit)

NOTE

The ADC reference voltage V_{RH} must remain at a constant level throughout the conversion process.

1.13.2 SCI Baud Rate Detection

The baud rate for SCI0 and SCI1 is achieved by using a timer channel to measure the data rate on the RXD signal.

1. Establish the link:
 - For SCI0: Set [T0IC3RR1:T0IC3RR0]=0b01 to disconnect IOC0_3 from TIM0 input capture channel 3 and reroute the timer input to the RXD0 signal of SCI0.
 - For SCI1: Set [T0IC3RR1:T0IC3RR0]=0b10 to disconnect IOC0_3 from TIM0 input capture channel 3 and reroute the timer input to the RXD1 signal of SCI1.
2. Determine pulse width of incoming data: Configure TIM0 IC3 to measure time between incoming signal edges.

1.13.3 Motor Control Application Overview

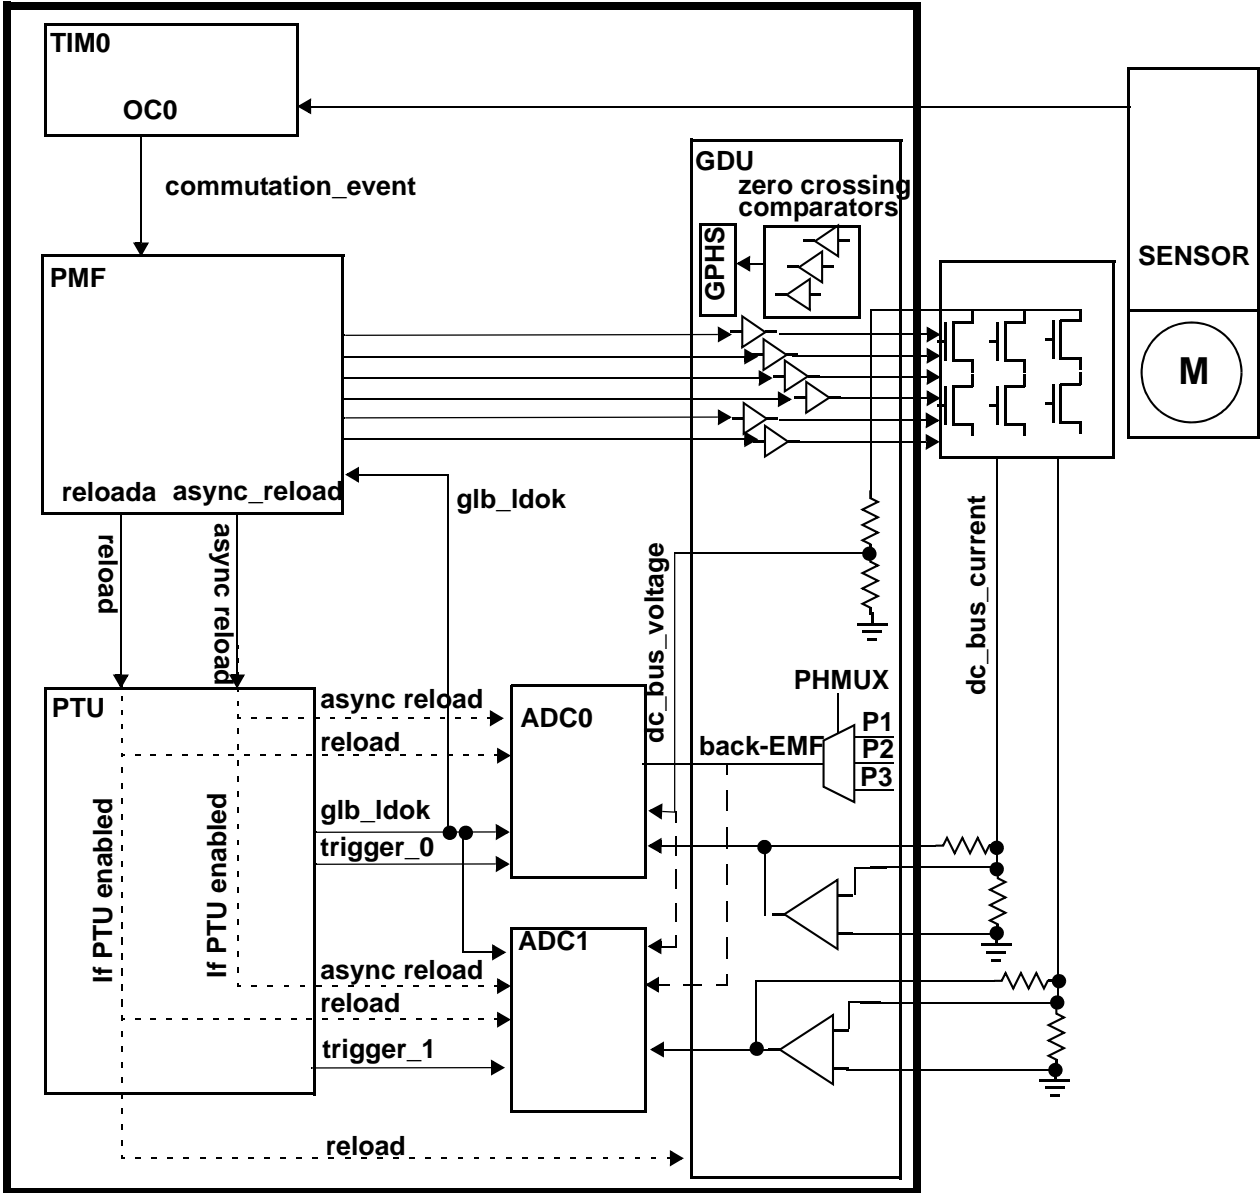

The following sections provide information for using the device in motor control applications. These sections provide a description of motor control loop considerations that are not detailed in the individual module sections, since they concern device level inter module operation specific for motor control. More detailed information is available in application notes. The applications described are as follows:

1. BDCM - wiper pumps fans
2. BLDCM - pumps, fans and blowers
 - based on Hall sensors
 - sensorless based on back-EMF zero crossing comparators
 - sensorless based on back-EMF ADC measurements
3. PMSM - high-end wiper, pumps, fans and blowers
 - simple sinewave commutation with position sensor Hall effect, sine-cos
 - FOC with sine-cos position sensor
 - sensorless 3-phase sinewave control

1.13.3.1 Motor Control Loop Overview

The mapping of motor control events at device level as depicted in Figure 1-9 is listed in Table 1-21, whereby the columns list the names used in the module level descriptions

Figure 1-9. Internal Control Loop Configuration

The control loop consists of the PMF, GDU, ADC and PTU modules. The control loop operates using either static, dynamic or asynchronous timing. In the following text the event names given in **bold type** correspond to those shown in Figure 1-9. The PTU and ADC operate using lists stored in memory. These lists define trigger points for the PTU, commands for the ADC and results from the ADC. If the PTU is enabled the reload and async_reload events are immediately passed through to the ADC and GDU modules.

Table 1-21. Control Loop Events

Device Level Event	TIM0	PMF	PTU	ADC0	ADC1
commutation_event	OC0 ⁽¹⁾	commutation_event	—	—	—
reload	—	reloada ⁽²⁾	reload	Restart	Restart
async_reload	—	async_reload	async_reload	Seq_abort	Seq_abort
trigger_0	—	—	trigger_0	Trigger	—
trigger_1	—	—	trigger_1	—	Trigger
glb_ldok	—	glb_ldok	glb_ldok	LoadOK	LoadOK

1. TIM channel OC0 must be configured to toggle on both edges.

2. PMF events reloada and reloadb are not connected at device level

Each control loop cycle is started by a PMF **reload** event. The PMF reload event restarts the PTU time base. If the PTU is enabled, the reload is immediately passed through to the ADC and GDU modules.

The PMF generates the **reload** event at the required PWM reload frequency. The PMF reload event causes the PTU time base to restart, to acquire the first trigger times from the list and the ADCs to start loading the ADC conversion command from the Command Sequence List (CSL).

NOTE

In the PTU there is time window after the **reload** event assertion before the first trigger is permitted. This time can be up to 10 bus cycles.

Subsequent triggers also require a load time of 6 bus clock cycles (one trigger generator enabled) or 10 bus clock cycles (both trigger generators enabled). This defines the minimal spacing between triggers without causing a PTU trigger generator timing error.

In the ADC there is 10 bus cycle maximum time window after the **reload** event assertion to access the first ADC command from the list. In this window the ADC conversion can not be started. If the measurement is control loop related these delays are negligible due to much larger delays in the PWM-GDU-feedback loop.

When the trigger time is encountered the corresponding PTU trigger generates the **trigger_x** event for the associated ADC. For simultaneous sampling the PTU generates simultaneous **trigger_x** events for both ADCs. At the **trigger_x** event the ADC starts the first conversion of the next conversion sequence in the CSL (the first ADC command is already downloaded).

A commutation event is used by the PMF to generate an **async_reload** event. The **async_reload** is used by the PTU to update lists and re-initialize the trigger lists. If the PTU is enabled the **async_reload** is immediately passed through to the ADC.

1.13.3.2 Control Loop Timing Considerations

Delays within the separate control loop elements require consideration to ensure correct synchronization.

Regarding the raw PWM0 signal as the starting point and stepping through the control loop stages, the factors shown in [Figure 1-10](#) contribute to delays within the control loop, starting with the deadtime insertion, going through the external FETs and back into the internal ADC measurements of external voltages and currents.

Figure 1-10. Control Loop Delay Overview

The PWM deadtime (T_{DEAD_X}) is an integral number of bus clock cycles, configured by the PMF deadtime registers.

The GDU propagation delays (t_{delon} , t_{deloff}) are specified in the electrical parameter [Table E-1](#).

The FET turn on times (t_{HGON}) are load dependent but are specified for particular loads in the electrical parameter [Table E-1](#).

The current sense amplifier delay is highly dependent on external components.

The ADC delay until a result is available is specified as the conversion period N_{CONV} in [Table C-1](#).

1.13.3.3 Static Timing Operation

The timing frame is static if it is the same in every control cycle (defined by reload frequency) and is relative to start of the control cycle. The only settings modified from one control cycle to the next one are the PWM duty cycle registers.

The main control cycle synchronization event is the PMF **reload** event. The PMF **reload** event can be generated every n PWM periods.

This mode can optionally be extended by a timer channel trigger to PMF to change the PWM channel operation (e.g. used for BLDCM commutation). In this case, the PMF configuration can propagate the

trigger through the control loop or can prevent propagation so the static timing of the control cycle and inter-block coherency are not affected by the trigger.

At the end of the conversion sequence the first ADC command from the new sequence is loaded and the ADC_x waits for the next **trigger_x**. The PTU continues to generate the **trigger_x** events for each trigger time from the list until a new **reload** or **async_reload** occurs.

Before the upcoming **reload** event the CPU:

- reads the ADC results from the buffered Conversion Result List
- clears the conversion complete flag
- services the **reload** by setting new duty cycle values
- sets the PTULDOK bit (corresponding to **glb_ldok**) to signal the duty cycle coherence

The CPU actions are typically performed in an ISR triggered by the conversion complete flag.

1.13.3.4 Static Timing Fault Handling

The following Faults and/or errors can occur:

- Desaturation error, Overvoltage, Undervoltage, External fault

The application run-time error is handled by the GDU without CPU interaction. Firstly the FETs are disabled and the PMF signals switched to an inactive state. To re-enable the operation first the GDU fault and then PWM fault must be cleared, to automatically re-enable the FET driving at the next PWM boundary.

- PTU reload overrun error

This is an application run-time error caused by the CPU not setting PTULDOK on time. Servicing this type of error is application dependent and may range from a further reload attempt to a total shut down.

- PTU trigger generator reload error, PTU trigger generator error

Since all timing is static, this error should only occur during application debugging. This type of error occurring in a static timing configuration indicates possible data corruption. This can be serviced by a control loop shutdown.

- PTU memory access error, Memory access double bit ECC error

This type of error occurring in an application indicates data corruption. This can be serviced by a control loop shutdown.

- ADC sequence overrun, ADC command overrun, ADC command error

Since all timing is static, this error should only occur during application debugging. This type of error occurring in an application indicates possible data corruption. This can be serviced by a control loop shutdown.

1.13.3.5 Dynamic Timing Operation

The timing frame is dynamic if the following are modified on a cycle by cycle basis:

- PMF - duty cycle value registers (PMF_VAL_x), modulo registers

- PTU - Trigger Event List (PTU_TEL x)
- ADC - Command Sequence List (ADC x _CSL)

The main philosophy is that all cycle-by-cycle settings for cycle n need to be done within cycle $n-1$. The main control cycle synchronization event is the PMF **reload** event, which can be generated every n PWM periods.

This mode can optionally be extended by a timer channel trigger PMF to change PWM channel operation (e.g. used for BLDCM commutation).

The event flow is the same as for static timing.

Before the upcoming **reload** event the CPU:

- reads the ADC results from the buffered Conversion Result List
- clears the conversion complete flag
- services the **reload** by setting new duty cycle values and a new PMF modulo value
- updates the non-active PTU_TEL x
- updates the non-active ADC x _CSL
- sets the PTULDOK bit (corresponding to **glb_ldok**) to signal the duty cycle coherence

The CPU actions are typically performed in an ISR triggered by the conversion complete flag.

1.13.3.6 Dynamic Timing Fault Handling

The following Faults and/or errors can occur:

- Desaturation error, Overvoltage, Undervoltage, External fault

The application run-time error is handled by the GDU without CPU interaction. Firstly the FETs are disabled and the PMF signals switched to an inactive state. To re-enable the operation first the GDU fault and then PWM fault must be cleared, to automatically re-enable the FET driving at the next PWM boundary.

- PTU reload overrun error

This is an application run-time error caused by the CPU not setting PTULDOK on time. Servicing this type of error is application dependent and may range from a further reload attempt to a total shut down.

- PTU trigger generator reload error, PTU trigger generator error

This indicates an application run-time error caused by a settings mismatch. Servicing this type of error is application dependent. In some cases, the ADC values for the current control cycle can be ignored.

- PTU memory access error, Memory access double bit ECC error

This type of error occurring in an application indicates possible data corruption. This can be serviced by a control loop shutdown.

- ADC sequence overrun, ADC command overrun, ADC command error

This indicates an application run-time error caused by a settings mismatch. Servicing this type of error is application dependent. In some cases, the ADC values for the current control cycle can be ignored.

1.13.3.7 Asynchronous Timing

This case is an extension of the dynamic timing case by an asynchronous event generated by the Timer. Note the asynchronous term is referenced to the control cycle.

The timing frame is the same as in dynamic timing case plus it can be asynchronously restarted at any time within the control cycle.

At the asynchronous **commutation_event**

- **the PMF actions are:**

1. counter re-start, re-initialization
2. PWM configuration re-initialization according to the selected PWM settings (center/edge-aligned pattern, normal/inverted type etc.)
3. re-initialization of the dead time generators (in case the commutation takes place at a time when one of the dead times is being generated)
4. re-initialization of the PWM outputs according to pre-set PWM channel output settings in double buffered registers (mask, swap, output control)
5. re-initialization of the automatic fault clearing
6. generates **async_reload** event for the PTU
7. optionally updates the PWM duty cycle values based on LDOK state

- **the PTU actions are:**

1. abortion of the **trigger_x** event generation
2. re-initialization and re-start the PTU counter
3. update of the current list index TGxList based on the **glb_ldok** state
4. fetch first trigger time from updated TGxList
5. passes the **async_reload** event immediately to the ADC (if the PTU is enabled)
6. generates the **reload** event for the ADC

- **the ADC actions are:**

1. the conversion in progress is completed
2. the ADC conversion sequence is aborted and the SEQA flag is set to indicate that the final conversion occurred during the abortion process (potentially coinciding with a commutation and is thus less precise than under normal conditions)
3. update of the current lists index ADxLists
4. re-start of the conversion sequencing upon successful abortion - fetches the first ADC command from the ADCx_CSL, re-sets the result pointer to the top of the list

Note: in case the lists index ADxLists is not updated at the sequence abortion the new restarted A/D conversions will overwrite the previously converted results.

- **the GDU actions are:**

1. standard operation

1.13.3.8 Control Loop Startup Guidelines

The sequence for control loop start up is to firstly configure the signal measurement (inputs/feedback). Once the measurement is properly configured (correct value is measured at defined time) the output actuation (control action) is configured. The following modules are involved in signal measurements.

- TIM (to identify asynchronous commutation) [BLDC applications only]
- PMF (to generate main synchronous events for PTU and ADC)
- PTU (to generate delay relative to synchronous events generated by PMF)
- ADC (to acquire analog signals under synchronous control)
- GDU (zero crossing comparators, Back-EMF muxing) [application dependent]

The TIM OC0 channel identifies the commutation event and restarts the PMF counter. In order to establish this link TIM and PMF need to be configured and started. Then to sample accurately within one PMF cycle the PTU needs to be used, so the next step is to configure the PTU to establish PMF to PTU link. The PTU sends triggers to the ADC to perform a measurement of control signals. So the next step is to configure the ADC. In some cases the GDU involvement is required and therefore configured.

The control action involves the PMF (to generate the duty cycle for GDU) and the GDU (to propagate the signal to the MOSFETs). Since the PMF has already been configured for the measurements, only the GDU need be configured to complete startup. Sometimes the GDU can be configured earlier but the GDU output is always enabled last.

The recommended startup sequence is summarized as follows:

- Configure TIM and PMF to establish the link between TIM OC0 commutation event and PMF
- Configure PTU to establish the PMF to PTU link and ensure correct sampling within PMF cycle
- Configure the ADC
- Configure the GDU

1.13.3.9 Control Loop Shutdown Guidelines

1. Remove energy stored in the system after the power stage
 - kinetic energy - stop all rotating/moving mass
 - magnetic energy - gracefully drive currents to zero
2. Put GDU and PMF outputs to safe state

1.13.3.10 Control Loop Stop Mode Considerations

In Stop mode the PMF, PTU, ADC can not run because the bus clock is not running. Thus the GDU must transition to a disabled state. Before entering Stop mode the application must perform the following steps:

1. Remove energy stored in the system after the power stage
 - kinetic energy - stop all rotating/moving mass
 - magnetic energy - gracefully drive currents to zero
2. Put GDU and PMF outputs to safe state
3. Verify GDU and PMF safe states

4. Verify fault flags and service if necessary
5. Execute the STOP instruction

The return from stop is expected in reverse order:

1. On returning from Stop mode the clocks are automatically enabled coherently
2. Initialize and check device proper functionality (charge pump etc.)
3. Check functionality of the external system
4. Initializes control loop operation, however with PMF and GDU outputs still in safe state
5. Read the ADC values to check the system
6. Start driving energy into the system
based on the measurements from the previous step, the PWM duty cycle values are calculated
7. PMF and GDU outputs are enabled (actively driven)

The device does not support putting the FETs in an active driving state during STOP as the GDU charge pump clock is not running. This means the device cannot be put in stop mode if the FETS need to be in an active driving state to protect the system from external energy supply (e.g. externally driven motor-generator).

NOTE

It is imperative, that whatever the modules perform on entering/exiting Stop mode, the pre-set complementary mode of operation and dead time insertion must be guaranteed all the times.

1.13.3.11 Application Signal Visibility

In typical motor control applications, TIM OC0 is used internally to indicate commutation events. To switch off OC0 visibility at port pin PT0:

- Disable output compare signal on pin PT0 in TIM: OCPD[OCPD0]=0b1.

1.13.3.12 Debug Signal Visibility

Depending on required visibility of internal signals on port pins enable the following registers:

- Set [PWMPRR]=0b1 in PIM if monitoring of internal PWM waveforms is needed. PWM0_[5:3] are driven out on pins PT[2:0] and PWM0_[2:0] on pins PP[2:0].
- Enable output compare channel OC0 to output commutation event on pin PT0 in TIM: OCPD[OCPD0]=0b0.
- Set PTUDEBUG[PTUREPE]=0b1 in PTU to output the reload event.
- Set PTUDEBUG[PTUTxPE]=0b1 with x=0,1 in PTU to output the trigger events.

1.13.4 BDCM Complementary Mode Operation

This section describes BDCM control using center aligned complementary mode with deadtime insertion.

The DC Brushed motor power stage topology is a classical full bridge as shown in Figure 1-11. The DC Brushed motor is driven by the DC voltage source. A rotational field is created by means of commutator and brushes on the motor. These drives are still very popular because sophisticated calculations and algorithms such as commutation, waveform generation, or space vector modulation are not required.

Figure 1-11. DC Brushed Motor External Configuration

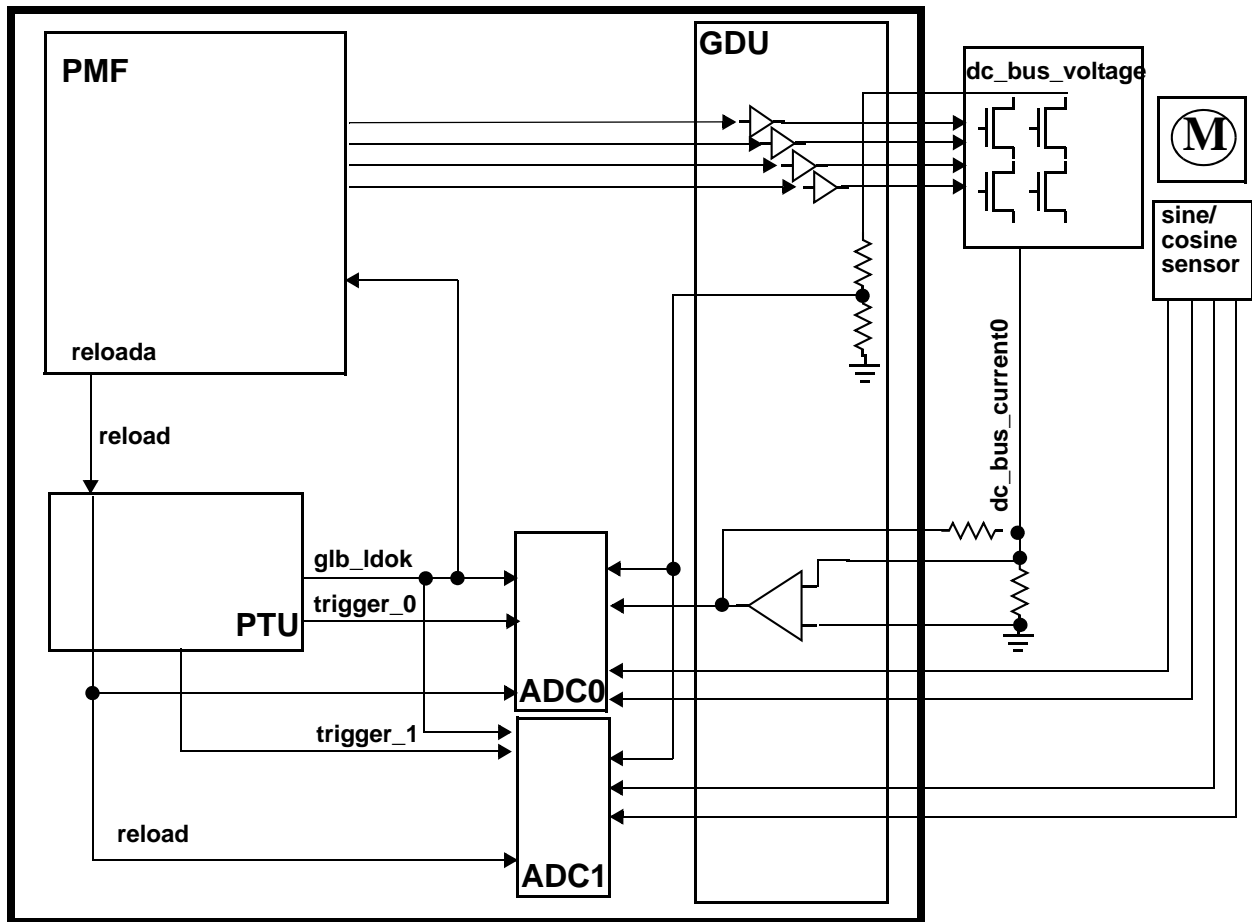

Usually the control consists of an outer, speed control loop with inner current (torque) control loop. The inner loop controls DC voltage applied onto the motor winding. The control loop is calculated regularly within a given period. In most cases, this period matches the PWM reload period.

Driving the DC motor from a DC voltage source, the motor can work in all four quadrants. The complementary mode of operation with deadtime insertion is needed for smooth reversal of the motor

current (motor torque), hence smooth full four quadrant control. Usually the center-aligned PWM is chosen to lower electromagnetic emissions.

Figure 1-12. BDCM Control Loop Configuration

The PWM frequency selection is always a compromise between audible noise, electromagnetic emissions, current ripples and power switching losses.

The BDCM control loop goal is to provide a controlled DC voltage to the motor winding, whereby it is controlled cycle-by-cycle using a speed, current or torque feedback loop.

The center aligned PWM waveforms generated by the PMF module are applied to the bridge as shown in [Figure 1-13](#) whereby the base waveform for PWM0_0 and PWM0_1 is depicted at the top and the complementary PWM0_0 and PWM0_1 waveforms are shown with deadtime insertion depicted by the gray phases before the switching edges.

Figure 1-13. BDCM Complementary Mode Waveform

Assuming first quadrant operation, forward accelerating operation, the applied voltage at node A must exceed the applied voltage at node B (Figure 1-11). Thus the PWM0_0 duty cycle must exceed the PWM0_2 duty cycle.

The duty cycle of PWM0_0 defines the voltage at the first power stage branch.

The duty cycle of PWM0_2 defines the voltage at the second power stage branch.

Modulating the duty cycle every period using the function F_{PWM} then the duty cycle is expressed as:

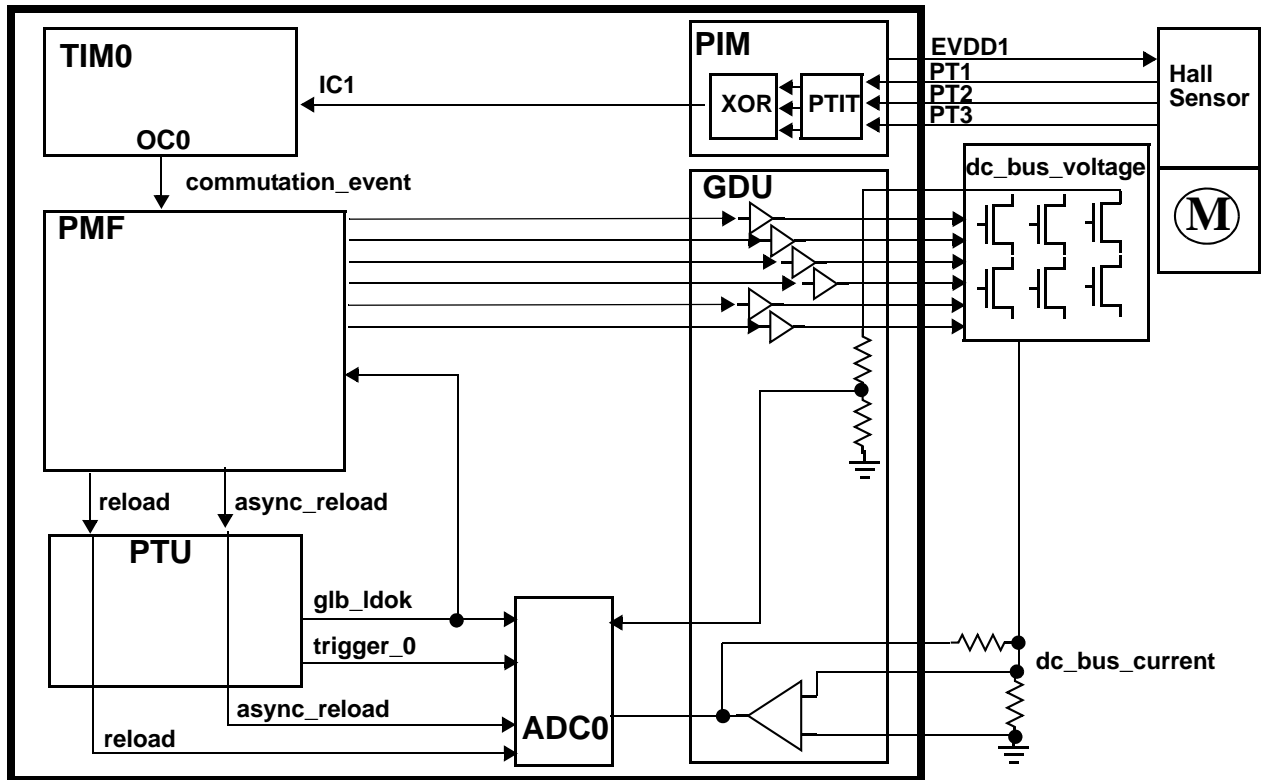

PWM0_0 duty-cycle = $0.5 + (0.5 * F_{PWM})$; For $-1 \leq F_{PWM} \leq 1$;

PWM0_2 duty-cycle = $0.5 - (0.5 * F_{PWM})$

1.13.5 BLDC Six-Step Commutation

1.13.5.1 Hall Sensor Triggered Commutation

Figure 1-14. BLDC Configuration With Hall Sensors

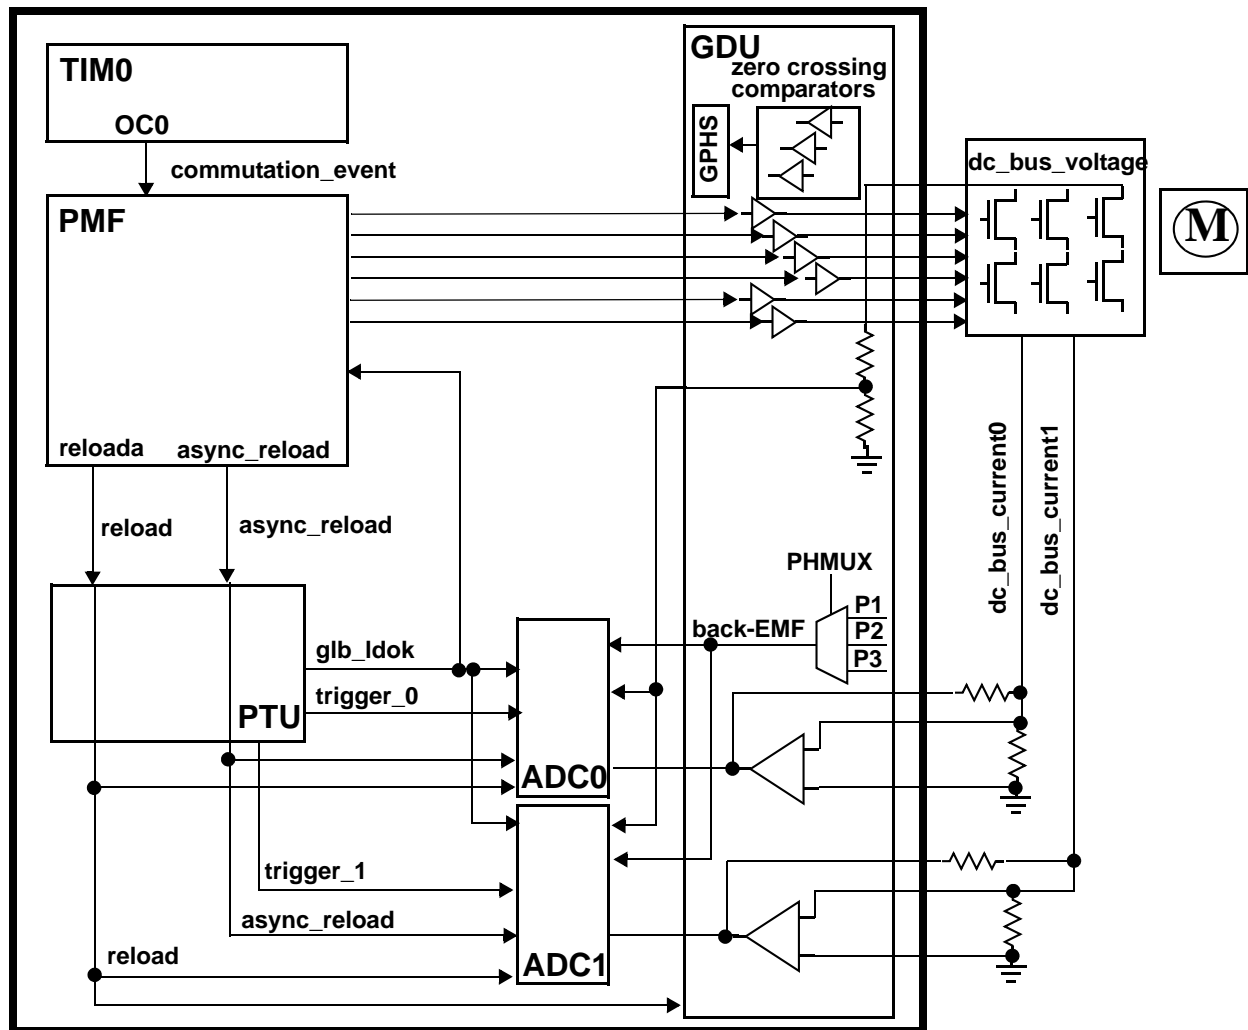

This BLDC application uses Hall sensor signals to create commutation triggers. The integrated sense amplifier and an ADC module are used to measure DC bus current, for torque calculation. The DC bus voltage measurement is used in the control algorithm to counter-modulate the PWM such that the variation of the DC-bus voltage does not affect the motor current closed loop. The configuration is as follows:

1. Connect the three Hall sensor signals from the motor to input pins PT3-1.
2. Set [T0IC1RR=1] in the register MODRR2 to establish the link from Hall sensor input pins to TIM input capture channel 1.
3. Setup TIM IC1 for speed measurement of XORed Hall sensor signals. Enable interrupt on both edges.
4. Enable TIM OC0 and select toggle action on output compare event: TCTL2[OM0:OL0]=01.
5. Configure PMF for edge-aligned PWM mode with or without restart at commutation: PMFENCx[RSTRT]. If using the restart option, then select generator A as reload signal source and keep the following configurations at their default setting: multi timebase generators (PMFCFG0[MTG]=b0), reload frequency (PMFFQCx[LDFQx]=b0), prescaler (PMFFQCx[PRSCx]=b00).
6. Enable PMF commutation event input: PMFCFG1[ENCE]=1.

7. Read port register PTIT[3:1] to determine starting sector.
8. Startup motor by applying PWM to the related motor phase.
9. In IC1 interrupt ISR calculate the delay to next commutation and store value to output compare register. Update registers with next values of mask and swap.
10. On next output compare event the buffered mask and swap information is transferred to the active PMF registers to execute the commutation.

1.13.5.2 Sensorless Commutation

Figure 1-15. Sensorless BLDC Configuration

To calculate the commutation time in a sensorless motor system the back-EMF zero crossing event of the currently non-fed phase within an electrical rotation cycle must be determined. For fast motor rotation, the ADC is used to measure the back-EMF voltage and the DC bus voltage to determine the zero crossing time. For slow motor rotation the GPHS register can be polled. In either case the zero crossing event is handled

by the CPU monitoring flags or responding to interrupts. The TIM then generates the `commutation_event` under CPU control, based on the zero crossing time.

1. Enable TIM OC0 and select toggle action on output compare event: `TCTL2[OM0:OL0]=0b01`.
2. Enable PMF commutation event input: `PMFCFG1[ENCE]=0b1`.
3. Enable internal ADC channel for measuring the phase voltages from the muxed GDU outputs.
4. Align rotor to stator field. Initialize phase MUX using register `GDUPHMUX`.
5. Startup motor by applying PWM to an arbitrary motor phase.
6. Take samples of the phase voltages periodically based on PWM cycle to detect zero crossing.
7. Calculate the delay to next commutation and store value to output compare register. Update registers with next values of mask and swap.
8. On next output compare event the buffered mask and swap information are transferred to the active PMF register to execute the commutation.

1.13.6 PMSM Control

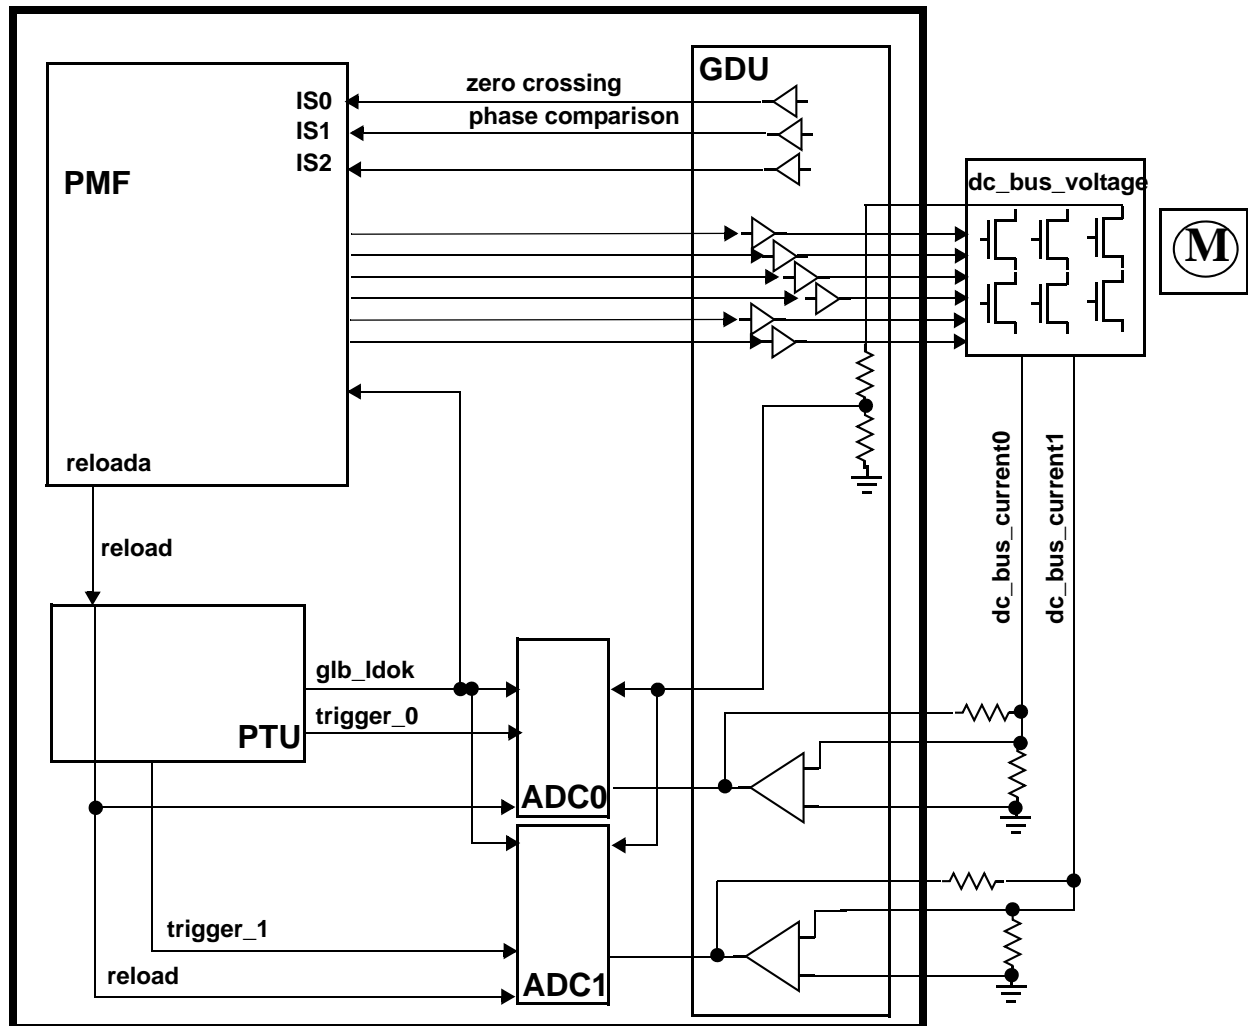

PMSM control drives all 3 phases simultaneously with sinusoidal waveforms. Both sensorless and Sine-Cosine position sensor control loop operation are supported.

1.13.6.1 PMSM Sensorless Operation

In this configuration the PMSM stator winding currents are driven sinusoidally and the back EMF waveform is also sinusoidal. Thus all 3 phases are active simultaneously. The rotor position and speed are determined by the current and calculated voltages respectively. The back EMF voltage is calculated based on the currents.

1. Configure PMF for complementary mode operation.
2. Configure PMF for center aligned or phase shifted operation.
3. Select correct PMF deadtime insertion based on external FET switches.
4. Enable GDU current sense opamps for measuring the phase currents from 2 external shunts.
5. Map the output pin of each current sense opamp to the ADC input.
6. Optionally use GDU phase comparators for zero crossing detection to correct deadtime distortion.
7. Fetch targeted motor speed parameter from external source (e.g. SCI)
8. Configure PMF period and duty cycle.
9. Startup motor by applying FOC startup algorithm.
10. Take samples of the phase currents periodically based on PWM cycle to determine motor speed.
11. Calculate FOC algorithm to determine back EMF and motor position.

Figure 1-16. Sensorless PMSM Control Loop Configuration

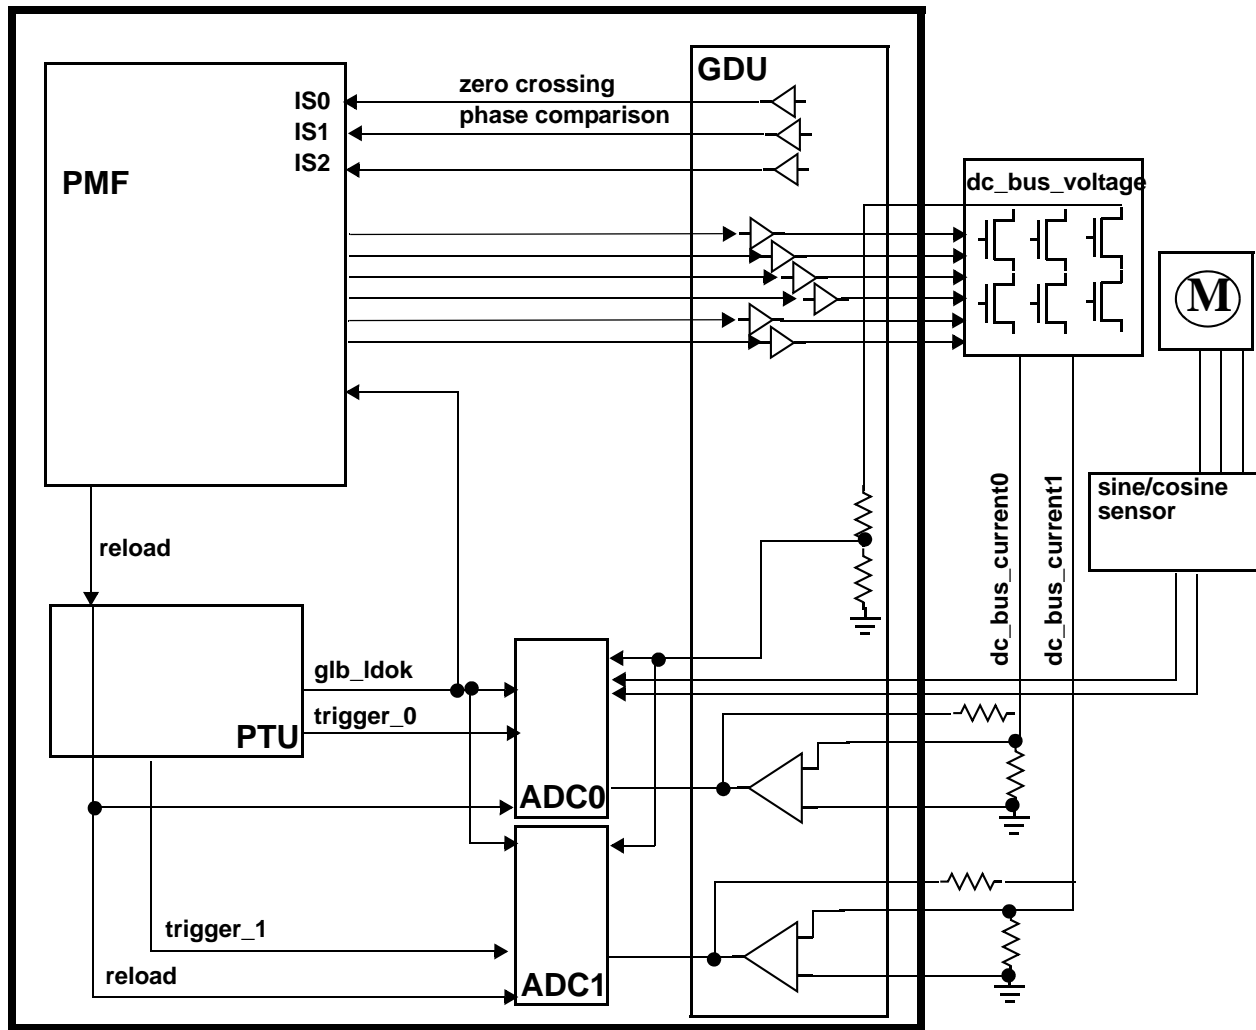

1.13.6.2 PMSM Operation With Sine-Cosine Position Sensor

In this configuration the PMSM stator winding currents are driven sinusoidally and the back EMF waveform is also sinusoidal. Thus all 3 phases are active simultaneously. The back EMF voltage is calculated based on the currents. The rotor position and speed are determined by a sine/cosine sensor, which generates sinusoidal sine/cosine signals, indicating the angle of the rotor in relation to sensor windings. The sensor is supplied by the EVDD1 pin.

1. Configure PMF for complementary mode operation.
2. Configure PMF for center aligned or phase shifted operation.
3. Select correct PMF deadtime insertion based on external FET switches.
4. Enable GDU current sense opamps for measuring the phase currents from external shunts.
5. Map the output pin of each current sense opamp to the ADC input.

6. Map the sine/cosine input signals to ADC input channels.
7. Configure the EVDD1 pin as output.
8. Optionally use GDU phase comparators for zero crossing detection to correct dead time distortion.
9. Fetch targeted motor speed parameter from external source (e.g. SCI)
10. Configure PMF period and duty cycle.
11. Start motor by applying startup algorithm.
12. Sample the sine/cosine voltages periodically based on PWM cycle to determine motor position.
13. Use FOC algorithm to determine back EMF and motor speed.

Figure 1-17. PMSM Sine/Cosine Control Loop Configuration

1.13.6.3 Dead time Distortion Correction

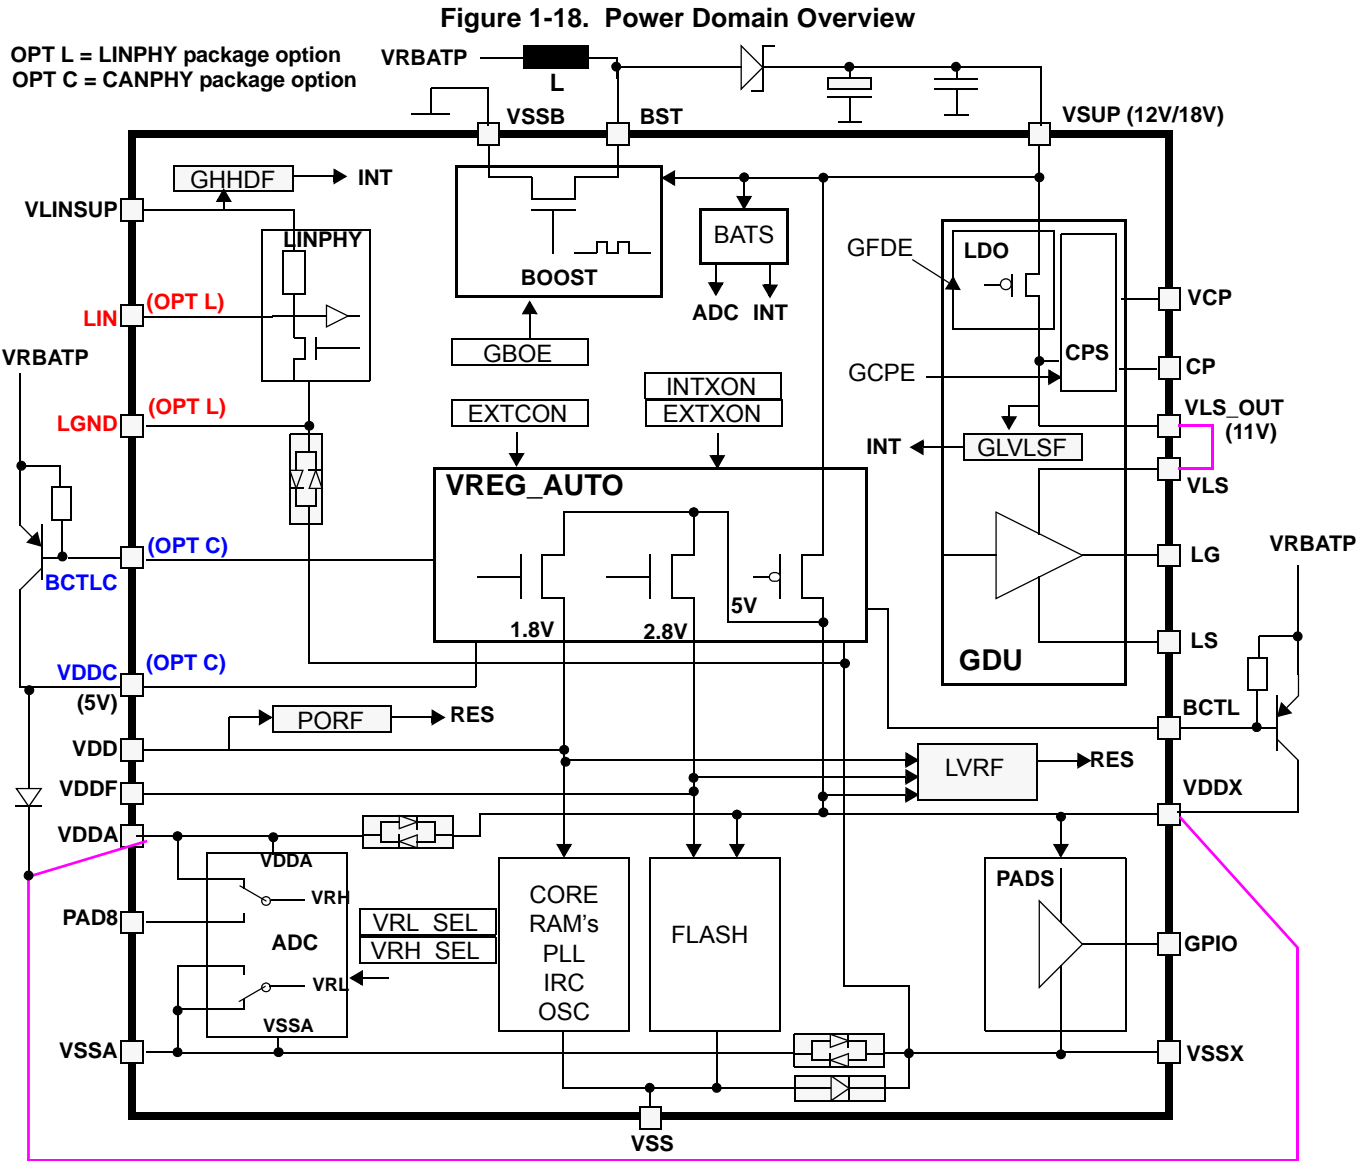

PMSM motor control applications driven by sinusoidal voltages by default require zero crossing information of phase currents to determine the point in time to change sign of deadtime compensation value to be added to duty cycles.

The GDU phase comparator signals are connected internally to the PMF ISx inputs. This allows the dead time distortion correction to be applied directly based on the phase status.

1. Align rotor to stator field.
2. Await phase comparator status change.
3. Switch to alternate duty cycle register to compensate distortion.

1.13.7 Power Domain Overview (All devices except ZVMC256)

The power domains are illustrated in Figure 1-18. More detailed information is included in the individual module descriptions.

The system supply voltage VRBATP is a reverse battery protected input voltage. It must be protected against reverse battery connections and must not be connected directly to the battery voltage (VBAT).

The device supply voltage VSUP provides the input voltage for the internal regulator, VREG_AUTO, which generates the voltages VDDX, VDD and VDDF. The VDDX domain supplies the device I/O pins, VDDA supplies the ADC and internal bias current generators. The VDDA and VDDX pins must be connected at board level, they are not connected directly internally. ESD protection diodes exist between VDDX and VDDA, therefore forcing a common operating range. The VDD domain supplies the internal device logic. The VDDF domain supplies sections of the internal Flash NVM circuitry.

The device supports the use of an external PNP to supplement the VDDX supply, for reducing on chip power dissipation. In this configuration, most of the current flowing from VRBATEP to VDDX, flows through the external PNP. This configuration, using the BCTL pin, can be enabled by register bits EXTCON and INTCON.

The maximum current that can be sourced by the voltage regulator without the external PNP is specified as IDDX, for different VSUP ranges, in the electrical parameter appendices. Depending on activity and external loading, an application current may exceed this specification limit. In such cases the external PNP configuration must be used.

A supply for an external CANPHY is offered via external device pins BCTL and VDDC, whereby BCTL provides the base current of an external PNP and VDDC is the CANPHY supply (output voltage of the external PNP). This is only available in the CANPHY package option. This configuration can be enabled by the register bit EXTCON. An external diode is recommended between VDDC and VDDA.

The LINPHY pull-up resistor is internally connected to VLINSUP.

The ADC register bit VRH_SEL maps the ADC reference VRH to VDDA or to the device pin PAD8.

1.13.8 Power Domain Overview (ZVMC256)

Figure 1-19. Power Domain Overview (ZVMC256)

The system supply voltage VRBATP is a reverse battery protected input voltage. It must be protected against reverse battery connections and must not be connected directly to the battery voltage (VBAT).

The device supply voltage VSUP provides the input voltage for the internal regulator, VREG_AUTO, which generates the voltages VDDX, VDD and VDDF. The VDDX domain supplies the device I/O pins, VDDA supplies the ADC and internal bias current generators. The VDDA and VDDX pins must be connected at board level, they are not connected directly internally. ESD protection diodes exist between VDDX and VDDA, therefore forcing a common operating range. The VDD domain supplies the internal device logic. The VDDF domain supplies sections of the internal Flash NVM circuitry.

The device supports the use of an external PNP to supplement the VDDX supply, for reducing on chip power dissipation. In this configuration, most of the current flowing from VRBAP to VDDX, flows through the external PNP, using the BCTL pin for PNP base current control. The configuration can be selected by register bits EXT_XON and INT_XON.

The maximum current that can be sourced by the voltage regulator without the external PNP is specified as IDDX, for different VSUP ranges, in the electrical parameter appendices. Depending on activity and external loading, an application current may exceed this specification limit. In such cases the external PNP configuration must be used.

A supply for the internal CANPHY is offered via device pins BCTLC and VDDC, whereby BCTLC provides the base current of an external PNP and VDDC is the CANPHY supply (output voltage of the external PNP). This configuration can be enabled by the register bit EXTCON.

Two separate 5V range supplies (VDDS1 and VDDS2) are provided for external (sensor) components. These supplies also use external PNP configurations, whereby the PNP base current is controlled by BCTLS1 and BCTLS2 for VDDS1 and VDDS2 respectively.

The VDDS1 and VDDS2 supplies feature sense inputs SNPS1 and SNPS2, to detect a short circuit or over current condition and subsequently limit the current to avoid damage.

For each ADC instantiation, the ADC register bit VRH_SEL maps the ADC reference VRH to VDDA or to a VDDS of a tracker regulator. The [Figure 1-19](#) example only shows one ADC to VDDS connection.

1.13.8.1 Voltage Domain Monitoring

The BATS module monitors the voltage on the VSUP pin, providing status and flag bits, an interrupt and a connection to the ADC, for accurate measurement of the scaled VSUP level.

The POR circuit monitors the VDD and VDDA domains, ensuring a reset assertion until an adequate voltage level is attained. The LVR circuit monitors the VDD, VDDF and VDDX domains, generating a reset when the voltage in any of these domains drops below the specified assert level. The VDDX LVR monitor is disabled when the VREG is in reduced power mode. A low voltage interrupt circuit monitors the VDDA domain.

The GDU high side drain voltage, pin HD, is monitored within the GDU and mapped to an interrupt. A connection to the ADC is provided for accurate measurement of a scaled HD level.

1.13.8.2 FET-Predriver (GDU) Supplies

A dedicated low drop regulator is used to generate the VLS_OUT voltage from VSUP. The VLS_OUT voltage is used to supply the low side drivers and can be directly connected to the VLS inputs of each low side driver. For FET-predriver operation at lower VSUP levels, a boost circuit can be enabled by the GBOE register bit. The boost circuit requires Shottky diodes, a coil and capacitors, as shown in [Figure 1-18](#). More detailed information is included in the GDU module description.

1.13.8.2.1 Bootstrap Precharge

The FET-predriver high side driver must provide a sufficient gate-source voltage and sufficient charge for the gate capacitance of the external FETs. A bootstrap circuit is used to provide sufficient charge, whereby

the capacitor C_{BS} is first charged to VLS_OUT via an external diode (GDUV4) or internal transistor (GDUV5), when the low side driver is active [Figure 1-20](#). When the high side driver switches on, the charge on this capacitor, supplies the FET-predriver via the VBSx pin. The C_{BS} capacitor can only be charged if the low side driver is active, so after a long period of inactivity of the low side driver, the C_{BS} capacitor becomes discharged. In this case, the low side driver must be switched on to charge C_{BS} before commencing high side driving. The time it takes to discharge the bootstrap capacitor C_{BS} can be calculated from the size of the bootstrap capacitor C_{BS} and the current on VBSx pin in the high side inactive phase.

The bootstrap capacitors must be precharged before turning on the high-side drivers for the first time. This can be done by using the PMF software output control mechanism:

```
PMFOUTC = 0x3F;           // SW control on all outputs
PMFOUTB = 0x2A;           // All high-sides off, all low-sides on
```

The PWM0 signals should be configured to start with turning on the low-side before the high-side drivers in order to assure precharged bootstraps. Therefore invert the PWM0 signals:

```
PMFCINV = 0x3F;           // Invert all channels to precharge bootstraps
```

1.13.8.2.2 High Side Charge Pump

A charge pump voltage is used to supply the high side FET-predriver with enough current to maintain the gate source voltage. To generate this voltage an external charge pump is driven by the pin CP, switching between 0V and 11V. The pumped voltage is then applied to the pin VCP.

At 100% duty cycle operation the low-side turn on time is zero during a masked commutation cycle before the attempting to turn on the high side drivers. This can cause bootstrap charge to decay.

In order to speed-up the high-side gate voltage level directly after commutation, the software should drive the first PWM cycle with a duty cycle meeting an on-time of at least $t_{minpulse}$ for the low-side drivers and then switch back to 100% again.

The recommended procedure for BLDC applications is to use the manual correction method (PMFCCTL[ISENS]) as described below:

Set odd PMF values to alternative duty cycle. At commutation event when one of the three high-side drivers is turned on (every 120°) set the PMFCCTL[IPOLx] bits and clear them at the next PWM reload event.

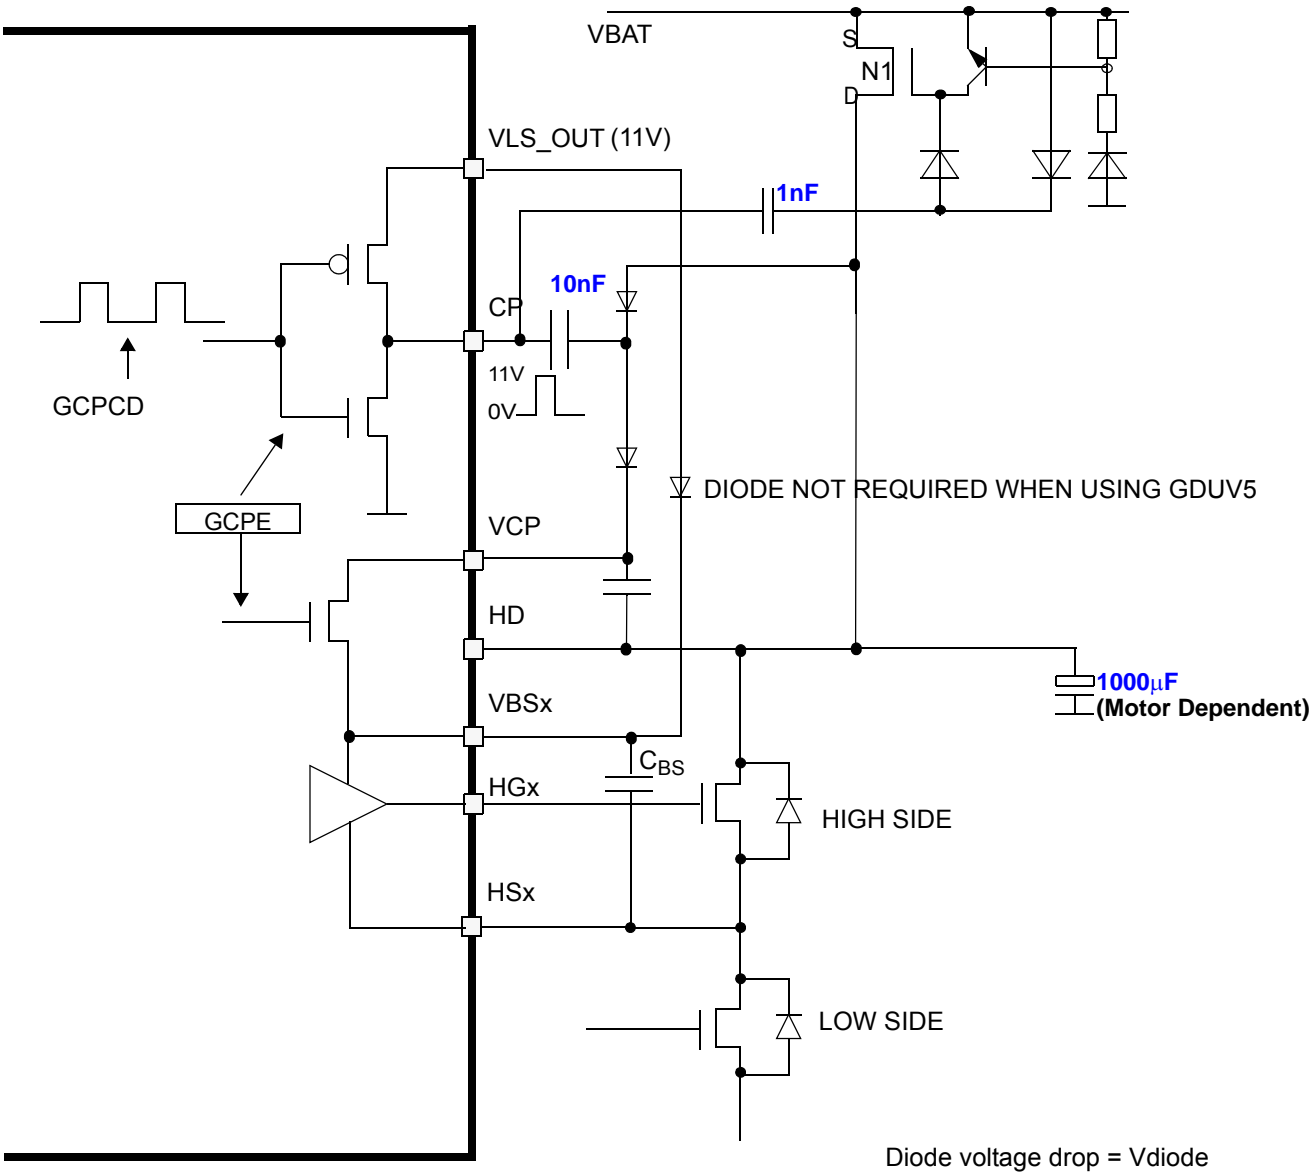

Given unipolar switching mode:

```
// TIM OC0 ISR:
if ((PMFOUTC == 0x1c) || (PMFOUTC == 0x07) || (PMFOUTC == 0x31)) // all high-side turn-on sectors
    PMFCCTL = 0x17; // select odd PMF values

// PMF reload ISR:
    PMFCCTL = 0x10; // select even PMF values
```

The GDU high side drain voltage, pin HD, is supplied from VBAT through a reverse battery protection circuit. In a typical application the charge pump is used to switch on an external NMOS, N1, with source connected to VBAT, by generating a voltage of $V_{BAT} + V_{LS} - (2 \times V_{diode})$. In a reverse battery scenario, the external bipolar turns on, ensuring that the HD pin is isolated from VBAT by the external NMOS, N1.

2.1 Introduction

2.1.1 Overview

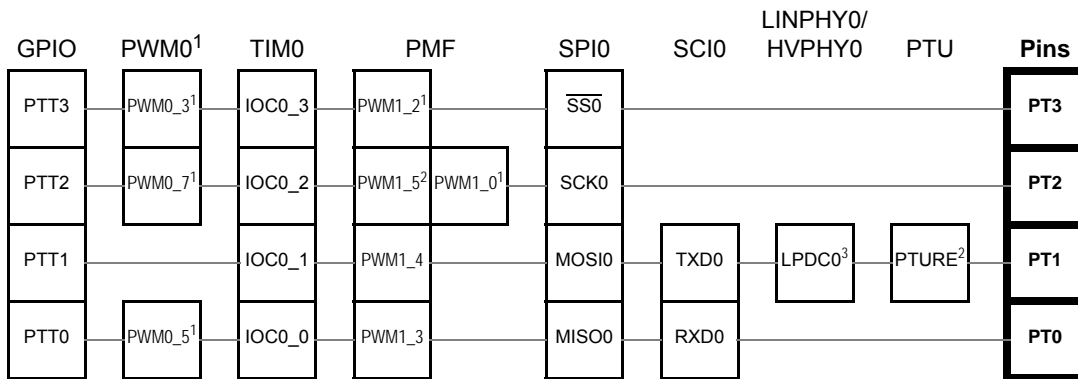

The S12ZVM-family port integration module establishes the interface between the peripheral modules and the I/O pins for all ports. It controls the electrical pin properties as well as the signal prioritization and multiplexing on shared pins.

This document covers:

- Port E

- Port T

1. Only available for ZVMC256
2. Not available for ZVMC256
3. Only available for ZVML128, ZVML64, ZVML32, ZVML31, ZVM32, and ZVM16

• Port S

1. Only available for ZVMC256, ZVMC128, ZVML128, ZVMC64, ZVML64, and ZVML32
2. Only available for ZVMC128, ZVML128, ZVMC64, ZVML64, and ZVML32
3. Not available for ZVMC256
4. Only available for ZVMC256
5. Only available for ZVML128, ZVML64, ZVML32, ZVML31, ZVM32, and ZVM16
6. Only available for ZVMC256, ZVML31, ZVM32, and ZVM16

• Port P

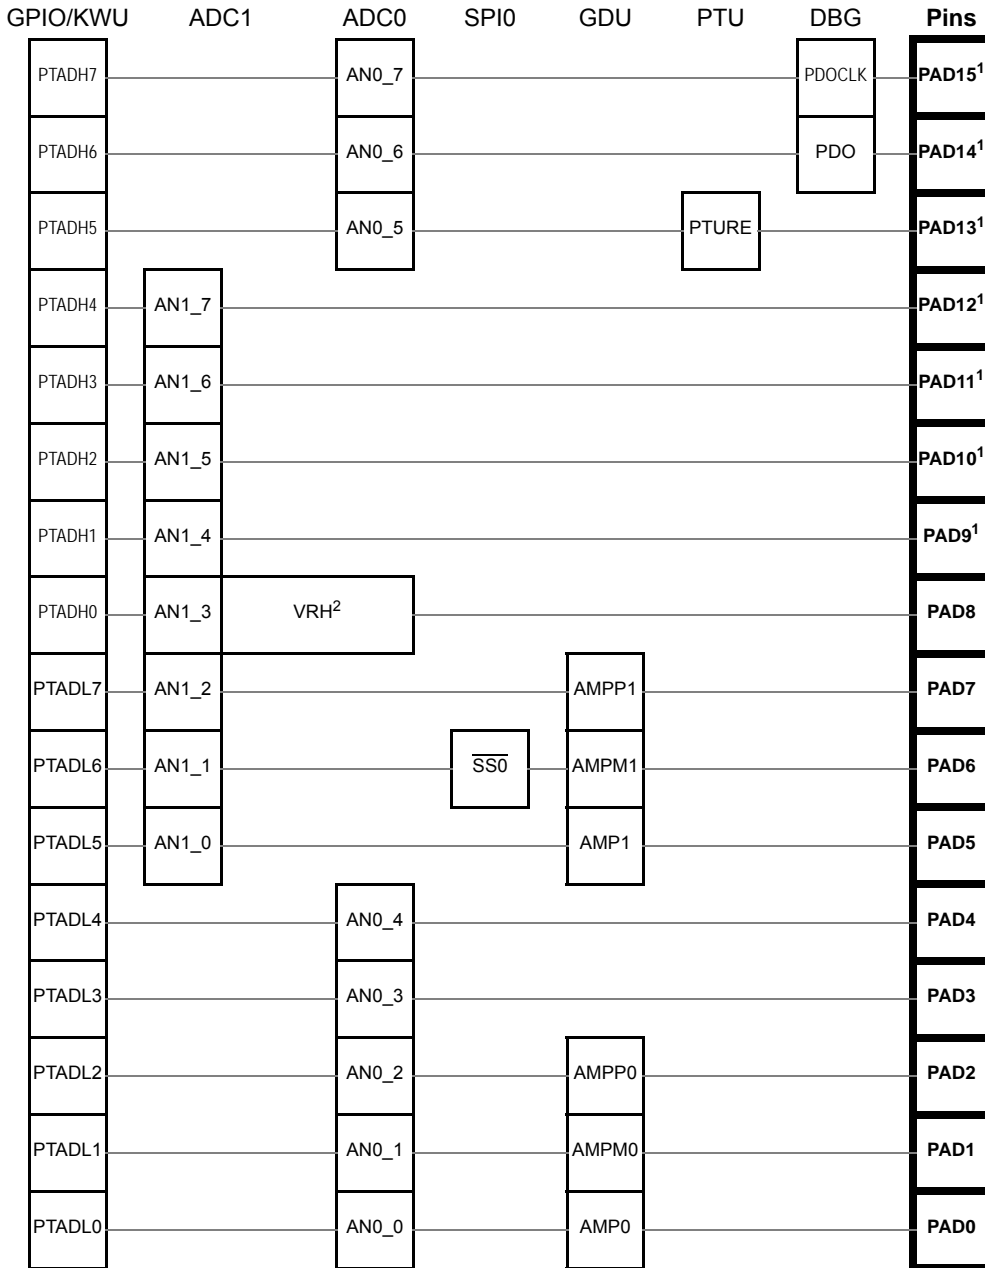

1. Only available for ZVMC256
2. Not available for ZVMC256

• Port L

1. Only available for ZVMC256

• Port AD

- 1. Only available for ZVMC256
- 2. Not available for ZVMC256

Most I/O pins can be configured by register bits to select data direction and to enable and select pullup or pulldown devices.

NOTE

This document shows the superset of all available features offered by the S12ZVM device family. Refer to the package and pinout section in the device overview for functions not available for a particular device or package option.

2.1.2 Features

The PIM includes these distinctive registers:

- Data registers and data direction registers for ports E, T, S, P and AD when used as general-purpose I/O
- Control registers to enable pull devices and select pullups/pulldowns on ports E, T, S, P and AD
- Control register to enable open-drain (wired-or) mode on port S
- Control register to enable digital input buffers on port AD and L¹
- Interrupt enable register for pin interrupts and key-wakeup (KWU) on port S, P, AD, and L¹
- Interrupt flag register for pin interrupts and key-wakeup (KWU) on port S, P, AD, and L¹
- Control register to configure $\overline{\text{IRQ}}$ pin operation
- Control register to enable ECLK output
- Routing registers to support signal relocation on external pins and control internal routings:
 - SPI0 to alternative pins
 - Various SCI0-LINPHY0 routing options supporting standalone use and conformance testing²
 - Various MSCAN0-CANPHY0 routing options for standalone use and conformance testing¹
 - Internal RXD0 and RXD1 link to TIM0 input capture channel (IC0_3) for baud rate detection
 - Internal ACLK link to TIM0 input capture channel
 - 3 pin input mux to one TIM0 IC channel
 - 2 TIM0 channels to alternative pins³
 - PMF channels to GDU and/or pins

A standard port pin has the following minimum features:

- Input/output selection
- 5V output drive
- 5V digital and analog input
- Input with selectable pullup or pulldown device

Optional features supported on dedicated pins:

- Open drain for wired-or connections
- Interrupt input with glitch filtering
- High current drive strength from VDDX with over-current protection

1. Only available for ZVMC256

2. Only available for ZVML128, ZVML64, ZVML32, and ZVML31

3. Only available for S12ZVMC256, S12ZVML31, S12ZVM32, and S12ZVM16

- Selectable drive strength for high current capable outputs

2.2 External Signal Description

This section lists and describes the signals that do connect off-chip.

Table 2-2 to Table 2-8 show all pins with the pins and functions that are controlled by the PIM. Routing options are denoted in parenthesis.

NOTE

If there is more than one function associated with a pin, the output priority is indicated by the position in the table from top (highest priority) to bottom (lowest priority). Inputs do not arbitrate priority unless noted differently in Table 2-40.

		✓	✓	✓	✓	✓	ECLK	O	Free-running clock	—	
				✓	✓	✓	(PWM1_0)	O	PMF channel 0 with over-current interrupt; high-current capable (20 mA)	PWM10RR PWMPRR	
		✓					(PWM1_5)	O	PMF channel 5 with over-current interrupt; high-current capable (20 mA)	PWM54RR PWMPRR	
		✓	✓	✓	✓	✓	PTP[0]/ KWP[0]/ EVDD1	I/O	General-purpose; with interrupt and wakeup Switchable external power supply output with over-current interrupt; high-current capable (20 mA)	—	

1. Signals in parentheses denote alternative module routing pins.

2. The interrupt is enabled by clearing the X mask bit in the CPU CCR. The pin is forced to input upon first clearing of the X bit and is held in this state until reset. A stop or wait recovery with the X bit set (refer to S12ZCPU reference manual) is not available.

Table 2-8. Port L Pin Functions and Priorities

Port	Pin Name	ZVMC256	ZVMC128/64	ZVML128/64/32	ZVML31	ZVM32/16	Pin Function & Priority	I/O	Description	Routing Register Bit	Pin Function after Reset
L	PL0/	✓					PTIL[0]/ KWL[0]	I	General-purpose high-voltage input (HVI); with interrupt and wakeup; optional ADC link	—	GPI (HVI)

2.3 Memory Map and Register Definition

This section provides a detailed description of all port integration module registers.

Subsection 2.3.1 shows all registers and bits at their related addresses within the global SoC register map. A detailed description of every register bit is given in subsection 2.3.2 to 2.3.4.

2.3.1 Register Map

1. Only available for ZVML128, ZVML64, ZVML32, and ZVML31
2. Only available for ZVMC256
3. PWMPRR[1] only writable for ZVMC256
4. Only available for ZVMC256, ZVML31, ZVM32, ZVM16
5. Not available for ZVMC256

2.3.2 PIM Registers 0x0200-0x020F

This section details the specific purposes of register implemented in address range 0x0200-0x020F. These registers serve for specific PIM related functions not part of the generic port registers.

- If not stated differently, writing to reserved bits has no effect and read returns zero.
- All register read accesses are synchronous to internal clocks.
- Register bits can be written at any time if not stated differently.

2.3.2.1 Module Routing Register 0 (MODRR0)

Address 0x0200

Access: User read/write¹

	7	6	5	4	3	2	1	0
R	0	0	SPI0SSRR	SPI0RR	SCI1RR	SOL0RR2-0 ²		
W	—	—	SPI0 $\overline{SS0}$	SPI0	SCI1	SCI0-LINPHY0/HVPHY0 (see Figure 2-2)		
Reset	0	0	0	0	0	0	0	0

Figure 2-1. Module Routing Register 0 (MODRR0)

1. Read: Anytime
Write: Once in normal, anytime in special mode
2. Only available for ZVML128, ZVML64, ZVML32, and ZVML31

Table 2-9. MODRR0 Routing Register Field Descriptions

Field	Description
5 SPI0SSRR	<p>Module Routing Register — SPI0 SS0 routing</p> <p>Note: This bit takes precedence over SPI0RR.</p> <p>1 $\overline{SS0}$ on PAD6 0 $\overline{SS0}$ based on SPI0RR</p>
4 SPI0RR	<p>Module Routing Register — SPI0 routing</p> <p>1 MISO0 on PT0; MOSI0 on PT1; SCK0 on PT2; $\overline{SS0}$ on PT3 or on pin selected by SPI0SSRR 0 MISO0 on PS2; MOSI0 on PS3; SCK0 on PS4 (PS1 for S12ZVMC256); $\overline{SS0}$ on PS5 (PS0 for S12ZVMC256) or on pin selected by SPI0SSRR</p>
3 SCI1RR	<p>Module Routing Register — SCI1 routing</p> <p>1 TXD1 on PS3; RXD1 on PS2 0 TXD1 on PS1; RXD1 on PS0</p>
2-0 SOL0RR2-0	<p>Module Routing Register — SCI0-LINPHY0/HVPHY0 routing</p> <p>Selection of SCI0-LINPHY0/HVPHY0 interface routing options to support probing and conformance testing. Refer to Figure 2-2 for an illustration and Table 2-10 for preferred settings. SCI0 must be enabled for TXD0 routing to take effect on pins. LINPHY0/HVPHY0 must be enabled for LPRXD0 and LPDC0 routings to take effect on pins.</p>

Figure 2-2. SCI0-to-LINPHY0 Routing Options Illustration

Table 2-10. Preferred Interface Configurations

S0L0RR[2:0]	Signal Routing	Description
000	TXD0 → LPTXD0 RXD0 ← LPRXD0	Default setting: SCI0 connects to LINPHY0/HVPHY0, interface internal only
001	LP0DR1 → LPTXD0 RXD0 ← LPRXD0	Direct control setting: LP0DR[LPDR1] register bit controls LPTXD0, interface internal only

SOL0RR[2:0]	Signal Routing	Description
100		Probe setting: SCI0 connects to LINPHY0/HVPHY0, interface accessible on 2 external pins
110		Conformance test setting: Interface opened and all 4 signals routed externally

NOTE

For standalone usage of SCI0 on external pins set [SOL0RR2:SOL0RR0]=0b110 and disable the LINPHY0/HVPHY0 (LPCR[LPE]=0). This releases PS0 and PS1 to other associated functions and maintains TXD0 and RXD0 signals on PT1 and PT0, respectively, if no other function with higher priority takes precedence.

2.3.2.2 Module Routing Register 1 (MODRR1)

Address 0x0201

Access: User read/write¹

Figure 2-3. Module Routing Register 1 (MODRR1)

- 1. Read: Anytime
Write: Once in normal, anytime in special mode
- 2. Only available for ZVMC256
- 3. PWMPRR[1] only writable for ZVMC256

Table 2-11. MODRR1 Routing Register Field Descriptions

Field	Description
7-5 MOC0RR2-0	<p>Module Routing Register — MSCAN0-CANPHY0 routing</p> <p>Selection of MSCAN0-CANPHY0 interface routing options to support probing and conformance testing. Refer to Figure 2-4 for an illustration and Table 2-12 for preferred settings. MSCAN0 must be enabled for TXCAN0 routing to take effect on pin. CANPHY0 must be enabled for CPRXD0 and CP0DR[CPDR1] routings to take effect on pins.</p>
4-3 PWMPRR1-0	<p>Module Routing Register — PMF probe</p> <p>Internal PMF outputs can be probed on related external pins. Probing can be enabled independent of the PWM54RR, PWM32RR, and PWM10RR settings.</p> <p>11 PMF channels 1, 3, 5 connected to related PWM1_x pins (only available for ZVMC256) 10 PMF channels 0, 2, 4 connected to related PWM1_x pins (only available for ZVMC256) 01 All PMF channels connected to related PWM1_x pins 00 No PMF channels connected to related PWM1_x pins</p>
2 PWM54RR	<p>Module Routing Register — PWM1_4 and PWM1_5 routing</p> <p>The PWM channel pair can be configured for internal use with the GDU or with its related external pins only. If set the signal routing to the pins is established and the related GDU inputs are forced low.</p> <p>1 PWM1_4 to PT1; PWM1_5 to PT2 (PP0 for S12ZVMC256) 0 PWM1_4 to GDU; PWM1_5 to GDU</p>
1 PWM32RR	<p>Module Routing Register — PWM1_2 and PWM1_3 routing</p> <p>The PWM channel pair can be configured for internal use with the GDU or with its related external pins only. If set the signal routing to the pins is established and the related GDU inputs are forced low.</p> <p>1 PWM1_2 to PP2 (PT3 for S12ZVMC256); PWM1_3 to PT0 0 PWM1_2 to GDU; PWM1_3 to GDU</p>
0 PWM10RR	<p>Module Routing Register — PWM1_0 and PWM1_1 routing</p> <p>The PWM channel pair can be configured for internal use with the GDU or with its related external pins only. If set the signal routing to the pins is established and the related GDU inputs are forced low.</p> <p>1 PWM1_0 to PP0 (PT2 for S12ZVMC256); PWM1_1 to PP1 0 PWM1_0 to GDU; PWM1_1 to GDU</p>

Figure 2-4. CAN Routing Options Illustration

Table 2-12. Preferred Interface Configurations

M0C0RR[2:0]	Description
000	Default setting: MSCAN connects to CANPHY, interface internal only
001	Direct control setting: CP0DR[CPDR1] connects to CPTXD, interface internal only
100	Probe setting: MSCAN connects to CANPHY, interface visible on 2 external pins
110	Conformance test setting: Interface opened and all 4 signals routed externally

NOTE

For standalone usage of MSCAN0 on external pins set M0C0RR[2:0]=0b110 and disable CANPHY0 (CPCR[CPE]=0). This releases the CANPHY0 associated pins to other shared functions.

2.3.2.3 Module Routing Register 2 (MODRR2)

Address 0x0202

Access: User read/write¹

Figure 2-5. Module Routing Register 2 (MODRR2)

1. Read: Anytime
Write: Once in normal, anytime in special mode
2. Only available for ZVMC256, ZVML31, ZVM32, and ZVM16
3. Only available for ZVMC256

Table 2-13. MODRR2 Routing Register Field Descriptions

Field	Description
7-6 T0C2RR1-0	<p>Module Routing Register — TIM0 IOC0_2 routing (ZVMC256, ZVML31, ZVM32, and ZVM16 only)</p> <p>11 reserved 10¹ TIM0 IOC0_2 is routed to the HVI, OC0_2 is disconnected from GPIO 01 TIM0 IOC0_2 is routed to PS1 00 TIM0 IOC0_2 is routed to PT2</p>
5 T0C1RR	<p>Module Routing Register — TIM0 IOC0_1 routing (ZVMC256, ZVML31, ZVM32, and ZVM16 only)</p> <p>1 TIM0 IOC0_1 is routed to PS0 0 TIM0 IOC0_1 is routed to PT1</p>
4 T1IC0RR	<p>Module Routing Register — TIM1 IOC1_0 routing (ZVMC256 only)</p> <p>1 TIM1 IOC1_0 is routed to the GDU delay measurement feature (t_{delon}) 0 TIM1 IOC1_0 is routed to PS2</p>
3-2 T0IC3RR1-0	<p>Module Routing Register — TIM0 IC3 routing</p> <p>One out of four different sources can be selected as input to timer channel 3.</p> <p>11 TIM0 input capture channel 3 is connected to ACLK 10 TIM0 input capture channel 3 is connected to RXD1 01 TIM0 input capture channel 3 is connected to RXD0 00 TIM0 input capture channel 3 is connected to PT3</p>

Table 2-13. MODRR2 Routing Register Field Descriptions

Field	Description
1 T0IC1RR	<p>Module Routing Register — TIM0 IC1 routing</p> <p>Timer input capture channel 1 can be used to determine the asynchronous commutation event in BLDC motor applications with Hall sensors. An integrated XOR gate supports direct connection of the three sensor inputs to the device.</p> <p>Note: This bit takes precedence over T0C1RR.</p> <p>1 TIM0 input capture channel 1 is connected to logically XORed input signals of pins PT3-1 0 TIM0 input capture channel 1 is connected to PT1 or to pin selected by T0C1RR0 (if available)</p>
0 T0IC1RR0	<p>Module Routing Register — TIM0 IC1 routing option 0 (ZVMC256, ZVML31, ZVM32, and ZVM16 only)</p> <p>Timer input capture channel 1 can be used to determine the asynchronous commutation event in BLDC motor applications with Hall sensors. An integrated XOR gate supports direct connection of the three sensor inputs to the device.</p> <p>Note: This bit takes precedence over T0C1RR and T0IC1RR.</p> <p>1 TIM0 input capture channel 1 is connected to logically XORed input signals of pins PT0, PS0 and PS1 0 TIM0 input capture channel 1 is connected to pin selected by T0IC1RR</p>

1. Only available for ZVMC256, Reserved for ZVML31, ZVM32, and ZVM16

2.3.2.4 ECLK Control Register (ECLKCTL)

Address 0x0208

Access: User read/write¹

Figure 2-6. ECLK Control Register (ECLKCTL)

1. Read: Anytime
Write: Anytime

Table 2-14. ECLKCTL Register Field Descriptions

Field	Description
7 NECLK	<p>No ECLK — Disable ECLK output</p> <p>This bit controls the availability of a free-running clock on the ECLK pin. This clock has a fixed rate equivalent to the internal bus clock.</p> <p>1 ECLK disabled 0 ECLK enabled</p>

2.3.2.5 IRQ Control Register (IRQCR)

Address 0x0209

Access: User read/write¹

Figure 2-7. IRQ Control Register (IRQCR)

1. Read: Anytime
Write:
IRQE: Once in normal mode, anytime in special mode
IRQEN: Anytime

Table 2-15. IRQCR Register Field Descriptions

Field	Description
7 IRQE	IRQ select edge sensitive only — 1 $\overline{\text{IRQ}}$ pin configured to respond only to falling edges. Falling edges on the $\overline{\text{IRQ}}$ pin are detected anytime when $\overline{\text{IRQE}}=1$ and will be cleared only upon a reset or the servicing of the $\overline{\text{IRQ}}$ interrupt. 0 $\overline{\text{IRQ}}$ configured for low level recognition
6 IRQEN	IRQ enable — 1 $\overline{\text{IRQ}}$ pin is connected to interrupt logic 0 $\overline{\text{IRQ}}$ pin is disconnected from interrupt logic

2.3.2.6 PIM Miscellaneous Register (PIMMISC)

Address 0x020A

Figure 2-9. Reserved Register

- 1. Read: Anytime
Write: Only in special mode.

This reserved register is designed for factory test purposes only and is not intended for general user access. Writing to this register when in special modes can alter the modules functionality.

2.3.2.8 Reserved Register

Figure 2-10. Reserved Register

- 1. Read: Anytime
Write: Only in special mode

This reserved register is designed for factory test purposes only and is not intended for general user access. Writing to this register when in special modes can alter the modules functionality.

2.3.2.9 Reserved Register

Figure 2-11. Reserved Register

- 1. Read: Anytime
Write: Only in special mode

NOTE

This reserved register is designed for factory test purposes only and is not intended for general user access. Writing to this register when in special modes can alter the modules functionality.

2.3.3 PIM Generic Registers

This section describes the details of all configuration registers.

- Writing to reserved bits has no effect and read returns zero.
- All register read accesses are synchronous to internal clocks.
- All registers can be written at any time, however a specific configuration might not become active. E.g. a pullup device does not become active while the port is used as a push-pull output.
- General-purpose data output availability depends on prioritization; input data registers always reflect the pin status independent of the use.
- Pull-device availability, pull-device polarity, wired-or mode, key-wake up functionality are independent of the prioritization unless noted differently.
- For availability of individual bits refer to [Section 2.3.1, “Register Map”](#) and [Table 2-39](#).

2.3.3.1 Port Data Register

Figure 2-12. Port Data Register

1. Read: Anytime. The data source is depending on the data direction value.
 Write: Anytime

This is a generic description of the standard port data registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-17. Port Data Register Field Descriptions

Field	Description
7-0 PTx7-0	<p>Port — General purpose input/output data</p> <p>This register holds the value driven out to the pin if the pin is used as a general purpose output. When not used with the alternative function (refer to Table 2-7), these pins can be used as general purpose I/O. If the associated data direction bits of these pins are set to 1, a read returns the value of the port register, otherwise the buffered pin input state is read.</p>

2.3.3.2 Port Input Register

Address 0x0262 PTIE
 0x0282 PTIADH
 0x0283 PTIADL
 0x02C1 PTIT
 0x02D1 PTIS
 0x02F1 PTIP

Access: User read only¹

Figure 2-13. Port Input Register

1. Read: Anytime
 Write: Never

This is a generic description of the standard port input registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-18. Port Input Register Field Descriptions

Field	Description
7-0 PTIx7-0	<p>Port Input — Data input</p> <p>A read always returns the buffered input state of the associated pin. It can be used to detect overload or short circuit conditions on output pins.</p>

2.3.3.3 Data Direction Register

Address 0x0264 DDRE
 0x0284 DDRADH
 0x0285 DDRADL
 0x02C2 DDRT
 0x02D2 DDRS
 0x02F2 DDRP

Access: User read/write¹

Figure 2-14. Data Direction Register

1. Read: Anytime
 Write: Anytime

This is a generic description of the standard data direction registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-19. Data Direction Register Field Descriptions

Field	Description
7-0 DDRx7-0	<p>Data Direction — Select general-purpose data direction</p> <p>This bit determines whether the pin is a general-purpose input or output. If a peripheral module controls the pin the content of the data direction register is ignored. Independent of the pin usage with a peripheral module this register determines the source of data when reading the associated data register address.</p> <p>Due to internal synchronization circuits, it can take up to two bus clock cycles until the correct value is read on port data and port input registers, when changing the data direction register. Eqn. 0-1</p> <p>1 Associated pin is configured as output 0 Associated pin is configured as input</p>

2.3.3.4 Pull Device Enable Register

Address 0x0266 PERE

Write: Anytime

This is a generic description of the standard port interrupt enable registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-22. Port Interrupt Enable Register Field Descriptions

Field	Description
7-0 PIEx7-0	<p>Port Interrupt Enable — Activate pin interrupt (KWU)</p> <p>This bit enables or disables the edge sensitive pin interrupt on the associated pin. An interrupt can be generated if the pin is operating in input or output mode when in use with the general-purpose or related peripheral function.</p> <p>1 Interrupt is enabled 0 Interrupt is disabled (interrupt flag masked)</p>

2.3.3.7 Port Interrupt Flag Register

Address 0x028E PIFADH
0x028F PIFADL
0x02D7 PIFS
0x0337 PIFL

Access: User read/write¹

Figure 2-18. Port Interrupt Flag Register

1. Read: Anytime
Write: Anytime, write 1 to clear

This is a generic description of the standard port interrupt flag registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-23. Port Interrupt Flag Register Field Descriptions

Field	Description
7-0 PIFx7-0	<p>Port Interrupt Flag — Signal pin event (KWU)</p> <p>This flag asserts after a valid active edge was detected on the related pin (see Section 2.4.4, “Pin interrupts and Key-Wakeup (KWU)”). This can be a rising or a falling edge based on the state of the polarity select register. An interrupt will occur if the associated interrupt enable bit is set.</p> <p>Writing a logic “1” to the corresponding bit field clears the flag.</p> <p>1 Active edge on the associated bit has occurred 0 No active edge occurred</p>

2.3.3.8 Digital Input Enable Register

Address 0x0298 DIENADH
0x0299 DIENADL

Access: User read/write¹

Figure 2-19. Digital Input Enable Register

1. Read: Anytime
Write: Anytime

This is a generic description of the standard digital input enable registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-24. Digital Input Enable Register Field Descriptions

Field	Description
7-0 DIENx7-0	<p>Digital Input Enable — Input buffer control</p> <p>This bit controls the digital input function. If set to 1 the input buffers are enabled and the pin can be used with the digital function. If a peripheral module is enabled which uses the pin with a digital function the input buffer is activated and the register bit is ignored. If the pin is used with an analog function this bit shall be cleared to avoid shoot-through current.</p> <p>1 Associated pin is configured as digital input 0 Associated pin digital input is disabled</p>

2.3.3.9 Reduced Drive Register

Address 0x02FD RDRP

Access: User read/write¹

Figure 2-20. Reduced Drive Register

1. Read: Anytime
Write: Anytime

This is a generic description of the standard reduced drive registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-25. Reduced Drive Register Field Descriptions

Field	Description
7-0 RDRx7-0	<p>Reduced Drive Register — Select reduced drive for output pin</p> <p>This bit configures the drive strength of the associated output pin as either full or reduced. If a pin is used as input this bit has no effect. The reduced drive function is independent of which function is being used on a particular pin.</p> <p>1 Reduced drive selected (approx. 1/10 of the full drive strength) 0 Full drive strength enabled</p>

2.3.3.10 Wired-Or Mode Register

Address 0x02DF WOMS

Access: User read/write¹

Figure 2-21. Wired-Or Mode Register

1. Read: Anytime
Write: Anytime

This is a generic description of the standard wired-or registers. Refer to [Table 2-39](#) to determine the implemented bits in the respective register. Unimplemented bits read zero.

Table 2-26. Wired-Or Mode Register Field Descriptions

Field	Description
7-0 WOMx7-0	<p>Wired-Or Mode — Enable open-drain output</p> <p>This bit configures the output buffer as wired-or. If enabled the output is driven active low only (open-drain) while the active high drive is turned off. This allows a multipoint connection of several serial modules. These bits have no influence on pins used as inputs.</p> <p>1 Output buffers operate as open-drain outputs 0 Output buffers operate as push-pull outputs</p>

2.3.3.11 PIM Reserved Register

Figure 2-22. PIM Reserved Register

- 1. Read: Always reads 0x00
- Write: Unimplemented

2.3.4 PIM Generic Register Exceptions

This section lists registers with deviations from the generic description in one or more register bits.

2.3.4.1 Port P Polarity Select Register (PPSP)

Figure 2-23. Port P Polarity Select Register

- 1. Read: Anytime
- Write: Anytime

Table 2-27. Port P Polarity Select Register Field Descriptions

Field	Description
2-1 PPSP	See Section 2.3.3.5, “Polarity Select Register”
0 PPSP	<p>Pull Polarity Select — Configure pull device and pin interrupt edge polarity on input pin</p> <p>This bit selects a pullup or a pulldown device if enabled on the associated port input pin. This bit also selects the polarity of the active interrupt edge.</p> <p>This bit selects if a high or a low level on FAULT5 generates a fault event in PMF.</p> <p>1 Pulldown device selected; rising edge selected; active-high level selected on FAULT5 input 0 Pullup device selected; falling edge selected; active-low level selected on FAULT5 input</p>

2.3.4.2 Port P Interrupt Enable Register (PIEP)

Figure 2-24. Port P Interrupt Enable Register

1. Read: Anytime
Write: Anytime

Table 2-28. Port P Interrupt Enable Register Field Descriptions

Field	Description
7 OCIE1	<p>Over-Current Interrupt Enable register —</p> <p>This bit enables or disables the over-current interrupt on PP0.</p> <p>1 PP0 over-current interrupt enabled 0 PP0 over-current interrupt disabled (interrupt flag masked)</p>
2-0 PIEP2-0	See Section 2.3.3.6, “Port Interrupt Enable Register”

2.3.4.3 Port P Interrupt Flag Register (PIFP)

Address 0x02F7 PIFP

Access: User read/write¹

Figure 2-25. Port P Interrupt Flag Register

- 1. Read: Anytime
- Write: Anytime, write 1 to clear

Table 2-29. Port P Interrupt Flag Register Field Descriptions

Field	Description
7 OCIF1	<p>Over-Current Interrupt Flag register —</p> <p>This flag asserts if an over-current condition is detected on PP0 (Section 2.4.5, “Over-Current Interrupt”).</p> <p>Writing a logic “1” to the corresponding bit field clears the flag.</p> <p>1 PP0 Over-current event occurred 0 No PP0 over-current event occurred</p>
2-0 PIFP2-0	<p>See Section 2.3.3.7, “Port Interrupt Flag Register”</p>

2.3.4.4 Port L Input Register (PTIL)

Address 0x0331

Access: User read only¹

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	PTILO ²
W								
Reset	0	0	0	0	0	0	0	-

Figure 2-26. Port L Input Register (PTIL)

1. Read: Anytime
Write: No Write
2. Only available for S12ZVMC256

Table 2-30. PTIL - Register Field Descriptions

Field	Description
0 PTILO	Port Input Data Register Port L — A read returns the synchronized input state if the associated pin is used in digital mode, that is the related DIENL bit is set to 1 and the pin is not used in analog mode (PTAENL[PTAENL0]=0). See Section 2.3.4.11, “Port L Input Divider Ratio Selection Register (PIRL)” . A one is read in any other case ¹ .

1. Refer to PTTEL bit description in [Section 2.3.4.11, “Port L Input Divider Ratio Selection Register \(PIRL\)”](#) for an override condition.

2.3.4.5 Port L Pull Select Register (PTPSL)

Address 0x0333

Access: User read/write¹

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	PTPSL0 ²
W

Figure 2-27. Port L Pull Select Register (PTPSL)

1. Read: Anytime
Write: Anytime
2. Only available for S12ZVMC256

Table 2-31. PTPSL Register Field Descriptions

Field	Description
1-0 PTPSL0	Port L Pull Select — This bit selects a pull device on the HVI pin in analog mode for open input detection. By default a pulldown device is active as part of the input voltage divider. If this bit set to 1 and PTTEL=1 and not in stop mode a pullup to a level close to V _{DDX} takes effect and overrides the weak pulldown device. Refer to Section 2.5.2, “Open Input Detection on HVI” . 1 Pullup enabled 0 Pulldown enabled

2.3.4.6 Port L Polarity Select Register (PPSL)

Address 0x0334 PPSL

Access: User read/write¹

Figure 2-28. Port L Polarity Select Register (PPSL)

1. Read: Anytime
Write: Anytime
2. Only available for S12ZVMC256

Table 2-32. PPSL Register Field Descriptions

Field	Description
1-0 PPSL0	Polarity Select — This bit selects the polarity of the active interrupt edge on the associated HVI pin. 1 Rising edge selected 0 Falling edge selected

2.3.4.7 Port L ADC Bypass Register (PTABYPL)

Address 0x033A

Access: User read/write¹

Figure 2-29. Port L ADC Bypass Register (PTABYPL)

1. Read: Anytime
Write: Anytime
2. Only available for S12ZVMC256

Table 2-33. PTABYPL Register Field Descriptions

Field	Description
1-0 PTABYPL0	Port L ADC Connection Bypass — This bit bypasses and powers down the impedance converter stage in the signal path from the analog input pin to the ADC channel input. This bit takes effect only if using direct input connection to the ADC channel (PTADIRL=1). 1 Impedance converter bypassed 0 Impedance converter used

2.3.4.8 Port L ADC Direct Register (PTADIRL)

Address 0x033B

Access: User read/write¹

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	PTADIRL0 ²
W								
Reset	0	0	0	0	0	0	0	0

Table 2-38. PTTEL Register Field Descriptions

Field	Description
1-0 PTTEL0	<p>Port L Test Enable —</p> <p>This bit forces the input buffer of the HVI pin active while using the analog function to support open input detection in run mode. Refer to Section 2.5.2, “Open Input Detection on HVI”). In stop mode this bit has no effect.</p> <p>Note: In direct mode (PTADIRL=1) the digital input buffer is not enabled.</p> <p>1 Input buffer enabled when used with analog function and not in direct mode (PTADIRL=0) 0 Input buffer disabled when used with analog function</p>

2.4 Functional Description

2.4.1 General

Each pin except BKGD can act as general-purpose I/O. In addition each pin can act as an output or input of a peripheral module.

2.4.2 Registers

[Table 2-39](#) lists the implemented configuration bits which are available on each port. These registers except the pin input registers can be written at any time, however a specific configuration might not become active. For example a pullup device does not become active while the port is used as a push-pull output.

Unimplemented bits read zero.

Table 2-39. Bit Indices of Implemented Register Bits per Port

	Port Data Register	Port Input Register	Data Direction Register	Pull Device Enable Register	Polarity Select Register	Port Interrupt Enable Register	Port Interrupt Flag Register	Digital Input Enable Register	Reduced Drive Register	Wired-Or Mode Register

1. If applicable the appropriate routing configuration must be set for the signals to take effect on the pins.

2. DDR maintains control

3. PER/PPS maintain control

4. DDR maintains control

5. PER/PPS maintain control

6. To use the digital input function the related bit in Digital Input Enable Register (DIENADx) must be set to logic level "1".

2.4.3 Pin I/O Control

Figure 2-35 illustrates the data paths to and from an I/O pin. Input and output data can always be read via the input register (PTIx, Section 2.3.3.2, "Port Input Register") independent if the pin is used as general-purpose I/O or with a shared peripheral function. If the pin is configured as input (DDRx=0, Section 2.3.3.3, "Data Direction Register"), the pin state can also be read through the data register (PTx, Section 2.3.3.1, "Port Data Register").

The general-purpose data direction configuration can be overruled by an enabled peripheral function shared on the same pin (Table 2-40). If more than one peripheral function is available and enabled at the same time, the highest ranked module according the predefined priority scheme in Table 2-7 will take precedence on the pin.

Figure 2-35. Illustration of I/O pin functionality

CAUTION Interrupts

This section describes the interrupts generated by the PIM and their individual sources. Vector addresses and interrupt priorities are defined at MCU level.

Table 2-41. PIM Interrupt Sources

Module Interrupt Sources	Local Enable
XIRQ	None
IRQ	IRQCR[IRQEN]
Port AD pin interrupt	PIEADH[PIEADH7-PIEADH0] PIEADL[PIEADL7-PIEADL0]
Port S pin interrupt	PIES[PIES5-PIES0]
Port P pin interrupt	PIEP[PIEP2-PIEP0]
Port L pin interrupt	PIEL[PIEL0]
PP0 over-current interrupt	PIEP[OCIE1]

2.4.3.1 XIRQ, IRQ Interrupts

The $\overline{\text{XIRQ}}$ pin allows requesting non-maskable interrupts after reset initialization. During reset, the X bit in the condition code register is set and any interrupts are masked until software enables them.

The $\overline{\text{IRQ}}$ pin allows requesting asynchronous interrupts. The interrupt input is disabled out of reset. To enable the interrupt the IRQCR[IRQEN] bit must be set and the I bit cleared in the condition code register. The interrupt can be configured for level-sensitive or falling-edge-sensitive triggering. If IRQCR[IRQEN] is cleared while an interrupt is pending, the request will deassert.

Both interrupts are capable to wake-up the device from stop mode. Means for glitch filtering are not provided on these pins.

2.4.4 Pin interrupts and Key-Wakeup (KWU)

Ports AD, S, P and L offer pin interrupt and key-wakeup capability. The related interrupt enable (PIE) as well as the sensitivity to rising or falling edges (PPS) can be individually configured on per-pin basis. All bits/pins in a port share the same interrupt vector. Interrupts can be used with the pins configured as inputs or outputs.

An interrupt is generated when a bit in the port interrupt flag (PIF) and its corresponding port interrupt enable (PIE) are both set. The pin interrupt feature is also capable to wake up the CPU when it is in stop or wait mode (key-wakeup).

A digital filter on each pin prevents short pulses from generating an interrupt. A valid edge on an input is detected if 4 consecutive samples of a passive level are followed by 4 consecutive samples of an active level. Else the sampling logic is restarted.

In run and wait mode the filters are continuously clocked by the bus clock. Pulses with a duration of $t_{PULSE} < n_{P_MASK}/f_{bus}$ are assuredly filtered out while pulses with a duration of $t_{PULSE} > n_{P_PASS}/f_{bus}$ guarantee a pin interrupt.

In stop mode the filter clock is generated by an RC-oscillator. The minimum pulse length varies over process conditions, temperature and voltage (Figure 2-36). Pulses with a duration of $t_{PULSE} < t_{P_MASK}$ are assuredly filtered out while pulses with a duration of $t_{PULSE} > t_{P_PASS}$ guarantee a wakeup event.

Please refer to the appendix table “Pin Timing Characteristics” for pulse length limits.

To maximize current saving the RC oscillator is active only if the following condition is true on any individual pin:

individual pin:

Sample count ≤ 4 (at active or passive level) and interrupt enabled ($PIE[x]=1$) and interrupt flag not set ($PIF[x]=0$).

Figure 2-36. Interrupt Glitch Filter (here: active low level selected)

2.4.5 Over-Current Interrupt

In case of an over-current condition on PP0 (see Section 2.5.2, “Open Input Detection on HVI”) the over-current interrupt flag PIFP[OCIF1] asserts. This flag generates an interrupt if the enable bit PIEP[OCIE1] is set.

An asserted flag immediately forces the output pin low to protect the device. The flag must be cleared to re-enable the driver.

2.4.6 High-Voltage Input

A high-voltage input (HVI) on port L has the following features:

- Input voltage proof up to V_{HVI}
- Digital input function with pin interrupt and wakeup from stop capability
- Analog input function with selectable divider ratio routable to ADC channel. Optional direct input bypassing voltage divider and impedance converter. Capable to wakeup from stop (pin interrupts in run mode not available). Open input detection.

Figure 2-37 shows a block diagram of the HVI.

NOTE

The term stop mode (STOP) is limited to voltage regulator operating in reduced performance mode (RPM). Refer to “Low Power Modes” section in device overview.

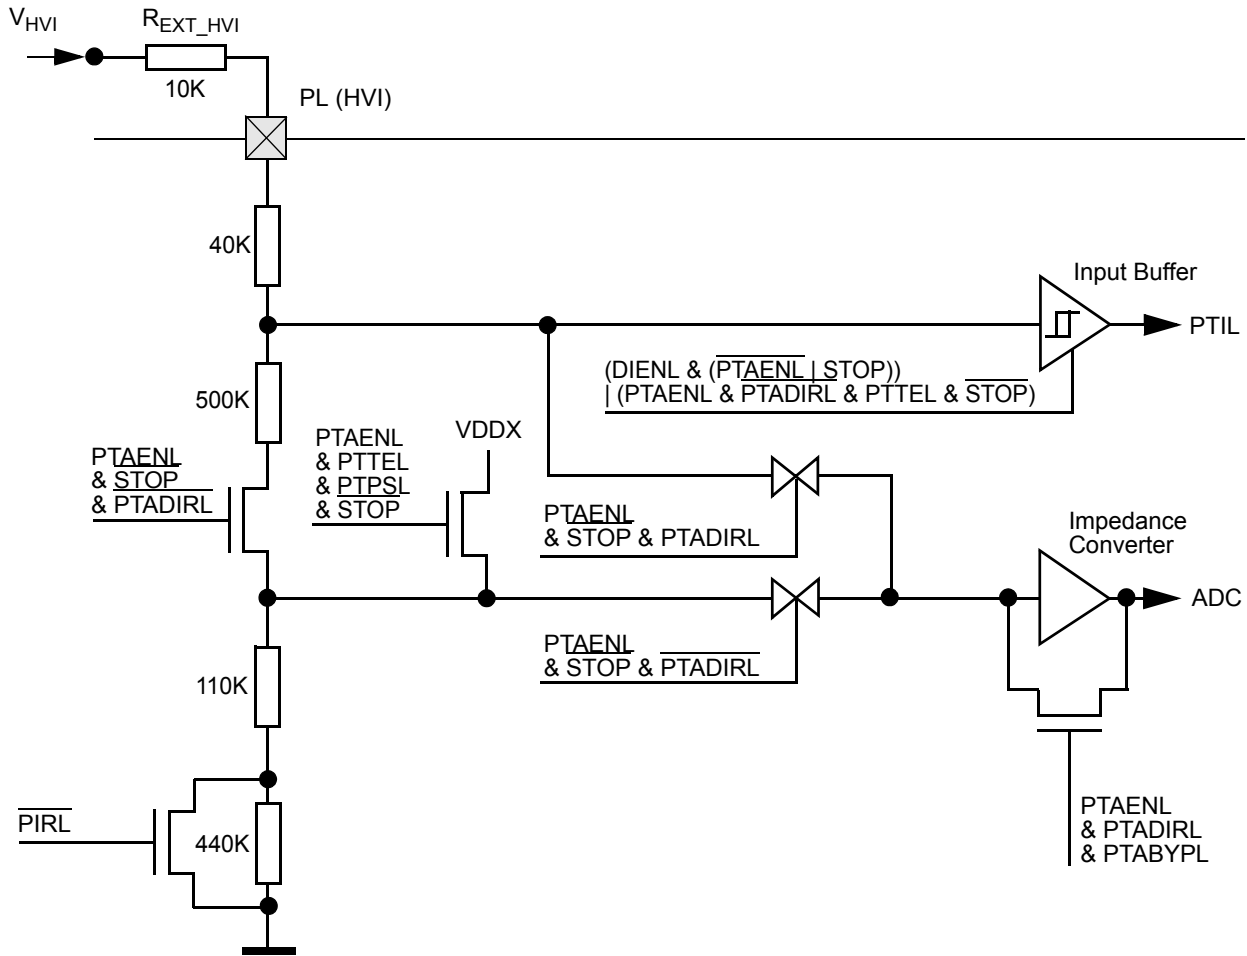

Figure 2-37. HVI Block Diagram

Voltages up to V_{HVI} can be applied to the HVI pin. Internal voltage dividers scale the input signals down to logic level. There are two modes, digital and analog, where these signals can be processed.

2.4.6.1 Digital Mode Operation

In digital mode ($PTAENL=0$) the input buffer is enabled if $DIENL=1$. The synchronized pin input state determined at threshold level V_{TH_HVI} can be read in register PTIL. Interrupt flag (PIFL) is set on input transitions if enabled ($PIEL=1$) and configured for the related edge polarity ($PPSL$). Wakeup from stop mode is supported.

2.4.6.2 Analog Mode Operation

In analog mode ($PTAENL=1$) the input buffer is forced off and the voltage applied to a selectable HVI pin can be measured on its related internal ADC channel (refer to device overview section for channel assignment). One of two input divider ratios ($Ratio_{H_HVI}$, $Ratio_{L_HVI}$) can be chosen ($PIRL$) on the analog

input or the voltage divider can be bypassed (PTADIRL=1). Additionally in latter case the impedance converter in the ADC signal path can be used or bypassed in direct input mode (PTABYPL).

Out of reset the digital input buffer of the selected pin is disabled to avoid shoot-through current. Thus pin interrupts can only be generated if DIENL=1.

In stop mode (RPM) the digital input buffer is enabled only if DIENL=1 to support wakeup functionality.

Table 2-42 shows the HVI input configuration depending on register bits and operation mode.

Table 2-42. HVI Input Configurations

Mode	DIENL	PTAENL	Digital Input	Analog Input	Resulting Function
Run	0	0	off	off	Input disabled (Reset)
	0	1	off ¹	enabled	Analog input, interrupt not supported
	1	0	enabled	off	Digital input, interrupt supported
	1	1	off ¹	enabled	Analog input, interrupt not supported
Stop ²	0	X	off	off	Input disabled, wakeup from stop not supported
	1	X	enabled	off	Digital input, wakeup from stop supported

1. Enabled if PTTEL=1 & PTADIRL=0)

2. The term “stop mode” is limited to voltage regulator operating in reduced performance mode (RPM; refer to “Low Power Modes” section in device overview). In any other case the HVI input configuration defaults to “run mode”. Therefore set PTAENL=0 before entering stop mode in order to generally support wakeup from stop.

NOTE

An external resistor R_{EXT_HVI} must always be connected to the high-voltage input to protect the device pins from fast transients and to achieve the specified pin input divider ratios when using the HVI in analog mode.

2.5 Initialization and Application Information

2.5.1 Port Data and Data Direction Register writes

It is not recommended to write PORTx/PTx and DDRx in a word access. When changing the register pins from inputs to outputs, the data may have extra transitions during the write access. Initialize the port data register before enabling the outputs.

2.5.2 Open Input Detection on HVI

The connection of an external pull device on a high-voltage input can be validated by using the built-in pull functionality of the HVI. Depending on the application type an external pull-down circuit can be detected with the internal pull-up device whereas an external pull-up circuit can be detected with the internal pull-down device which is part of the input voltage divider.

Note that the following procedures make use of a function that overrides the automatic disable mechanism of the digital input buffer when using the HVI in analog mode. Make sure to switch off the override function when using the HVI in analog mode after the check has been completed.

External pulldown device (Figure 2-38):

1. Enable analog function on HVI in non-direct mode (PTAENL[PTAENL0]=1, PTADIRL[PTADIRL0]=0)
2. Select internal pullup device on HVI (PTPSL[PTPSL0]=1)
3. Enable function to force input buffer active on HVI in analog mode (PTTEL[PTTEL0]=1)
4. Verify PTIL=0 for a connected external pulldown device; read PTIL=1 for an open input

Figure 2-38. Digital Input Read with Pullup Enabled

External pullup device (Figure 2-39):

1. Enable analog function on HVI in non-direct mode (PTAENL[PTAENL0]=1, PTADIRL[PTADIRL0]=0)
2. Select internal pulldown device on HVI (PTPSL[PTPSL0]=0)
3. Enable function to force input buffer active on HVI in analog mode (PTTEL[PTTEL0]=1)
4. Verify PTIL0=1 for a connected external pullup device; read PTIL0=0 for an open input

Figure 2-39. Digital Input Read with Pulldown Enabled

2.5.3 Over-Current Protection on EVDD1

Pin PP0 can be used as general-purpose I/O or due to its increased current capability in output mode as a switchable external power supply pin (EVDD1) for external devices like Hall sensors.

EVDD1 is supplied by the digital pad supply VDDX.

An over-current monitor is implemented to protect the controller from short circuits or excess currents on the output which can only arise if the pin is configured for full drive. Although the full drive current is available on the high and low side, the protection is only available on the high side with a current direction from EVDD1 to VSSX. There is also no protection to voltages higher than V_{DDX} .

To enable the over-current monitor set the related OCPE1 bit in register PIMMISC.

In stop mode the over-current monitor is disabled for power saving. The increased current capability cannot be maintained to supply the external device. Therefore when using the pin as power supply the external load must be powered down prior to entering stop mode by driving the output low.

An over-current condition is detected if the output current level exceeds the threshold I_{OCD} in run mode. The output driver is immediately forced low and the over-current interrupt flag OCIFx asserts. Refer to Section 2.4.5, “Over-Current Interrupt”.

Chapter 3

Memory Mapping Control (S12ZMMCV1)

Table 3-1. Revision History

Revision Number	Revision Date	Sections Affected	Description of Changes
V01.03	27 Jul 2012		Corrected Table 3-9
V01.04	27 Jul 2012		Added feature tags
V01.05	6 Aug 2012		Fixed wording
V01.06	12 Feb 2013	Figure 3-8 3.3.2.2/3-162	<ul style="list-style-type: none">• Changed “KByte:to “KB”• Corrected the description of the MMCECH/L register

3.1 Introduction

The S12ZMMC module controls the access to all internal memories and peripherals for the S12ZCPU, and the S12ZBDC module. It also provides access to the RAM for ADCs and the PTU module. The S12ZMMC determines the address mapping of the on-chip resources, regulates access priorities and enforces memory protection. [Figure 3-1](#) shows a block diagram of the S12ZMMC module.

3.1.1 Glossary

Table 3-2. Glossary Of Terms

Term	Definition
MCU	Microcontroller Unit
CPU	S12Z Central Processing Unit
BDC	S12Z Background Debug Controller
ADC	Analog-to-Digital Converter
PTU	Programmable Trigger Unit
unmapped address range	Address space that is not assigned to a memory
reserved address range	Address space that is reserved for future use cases
illegal access	Memory access, that is not supported or prohibited by the S12ZMMC, e.g. a data store to NVM
access violation	Either an illegal access or an uncorrectable ECC error
byte	8-bit data
word	16-bit data

3.1.2 Overview

The S12ZMMC provides access to on-chip memories and peripherals for the S12ZCPU, the S12ZBDC, the PTU, and the ADC. It arbitrates memory accesses and determines all of the MCU memory maps. Furthermore, the S12ZMMC is responsible for selecting the MCUs functional mode.

3.1.3 Features

- S12ZMMC mode operation control
- Memory mapping for S12ZCPU and S12ZBDC, PTU and ADCs
 - Maps peripherals and memories into a 16 MByte address space for the S12ZCPU, the S12ZBDC, the PTU, and the ADCs
 - Handles simultaneous accesses to different on-chip resources (NVM, RAM, and peripherals)
- Access violation detection and logging
 - Triggers S12ZCPU machine exceptions upon detection of illegal memory accesses and uncorrectable ECC errors
 - Logs the state of the S12ZCPU and the cause of the access error

3.1.4 Modes of Operation

3.1.4.1 Chip configuration modes

The S12ZMMC determines the chip configuration mode of the device. It captures the state of the MODC pin at reset and provides the ability to switch from special-single chip mode to normal single chip-mode.

3.1.4.2 Power modes

The S12ZMMC module is only active in run and wait mode. There is no bus activity in stop mode.

3.1.5 Block Diagram

Figure 3-1. S12ZMMC Block Diagram

3.2 External Signal Description

The S12ZMMC uses two external pins to determine the device's operating mode: RESET and MODC (Table 3-3)

See device overview for the mapping of these signals to device pins.

Table 3-3. External System Pins Associated With S12ZMMC

Pin Name	Description
RESET	External reset signal. The $\overline{\text{RESET}}$ signal is active low.
MODC	This input is captured in bit MODC of the MODE register when the external $\overline{\text{RESET}}$ pin deasserts.

3.3 Memory Map and Register Definition

3.3.1 Memory Map

A summary of the registers associated with the MMC block is shown in [Figure 3-2](#). Detailed descriptions of the registers and bits are given in the subsections that follow.

Address	Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 3-2. S12ZMMC Register Summary

3.3.2 Register Descriptions

This section consists of the S12ZMMC control and status register descriptions in address order.

3.3.2.1 Mode Register (MODE)

Address: 0x0070

	7	6	5	4	3	2	1	0
R	MODC	0	0	0	0	0	0	0
W								
Reset	MODC ¹	0	0	0	0	0	0	0

1. External signal (see Table 3-3).

 = Unimplemented or Reserved

Figure 3-3. Mode Register (MODE)

Read: Anytime.

Write: Only if a transition is allowed (see Figure 3-4).

The MODE register determines the operating mode of the MCU.

CAUTION

Table 3-4. MODE Field Descriptions

Field	Description
7 MODC	Mode Select Bit — This bit determines the current operating mode of the MCU. Its reset value is captured from the MODC pin at the rising edge of the $\overline{\text{RESET}}$ pin. Figure 3-4 illustrates the only valid mode transition from special single-chip mode to normal single chip mode.

Figure 3-4. Mode Transition Diagram

3.3.2.2 Error Code Register (MMCECH, MMCECL)

Address: 0x0080 (MMCECH)

Address: 0x0081 (MMCECL)

Figure 3-5. Error Code Register (MMCEC)

Read: Anytime

Write: Write of 0xFFFF to MMCECH:MMCECL resets both registers to 0x0000

Table 3-5. MMCECH and MMCECL Field Descriptions

Field	Description
7-4 (MMCECH) ITR[3:0]	<p>Initiator Field — The ITR[3:0] bits capture the initiator which caused the access violation. The initiator is captured in form of a 4 bit value which is assigned as follows:</p> <ul style="list-style-type: none"> 0: none (no error condition detected) 1: S12ZCPU 2: reserved 3: ADC0 4: ADC1 5: PTU 6-15: reserved
3-0 (MMCECH) TGT[3:0]	<p>Target Field — The TGT[3:0] bits capture the target of the faulty access. The target is captured in form of a 4 bit value which is assigned as follows:</p> <ul style="list-style-type: none"> 0: none 1: register space 2: RAM 3: EEPROM 4: program flash 5: IFR 6-15: reserved

Field	Description
7-4 (MMCECL) ACC[3:0]	Access Type Field — The ACC[3:0] bits capture the type of memory access, which caused the access violation. The access type is captured in form of a 4 bit value which is assigned as follows: 0: none (no error condition detected) 1: opcode fetch 2: vector fetch 3: data load 4: data store 5-15: reserved
3-0 (MMCECL) ERR[3:0]	Error Type Field — The EC[3:0] bits capture the type of the access violation. The type is captured in form of a 4 bit value which is assigned as follows: 0: none (no error condition detected) 1: access to an illegal access 2: uncorrectable ECC error 3-15:reserved

The MMCEC register captures debug information about access violations. It is set to a non-zero value if a S12ZCPU access violation or an uncorrectable ECC error has occurred. At the same time this register is set to a non-zero value, access information is captured in the MMPCn and MMCCCRn registers. The MMCECn, the MMPCn and the MMCCCRn registers are not updated if the MMCECn registers contain a non-zero value. The MMCECn registers are cleared by writing the value 0xFFFF.

3.3.2.3 Captured S12ZCPU Condition Code Register (MMCCCRH, MMCCRL)

Address: 0x0082 (MMCCCRH)

	7	6	5	4	3	2	1	0
R	CPUJ	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

Address: 0x0083 (MMCCRL)

Reset	0	0	0	0	0	0	0	0

Figure 3-6. Captured S12ZCPU Condition Code Register (MMCCCRH, MMCCRL)

Read: Anytime

Write: Never

Table 3-6. MMCCRH and MMCCRL Field Descriptions

Field	Description
7 (MMCCRH) CPUU	S12ZCPU User State Flag — This bit shows the state of the user/supervisor mode bit in the S12ZCPU's CCR at the time the access violation has occurred. The S12ZCPU user state flag is read-only; it will be automatically updated when the next error condition is flagged through the MMCEC register. This bit is undefined if the error code registers (MMCECn) are cleared.
6 (MMCCRL) CPUX	S12ZCPU X-Interrupt Mask — This bit shows the state of the X-interrupt mask in the S12ZCPU's CCR at the time the access violation has occurred. The S12ZCPU X-interrupt mask is read-only; it will be automatically updated when the next error condition is flagged through the MMCEC register. This bit is undefined if the error code registers (MMCECn) are cleared.
4 (MMCCRL) CPUI	S12ZCPU I-Interrupt Mask — This bit shows the state of the I-interrupt mask in the CPU's CCR at the time the access violation has occurred. The S12ZCPU I-interrupt mask is read-only; it will be automatically updated when the next error condition is flagged through the MMCEC register. This bit is undefined if the error code registers (MMCECn) are cleared.

3.3.2.4 Captured S12ZCPU Program Counter (MMCPCH, MMPCM, MMCPCL)

Address: 0x0085 (MMCPCH)

Address: 0x0086 (MMPCM)

Address: 0x0087 (MMCPCL)

Figure 3-7. Captured S12ZCPU Program Counter (MMCPCH, MMPCM, MMCPCL)

Read: Anytime

Write: Never

Table 3-7. MMCPCH, MMPCPM, and MMCPCL Field Descriptions

Field	Description
7-0 (MMCPCH)	S12ZCPU Program Counter Value — The CPUPC[23:0] stores the CPU's program counter value at the time the access violation occurred. CPUPC[23:0] always points to the instruction which triggered the violation. These bits are undefined if the error code registers (MMCECn) are cleared.
7-0 (MMPCPM)	
7-0 (MMCPCL)	
CPUPC[23:0]	

3.4 Functional Description

This section provides a complete functional description of the S12ZMMC module.

3.4.1 Global Memory Map

The S12ZMMC maps all on-chip resources into an 16MB address space, the global memory map. The exact resource mapping is shown in [Figure 3-8](#). The global address space is used by the S12ZCPU, ADCs, PTU, and the S12ZBDC module.

Figure 3-8. Global Memory Map

3.4.2 Illegal Accesses

The S12ZMMC module monitors all memory traffic for illegal accesses. See [Table 3-9](#) for a complete list of all illegal accesses.

Table 3-9. Illegal memory accesses

		S12ZCPU	S12ZBDC	ADCs and PTU
Register space	Read access	ok	ok	illegal access
	Write access	ok	ok	illegal access
	Code execution	illegal access		
RAM	Read access	ok	ok	ok
	Write access	ok	ok	ok
	Code execution	ok		
EEPROM	Read access	ok ⁽¹⁾	ok ¹	ok ¹
	Write access	illegal access	illegal access	illegal access
	Code execution	ok ¹		
Reserved Space	Read access	ok	ok	illegal access
	Write access	only permitted in SS mode	ok	illegal access
	Code execution	illegal access		
Reserved Read-only Space	Read access	ok	ok	illegal access
	Write access	illegal access	illegal access	illegal access
	Code execution	illegal access		
NVM IFR	Read access	ok ¹	ok ¹	illegal access
	Write access	illegal access	illegal access	illegal access
	Code execution	illegal access		
Program NVM	Read access	ok ¹	ok ¹	ok ¹
	Write access	illegal access	illegal access	illegal access
	Code execution	ok ¹		
Unmapped Space	Read access	illegal access	illegal access	illegal access
	Write access	illegal access	illegal access	illegal access
	Code execution	illegal access		

1. Unsupported NVM accesses during NVM command execution ("collisions"), are treated as illegal accesses.

Illegal accesses are reported in several ways:

- All illegal accesses performed by the S12ZCPU trigger machine exceptions.
- All illegal accesses performed through the S12ZBDC interface, are captured in the ILLACC bit of the BDCCSRL register.

- All illegal accesses performed by an ADC or PTU module trigger error interrupts. See ADC and PTU section for details.

NOTE

Illegal accesses caused by S12ZCPU opcode prefetches will also trigger machine exceptions, even if those opcodes might not be executed in the program flow. To avoid these machine exceptions, S12ZCPU instructions must not be executed from the last (high addresses) 8 bytes of RAM, EEPROM, and Flash.

3.4.3 Uncorrectable ECC Faults

RAM and flash use error correction codes (ECC) to detect and correct memory corruption. Each uncorrectable memory corruption, which is detected during a S12ZCPU, ADC or PTU access triggers a machine exception. Uncorrectable memory corruptions which are detected during a S12ZBDC access, are captured in the RAMWF or the RDINV bit of the BDCCSRL register.

Chapter 4

Interrupt (S12ZINTV0)

Table 4-1. Revision History

Version Number	Revision Date	Effective Date	Description of Changes
V00.01	17 Apr 2009	all	Initial version based on S12XINT V2.06
V00.02	14 Jul 2009	all	Reduce RESET vectors from three to one.
V00.03	05 Oct 2009	all	Removed dedicated ECC machine exception vector and marked vector-table entry "reserved for future use". Added a second illegal op-code vector (to distinguish between SPARE and TRAP).
V00.04	04 Jun 2010	all	Fixed remaining descriptions of RESET vectors. Split non-maskable hardware interrupts into XGATE software error and machine exception requests. Replaced mentions of CCR (old name from S12X) with CCW (new name).
V00.05	12 Jan 2011	all	Corrected wrong IRQ vector address in some descriptions.
V00.06	22 Mar 2011	all	Added vectors for RAM ECC and NVM ECC machine exceptions. And moved position to 1E0..1E8. Moved XGATE error interrupt to vector 1DC. Remaining vectors accordingly. Removed illegal address reset as a potential reset source.
V00.07	15 Apr 2011	all	Removed illegal address reset as a potential reset source from Exception vector table as well. Added the other possible reset sources to the table. Changed register addresses according to S12Z platform definition.
V00.08	02 May 2011	all	Reduced machine exception vectors to one. Removed XGATE error interrupt. Moved Spurious interrupt vector to 1DC. Moved vector base address to 010 to make room for NVM non-volatile registers.
V00.09	12 Aug 2011	all	Added: Machine exceptions can cause wake-up from STOP or WAIT
V00.10	21 Feb 2012	all	Corrected reset value for INT_CFADDR register
V00.11	02 Jul 2012	all	Removed references and functions related to XGATE
V00.12	22 May 2013	all	added footnote about availability of "Wake-up from STOP or WAIT by XIRQ with X bit set" feature

4.1 Introduction

The INT module decodes the priority of all system exception requests and provides the applicable vector for processing the exception to the CPU. The INT module supports:

- I-bit and X-bit maskable interrupt requests
- One non-maskable unimplemented page1 op-code trap

- One non-maskable unimplemented page2 op-code trap
- One non-maskable software interrupt (SWI)
- One non-maskable system call interrupt (SYS)
- One non-maskable machine exception vector request
- One spurious interrupt vector request
- One system reset vector request

Each of the I-bit maskable interrupt requests can be assigned to one of seven priority levels supporting a flexible priority scheme. The priority scheme can be used to implement nested interrupt capability where interrupts from a lower level are automatically blocked if a higher level interrupt is being processed.

4.1.1 Glossary

The following terms and abbreviations are used in the document.

Table 4-2. Terminology

Term	Meaning
CCW	Condition Code Register (in the S12Z CPU)
DMA	Direct Memory Access
INT	Interrupt
IPL	Interrupt Processing Level
ISR	Interrupt Service Routine
MCU	Micro-Controller Unit
$\overline{\text{IRQ}}$	refers to the interrupt request associated with the $\overline{\text{IRQ}}$ pin
$\overline{\text{XIRQ}}$	refers to the interrupt request associated with the $\overline{\text{XIRQ}}$ pin

4.1.2 Features

- Interrupt vector base register (IVBR)
- One system reset vector (at address 0xFFFFFC).
- One non-maskable unimplemented page1 op-code trap (SPARE) vector (at address vector base¹ + 0x0001F8).
- One non-maskable unimplemented page2 op-code trap (TRAP) vector (at address vector base¹ + 0x0001F4).
- One non-maskable software interrupt request (SWI) vector (at address vector base¹ + 0x0001F0).
- One non-maskable system call interrupt request (SYS) vector (at address vector base¹ + 0x00001EC).
- One non-maskable machine exception vector request (at address vector base¹ + 0x0001E8).
- One spurious interrupt vector (at address vector base¹ + 0x0001DC).
- One X-bit maskable interrupt vector request associated with $\overline{\text{XIRQ}}$ (at address vector base¹ + 0x0001D8).

1. The vector base is a 24-bit address which is accumulated from the contents of the interrupt vector base register (IVBR, used as the upper 15 bits of the address) and 0x000 (used as the lower 9 bits of the address).

- One I-bit maskable interrupt vector request associated with $\overline{\text{IRQ}}$ (at address vector base¹ + 0x0001D4).
- up to 113 additional I-bit maskable interrupt vector requests (at addresses vector base¹ + 0x000010 .. vector base + 0x0001D0).
- Each I-bit maskable interrupt request has a configurable priority level.
- I-bit maskable interrupts can be nested, depending on their priority levels.
- Wakes up the system from stop or wait mode when an appropriate interrupt request occurs or whenever $\overline{\text{XIRQ}}$ is asserted, even if X interrupt is masked.

4.1.3 Modes of Operation

- Run mode
This is the basic mode of operation.
- Wait mode
In wait mode, the INT module is capable of waking up the CPU if an eligible CPU exception occurs. Please refer to [Section 4.5.3, “Wake Up from Stop or Wait Mode”](#) for details.
- Stop Mode
In stop mode, the INT module is capable of waking up the CPU if an eligible CPU exception occurs. Please refer to [Section 4.5.3, “Wake Up from Stop or Wait Mode”](#) for details.

4.1.4 Block Diagram

[Figure 4-1](#) shows a block diagram of the INT module.

Figure 4-1. INT Block Diagram

4.2 External Signal Description

The INT module has no external signals.

4.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the INT module.

4.3.1 Module Memory Map

Table 4-3 gives an overview over all INT module registers.

Table 4-3. INT Memory Map

Address	Use	Access
0x000010–0x000011	Interrupt Vector Base Register (IVBR)	R/W
0x000012–0x000016	RESERVED	—
0x000017	Interrupt Request Configuration Address Register (INT_CFADDR)	R/W
0x000018	Interrupt Request Configuration Data Register 0 (INT_CFDATA0)	R/W

Table 4-3. INT Memory Map

0x000019	Interrupt Request Configuration Data Register 1 (INT_CFDATA1)	R/W
0x00001A	Interrupt Request Configuration Data Register 2 (INT_CFDATA2)	R/W
0x00001B	Interrupt Request Configuration Data Register 3 (INT_CFDATA3)	R/W
0x00001C	Interrupt Request Configuration Data Register 4 (INT_CFDATA4)	R/W
0x00001D	Interrupt Request Configuration Data Register 5 (INT_CFDATA5)	R/W
0x00001E	Interrupt Request Configuration Data Register 6 (INT_CFDATA6)	R/W
0x00001F	Interrupt Request Configuration Data Register 7 (INT_CFDATA7)	R/W

4.3.2 Register Descriptions

This section describes in address order all the INT module registers and their individual bits.

Address	Register Name		Bit 7	6	5	4	3	2	1	Bit 0	
0x000010	IVBR	R	IVB_ADDR[15:8]								
		W									
0x000011		R	IVB_ADDR[7:1]								0
		W									
0x000017	INT_CFADDR	R	0	INT_CFADDR[6:3]				0	0	0	
		W									
0x000018	INT_CFDATA0	R	0	0	0	0	0	PRIOLVL[2:0]			
		W									
0x000019	INT_CFDATA1	R	0	0	0	0	0	PRIOLVL[2:0]			
		W

Write: Anytime

Table 4-4. IVBR Field Descriptions

Field	Description
15–1 IVB_ADDR [15:1]	<p>Interrupt Vector Base Address Bits — These bits represent the upper 15 bits of all vector addresses. Out of reset these bits are set to 0xFFFE (i.e., vectors are located at 0xFFFE00–0xFFFFF).</p> <p>Note: A system reset will initialize the interrupt vector base register with “0xFFFE” before it is used to determine the reset vector address. Therefore, changing the IVBR has no effect on the location of the reset vector (0xFFFFFC–0xFFFFF).</p>

4.3.2.2 Interrupt Request Configuration Address Register (INT_CFADDR)

Address: 0x000017

Figure 4-4. Interrupt Configuration Address Register (INT_CFADDR)

Read: Anytime

Write: Anytime

Table 4-5. INT_CFADDR Field Descriptions

Field	Description
6–3 INT_CFADDR[6:3]	Interrupt Request Configuration Data Register Select Bits — These bits determine which of the 128 configuration data registers are accessible in the 8 register window at INT_CFDATA0–7. The hexadecimal value written to this register corresponds to the upper 4 bits of the vector number (multiply with 4 to get the vector address offset). If, for example, the value 0x70 is written to this register, the configuration data register block for the 8 interrupt vector requests starting with vector at address (vector base + (0x70*4 = 0x0001C0)) is selected and can be accessed as INT_CFDATA0–7.

4.3.2.3 Interrupt Request Configuration Data Registers (INT_CFDATA0–7)

The eight register window visible at addresses INT_CFDATA0–7 contains the configuration data for the block of eight interrupt requests (out of 128) selected by the interrupt configuration address register (INT_CFADDR) in ascending order. INT_CFDATA0 represents the interrupt configuration data register of the vector with the lowest address in this block, while INT_CFDATA7 represents the interrupt configuration data register of the vector with the highest address, respectively.

Table 4-6. INT_CFDATA0–7 Field Descriptions

Field	Description
2–0 PRIOLVL[2:0]	<p>Interrupt Request Priority Level Bits — The PRIOLVL[2:0] bits configure the interrupt request priority level of the associated interrupt request. Out of reset all interrupt requests are enabled at the lowest active level (“1”). Please also refer to Table 4-7 for available interrupt request priority levels.</p> <p>Note: Write accesses to configuration data registers of unused interrupt channels are ignored and read accesses return all 0s. For information about what interrupt channels are used in a specific MCU, please refer to the Device Reference Manual for that MCU.</p> <p>Note: When non I-bit maskable request vectors are selected, writes to the corresponding INT_CFDATA registers are ignored and read accesses return all 0s. The corresponding vectors do not have configuration data registers associated with them.</p> <p>Note: Write accesses to the configuration register for the spurious interrupt vector request (vector base + 0x0001DC) are ignored and read accesses return 0x07 (request is handled by the CPU, PRIOLVL = 7).</p>

Table 4-7. Interrupt Priority Levels

Priority	PRIOLVL2	PRIOLVL1	PRIOLVL0	Meaning
	0	0	0	Interrupt request is disabled
low	0	0	1	Priority level 1
	0	1	0	Priority level 2
	0	1	1	Priority level 3

Table 4-7. Interrupt Priority Levels

Priority	PRIOLVL2	PRIOLVL1	PRIOLVL0	Meaning
	1	0	0	Priority level 4
	1	0	1	Priority level 5
	1	1	0	Priority level 6
high	1	1	1	Priority level 7

4.4 Functional Description

The INT module processes all exception requests to be serviced by the CPU module. These exceptions include interrupt vector requests and reset vector requests. Each of these exception types and their overall priority level is discussed in the subsections below.

4.4.1 S12Z Exception Requests

The CPU handles both reset requests and interrupt requests. The INT module contains registers to configure the priority level of each I-bit maskable interrupt request which can be used to implement an interrupt priority scheme. This also includes the possibility to nest interrupt requests. A priority decoder is used to evaluate the relative priority of pending interrupt requests.

4.4.2 Interrupt Prioritization

After system reset all I-bit maskable interrupt requests are configured to be enabled, are set up to be handled by the CPU and have a pre-configured priority level of 1. Exceptions to this rule are the non-maskable interrupt requests and the spurious interrupt vector request at (vector base + 0x0001DC) which cannot be disabled, are always handled by the CPU and have a fixed priority levels. A priority level of 0 effectively disables the associated I-bit maskable interrupt request.

If more than one interrupt request is configured to the same interrupt priority level the interrupt request with the higher vector address wins the prioritization.

The following conditions must be met for an I-bit maskable interrupt request to be processed.

1. The local interrupt enabled bit in the peripheral module must be set.
2. The setup in the configuration register associated with the interrupt request channel must meet the following conditions:
 - a) The priority level must be set to non zero.
 - b) The priority level must be greater than the current interrupt processing level in the condition code register (CCW) of the CPU ($PRIOLVL[2:0] > IPL[2:0]$).
3. The I-bit in the condition code register (CCW) of the CPU must be cleared.
4. There is no access violation interrupt request pending.
5. There is no SYS, SWI, SPARE, TRAP, Machine Exception or \overline{XIRQ} request pending.

NOTE

All non I-bit maskable interrupt requests always have higher priority than I-bit maskable interrupt requests. If an I-bit maskable interrupt request is interrupted by a non I-bit maskable interrupt request, the currently active interrupt processing level (IPL) remains unaffected. It is possible to nest non I-bit maskable interrupt requests, e.g., by nesting SWI, SYS or TRAP calls.

4.4.2.1 Interrupt Priority Stack

The current interrupt processing level (IPL) is stored in the condition code register (CCW) of the CPU. This way the current IPL is automatically pushed to the stack by the standard interrupt stacking procedure. The new IPL is copied to the CCW from the priority level of the highest priority active interrupt request channel which is configured to be handled by the CPU. The copying takes place when the interrupt vector is fetched. The previous IPL is automatically restored from the stack by executing the RTI instruction.

4.4.3 Priority Decoder

The INT module contains a priority decoder to determine the relative priority for all interrupt requests pending for the CPU.

A CPU interrupt vector is not supplied until the CPU requests it. Therefore, it is possible that a higher priority interrupt request could override the original exception which caused the CPU to request the vector. In this case, the CPU will receive the highest priority vector and the system will process this exception first instead of the original request.

If the interrupt source is unknown (for example, in the case where an interrupt request becomes inactive after the interrupt has been recognized, but prior to the vector request), the vector address supplied to the CPU defaults to that of the spurious interrupt vector.

NOTE

Care must be taken to ensure that all exception requests remain active until the system begins execution of the applicable service routine; otherwise, the exception request may not get processed at all or the result may be a spurious interrupt request (vector at address (vector base + 0x0001DC)).

4.4.4 Reset Exception Requests

The INT module supports one system reset exception request. The different reset types are mapped to this vector (for details please refer to the Clock and Power Management Unit module (CPMU)):

1. Pin reset
2. Power-on reset
3. Low-voltage reset
4. Clock monitor reset request
5. COP watchdog reset request

4.4.5 Exception Priority

The priority (from highest to lowest) and address of all exception vectors issued by the INT module upon request by the CPU are shown in Table 4-8. Generally, all non-maskable interrupts have higher priorities than maskable interrupts. Please note that between the four software interrupts (Unimplemented op-code trap page1/page2 requests, SWI request, SYS request) there is no real priority defined since they cannot occur simultaneously (the S12Z CPU executes one instruction at a time).

Table 4-8. Exception Vector Map and Priority

Vector Address ⁽¹⁾	Source
0xFFFFFC	Pin reset, power-on reset, low-voltage reset, clock monitor reset, COP watchdog reset
(Vector base + 0x0001F8)	Unimplemented page1 op-code trap (SPARE) vector request
(Vector base + 0x0001F4)	Unimplemented page2 op-code trap (TRAP) vector request
(Vector base + 0x0001F0)	Software interrupt instruction (SWI) vector request
(Vector base + 0x0001EC)	System call interrupt instruction (SYS) vector request
(Vector base + 0x0001E8)	Machine exception vector request
(Vector base + 0x0001E4)	Reserved
(Vector base + 0x0001E0)	Reserved
(Vector base + 0x0001DC)	Spurious interrupt
(Vector base + 0x0001D8)	$\overline{\text{XIRQ}}$ interrupt request
(Vector base + 0x0001D4)	$\overline{\text{IRQ}}$ interrupt request
(Vector base + 0x000010 .. Vector base + 0x0001D0)	Device specific I-bit maskable interrupt sources (priority determined by the associated configuration registers, in descending order)

1. 24 bits vector address based

4.4.6 Interrupt Vector Table Layout

The interrupt vector table contains 128 entries, each 32 bits (4 bytes) wide. Each entry contains a 24-bit address (3 bytes) which is stored in the 3 low-significant bytes of the entry. The content of the most significant byte of a vector-table entry is ignored. Figure 4-13 illustrates the vector table entry format.

Figure 4-13. Interrupt Vector Table Entry

4.5 Initialization/Application Information

4.5.1 Initialization

After system reset, software should:

- Initialize the interrupt vector base register if the interrupt vector table is not located at the default location (0xFFFE00–0xFFFFFB).

- Initialize the interrupt processing level configuration data registers (INT_CFADDR, INT_CFDATA0–7) for all interrupt vector requests with the desired priority levels. It might be a good idea to disable unused interrupt requests.
- Enable I-bit maskable interrupts by clearing the I-bit in the CCW.
- Enable the X-bit maskable interrupt by clearing the X-bit in the CCW (if required).

4.5.2 Interrupt Nesting

The interrupt request priority level scheme makes it possible to implement priority based interrupt request nesting for the I-bit maskable interrupt requests.

- I-bit maskable interrupt requests can be interrupted by an interrupt request with a higher priority, so that there can be up to seven nested I-bit maskable interrupt requests at a time (refer to [Figure 4-14](#) for an example using up to three nested interrupt requests).

I-bit maskable interrupt requests cannot be interrupted by other I-bit maskable interrupt requests per default. In order to make an interrupt service routine (ISR) interruptible, the ISR must explicitly clear the I-bit in the CCW (CLI). After clearing the I-bit, I-bit maskable interrupt requests with higher priority can interrupt the current ISR.

An ISR of an interruptible I-bit maskable interrupt request could basically look like this:

- Service interrupt, e.g., clear interrupt flags, copy data, etc.
- Clear I-bit in the CCW by executing the CPU instruction CLI (thus allowing interrupt requests with higher priority)
- Process data
- Return from interrupt by executing the instruction RTI

Figure 4-14. Interrupt Processing Example

4.5.3 Wake Up from Stop or Wait Mode

4.5.3.1 CPU Wake Up from Stop or Wait Mode

Every I-bit maskable interrupt request which is configured to be handled by the CPU is capable of waking the MCU from stop or wait mode. Additionally machine exceptions can wake-up the MCU from stop or wait mode.

To determine whether an I-bit maskable interrupts is qualified to wake up the CPU or not, the same settings as in normal run mode are applied during stop or wait mode:

- If the I-bit in the CCW is set, all I-bit maskable interrupts are masked from waking up the MCU.
- An I-bit maskable interrupt is ignored if it is configured to a priority level below or equal to the current IPL in CCW.

The X-bit maskable interrupt request can wake up the MCU from stop or wait mode at anytime, even if the X-bit in CCW is set¹. If the X-bit maskable interrupt request is used to wake-up the MCU with the X-bit in the CCW set, the associated ISR is not called. The CPU then resumes program execution with the instruction following the WAI or STOP instruction. This feature works following the same rules like any interrupt request, i.e. care must be taken that the X-bit maskable interrupt request used for wake-up remains active at least until the system begins execution of the instruction following the WAI or STOP instruction; otherwise, wake-up may not occur.

1. The capability of the $\overline{\text{XIRQ}}$ pin to wake-up the MCU with the X bit set may not be available if, for example, the $\overline{\text{XIRQ}}$ pin is shared with other peripheral modules on the device. Please refer to the Port Integration Module (PIM) section of the MCU reference manual for details.

5.1 Introduction

The background debug controller (BDC) is a single-wire, background debug system implemented in on-chip hardware for minimal CPU intervention. The device BKGD pin interfaces directly to the BDC.

The S12ZBDC maintains the standard S12 serial interface protocol but introduces an enhanced handshake protocol and enhanced BDC command set to support the linear instruction set family of S12Z devices and offer easier, more flexible internal resource access over the BDC serial interface.

5.1.1 Glossary

Table 5-2. Glossary Of Terms

Term	Definition
DBG	On chip Debug Module
BDM	Active Background Debug Mode
CPU	S12Z CPU
SSC	Special Single Chip Mode (device operating mode)
NSC	Normal Single Chip Mode (device operating mode)
BDCSI	Background Debug Controller Serial Interface. This refers to the single pin BKGD serial interface.
EWAIT	Optional S12 feature which allows external devices to delay external accesses until deassertion of EWAIT

5.1.2 Features

The BDC includes these distinctive features:

- Single-wire communication with host development system
- SYNC command to determine communication rate
- Genuine non-intrusive handshake protocol
- Enhanced handshake protocol for error detection and stop mode recognition
- Active out of reset in special single chip mode
- Most commands not requiring active BDM, for minimal CPU intervention
- Full global memory map access without paging
- Simple flash mass erase capability

5.1.3 Modes of Operation

S12 devices feature power modes (run, wait, and stop) and operating modes (normal single chip, special single chip). Furthermore, the operation of the BDC is dependent on the device security status.

5.1.3.1 BDC Modes

The BDC features module specific modes, namely disabled, enabled and active. These modes are dependent on the device security and operating mode. In active BDM the CPU ceases execution, to allow BDC system access to all internal resources including CPU internal registers.

5.1.3.2 Security and Operating mode Dependency

In device run mode the BDC dependency is as follows

- Normal modes, unsecure device
General BDC operation available. The BDC is disabled out of reset.
- Normal modes, secure device
BDC disabled. No BDC access possible.
- Special single chip mode, unsecure
BDM active out of reset. All BDC commands are available.
- Special single chip mode, secure
BDM active out of reset. Restricted command set available.

When operating in secure mode, BDC operation is restricted to allow checking and clearing security by mass erasing the on-chip flash memory. Secure operation prevents BDC access to on-chip memory other than mass erase. The BDC command set is restricted to those commands classified as Always-available.

5.1.3.3 Low-Power Modes

5.1.3.3.1 Stop Mode

The execution of the CPU STOP instruction leads to stop mode only when all bus masters (CPU, or others, depending on the device) have finished processing. The operation during stop mode depends on the ENBDC and BDCCIS bit settings as summarized in [Table 5-3](#)

Table 5-3. BDC STOP Operation Dependencies

ENBDC	BDCCIS	Description Of Operation
0	0	BDC has no effect on STOP mode.
0	1	BDC has no effect on STOP mode.
1	0	Only BDCCLK clock continues
1	1	All clocks continue

A disabled BDC has no influence on stop mode operation. In this case the BDCSI clock is disabled in stop mode thus it is not possible to enable the BDC from within stop mode.

STOP Mode With BDC Enabled And BDCCIS Clear

If the BDC is enabled and BDCCIS is clear, then the BDC prevents the BDCCLK clock ([Figure 5-5](#)) from being disabled in stop mode. This allows BDC communication to continue throughout stop mode in order to access the BDCCSR register. All other device level clock signals are disabled on entering stop mode.

NOTE

This is intended for application debugging, not for fast flash programming.
Thus the CLKSW bit must be clear to map the BDCSI to BDCCLK.

With the BDC enabled, an internal acknowledge delays stop mode entry and exit by 2 BDCSI clock + 2 bus clock cycles. If no other module delays stop mode entry and exit, then these additional clock cycles represent a difference between the debug and not debug cases. Furthermore if a BDC internal access is being executed when the device is entering stop mode, then the stop mode entry is delayed until the internal access is complete (typically for 1 bus clock cycle).

Accesses to the internal memory map are not possible when the internal device clocks are disabled. Thus attempted accesses to memory mapped resources are suppressed and the NORESP flag is set. Resources can be accessed again by the next command received following exit from Stop mode.

A BACKGROUND command issued whilst in stop mode remains pending internally until the device leaves stop mode. This means that subsequent active BDM commands, issued whilst BACKGROUND is pending, set the ILLCMD flag because the device is not yet in active BDM.

If ACK handshaking is enabled, then the first ACK, following a stop mode entry is long to indicate a stop exception. The BDC indicates a stop mode occurrence by setting the BDCCSR bit STOP. If the host attempts further communication before the ACK pulse generation then the OVRUN bit is set.

STOP Mode With BDC Enabled And BDCCIS Set

If the BDC is enabled and BDCCIS is set, then the BDC prevents core clocks being disabled in stop mode. This allows BDC communication, for access of internal memory mapped resources, but not CPU registers, to continue throughout stop mode.

A BACKGROUND command issued whilst in stop mode remains pending internally until the device leaves stop mode. This means that subsequent active BDM commands, issued whilst BACKGROUND is pending, set the ILLCMD flag because the device is not yet in active BDM.

If ACK handshaking is enabled, then the first ACK, following a stop mode entry is long to indicate a stop exception. The BDC indicates a stop mode occurrence by setting the BDCCSR bit STOP. If the host attempts further communication before the ACK pulse generation then the OVRUN bit is set.

5.1.3.3.2 Wait Mode

The device enters wait mode when the CPU starts to execute the WAI instruction. The second part of the WAI instruction (return from wait mode) can only be performed when an interrupt occurs. Thus on entering wait mode the CPU is in the middle of the WAI instruction and cannot permit access to CPU internal resources, nor allow entry to active BDM. Thus only commands classified as Non-Intrusive or Always-Available are possible in wait mode.

On entering wait mode, the WAIT flag in BDCCSR is set. If the ACK handshake protocol is enabled then the first ACK generated after WAIT has been set is a long-ACK pulse. Thus the host can recognize a wait mode occurrence. The WAIT flag remains set and cannot be cleared whilst the device remains in wait mode. After the device leaves wait mode the WAIT flag can be cleared by writing a “1” to it.

A BACKGROUND command issued whilst in wait mode sets the NORESP bit and the BDM active request remains pending internally until the CPU leaves wait mode due to an interrupt. The device then enters BDM with the PC pointing to the address of the first instruction of the ISR.

With ACK disabled, further Non-Intrusive or Always-Available commands are possible, in this pending state, but attempted Active-Background commands set NORESP and ILLCMD because the BDC is not in active BDM state.

With ACK enabled, if the host attempts further communication before the ACK pulse generation then the OVRUN bit is set.

Similarly the STEP1 command issued from a WAI instruction cannot be completed by the CPU until the CPU leaves wait mode due to an interrupt. The first STEP1 into wait mode sets the BDCCSR WAIT bit.

If the part is still in Wait mode and a further STEP1 is carried out then the NORESP and ILLCMD bits are set because the device is no longer in active BDM for the duration of WAI execution.

5.1.4 Block Diagram

A block diagram of the BDC is shown in [Figure 5-1](#).

Figure 5-1. BDC Block Diagram

5.2 External Signal Description

A single-wire interface pin (BKGD) is used to communicate with the BDC system. During reset, this pin is a device mode select input. After reset, this pin becomes the dedicated serial interface pin for the BDC.

BKGD is a pseudo-open-drain pin with an on-chip pull-up. Unlike typical open-drain pins, the external RC time constant on this pin due to external capacitance, plays almost no role in signal rise time. The custom protocol provides for brief, actively driven speed-up pulses to force rapid rise times on this pin without risking harmful drive level conflicts. Refer to [Section 5.4.6](#) for more details.

5.3 Memory Map and Register Definition

5.3.1 Module Memory Map

[Table 5-4](#) shows the BDC memory map.

Table 5-4. BDC Memory Map

Global Address	Module	Size (Bytes)
Not Applicable	BDC registers	2

5.3.2 Register Descriptions

The BDC registers are shown in Figure 5-2. Registers are accessed only by host-driven communications to the BDC hardware using READ_BDCCSR and WRITE_BDCCSR commands. They are not accessible in the device memory map.

Global Address	Register Name	Bit 7	6	5	4	3	2	1	Bit 0	
Not Applicable	BDCCSRH	R	ENBDC	BDMACT	BDCCIS	0	STEAL	CLKSW	UNSEC	ERASE
		W								
Not Applicable	BDCCSRL	R	WAIT	STOP	RAMWF	OVRUN	NORESP	RDINV	ILLACC	ILLCMD
		W								

= Unimplemented, Reserved
 0 = Always read zero

Figure 5-2. BDC Register Summary

5.3.2.1 BDC Control Status Register High (BDCCSRH)

Register Address: This register is not in the device memory map. It is accessible using BDC inherent addressing commands

	7	6	5	4	3	2	1	0
R	ENBDC	BDMACT	BDCCIS	0	STEAL	CLKSW	UNSEC	ERASE
W								
Reset								
Secure AND SSC-Mode	1	1	0	0	0	0	0	0
Unsecure AND SSC-Mode	1	1	0	0	0	0	1	0
Secure AND NSC-Mode	0	0	0	0	0	0	0	0
Unsecure AND NSC-Mode	0	0	0	0	0	0	1	0

= Unimplemented, Reserved
 0 = Always read zero

Figure 5-3. BDC Control Status Register High (BDCCSRH)

Read: All modes through BDC operation only.

Write: All modes through BDC operation only, when not secured, but subject to the following:

- Bits 7,3 and 2 can only be written by WRITE_BDCCSR commands.
- Bit 5 can only be written by WRITE_BDCCSR commands when the device is not in stop mode.
- Bits 6, 1 and 0 cannot be written. They can only be updated by internal hardware.

Table 5-5. BDCCSRH Field Descriptions

Field	Description
7 ENBDC	<p>Enable BDC — This bit controls whether the BDC is enabled or disabled. When enabled, active BDM can be entered and non-intrusive commands can be carried out. When disabled, active BDM is not possible and the valid command set is restricted. Further information is provided in Table 5-7.</p> <p>0 BDC disabled 1 BDC enabled</p> <p>Note: ENBDC is set out of reset in special single chip mode.</p>
6 BDMACT	<p>BDM Active Status — This bit becomes set upon entering active BDM. BDMACT is cleared as part of the active BDM exit sequence.</p> <p>0 BDM not active 1 BDM active</p> <p>Note: BDMACT is set out of reset in special single chip mode.</p>
5 BDCCIS	<p>BDC Continue In Stop — If ENBDC is set then BDCCIS selects the type of BDC operation in stop mode (as shown in Table 5-3). If ENBDC is clear, then the BDC has no effect on stop mode and no BDC communication is possible. If ACK pulse handshaking is enabled, then the first ACK pulse following stop mode entry is a long ACK. This bit cannot be written when the device is in stop mode.</p> <p>0 Only the BDCCLK clock continues in stop mode 1 All clocks continue in stop mode</p>
3 STEAL	<p>Steal enabled with ACK— This bit forces immediate internal accesses with the ACK handshaking protocol enabled. If ACK handshaking is disabled then BDC accesses steal the next bus cycle.</p> <p>0 If ACK is enabled then BDC accesses await a free cycle, with a timeout of 512 cycles 1 If ACK is enabled then BDC accesses are carried out in the next bus cycle</p>
2 CLKSW	<p>Clock Switch — The CLKSW bit controls the BDCSI clock source. This bit is initialized to “0” by each reset and can be written to “1”. Once it has been set, it can only be cleared by a reset. When setting CLKSW a minimum delay of 150 cycles at the initial clock speed must elapse before the next command can be sent. This guarantees that the start of the next BDC command uses the new clock for timing subsequent BDC communications.</p> <p>0 BDCCLK used as BDCSI clock source 1 Device fast clock used as BDCSI clock source</p> <p>Note: Refer to the device specification to determine which clock connects to the BDCCLK and fast clock inputs.</p>
1 UNSEC	<p>Unsecure — If the device is unsecure, the UNSEC bit is set automatically.</p> <p>0 Device is secure. 1 Device is unsecure.</p> <p>Note: When UNSEC is set, the device is unsecure and the state of the secure bits in the on-chip Flash EEPROM can be changed.</p>
0 ERASE	<p>Erase Flash — This bit can only be set by the dedicated ERASE_FLASH command. ERASE is unaffected by write accesses to BDCCSR. ERASE is cleared either when the mass erase sequence is completed, independent of the actual status of the flash array or by a soft reset. Reading this bit indicates the status of the requested mass erase sequence.</p> <p>0 No flash mass erase sequence pending completion 1 Flash mass erase sequence pending completion.</p>

5.3.2.2 BDC Control Status Register Low (BDCCSRL)

Register Address: This register is not in the device memory map. It is accessible using BDC inherent addressing commands

Figure 5-4. BDC Control Status Register Low (BDCCSRL)

Read: BDC access only.

Write: Bits [7:5], [3:0] BDC access only, restricted to flag clearing by writing a “1” to the bit position.

Write: Bit 4 never. It can only be cleared by a SYNC pulse.

If ACK handshaking is enabled then BDC commands with ACK causing a BDCCSRL[3:1] flag setting condition also generate a long ACK pulse. Subsequent commands that are executed correctly generate a normal ACK pulse. Subsequent commands that are not correctly executed generate a long ACK pulse. The first ACK pulse after WAIT or STOP have been set also generates a long ACK. Subsequent ACK pulses are normal, whilst STOP and WAIT remain set.

Long ACK pulses are not immediately generated if an overrun condition is caused by the host driving the BKGD pin low whilst a target ACK is pending, because this would conflict with an attempted host transmission following the BKGD edge. When a whole byte has been received following the offending BKGD edge, the OVRUN bit is still set, forcing subsequent ACK pulses to be long.

Unimplemented BDC opcodes causing the ILLCMD bit to be set do not generate a long ACK because this could conflict with further transmission from the host. If the ILLCMD is set for another reason, then a long ACK is generated for the current command if it is a BDC command with ACK.

Table 5-6. BDCCSRL Field Descriptions

Field	Description
7 WAIT	WAIT Indicator Flag — Indicates that the device entered wait mode. Writing a “1” to this bit whilst in wait mode has no effect. Writing a “1” after exiting wait mode, clears the bit. 0 Device did not enter wait mode 1 Device entered wait mode.
6 STOP	STOP Indicator Flag — Indicates that the CPU requested stop mode following a STOP instruction. Writing a “1” to this bit whilst not in stop mode clears the bit. Writing a “1” to this bit whilst in stop mode has no effect. This bit can only be set when the BDC is enabled. 0 Device did not enter stop mode 1 Device entered stop mode.
5 RAMWF	RAM Write Fault — Indicates an ECC double fault during a BDC write access to RAM. Writing a “1” to this bit, clears the bit. 0 No RAM write double fault detected. 1 RAM write double fault detected.

Table 5-6. BDCCSRL Field Descriptions (continued)

Field	Description
4 OVRUN	<p>Overflow Flag — Indicates unexpected host activity before command completion. This occurs if a new command is received before the current command completion. With ACK enabled this also occurs if the host drives the BKGD pin low whilst a target ACK pulse is pending. To protect internal resources from misinterpreted BDC accesses following an overrun, internal accesses are suppressed until a SYNC clears this bit. A SYNC clears the bit.</p> <p>0 No overrun detected. 1 Overrun detected when issuing a BDC command.</p>
3 NORESP	<p>No Response Flag — Indicates that the BDC internal action or data access did not complete. This occurs in the following scenarios:</p> <ul style="list-style-type: none"> a) If no free cycle for an access is found within 512 core clock cycles. This could typically happen if a code loop without free cycles is executing with ACK enabled and STEAL clear. b) With ACK disabled or STEAL set, when an internal access is not complete before the host starts data/BDCCSRL retrieval or an internal write access is not complete before the host starts the next BDC command. c) Attempted internal memory or SYNC_PC accesses during STOP mode set NORESP if BDCCIS is clear. In the above cases, on setting NORESP, the BDC aborts the access if permitted. (For devices supporting EWAIT, BDC external accesses with EWAIT assertions, prevent a command from being aborted until EWAIT is deasserted). d) If a BACKGROUND command is issued whilst the device is in wait mode the NORESP bit is set but the command is not aborted. The active BDM request is completed when the device leaves wait mode. Furthermore subsequent CPU register access commands during wait mode set the NORESP bit, should it have been cleared. e) If a command is issued whilst awaiting return from Wait mode. This can happen when using STEP1 to step over a CPU WAI instruction, if the CPU has not returned from Wait mode before the next BDC command is received. f) If STEP1 is issued with the BDC enabled as the device enters Wait mode regardless of the BDMACT state. <p>When NORESP is set a value of 0xEE is returned for each data byte associated with the current access. Writing a “1” to this bit, clears the bit.</p> <p>0 Internal action or data access completed. 1 Internal action or data access did not complete.</p>
2 RDINV	<p>Read Data Invalid Flag — Indicates invalid read data due to an ECC error during a BDC initiated read access. The access returns the actual data read from the location. Writing a “1” to this bit, clears the bit.</p> <p>0 No invalid read data detected. 1 Invalid data returned during a BDC read access.</p>
1 ILLACC	<p>Illegal Access Flag — Indicates an attempted illegal access. This is set in the following cases:</p> <ul style="list-style-type: none"> When the attempted access addresses unimplemented memory When the access attempts to write to the flash array When a CPU register access is attempted with an invalid CRN (Section 5.4.5.1). <p>Illegal accesses return a value of 0xEE for each data byte. Writing a “1” to this bit, clears the bit.</p> <p>0 No illegal access detected. 1 Illegal BDC access detected.</p>

Table 5-6. BDCCSR Field Descriptions (continued)

Field	Description
0 ILLCMD	<p>Illegal Command Flag — Indicates an illegal BDC command. This bit is set in the following cases:</p> <ul style="list-style-type: none"> When an unimplemented BDC command opcode is received. When a DUMP_MEM{_WS}, FILL_MEM{_WS} or READ_SAME{_WS} is attempted in an illegal sequence. When an active BDM command is received whilst BDM is not active When a non Always-available command is received whilst the BDC is disabled or a flash mass erase is ongoing. When a non Always-available command is received whilst the device is secure <p>Read commands return a value of 0xEE for each data byte</p> <p>Writing a “1” to this bit, clears the bit.</p> <p>0 No illegal command detected. 1 Illegal BDC command detected.</p>

5.4 Functional Description

5.4.1 Security

If the device resets with the system secured, the device clears the BDCCSR UNSEC bit. In the secure state BDC access is restricted to the BDCCSR register. A mass erase can be requested using the ERASE_FLASH command. If the mass erase is completed successfully, the device programs the security bits to the unsecure state and sets the BDC UNSEC bit. If the mass erase is unsuccessful, the device remains secure and the UNSEC bit is not set.

For more information regarding security, please refer to device specific security information.

5.4.2 Enabling BDC And Entering Active BDM

BDM can be activated only after being enabled. BDC is enabled by setting the ENBDC bit in the BDCCSR register, via the single-wire interface, using the command WRITE_BDCCSR.

After being enabled, BDM is activated by one of the following¹:

- The BDC BACKGROUND command
- A CPU BGND instruction
- The DBG Breakpoint mechanism

Alternatively BDM can be activated directly from reset when resetting into Special Single Chip Mode.

The BDC is ready for receiving the first command 10 core clock cycles after the deassertion of the internal reset signal. This is delayed relative to the external pin reset as specified in the device reset documentation. On S12Z devices an NVM initialization phase follows reset. During this phase the BDC commands classified as always available are carried out immediately, whereas other BDC commands are subject to delayed response due to the NVM initialization phase.

NOTE

After resetting into SSC mode, the initial PC address must be supplied by the host using the WRITE_Rn command before issuing the GO command.

1. BDM active immediately out of special single-chip reset.

When BDM is activated, the CPU finishes executing the current instruction. Thereafter only BDC commands can affect CPU register contents until the BDC GO command returns from active BDM to user code or a device reset occurs. When BDM is activated by a breakpoint, the type of breakpoint used determines if BDM becomes active before or after execution of the next instruction.

NOTE

Attempting to activate BDM using a BGND instruction whilst the BDC is disabled, the CPU requires clock cycles for the attempted BGND execution. However BACKGROUND commands issued whilst the BDC is disabled are ignored by the BDC and the CPU execution is not delayed.

5.4.3 Clock Source

The BDC clock source can be mapped to a constant frequency clock source or a PLL based fast clock. The clock source for the BDC is selected by the CLKSW bit as shown in [Figure 5-5](#). The BDC internal clock is named BDCSI clock. If BDCSI clock is mapped to the BDCCLK by CLKSW then the serial interface communication is not affected by bus/core clock frequency changes. If the BDC is mapped to BDCFCLK then the clock is connected to a PLL derived source at device level (typically bus clock), thus can be subject to frequency changes in application. Debugging through frequency changes requires SYNC pulses to re-synchronize. The sources of BDCCLK and BDCFCLK are specified at device level.

BDC accesses of internal device resources always use the device core clock. Thus if the ACK handshake protocol is not enabled, the clock frequency relationship must be taken into account by the host.

When changing the clock source via the CLKSW bit a minimum delay of 150 cycles at the initial clock speed must elapse before a SYNC can be sent. This guarantees that the start of the next BDC command uses the new clock for timing subsequent BDC communications.

Figure 5-5. Clock Switch

5.4.4 BDC Commands

BDC commands can be classified into three types as shown in [Table 5-7](#).

Table 5-7. BDC Command Types

Command Type	Secure Status	BDC Status	CPU Status	Command Set
Always-available	Secure or Unsecure	Enabled or Disabled	—	<ul style="list-style-type: none"> • Read/write access to BDCCSR • Mass erase flash memory using ERASE_FLASH • SYNC • ACK enable/disable
Non-intrusive	Unsecure	Enabled	Code execution allowed	<ul style="list-style-type: none"> • Read/write access to BDCCSR • Memory access • Memory access with status • Mass erase flash memory using ERASE_FLASH • Debug register access • BACKGROUND • SYNC • ACK enable/disable
Active background	Unsecure	Active	Code execution halted	<ul style="list-style-type: none"> • Read/write access to BDCCSR • Memory access • Memory access with status • Mass erase flash memory using ERASE_FLASH • Debug register access • Read or write CPU registers • Single-step the application • Exit active BDM to return to the application program (GO) • SYNC • ACK enable/disable

Non-intrusive commands are used to read and write target system memory locations and to enter active BDM. Target system memory includes all memory and registers within the global memory map, including external memory.

Active background commands are used to read and write all memory locations and CPU resources. Furthermore they allow single stepping through application code and to exit from active BDM.

Non-intrusive commands can only be executed when the BDC is enabled and the device unsecure. Active background commands can only be executed when the system is not secure and is in active BDM.

Non-intrusive commands do not require the system to be in active BDM for execution, although, they can still be executed in this mode. When executing a non-intrusive command with the ACK pulse handshake protocol disabled, the BDC steals the next bus cycle for the access. If an operation requires multiple cycles, then multiple cycles can be stolen. Thus if stolen cycles are not free cycles, the application code execution is delayed. The delay is negligible because the BDC serial transfer rate dictates that such accesses occur infrequently.

For data read commands, the external host must wait at least 16 BDCSI clock cycles after sending the address before attempting to obtain the read data. This is to be certain that valid data is available in the BDC shift register, ready to be shifted out. For write commands, the external host must wait 16 bdcsl cycles after sending the data to be written before attempting to send a new command. This is to avoid disturbing the BDC shift register before the write has been completed. The external host must wait at least for 16 bdcsl cycles after a control command before starting any new serial command.

If the ACK pulse handshake protocol is enabled and STEAL is cleared, then the BDC waits for the first free bus cycle to make a non-intrusive access. If no free bus cycle occurs within 512 core clock cycles then the BDC aborts the access, sets the NORESP bit and uses a long ACK pulse to indicate an error condition to the host.

Table 5-8 summarizes the BDC command set. The subsequent sections describe each command in detail and illustrate the command structure in a series of packets, each consisting of eight bit times starting with a falling edge. The bar across the top of the blocks indicates that the BKGD line idles in the high state. The time for an 8-bit command is 8×16 target BDCSI clock cycles.

The nomenclature below is used to describe the structure of the BDC commands. Commands begin with an 8-bit hexadecimal command code in the host-to-target direction (most significant bit first)

/	=	separates parts of the command
d	=	delay 16 target BDCSI clock cycles (DLY)
dack	=	delay (16 cycles) no ACK; or delay (\Rightarrow 32 cycles) then ACK. (DACK)
ad24	=	24-bit memory address in the host-to-target direction
rd8	=	8 bits of read data in the target-to-host direction
rd16	=	16 bits of read data in the target-to-host direction
rd24	=	24 bits of read data in the target-to-host direction
rd32	=	32 bits of read data in the target-to-host direction
rd64	=	64 bits of read data in the target-to-host direction
rd.sz	=	read data, size defined by sz, in the target-to-host direction
wd8	=	8 bits of write data in the host-to-target direction
wd16	=	16 bits of write data in the host-to-target direction
wd32	=	32 bits of write data in the host-to-target direction
wd.sz	=	write data, size defined by sz, in the host-to-target direction
ss	=	the contents of BDCCSRL in the target-to-host direction
sz	=	memory operand size (00 = byte, 01 = word, 10 = long) (sz = 11 is reserved and currently defaults to long)
crn	=	core register number, 32-bit data width
WS	=	command suffix signaling the operation is with status

Table 5-8. BDC Command Summary

Command Mnemonic	Command Classification	ACK	Command Structure	Description
SYNC	Always Available	N/A	N/A ⁽¹⁾	Request a timed reference pulse to determine the target BDC communication speed
ACK_DISABLE	Always Available	No	0x03/d	Disable the communication handshake. This command does not issue an ACK pulse.
ACK_ENABLE	Always Available	Yes	0x02/dack	Enable the communication handshake. Issues an ACK pulse after the command is executed.
BACKGROUND	Non-Intrusive	Yes	0x04/dack	Halt the CPU if ENBDC is set. Otherwise, ignore as illegal command.

Table 5-8. BDC Command Summary (continued)

Command Mnemonic	Command Classification	ACK	Command Structure	Description
DUMP_MEM.sz	Non-Intrusive	Yes	(0x32+4 x sz)/dack/rd.sz	Dump (read) memory based on operand size (sz). Used with READ_MEM to dump large blocks of memory. An initial READ_MEM is executed to set up the starting address of the block and to retrieve the first result. Subsequent DUMP_MEM commands retrieve sequential operands.
DUMP_MEM.sz_WS	Non-Intrusive	No	(0x33+4 x sz)/d/ss/rd.sz	Dump (read) memory based on operand size (sz) and report status. Used with READ_MEM{ _WS} to dump large blocks of memory. An initial READ_MEM{ _WS} is executed to set up the starting address of the block and to retrieve the first result. Subsequent DUMP_MEM{ _WS} commands retrieve sequential operands.
FILL_MEM.sz	Non-Intrusive	Yes	(0x12+4 x sz)/wd.sz/dack	Fill (write) memory based on operand size (sz). Used with WRITE_MEM to fill large blocks of memory. An initial WRITE_MEM is executed to set up the starting address of the block and to write the first operand. Subsequent FILL_MEM commands write sequential operands.
FILL_MEM.sz_WS	Non-Intrusive	No	(0x13+4 x sz)/wd.sz/d/ss	Fill (write) memory based on operand size (sz) and report status. Used with WRITE_MEM{ _WS} to fill large blocks of memory. An initial WRITE_MEM{ _WS} is executed to set up the starting address of the block and to write the first operand. Subsequent FILL_MEM{ _WS} commands write sequential operands.
GO	Active Background	Yes	0x08/dack	Resume CPU user code execution
GO_UNTIL ⁽²⁾	Active Background	Yes	0x0C/dack	Go to user program. ACK is driven upon returning to active background mode.
NOP	Non-Intrusive	Yes	0x00/dack	No operation
READ_Rn	Active Background	Yes	(0x60+CRN)/dack/rd32	Read the requested CPU register
READ_MEM.sz	Non-Intrusive	Yes	(0x30+4 x sz)/ad24/dack/rd.sz	Read the appropriately-sized (sz) memory value from the location specified by the 24-bit address
READ_MEM.sz_WS	Non-Intrusive	No	(0x31+4 x sz)/ad24/d/ss/rd.sz	Read the appropriately-sized (sz) memory value from the location specified by the 24-bit address and report status
READ_DBGTB	Non-Intrusive	Yes	(0x07)/dack/rd32/dack/rd32	Read 64-bits of DBG trace buffer

Table 5-8. BDC Command Summary (continued)

Command Mnemonic	Command Classification	ACK	Command Structure	Description
READ_SAME.sz	Non-Intrusive	Yes	(0x50+4 x sz)/dack/rd.sz	Read from location. An initial READ_MEM defines the address, subsequent READ_SAME reads return content of same address
READ_SAME.sz_WS	Non-Intrusive	No	(0x51+4 x sz)/d/ss/rd.sz	Read from location. An initial READ_MEM defines the address, subsequent READ_SAME reads return content of same address
READ_BDCCSR	Always Available	No	0x2D/rd16	Read the BDCCSR register
SYNC_PC	Non-Intrusive	Yes	0x01/dack/rd24	Read current PC
WRITE_MEM.sz	Non-Intrusive	Yes	(0x10+4 x sz)/ad24/wd.sz/dack	Write the appropriately-sized (sz) memory value to the location specified by the 24-bit address
WRITE_MEM.sz_WS	Non-Intrusive	No	(0x11+4 x sz)/ad24/wd.sz/d/ss	Write the appropriately-sized (sz) memory value to the location specified by the 24-bit address and report status
WRITE_Rn	Active Background	Yes	(0x40+CRN)/wd32/dack	Write the requested CPU register
WRITE_BDCCSR	Always Available	No	0x0D/wd16	Write the BDCCSR register
ERASE_FLASH	Always Available	No	0x95/d	Mass erase internal flash
STEP1 (TRACE1)	Active Background	Yes	0x09/dack	Execute one CPU command.

1. The SYNC command is a special operation which does not have a command code.

2. The GO_UNTIL command is identical to the GO command if ACK is not enabled.

5.4.4.1 SYNC

The SYNC command is unlike other BDC commands because the host does not necessarily know the correct speed to use for serial communications until after it has analyzed the response to the SYNC command.

To issue a SYNC command, the host:

1. Ensures that the BKGD pin is high for at least 4 cycles of the slowest possible BDCSI clock without reset asserted.
2. Drives the BKGD pin low for at least 128 cycles of the slowest possible BDCSI clock.
3. Drives BKGD high for a brief speed-up pulse to get a fast rise time. (This speedup pulse is typically one cycle of the host clock which is as fast as the maximum target BDCSI clock).
4. Removes all drive to the BKGD pin so it reverts to high impedance.

5. Listens to the BKGD pin for the sync response pulse.

Upon detecting the sync request from the host (which is a much longer low time than would ever occur during normal BDC communications), the target:

1. Discards any incomplete command
2. Waits for BKGD to return to a logic high.
3. Delays 16 cycles to allow the host to stop driving the high speed-up pulse.
4. Drives BKGD low for 128 BDCSI clock cycles.
5. Drives a 1-cycle high speed-up pulse to force a fast rise time on BKGD.
6. Removes all drive to the BKGD pin so it reverts to high impedance.
7. Clears the OVRRUN flag (if set).

The host measures the low time of this 128-cycle SYNC response pulse and determines the correct speed for subsequent BDC communications. Typically, the host can determine the correct communication speed within a few percent of the actual target speed and the serial protocol can easily tolerate this speed error.

If the SYNC request is detected by the target, any partially executed command is discarded. This is referred to as a soft-reset, equivalent to a timeout in the serial communication. After the SYNC response, the target interprets the next negative edge (issued by the host) as the start of a new BDC command or the start of new SYNC request.

A SYNC command can also be used to abort a pending ACK pulse. This is explained in [Section 5.4.8](#).

5.4.4.2 ACK_DISABLE

Disable host/target handshake protocol

Always Available

Disables the serial communication handshake protocol. The subsequent commands, issued after the ACK_DISABLE command, do not execute the hardware handshake protocol. This command is not followed by an ACK pulse.

5.4.4.3 ACK_ENABLE

Enable host/target handshake protocol

Always Available

Enables the hardware handshake protocol in the serial communication. The hardware handshake is implemented by an acknowledge (ACK) pulse issued by the target MCU in response to a host command. The ACK_ENABLE command is interpreted and executed in the BDC logic without the need to interface with the CPU. An ACK pulse is issued by the target device after this command is executed. This command can be used by the host to evaluate if the target supports the hardware handshake protocol. If the target supports the hardware handshake protocol, subsequent commands are enabled to execute the hardware handshake protocol, otherwise this command is ignored by the target. [Table 5-8](#) indicates which commands support the ACK hardware handshake protocol.

For additional information about the hardware handshake protocol, refer to [Section 5.4.7,](#) and [Section 5.4.8.](#)

5.4.4.4 BACKGROUND

Enter active background mode (if enabled)

Non-intrusive

Provided ENBDC is set, the BACKGROUND command causes the target MCU to enter active BDM as soon as the current CPU instruction finishes. If ENBDC is cleared, the BACKGROUND command is ignored.

A delay of 16 BDCSI clock cycles is required after the BACKGROUND command to allow the target MCU to finish its current CPU instruction and enter active background mode before a new BDC command can be accepted.

The host debugger must set ENBDC before attempting to send the BACKGROUND command the first time. Normally the host sets ENBDC once at the beginning of a debug session or after a target system reset. During debugging, the host uses GO commands to move from active BDM to application program execution and uses the BACKGROUND command or DBG breakpoints to return to active BDM.

A BACKGROUND command issued during stop or wait modes cannot immediately force active BDM because the WAI instruction does not end until an interrupt occurs. For the detailed mode dependency description refer to [Section 5.1.3.3](#).

The host can recognize this pending BDM request condition because both NORESP and WAIT are set, but BDMACT is clear. Whilst in wait mode, with the pending BDM request, non-intrusive BDC commands are allowed.

5.4.4.5 DUMP_MEM.sz, DUMP_MEM.sz_WS

DUMP_MEM.sz

Read memory specified by debug address register, then increment address

Non-intrusive

DUMP_MEM.sz_WS

Read memory specified by debug address register with status, then increment address

Non-intrusive

DUMP_MEM{_WS} is used with the READ_MEM{_WS} command to access large blocks of memory. An initial READ_MEM{_WS} is executed to set-up the starting address of the block and to retrieve the first result. The DUMP_MEM{_WS} command retrieves subsequent operands. The initial address is incremented by the operand size (1, 2, or 4) and saved in a temporary register. Subsequent DUMP_MEM{_WS} commands use this address, perform the memory read, increment it by the current operand size, and store the updated address in the temporary register. If the with-status option is specified,

the BDCCSRL status byte is returned before the read data. This status byte reflects the state after the memory read was performed. If enabled, an ACK pulse is driven before the data bytes are transmitted. The effect of the access size and alignment on the next address to be accessed is explained in more detail in [Section 5.4.5.2](#)”.

NOTE

DUMP_MEM{WS} is a valid command only when preceded by SYNC, NOP, READ_MEM{WS}, or another DUMP_MEM{WS} command. Otherwise, an illegal command response is returned, setting the ILLCMD bit. NOP can be used for inter-command padding without corrupting the address pointer.

The size field (sz) is examined each time a DUMP_MEM{WS} command is processed, allowing the operand size to be dynamically altered. The examples show the DUMP_MEM.B{WS}, DUMP_MEM.W{WS} and DUMP_MEM.L{WS} commands.

5.4.4.6 FILL_MEM.sz, FILL_MEM.sz_WS

FILL_MEM.sz

Write memory specified by debug address register, then increment address

Non-intrusive

FILL_MEM.sz_WS

Write memory specified by debug address register with status, then increment address

Non-intrusive

FILL_MEM.sz_WS

FILL_MEM{ _WS } is used with the WRITE_MEM{ _WS } command to access large blocks of memory. An initial WRITE_MEM{ _WS } is executed to set up the starting address of the block and write the first datum. If an initial WRITE_MEM{ _WS } is not executed before the first FILL_MEM{ _WS }, an illegal command response is returned. The FILL_MEM{ _WS } command stores subsequent operands. The initial address is incremented by the operand size (1, 2, or 4) and saved in a temporary register. Subsequent FILL_MEM{ _WS } commands use this address, perform the memory write, increment it by the current operand size, and store the updated address in the temporary register. If the with-status option is specified, the BDCCSRL status byte is returned after the write data. This status byte reflects the state after the memory write was performed. If enabled an ACK pulse is generated after the internal write access has been completed or aborted. The effect of the access size and alignment on the next address to be accessed is explained in more detail in [Section 5.4.5.2](#)”

NOTE

FILL_MEM{ _WS } is a valid command only when preceded by SYNC, NOP, WRITE_MEM{ _WS }, or another FILL_MEM{ _WS } command. Otherwise, an illegal command response is returned, setting the ILLCMD bit. NOP can be used for inter command padding without corrupting the address pointer.

The size field (sz) is examined each time a FILL_MEM{ _WS } command is processed, allowing the operand size to be dynamically altered. The examples show the FILL_MEM.B{ _WS }, FILL_MEM.W{ _WS } and FILL_MEM.L{ _WS } commands.

5.4.4.7 GO

This command is used to exit active BDM and begin (or resume) execution of CPU application code. The CPU pipeline is flushed and refilled before normal instruction execution resumes. Prefetching begins at the current address in the PC. If any register (such as the PC) is altered by a BDC command whilst in BDM, the updated value is used when prefetching resumes. If enabled, an ACK is driven on exiting active BDM.

If a GO command is issued whilst the BDM is inactive, an illegal command response is returned and the ILLCMD bit is set.

5.4.4.8 GO_UNTIL

This command is used to exit active BDM and begin (or resume) execution of application code. The CPU pipeline is flushed and refilled before normal instruction execution resumes. Prefetching begins at the current address in the PC. If any register (such as the PC) is altered by a BDC command whilst in BDM, the updated value is used when prefetching resumes.

After resuming application code execution, if ACK is enabled, the BDC awaits a return to active BDM before driving an ACK pulse. timeouts do not apply when awaiting a GO_UNTIL command ACK.

If a GO_UNTIL is not acknowledged then a SYNC command must be issued to end the pending GO_UNTIL.

If a GO_UNTIL command is issued whilst BDM is inactive, an illegal command response is returned and the ILLCMD bit is set.

If ACK handshaking is disabled, the GO_UNTIL command is identical to the GO command.

5.4.4.9 NOP

NOP performs no operation and may be used as a null command where required.

5.4.4.10 READ_Rn

Read CPU register

Active Background

This command reads the selected CPU registers and returns the 32-bit result. Accesses to CPU registers are always 32-bits wide, regardless of implemented register width. Bytes that are not implemented return zero. The register is addressed through the CPU register number (CRN). See [Section 5.4.5.1](#) for the CRN address decoding. If enabled, an ACK pulse is driven before the data bytes are transmitted.

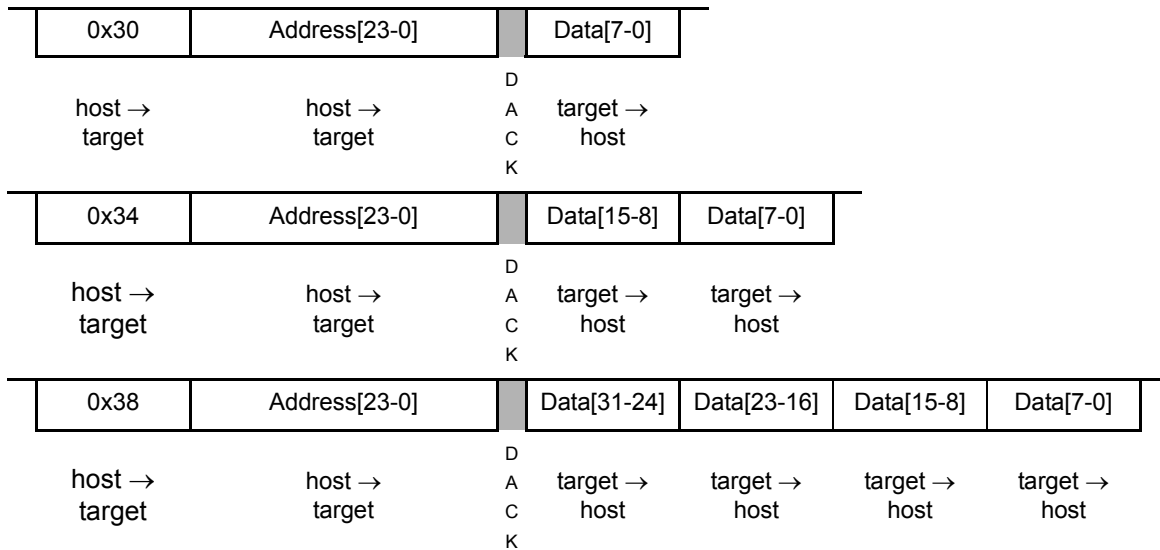

If the device is not in active BDM, this command is illegal, the ILLCMD bit is set and no access is performed.

5.4.4.11 READ_MEM.sz, READ_MEM.sz_WS

READ_MEM.sz

Read memory at the specified address

Non-intrusive

READ_MEM.sz_WS**Read memory at the specified address with status****Non-intrusive**

0x31	Address[23-0]		BDCCSRL	Data[7-0]				
host → target	host → target	D L Y	target → host	target → host				
0x35	Address[23-0]		BDCCSRL	Data [15-8]	Data [7-0]			
host → target	host → target	D L Y	target → host	target → host	target → host			
0x39	Address[23-0]		BDCCSRL	Data[31-24]	Data[23-16]	Data [15-8]	Data [7-0]	
host → target	host → target	D L Y	target → host	target → host	target → host	target → host	target → host	target → host

Read data at the specified memory address. The address is transmitted as three 8-bit packets (msb to lsb) immediately after the command.

The hardware forces low-order address bits to zero longword accesses to ensure these accesses are on 0-modulo-size alignments. Byte alignment details are described in [Section 5.4.5.2](#). If the with-status option is specified, the BDCCSR status byte is returned before the read data. This status byte reflects the state after the memory read was performed. If enabled, an ACK pulse is driven before the data bytes are transmitted.

The examples show the READ_MEM.B{ _WS }, READ_MEM.W{ _WS } and READ_MEM.L{ _WS } commands.

5.4.4.12 READ_DBGTB**Read DBG trace buffer****Non-intrusive**

0x07	TB Line [31-24]	TB Line [23-16]	TB Line [15-8]	TB Line [7-0]	TB Line [63-56]	TB Line [55-48]	TB Line [47-40]	TB Line [39-32]
host → target	D A C K target → host	target → host	target → host	target → host	D A C K target → host	target → host	target → host	target → host

This command is only available on devices, where the DBG module includes a trace buffer. Attempted use of this command on devices without a trace buffer return 0x00.

Read 64 bits from the DBG trace buffer. Refer to the DBG module description for more detailed information. If enabled an ACK pulse is generated before each 32-bit longword is ready to be read by the host. After issuing the first ACK a timeout is still possible whilst accessing the second 32-bit longword, since this requires separate internal accesses. The first 32-bit longword corresponds to trace buffer line

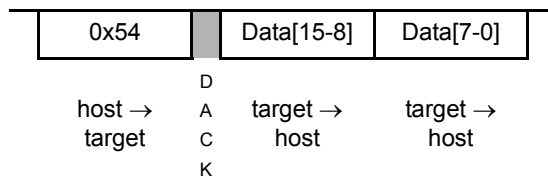

bits[31:0]; the second to trace buffer line bits[63:32]. If ACK handshaking is disabled, the host must wait 16 clock cycles (DLY) after completing the first 32-bit read before starting the second 32-bit read.

5.4.4.13 READ_SAME.sz, READ_SAME.sz_WS

READ_SAME

Read same location specified by previous READ_MEM{_WS}

Non-intrusive

READ_SAME_WS

Read same location specified by previous READ_MEM{_WS}

Non-intrusive

Read from location defined by the previous READ_MEM. The previous READ_MEM command defines the address, subsequent READ_SAME commands return contents of same address. The example shows the sequence for reading a 16-bit word size. Byte alignment details are described in [Section 5.4.5.2](#). If enabled, an ACK pulse is driven before the data bytes are transmitted.

NOTE

READ_SAME{_WS} is a valid command only when preceded by SYNC, NOP, READ_MEM{_WS}, or another READ_SAME{_WS} command. Otherwise, an illegal command response is returned, setting the ILLCMD bit. NOP can be used for inter-command padding without corrupting the address pointer.

5.4.4.14 READ_BDCCSR

Read BDCCSR Status Register

Always Available

Read the BDCCSR status register. This command can be executed in any mode.

5.4.4.15 SYNC_PC

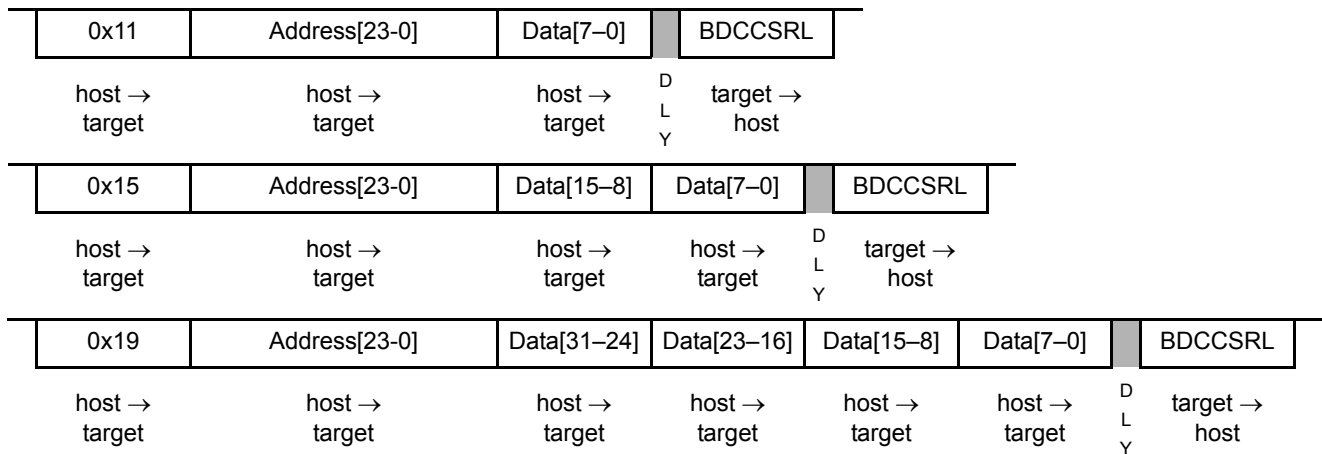

This command returns the 24-bit CPU PC value to the host. Unsuccessful SYNC_PC accesses return 0xEE for each byte. If enabled, an ACK pulse is driven before the data bytes are transmitted. The value of 0xEE is returned if a timeout occurs, whereby NORESP is set. This can occur if the CPU is executing the WAI instruction, or the STOP instruction with BDCCIS clear, or if a CPU access is delayed by EWAIT. If the CPU is executing the STOP instruction and BDCCIS is set, then SYNC_PC returns the PC address of the instruction following STOP in the code listing.

This command can be used to dynamically access the PC for performance monitoring as the execution of this command is considerably less intrusive to the real-time operation of an application than a BACKGROUND/read-PC/GO command sequence. Whilst the BDC is not in active BDM, SYNC_PC returns the PC address of the instruction currently being executed by the CPU. In active BDM, SYNC_PC returns the address of the next instruction to be executed on returning from active BDM. Thus following a write to the PC in active BDM, a SYNC_PC returns that written value.

5.4.4.16 WRITE_MEM.sz, WRITE_MEM.sz_WS

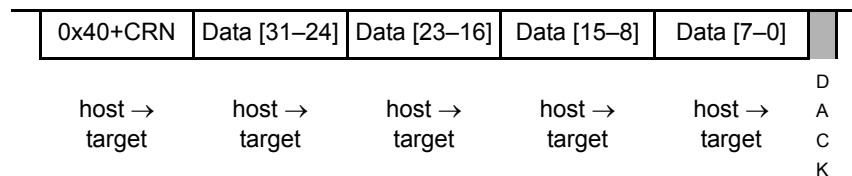

WRITE_MEM.sz_WS**Write memory at the specified address with status****Non-intrusive**

Write data to the specified memory address. The address is transmitted as three 8-bit packets (msb to lsb) immediately after the command.

If the with-status option is specified, the status byte contained in BDCCSRL is returned after the write data. This status byte reflects the state after the memory write was performed. The examples show the `WRITE_MEM.B{ _WS }`, `WRITE_MEM.W{ _WS }`, and `WRITE_MEM.L{ _WS }` commands. If enabled an ACK pulse is generated after the internal write access has been completed or aborted.

The hardware forces low-order address bits to zero longword accesses to ensure these accesses are on 0-modulo-size alignments. Byte alignment details are described in [Section 5.4.5.2](#)”.

5.4.4.17 WRITE_Rn**Write general-purpose CPU register****Active Background**

If the device is in active BDM, this command writes the 32-bit operand to the selected CPU general-purpose register. See [Section 5.4.5.1](#) for the CRN details. Accesses to CPU registers are always 32-bits wide, regardless of implemented register width. If enabled an ACK pulse is generated after the internal write access has been completed or aborted.

If the device is not in active BDM, this command is rejected as an illegal operation, the ILLCMD bit is set and no operation is performed.

5.4.4.18 WRITE_BDCCSR

Write BDCCSR

Always Available

16-bit write to the BDCCSR register. No ACK pulse is generated. Writing to this register can be used to configure control bits or clear flag bits. Refer to the register bit descriptions.

5.4.4.19 ERASE_FLASH

Erase FLASH

Always Available

Mass erase the internal flash. This command can always be issued. On receiving this command twice in succession, the BDC sets the ERASE bit in BDCCSR and requests a flash mass erase. Any other BDC command following a single ERASE_FLASH initializes the sequence, such that thereafter the ERASE_FLASH must be applied twice in succession to request a mass erase. If 512 BDCSI clock cycles elapse between the consecutive ERASE_FLASH commands then a timeout occurs, which forces a soft reset and initializes the sequence. The ERASE bit is cleared when the mass erase sequence has been completed. No ACK is driven.

During the mass erase operation, which takes many clock cycles, the command status is indicated by the ERASE bit in BDCCSR. Whilst a mass erase operation is ongoing, Always-available commands can be issued. This allows the status of the erase operation to be polled by reading BDCCSR to determine when the operation is finished.

The status of the flash array can be verified by subsequently reading the flash error flags to determine if the erase completed successfully.

ERASE_FLASH can be aborted by a SYNC pulse forcing a soft reset.

NOTE: Device Bus Frequency Considerations

The ERASE_FLASH command requires the default device bus clock frequency after reset. Thus the bus clock frequency must not be changed following reset before issuing an ERASE_FLASH command.

5.4.4.20 STEP1

Step1

Active Background

This command is used to step through application code. In active BDM this command executes the next CPU instruction in application code. If enabled an ACK is driven.

If a STEP1 command is issued and the CPU is not halted, the command is ignored.

Using STEP1 to step through a CPU WAI instruction is explained in [Section 5.1.3.3.2](#).

5.4.5 BDC Access Of Internal Resources

Unsuccessful read accesses of internal resources return a value of 0xEE for each data byte. This enables a debugger to recognize a potential error, even if neither the ACK handshaking protocol nor a status command is currently being executed. The value of 0xEE is returned in the following cases.

- Illegal address access, whereby ILLACC is set
- Invalid READ_SAME or DUMP_MEM sequence
- Invalid READ_Rn command (BDM inactive or CRN incorrect)
- Internal resource read with timeout, whereby NORESP is set

5.4.5.1 BDC Access Of CPU Registers

The CRN field of the READ_Rn and WRITE_Rn commands contains a pointer to the CPU registers. The mapping of CRN to CPU registers is shown in [Table 5-9](#). Accesses to CPU registers are always 32-bits wide, regardless of implemented register width. This means that the BDC data transmission for these commands is 32-bits long. The valid bits of the transfer are listed in the Valid Data Bits column. The other bits of the transmission are redundant.

Attempted accesses of CPU registers using a CRN of 0xD, 0xE or 0xF is invalid, returning the value 0xEE for each byte and setting the ILLACC bit.

Table 5-9. CPU Register Number (CRN) Mapping

CPU Register	Valid Data Bits	Command	Opcode	Command	Opcode
D0	[7:0]	WRITE_D0	0x40	READ_D0	0x60
D1	[7:0]	WRITE_D1	0x41	READ_D1	0x61
D2	[15:0]	WRITE_D2	0x42	READ_D2	0x62
D3	[15:0]	WRITE_D3	0x43	READ_D3	0x63
D4	[15:0]	WRITE_D4	0x44	READ_D4	0x64
D5	[15:0]	WRITE_D5	0x45	READ_D5	0x65
D6	[31:0]	WRITE_D6	0x46	READ_D6	0x66

Table 5-9. CPU Register Number (CRN) Mapping

CPU Register	Valid Data Bits	Command	Opcode	Command	Opcode
D7	[31:0]	WRITE_D7	0x47	READ_D7	0x67
X	[23:0]	WRITE_X	0x48	READ_X	0x68
Y	[23:0]	WRITE_Y	0x49	READ_Y	0x69
SP	[23:0]	WRITE_SP	0x4A	READ_SP	0x6A
PC	[23:0]	WRITE_PC	0x4B	READ_PC	0x6B
CCR	[15:0]	WRITE_CCR	0x4C	READ_CCR	0x6C

5.4.5.2 BDC Access Of Device Memory Mapped Resources

The device memory map is accessed using READ_MEM, DUMP_MEM, WRITE_MEM, FILL_MEM and READ_SAME, which support different access sizes, as explained in the command descriptions.

When an unimplemented command occurs during a DUMP_MEM, FILL_MEM or READ_SAME sequence, then that sequence is ended.

Illegal read accesses return a value of 0xEE for each byte. After an illegal access FILL_MEM and READ_SAME commands are not valid, and it is necessary to restart the internal access sequence with READ_MEM or WRITE_MEM. An illegal access does not break a DUMP_MEM sequence. After read accesses that cause the RDINV bit to be set, DUMP_MEM and READ_SAME commands are valid, it is not necessary to restart the access sequence with a READ_MEM.

The hardware forces low-order address bits to zero for longword accesses to ensure these accesses are realigned to 0-modulo-size alignments.

Word accesses map to 2-bytes from within a 4-byte field as shown in Table 5-10. Thus if address bits [1:0] are both logic “1” the access is realigned so that it does not straddle the 4-byte boundary but accesses data from within the addressed 4-byte field.

Table 5-10. Field Location to Byte Access Mapping

Address[1:0]	Access Size	00	01	10	11	Note
00	32-bit	Data[31:24]	Data[23:16]	Data [15:8]	Data [7:0]	
01	32-bit	Data[31:24]	Data[23:16]	Data [15:8]	Data [7:0]	Realigned
10	32-bit	Data[31:24]	Data[23:16]	Data [15:8]	Data [7:0]	Realigned
11	32-bit	Data[31:24]	Data[23:16]	Data [15:8]	Data [7:0]	Realigned
00	16-bit	Data [15:8]	Data [7:0]			
01	16-bit		Data [15:8]	Data [7:0]		
10	16-bit			Data [15:8]	Data [7:0]	
11	16-bit			Data [15:8]	Data [7:0]	Realigned
00	8-bit	Data [7:0]				
01	8-bit		Data [7:0]			
10	8-bit			Data [7:0]		
11	8-bit				Data [7:0]	
			Denotes byte that is not transmitted			

5.4.5.2.1 FILL_MEM and DUMP_MEM Increments and Alignment

FILL_MEM and DUMP_MEM increment the previously accessed address by the previous access size to calculate the address of the current access. On misaligned longword accesses, the address bits [1:0] are forced to zero, therefore the following FILL_MEM or DUMP_MEM increment to the first address in the next 4-byte field. This is shown in Table 5-11, the address of the first DUMP_MEM.32 following READ_MEM.32 being calculated from 0x004000+4.

When misaligned word accesses are realigned, then the original address (not the realigned address) is incremented for the following FILL_MEM, DUMP_MEM command.

Misaligned word accesses can cause the same locations to be read twice as shown in rows 6 and 7. The hardware ensures alignment at an attempted misaligned word access across a 4-byte boundary, as shown in row 7. The following word access in row 8 continues from the realigned address of row 7.

Table 5-11. Consecutive Accesses With Variable Size

Row	Command	Address	Address[1:0]	00	01	10	11
1	READ_MEM.32	0x004003	11	Accessed	Accessed	Accessed	Accessed
2	DUMP_MEM.32	0x004004	00	Accessed	Accessed	Accessed	Accessed
3	DUMP_MEM.16	0x004008	00	Accessed	Accessed		
4	DUMP_MEM.16	0x00400A	10			Accessed	Accessed
5	DUMP_MEM.08	0x00400C	00	Accessed			
6	DUMP_MEM.16	0x00400D	01		Accessed	Accessed	
7	DUMP_MEM.16	0x00400E	10			Accessed	Accessed
8	DUMP_MEM.16	0x004010	01	Accessed	Accessed		

5.4.5.2.2 READ_SAME Effects Of Variable Access Size

READ_SAME uses the unadjusted address given in the previous READ_MEM command as a base address for subsequent READ_SAME commands. When the READ_MEM and READ_SAME size parameters differ then READ_SAME uses the original base address but aligns 32-bit and 16-bit accesses, where those accesses would otherwise cross the aligned 4-byte boundary. Table 5-12 shows some examples of this.

Table 5-12. Consecutive READ_SAME Accesses With Variable Size

Row	Command	Base Address	00	01	10	11
1	READ_MEM.32	0x004003	Accessed	Accessed	Accessed	Accessed
2	READ_SAME.32	—	Accessed	Accessed	Accessed	Accessed
3	READ_SAME.16	—			Accessed	Accessed
4	READ_SAME.08	—				Accessed
5	READ_MEM.08	0x004000	Accessed			
6	READ_SAME.08	—	Accessed			
7	READ_SAME.16	—	Accessed	Accessed

5.4.6 BDC Serial Interface

The BDC communicates with external devices serially via the BKGD pin. During reset, this pin is a mode select input which selects between normal and special modes of operation. After reset, this pin becomes the dedicated serial interface pin for the BDC.

The BDC serial interface uses an internal clock source, selected by the CLKSW bit in the BDCCSR register. This clock is referred to as the target clock in the following explanation.

The BDC serial interface uses a clocking scheme in which the external host generates a falling edge on the BKGD pin to indicate the start of each bit time. This falling edge is sent for every bit whether data is transmitted or received. Data is transferred most significant bit (MSB) first at 16 target clock cycles per bit. The interface times out if during a command 512 clock cycles occur between falling edges from the host. The timeout forces the current command to be discarded.

The BKGD pin is a pseudo open-drain pin and has a weak on-chip active pull-up that is enabled at all times. It is assumed that there is an external pull-up and that drivers connected to BKGD do not typically drive the high level. Since R-C rise time could be unacceptably long, the target system and host provide brief drive-high (speedup) pulses to drive BKGD to a logic 1. The source of this speedup pulse is the host for transmit cases and the target for receive cases.

The timing for host-to-target is shown in [Figure 5-6](#) and that of target-to-host in [Figure 5-7](#) and [Figure 5-8](#). All cases begin when the host drives the BKGD pin low to generate a falling edge. Since the host and target operate from separate clocks, it can take the target up to one full clock cycle to recognize this edge; this synchronization uncertainty is illustrated in [Figure 5-6](#). The target measures delays from this perceived start of the bit time while the host measures delays from the point it actually drove BKGD low

to start the bit up to one target clock cycle earlier. Synchronization between the host and target is established in this manner at the start of every bit time.

Figure 5-6 shows an external host transmitting a logic 1 and transmitting a logic 0 to the BKGD pin of a target system. The host is asynchronous to the target, so there is up to a one clock-cycle delay from the host-generated falling edge to where the target recognizes this edge as the beginning of the bit time. Ten target clock cycles later, the target senses the bit level on the BKGD pin. Internal glitch detect logic requires the pin be driven high no later than eight target clock cycles after the falling edge for a logic 1 transmission.

Since the host drives the high speedup pulses in these two cases, the rising edges look like digitally driven signals.

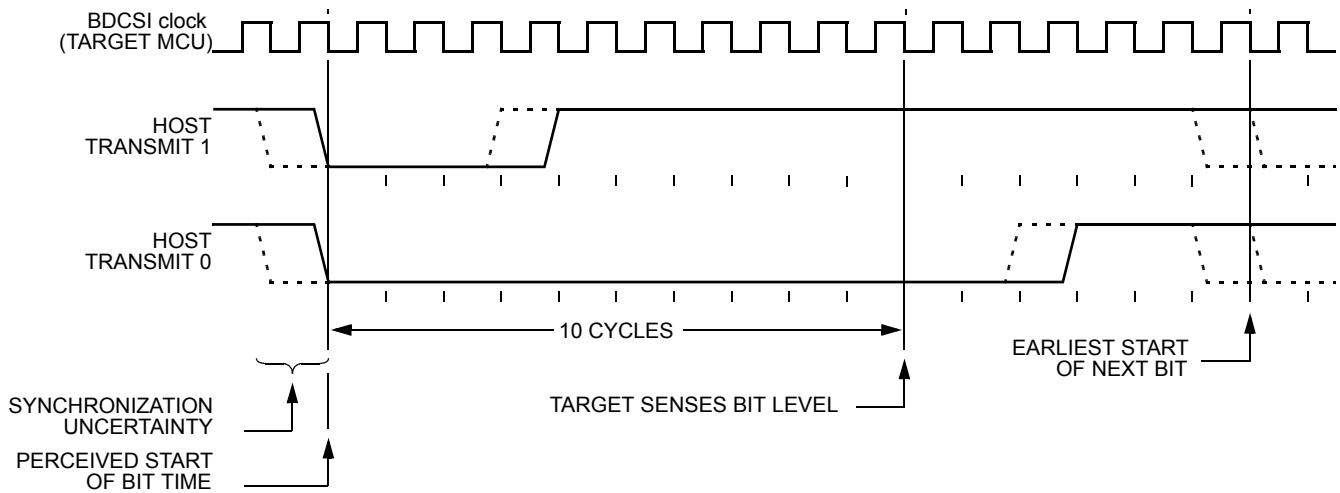

Figure 5-6. BDC Host-to-Target Serial Bit Timing

Figure 5-7 shows the host receiving a logic 1 from the target system. The host holds the BKGD pin low long enough for the target to recognize it (at least two target clock cycles). The host must release the low drive at the latest after 6 clock cycles, before the target drives a brief high speedup pulse seven target clock cycles after the perceived start of the bit time. The host should sample the bit level about 10 target clock cycles after it started the bit time.

Figure 5-7. BDC Target-to-Host Serial Bit Timing (Logic 1)

Figure 5-8 shows the host receiving a logic 0 from the target. The host initiates the bit time but the target finishes it. Since the target wants the host to receive a logic 0, it drives the BKGD pin low for 13 target clock cycles then briefly drives it high to speed up the rising edge. The host samples the bit level about 10 target clock cycles after starting the bit time.

Figure 5-8. BDC Target-to-Host Serial Bit Timing (Logic 0)

5.4.7 Serial Interface Hardware Handshake (ACK Pulse) Protocol

BDC commands are processed internally at the device core clock rate. Since the BDCSI clock can be asynchronous relative to the bus frequency, a handshake protocol is provided so the host can determine when an issued command has been executed. This section describes the hardware handshake protocol.

The hardware handshake protocol signals to the host controller when a BDC command has been executed by the target. This protocol is implemented by a low pulse (16 BDCSI clock cycles) followed by a brief speedup pulse on the BKGD pin, generated by the target MCU when a command, issued by the host, has been successfully executed (see Figure 5-9). This pulse is referred to as the ACK pulse. After the ACK pulse has finished, the host can start the bit retrieval if the last issued command was a read command, or start a new command if the last command was a write command or a control command.

Figure 5-9. Target Acknowledge Pulse (ACK)

The handshake protocol is enabled by the ACK_ENABLE command. The BDC sends an ACK pulse when the ACK_ENABLE command has been completed. This feature can be used by the host to evaluate if the target supports the hardware handshake protocol. If an ACK pulse is issued in response to this command, the host knows that the target supports the hardware handshake protocol.

Unlike the normal bit transfer, where the host initiates the transmission by issuing a negative edge on the BKGD pin, the serial interface ACK handshake pulse is initiated by the target MCU by issuing a negative edge on the BKGD pin. Figure 5-9 specifies the timing when the BKGD pin is being driven. The host must follow this timing constraint in order to avoid the risk of an electrical conflict at the BKGD pin.

When the handshake protocol is enabled, the STEAL bit in BDCCSR selects if bus cycle stealing is used to gain immediate access. If STEAL is cleared, the BDC is configured for low priority bus access using free cycles, without stealing cycles. This guarantees that BDC accesses remain truly non-intrusive to not affect the system timing during debugging. If STEAL is set, the BDC gains immediate access, if necessary stealing an internal bus cycle.

NOTE

If bus steals are disabled then a loop with no free cycles cannot allow access. In this case the host must recognize repeated NORESP messages and then issue a BACKGROUND command to stop the target and access the data.

Figure 5-10 shows the ACK handshake protocol without steal in a command level timing diagram. The READ_MEM.B command is used as an example. First, the 8-bit command code is sent by the host, followed by the address of the memory location to be read. The target BDC decodes the command. Then an internal access is requested by the BDC. When a free bus cycle occurs the READ_MEM.B operation is carried out. If no free cycle occurs within 512 core clock cycles then the access is aborted, the NORESP flag is set and the target generates a Long-ACK pulse.

Having retrieved the data, the BDC issues an ACK pulse to the host controller, indicating that the addressed byte is ready to be retrieved. After detecting the ACK pulse, the host initiates the data read part of the command.

Figure 5-10. Handshake Protocol at Command Level

Alternatively, setting the STEAL bit configures the handshake protocol to make an immediate internal access, independent of free bus cycles.

The ACK handshake protocol does not support nested ACK pulses. If a BDC command is not acknowledged by an ACK pulse, the host needs to abort the pending command first in order to be able to issue a new BDC command. The host can decide to abort any possible pending ACK pulse in order to be sure a new command can be issued. Therefore, the protocol provides a mechanism in which a command, and its corresponding ACK, can be aborted.

Commands With-Status do not generate an ACK, thus if ACK is enabled and a With-Status command is issued, the host must use the 512 cycle timeout to calculate when the data is ready for retrieval.

5.4.7.1 Long-ACK Hardware Handshake Protocol

If a command results in an error condition, whereby a BDCCSR flag is set, then the target generates a “Long-ACK” low pulse of 64 BDCSI clock cycles, followed by a brief speed pulse. This indicates to the host that an error has occurred. The host can subsequently read BDCCSR to determine the type of error. Whether normal ACK or Long-ACK, the ACK pulse is not issued earlier than 32 BDCSI clock cycles after the BDC command was issued. The end of the BDC command is assumed to be the 16th BDCSI clock cycle of the last bit. The 32 cycle minimum delay differs from the 16 cycle delay time with ACK disabled.

If a BDC access request does not gain access within 512 core clock cycles, the request is aborted, the NORESP flag is set and a Long-ACK pulse is transmitted to indicate an error case.

Following a STOP or WAI instruction, if the BDC is enabled, the first ACK, following stop or wait mode entry is a long ACK to indicate an exception.

5.4.8 Hardware Handshake Abort Procedure

The abort procedure is based on the SYNC command. To abort a command that has not responded with an ACK pulse, the host controller generates a sync request (by driving BKGD low for at least 128 BDCSI clock cycles and then driving it high for one BDCSI clock cycle as a speedup pulse). By detecting this long low pulse in the BKGD pin, the target executes the SYNC protocol, see [Section 5.4.4.1](#), and assumes that the pending command and therefore the related ACK pulse are being aborted. After the SYNC protocol has been completed the host is free to issue new BDC commands.

The host can issue a SYNC close to the 128 clock cycles length, providing a small overhead on the pulse length to assure the sync pulse is not misinterpreted by the target. See [Section 5.4.4.1](#).

[Figure 5-11](#) shows a SYNC command being issued after a READ_MEM, which aborts the READ_MEM command. Note that, after the command is aborted a new command is issued by the host.

Figure 5-11. ACK Abort Procedure at the Command Level (Not To Scale)

[Figure 5-12](#) shows a conflict between the ACK pulse and the SYNC request pulse. The target is executing a pending BDC command at the exact moment the host is being connected to the BKGD pin. In this case, an ACK pulse is issued simultaneously to the SYNC command. Thus there is an electrical conflict between the ACK speedup pulse and the SYNC pulse. As this is not a probable situation, the protocol does not prevent this conflict from happening.

Figure 5-12. ACK Pulse and SYNC Request Conflict

5.4.9 Hardware Handshake Disabled (ACK Pulse Disabled)

The default state of the BDC after reset is hardware handshake protocol disabled. It can also be disabled by the `ACK_DISABLE` BDC command. This provides backwards compatibility with the existing host devices which are not able to execute the hardware handshake protocol. For host devices that support the hardware handshake protocol, true non-intrusive debugging and error flagging is offered.

If the ACK pulse protocol is disabled, the host needs to use the worst case delay time at the appropriate places in the protocol.

If the handshake protocol is disabled, the access is always independent of free cycles, whereby BDC has higher priority than CPU. Since at least 2 bytes (command byte + data byte) are transferred over BKGD the maximum intrusiveness is only once every few hundred cycles.

After decoding an internal access command, the BDC then awaits the next internal core clock cycle. The relationship between BDCSI clock and core clock must be considered. If the host retrieves the data immediately, then the BDCSI clock frequency must not be more than 4 times the core clock frequency, in order to guarantee that the BDC gains bus access within 16 the BDCSI cycle `DLY` period following an access command. If the BDCSI clock frequency is more than 4 times the core clock frequency, then the host must use a suitable delay time before retrieving data (see 5.5.1/5-221). Furthermore, for stretched read accesses to external resources via a device expanded bus (if implemented) the potential extra stretch cycles must be taken into consideration before attempting to obtain read data.

If the access does not succeed before the host starts data retrieval then the `NORESP` flag is set but the access is not aborted. The `NORESP` state can be used by the host to recognize an unexpected access conflict due to stretched expanded bus accesses. Although the `NORESP` bit is set when an access does not succeed before the start of data retrieval, the access may succeed in following bus cycles if the internal access has already been initiated.

5.4.10 Single Stepping

When a STEP1 command is issued to the BDC in active BDM, the CPU executes a single instruction in the user code and returns to active BDM. The STEP1 command can be issued repeatedly to step through the user code one instruction at a time.

If an interrupt is pending when a STEP1 command is issued, the interrupt stacking operation occurs but no user instruction is executed. In this case the stacking counts as one instruction. The device re-enters active BDM with the program counter pointing to the first instruction in the interrupt service routine.

When stepping through the user code, the execution of the user code is done step by step but peripherals are free running. Some peripheral modules include a freeze feature, whereby their clocks are halted when the device enters active BDM. Timer modules typically include the freeze feature. Serial interface modules typically do not include the freeze feature. Hence possible timing relations between CPU code execution and occurrence of events of peripherals no longer exist.

If the handshake protocol is enabled and BDCCIS is set then stepping over the STOP instruction causes the Long-ACK pulse to be generated and the BDCCSR STOP flag to be set. When stop mode is exited due to an interrupt the device enters active BDM and the PC points to the start of the corresponding interrupt service routine. Stepping can be continued.

Stepping over a WAI instruction, the STEP1 command cannot be finished because active BDM cannot be entered after CPU starts to execute the WAI instruction.

Stepping over the WAI instruction causes the BDCCSR WAIT and NORESP flags to be set and, if the handshake protocol is enabled, then the Long-ACK pulse is generated. Then the device enters wait mode, clears the BDMACT bit and awaits an interrupt to leave wait mode. In this time non-intrusive BDC commands are possible, although the STEP1 has actually not finished. When an interrupt occurs the device leaves wait mode, enters active BDM and the PC points to the start of the corresponding interrupt service routine. A further ACK related to stepping over the WAI is not generated.

5.4.11 Serial Communication Timeout

The host initiates a host-to-target serial transmission by generating a falling edge on the BKGD pin. If BKGD is kept low for more than 128 target clock cycles, the target understands that a SYNC command was issued. In this case, the target waits for a rising edge on BKGD in order to answer the SYNC request pulse. When the BDC detects the rising edge a soft reset is generated, whereby the current BDC command is discarded. If the rising edge is not detected, the target keeps waiting forever without any timeout limit.

If a falling edge is not detected by the target within 512 clock cycles since the last falling edge, a timeout occurs and the current command is discarded without affecting memory or the operating mode of the MCU. This is referred to as a soft-reset. This timeout also applies if 512 cycles elapse between 2 consecutive ERASE_FLASH commands. The soft reset is disabled whilst the internal flash mass erase operation is pending completion.

timeouts are also possible if a BDC command is partially issued, or data partially retrieved. Thus if a time greater than 512 BDCSI clock cycles is observed between two consecutive negative edges, a soft-reset occurs causing the partially received command or data retrieved to be discarded. The next negative edge

at the BKGD pin, after a soft-reset has occurred, is considered by the target as the start of a new BDC command, or the start of a SYNC request pulse.

5.5 Application Information

5.5.1 Clock Frequency Considerations

Read commands without status and without ACK must consider the frequency relationship between BDCSI and the internal core clock. If the core clock is slow, then the internal access may not have been carried out within the standard 16 BDCSI cycle delay period (DLY). The host must then extend the DLY period or clock frequencies accordingly. Taking internal clock domain synchronizers into account, the minimum number of BDCSI periods required for the DLY is expressed by:

$$\#DLY > 3(f_{\text{BDCSI clock}} / f_{\text{core clock}}) + 4$$

and the minimum core clock frequency with respect to BDCSI clock frequency is expressed by

$$\text{Minimum } f_{\text{core clock}} = (3/(\#DLY \text{ cycles} - 4))f_{\text{BDCSI clock}}$$

For the standard 16 period DLY this yields $f_{\text{core clock}} \geq (1/4)f_{\text{BDCSI clock}}$

6.1 Introduction

NOTE

Device reference manuals specify which S12Z Debug module version is integrated on the device. Some reference manuals support families of devices, with device dependent Debug module versions. This chapter describes the superset. The feature differences are listed in [Table 6-2](#).

Table 6-2. Comparison of S12Z Debug Module Versions

S12Z Debug V2	S12Z Debug V4	S12Z Debug V3 (Lite)
Tracing included	Tracing included	Tracing not included
Profiling included	Profiling included	Profiling not included
Comparator C included	Comparator C included	Comparator C not included
Match 2 trigger included	Match 2 trigger included	Match 2 trigger not included
PREND bit not included	PREND bit included	PREND bit not included

The DBG module provides on-chip breakpoints and trace buffer with flexible triggering capability to allow non-intrusive debug of application software. The DBG module is optimized for the S12Z architecture and allows debugging of CPU module operations.

Typically the DBG module is used in conjunction with the BDC module, whereby the user configures the DBG module for a debugging session over the BDC interface. Once configured the DBG module is armed and the device leaves active BDM returning control to the user program, which is then monitored by the DBG module. Alternatively the DBG module can be configured over a serial interface using SWI routines.

6.1.1 Glossary

Table 6-3. Glossary Of Terms

Term	Definition
COF	Change Of Flow. Change in the program flow due to a conditional branch, indexed jump or interrupt
PC	Program Counter
BDM	Background Debug Mode. In this mode CPU application code execution is halted. Execution of BDC "active BDM" commands is possible.
BDC	Background Debug Controller
WORD	16-bit data entity
Data Line	64-bit data entity
CPU	S12Z CPU module
Trigger	A trace buffer input that triggers tracing start, end or mid point

6.1.2 Overview

The comparators monitor the bus activity of the CPU. A single comparator match or a series of matches can trigger bus tracing and/or generate breakpoints. A state sequencer determines if the correct series of matches occurs. Similarly an external event can trigger bus tracing and/or generate breakpoints.

The trace buffer is visible through a 2-byte window in the register address map and can be read out using standard 16-bit word reads.

6.1.3 Features

- Four comparators (A, B, C, and D)
 - Comparators A and C compare the full address bus and full 32-bit data bus
 - Comparators A and C feature a data bus mask register
 - Comparators B and D compare the full address bus only
 - Each comparator can be configured to monitor PC addresses or addresses of data accesses
 - Each comparator can select either read or write access cycles
 - Comparator matches can force state sequencer state transitions

- Three comparator modes
 - Simple address/data comparator match mode
 - Inside address range mode, $\text{Addmin} \leq \text{Address} \leq \text{Addmax}$
 - Outside address range match mode, $\text{Address} < \text{Addmin}$ or $\text{Address} > \text{Addmax}$
- State sequencer control
 - State transitions forced by comparator matches
 - State transitions forced by software write to TRIG
 - State transitions forced by an external event
- The following types of breakpoints
 - CPU breakpoint entering active BDM on breakpoint (BDM)
 - CPU breakpoint executing SWI on breakpoint (SWI)
- Trace control
 - Tracing session triggered by state sequencer
 - Begin, End, and Mid alignment of tracing to trigger
- Four trace modes
 - Normal: change of flow (COF) PC information is stored (see [Section 6.4.5.2.1](#)) for change of flow definition.
 - Loop1: same as Normal but inhibits consecutive duplicate source address entries
 - Detail: address and data for all read/write access cycles are stored
 - Pure PC: All program counter addresses are stored.
- 2 Pin (data and clock) profiling interface
 - Output of code flow information

6.1.4 Modes of Operation

The DBG module can be used in all MCU functional modes.

The DBG module can issue breakpoint requests to force the device to enter active BDM or an SWI ISR. The BDC BACKGROUND command is also handled by the DBG to force the device to enter active BDM. When the device enters active BDM through a BACKGROUND command with the DBG module armed, the DBG remains armed.

6.1.5 Block Diagram

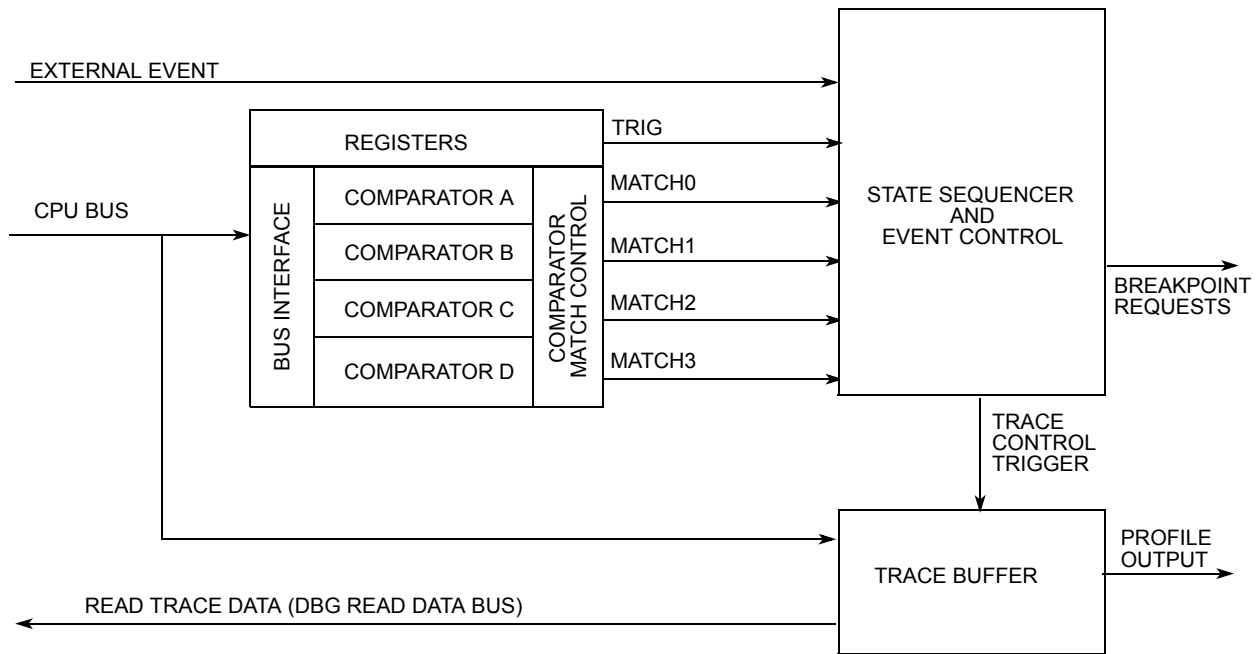

Figure 6-1. Debug Module Block Diagram

6.2 External Signal Description

6.2.1 External Event Input

The DBG module features an external event input signal, DBGEV. The mapping of this signal to a device pin is specified in the device specific documentation. This function can be enabled and configured by the EEVE field in the DBG C1 control register. This signal is input only and allows an external event to force a state sequencer transition, or trace buffer entry, or to gate trace buffer entries. With the external event function enabled, a falling edge at the external event pin constitutes an event. Rising edges have no effect. If configured for gating trace buffer entries, then a low level at the pin allows entries, but a high level suppresses entries. The maximum frequency of events is half the internal core bus frequency. The function is explained in the EEVE field description.

NOTE

Due to input pin synchronization circuitry, the DBG module sees external events 2 bus cycles after they occur at the pin. Thus an external event occurring less than 2 bus cycles before arming the DBG module is perceived to occur whilst the DBG is armed.

When the device is in stop mode the synchronizer clocks are disabled and the external events are ignored.

6.2.2 Profiling Output

The DBG module features a profiling data output signal PDO. The mapping of this signal to a device pin is specified in the device specific documentation. The device pin is enabled for profiling by setting the PDOE bit. The profiling function can be enabled by the PROFILE bit in the DBGTCRL control register. This signal is output only and provides a serial, encoded data stream that can be used by external development tools to reconstruct the internal CPU code flow, as specified in [Section 6.4.6](#). During code profiling the device PDOCLK output is used as a clock signal.

6.3 Memory Map and Registers

6.3.1 Module Memory Map

A summary of the registers associated with the DBG module is shown in [Figure 6-2](#). Detailed descriptions of the registers and bits are given in the subsections that follow.

6.3.2 Register Descriptions

This section consists of the DBG register descriptions in address order. When ARM is set in DBG1, the only bits in the DBG module registers that can be written are ARM, and TRIG

6.3.2.1 Debug Control Register 1 (DBG1)

Address: 0x0100

	7	6	5	4	3	2	1	0
0x0100	ARM	0 TRIG	reserved	BDMBP	BRKCPU	reserved	EEVE	
Reset	0	0	0	0	0	0	0	0

Figure 6-3. Debug Control Register (DBG1)

Read: Anytime

Write: Bit 7 Anytime with the exception that it cannot be set if PTACT is set. An ongoing profiling session must be finished before DBG can be armed again.

Bit 6 can be written anytime but always reads back as 0.

Bits 5:0 anytime DBG is not armed and PTACT is clear.

NOTE

On a write access to DBG1 and simultaneous hardware disarm from an internal event, the hardware disarm has highest priority, clearing the ARM bit and generating a breakpoint, if enabled.

NOTE

When disarming the DBG by clearing ARM with software, the contents of bits[5:0] are not affected by the write, since up until the write operation, ARM = 1 preventing these bits from being written. These bits must be cleared using a second write if required.

Table 6-4. DBGC1 Field Descriptions

Field	Description
7 ARM	Arm Bit — The ARM bit controls whether the DBG module is armed. This bit can be set and cleared by register writes and is automatically cleared when the state sequencer returns to State0 on completing a debugging session. On setting this bit the state sequencer enters State1. 0 Debugger disarmed. No breakpoint is generated when clearing this bit by software register writes. 1 Debugger armed
6 TRIG	Immediate Trigger Request Bit — This bit when written to 1 requests an immediate transition to final state independent of comparator status. This bit always reads back a 0. Writing a 0 to this bit has no effect. 0 No effect. 1 Force state sequencer immediately to final state.
4 BDMBP	Background Debug Mode Enable — This bit determines if a CPU breakpoint causes the system to enter Background Debug Mode (BDM) or initiate a Software Interrupt (SWI). If this bit is set but the BDC is not enabled, then no breakpoints are generated. 0 Breakpoint to Software Interrupt if BDM inactive. Otherwise no breakpoint. 1 Breakpoint to BDM, if BDC enabled. Otherwise no breakpoint.
3 BRKCPU	CPU Breakpoint Enable — The BRKCPU bit controls whether the debugger requests a breakpoint to CPU upon transitions to State0. If tracing is enabled, the breakpoint is generated on completion of the tracing session. If tracing is not enabled, the breakpoint is generated immediately. Please refer to Section 6.4.7 for further details. 0 Breakpoints disabled 1 Breakpoints enabled
1–0 EEVE	External Event Enable — The EEVE bits configure the external event function. Table 6-5 explains the bit encoding.

Table 6-5. EEVE Bit Encoding

EEVE	Description
00	External event function disabled
01	External event forces a trace buffer entry if tracing is enabled
10	External event is mapped to the state sequencer, replacing comparator channel 3
11	External event pin gates trace buffer entries

6.3.2.2 Debug Control Register2 (DBGC2)

Address: 0x0101

Figure 6-4. Debug Control Register2 (DBGC2)

Read: Anytime.

Write: Anytime the module is disarmed and PTACT is clear.

This register configures the comparators for range matching.

Table 6-6. DBGC2 Field Descriptions

Field	Description
3–2 CDCM[1:0]	C and D Comparator Match Control — These bits determine the C and D comparator match mapping as described in Table 6-7.
1–0 ABCM[1:0]	A and B Comparator Match Control — These bits determine the A and B comparator match mapping as described in Table 6-8.

Table 6-7. CDCM Encoding

CDCM	Description
00	Match2 mapped to comparator C match..... Match3 mapped to comparator D match.
01	Match2 mapped to comparator C/D inside range..... Match3 disabled.
10	Match2 mapped to comparator C/D outside range..... Match3 disabled.
11	Reserved ⁽¹⁾

1. Currently defaults to Match2 mapped to inside range: Match3 disabled.

Table 6-8. ABCM Encoding

ABCM	Description
00	Match0 mapped to comparator A match..... Match1 mapped to comparator B match.
01	Match0 mapped to comparator A/B inside range..... Match1 disabled.
10	Match0 mapped to comparator A/B outside range..... Match1 disabled.
11	Reserved ⁽¹⁾

1. Currently defaults to Match0 mapped to inside range: Match1 disabled

6.3.2.3 Debug Trace Control Register High (DBGTCRH)

Address: 0x0102

Figure 6-5. Debug Trace Control Register (DBGTCRH)

Read: Anytime.

Write: Anytime the module is disarmed and PTACT is clear.

WARNING

DBGTCR[7] is reserved. Setting this bit maps the tracing to an unimplemented bus, thus preventing proper operation.

This register configures the trace buffer for tracing and profiling.

Table 6-9. DBGTCRH Field Descriptions

Field	Description
6 TSOURCE	Trace Control Bits — The TSOURCE enables the tracing session. 0 No CPU tracing/profiling selected 1 CPU tracing/profiling selected
5–4 TRANGE	Trace Range Bits — The TRANGE bits allow filtering of trace information from a selected address range when tracing from the CPU in Detail mode. These bits have no effect in other tracing modes. To use a comparator for range filtering, the corresponding COMPE bit must remain cleared. If the COMPE bit is set then the comparator is used to generate events and the TRANGE bits have no effect. See Table 6-10 for range boundary definition.
3–2 TRCMOD	Trace Mode Bits — See Section 6.4.5.2 for detailed Trace Mode descriptions. In Normal Mode, change of flow information is stored. In Loop1 Mode, change of flow information is stored but redundant entries into trace memory are inhibited. In Detail Mode, address and data for all memory and register accesses is stored. See Table 6-11 .
1–0 TALIGN	Trigger Align Bits — These bits control whether the trigger is aligned to the beginning, end or the middle of a tracing or profiling session. See Table 6-12 .

Table 6-10. TRANGE Trace Range Encoding

TRANGE	Tracing Range
00	Trace from all addresses (No filter)
01	Trace only in address range from \$00000 to Comparator D
10	Trace only in address range from Comparator C to \$FFFFFF
11	Trace only in range from Comparator C to Comparator D

Table 6-11. TRCMOD Trace Mode Bit Encoding

TRCMOD	Description
00	Normal
01	Loop1
10	Detail
11	Pure PC

Table 6-12. TALIGN Trace Alignment Encoding

TALIGN	Description
00	Trigger ends data trace
01	Trigger starts data trace
10	32 lines of data trace follow trigger
11 ⁽¹⁾	Reserved

1. Tracing/Profiling disabled.

6.3.2.4 Debug Trace Control Register Low (DBGTCRL)

Address: 0x0103

Figure 6-6. Debug Trace Control Register Low (DBGTCRL)

Read: Anytime.

Write: Anytime the module is disarmed and PTACT is clear.

This register configures the profiling and timestamp features

Table 6-13. DBGTCRL Field Descriptions

Field	Description
4 PREND	Profiling End — This bit, when set, forces the profiling session to end when the trace buffer has been filled. This prevents a rollover of the trace buffer from overwriting the initial entry containing the start address 0 Trace buffer rollover is enabled during profiling. After the last line has been filled, the entries continue, starting at line0 and overwriting the older data 1 Trace buffer rollover is disabled during profiling. When the trace buffer is full, the profiling session ends, the PTBOVF bit is set and the ARM bit is cleared.
3 DSTAMP	Comparator D Timestamp Enable — This bit, when set, enables Comparator D matches to generate timestamps in Detail, Normal and Loop1 trace modes. 0 Comparator D match does not generate timestamp 1 Comparator D match generates timestamp if timestamp function is enabled
2 PDOE	Profile Data Out Enable — This bit, when set, configures the device profiling pins for profiling. 0 Device pins not configured for profiling 1 Device pins configured for profiling
1 PROFILE	Profile Enable — This bit, when set, enables the profile function, whereby a subsequent arming of the DBG activates profiling. When PROFILE is set, the TRCMOD bits are ignored. 0 Profile function disabled 1 Profile function enabled
0 STAMP	Timestamp Enable — This bit, when set, enables the timestamp function. The timestamp function adds a timestamp to each trace buffer entry in Detail, Normal and Loop1 trace modes. 0 Timestamp function disabled 1 Timestamp function enabled

6.3.2.5 Debug Trace Buffer Register (DBGTB)

Other Resets	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Figure 6-7. Debug Trace Buffer Register (DBGTB)

Read: Only when unlocked AND not armed and the TSOURCE bit is set, otherwise an error code (0xEE) is returned. Only aligned word read operations are supported. Misaligned word reads or byte reads return the error code 0xEE for each byte.

Write: Aligned word writes when the DBG is disarmed and the PTACT is clear unlock the trace buffer for reading but do not affect trace buffer contents.

Table 6-14. DBGTB Field Descriptions

Field	Description
15–0 Bit[15:0]	Trace Buffer Data Bits — The Trace Buffer Register is a window through which the lines of the trace buffer may be read 16 bits at a time. Each valid read of DBGTB increments an internal trace buffer pointer which points to the next address to be read. When the ARM bit is written to 1 the trace buffer is locked to prevent reading. The trace buffer can only be unlocked for reading by writing to DBGTB with an aligned word write when the module is disarmed. The DBGTB register can be read only as an aligned word. Byte reads or misaligned access of these registers returns 0xEE and does not increment the trace buffer pointer. Similarly word reads while the debugger is armed or trace buffer is locked return 0xEEEE. The POR state is undefined Other resets do not affect the trace buffer contents.

6.3.2.6 Debug Count Register (DBGCNT)

Address: 0x0106

	7	6	5	4	3	2	1	0
R	0	CNT						
W								
Reset	0	—	—	—	—	—	—	—
POR	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 6-8. Debug Count Register (DBGCNT)

Read: Anytime.

Write: Never.

Table 6-15. DBGCNT Field Descriptions

Field	Description
6–0 CNT[6:0]	<p>Count Value — The CNT bits [6:0] indicate the number of valid data lines stored in the trace buffer. Table 6-16 shows the correlation between the CNT bits and the number of valid data lines in the trace buffer. When the CNT rolls over to zero, the TBF bit in DBGSR is set. Thereafter incrementing of CNT continues if configured for end-alignment or mid-alignment.</p> <p>The DBGCNT register is cleared when ARM in DBGCR1 is written to a one. The DBGCNT register is cleared by power-on-reset initialization but is not cleared by other system resets. If a reset occurs during a debug session, the DBGCNT register still indicates after the reset, the number of valid trace buffer entries stored before the reset occurred. The DBGCNT register is not decremented when reading from the trace buffer.</p>

Table 6-16. CNT Decoding Table

TBF (DBGSR)	CNT[6:0]	Description
0	0000000	No data valid
0	0000001	32 bits of one line valid
0	0000010 0000100 0000110 .. 1111100	1 line valid 2 lines valid 3 lines valid .. 62 lines valid
0	1111110	63 lines valid
1	0000000	64 lines valid; if using Begin trigger alignment, ARM bit is cleared and the tracing session ends.
1	0000010 .. 1111110	64 lines valid, oldest data has been overwritten by most recent data

6.3.2.7 Debug State Control Register 1 (DBGSCR1)

Address: 0x0107

	7	6	5	4	3	2	1	0
R	C3SC1	C3SC0	C2SC1	C2SC0	C1SC1	C1SC0	C0SC1	C0SC0
W	0	0	0	0	0	0	0	0
Reset	0	0	0	0	0	0	0	0

Figure 6-9. Debug State Control Register 1 (DBGSCR1)

Read: Anytime.

Write: If DBG is not armed and PTACT is clear.

The state control register 1 selects the targeted next state whilst in State1. The matches refer to the outputs of the comparator match control logic as depicted in [Figure 6-1](#) and described in [Section 6.3.2.12](#)".

Comparators must be enabled by setting the comparator enable bit in the associated DBGXCTL control register.

Table 6-17. DBGSCR1 Field Descriptions

Field	Description
1–0 C0SC[1:0]	Channel 0 State Control. These bits select the targeted next state whilst in State1 following a match0.
3–2 C1SC[1:0]	Channel 1 State Control. These bits select the targeted next state whilst in State1 following a match1.
5–4 C2SC[1:0]	Channel 2 State Control. These bits select the targeted next state whilst in State1 following a match2.
7–6 C3SC[1:0]	Channel 3 State Control. If EEVE !=10, these bits select the targeted next state whilst in State1 following a match3. If EEVE = 10, these bits select the targeted next state whilst in State1 following an external event.

Table 6-18. State1 Match State Sequencer Transitions

CxSC[1:0]	Function
00	Match has no effect
01	Match forces sequencer to State2
10	Match forces sequencer to State3
11	Match forces sequencer to Final State

In the case of simultaneous matches, the match on the higher channel number (3...0) has priority.

6.3.2.8 Debug State Control Register 2 (DBGSCR2)

Address: 0x0108

Figure 6-10. Debug State Control Register 2 (DBGSCR2)

Read: Anytime.

Write: If DBG is not armed and PTACT is clear.

The state control register 2 selects the targeted next state whilst in State2. The matches refer to the outputs of the comparator match control logic as depicted in [Figure 6-1](#) and described in [Section 6.3.2.12](#)".

Comparators must be enabled by setting the comparator enable bit in the associated DBGXCTL control register.

Table 6-19. DBGSCR2 Field Descriptions

Field	Description
1–0 C0SC[1:0]	Channel 0 State Control. These bits select the targeted next state whilst in State2 following a match0.
3–2 C1SC[1:0]	Channel 1 State Control. These bits select the targeted next state whilst in State2 following a match1.

Table 6-19. DBGSCR2 Field Descriptions (continued)

Field	Description
5–4 C2SC[1:0]	Channel 2 State Control. These bits select the targeted next state whilst in State2 following a match2.
7–6 C3SC[1:0]	Channel 3 State Control. If EEVE !=10, these bits select the targeted next state whilst in State2 following a match3. If EEVE =10, these bits select the targeted next state whilst in State2 following an external event.

Table 6-20. State2 Match State Sequencer Transitions

CxSC[1:0]	Function
00	Match has no effect
01	Match forces sequencer to State1
10	Match forces sequencer to State3
11	Match forces sequencer to Final State

In the case of simultaneous matches, the match on the higher channel number (3...0) has priority.

6.3.2.9 Debug State Control Register 3 (DBGSCR3)

Address: 0x0109

Figure 6-11. Debug State Control Register 3 (DBGSCR3)

Read: Anytime.

Write: If DBG is not armed and PTACT is clear.

The state control register three selects the targeted next state whilst in State3. The matches refer to the outputs of the comparator match control logic as depicted in [Figure 6-1](#) and described in [Section 6.3.2.12](#)". Comparators must be enabled by setting the comparator enable bit in the associated DBGxCTL control register.

Table 6-21. DBGSCR3 Field Descriptions

Field	Description
1–0 C0SC[1:0]	Channel 0 State Control. These bits select the targeted next state whilst in State3 following a match0.
3–2 C1SC[1:0]	Channel 1 State Control. These bits select the targeted next state whilst in State3 following a match1.
5–4 C2SC[1:0]	Channel 2 State Control. These bits select the targeted next state whilst in State3 following a match2.

Table 6-21. DBGSCR3 Field Descriptions (continued)

Field	Description
7–6 C3SC[1:0]	Channel 3 State Control. If EEVE !=10, these bits select the targeted next state whilst in State3 following a match3. If EEVE =10, these bits select the targeted next state whilst in State3 following an external event.

Table 6-22. State3 Match State Sequencer Transitions

CxSC[1:0]	Function
00	Match has no effect
01	Match forces sequencer to State1
10	Match forces sequencer to State2
11	Match forces sequencer to Final State

In the case of simultaneous matches, the match on the higher channel number (3...0) has priority.

6.3.2.10 Debug Event Flag Register (DBGEFR)

Address: 0x010A

Figure 6-12. Debug Event Flag Register (DBGEFR)

Read: Anytime.

Write: Never

DBGEFR contains flag bits each mapped to events whilst armed. Should an event occur, then the corresponding flag is set. With the exception of TRIGF, the bits can only be set when the ARM bit is set. The TRIGF bit is set if a TRIG event occurs when ARM is already set, or if the TRIG event occurs simultaneous to setting the ARM bit. All other flags can only be cleared by arming the DBG module. Thus the contents are retained after a debug session for evaluation purposes.

A set flag does not inhibit the setting of other flags.

Table 6-23. DBGEFR Field Descriptions

Field	Description
7 PTBOVF	Profiling Trace Buffer Overflow Flag — Indicates the occurrence of a trace buffer overflow event during a profiling session. 0 No trace buffer overflow event 1 Trace buffer overflow event
6 TRIGF	TRIG Flag — Indicates the occurrence of a TRIG event during the debug session. 0 No TRIG event 1 TRIG event

Table 6-23. DBGEFR Field Descriptions

Field	Description
4 EEVF	External Event Flag — Indicates the occurrence of an external event during the debug session. 0 No external event 1 External event
3–0 ME[3:0]	Match Event[3:0] — Indicates a comparator match event on the corresponding comparator channel.

6.3.2.11 Debug Status Register (DBGSR)

Address: 0x010B

	7	6	5	4	3	2	1	0
R	TBF	0	0	PTACT	0	SSF2	SSF1	SSF0
W								
Reset	—	0	0	0	0	0	0	0
POR	0	0	0	0	0	0	0	0

□ = Unimplemented or Reserved

Figure 6-13. Debug Status Register (DBGSR)

Read: Anytime.

Write: Never.

Table 6-24. DBGSR Field Descriptions

Field	Description
7 TBF	Trace Buffer Full — The TBF bit indicates that the trace buffer has been filled with data since it was last armed. If this bit is set, then all trace buffer lines contain valid data, regardless of the value of DBGCNT bits CNT[6:0]. The TBF bit is cleared when ARM in DBG1 is written to a one. The TBF is cleared by the power on reset initialization. Other system generated resets have no affect on this bit
4 PTACT	Profiling Transmission Active — The PTACT bit, when set, indicates that the profiling transmission is still active. When clear, PTACT then profiling transmission is not active. The PTACT bit is set when profiling begins with the first PTS format entry to the trace buffer. The PTACT bit is cleared when the profiling transmission ends.
2–0 SSF[2:0]	State Sequencer Flag Bits — The SSF bits indicate the current State Sequencer state. During a debug session on each transition to a new state these bits are updated. If the debug session is ended by software clearing the ARM bit, then these bits retain their value to reflect the last state of the state sequencer before disarming. If a debug session is ended by an internal event, then the state sequencer returns to State0 and these bits are cleared to indicate that State0 was entered during the session. On arming the module the state sequencer enters State1 and these bits are forced to SSF[2:0] = 001. See Table 6-25 .

Table 6-25. SSF[2:0] — State Sequence Flag Bit Encoding

SSF[2:0]	Current State
000	State0 (disarmed)
001	State1
010	State2
011	State3

Table 6-25. SSF[2:0] — State Sequence Flag Bit Encoding

SSF[2:0]	Current State
100	Final State
101,110,111	Reserved

6.3.2.12 Debug Comparator A Control Register (DBGACTL)

Address: 0x0110

Figure 6-14. Debug Comparator A Control Register

Read: Anytime.

Write: If DBG not armed and PTACT is clear.

Table 6-26. DBGACTL Field Descriptions

Field	Description
6 NDB	Not Data Bus — The NDB bit controls whether the match occurs when the data bus matches the comparator register value or when the data bus differs from the register value. This bit is ignored if the INST bit in the same register is set. 0 Match on data bus equivalence to comparator register contents 1 Match on data bus difference to comparator register contents
5 INST	Instruction Select — This bit configures the comparator to compare PC or data access addresses. 0 Comparator compares addresses of data accesses 1 Comparator compares PC address
3 RW	Read/Write Comparator Value Bit — The RW bit controls whether read or write is used in compare for the associated comparator. The RW bit is ignored if RWE is clear or INST is set. 0 Write cycle is matched 1 Read cycle is matched
2 RWE	Read/Write Enable Bit — The RWE bit controls whether read or write comparison is enabled for the associated comparator. This bit is ignored when INST is set. 0 Read/Write is not used in comparison 1 Read/Write is used in comparison
0 COMPE	Enable Bit — Determines if comparator is enabled 0 The comparator is not enabled 1 The comparator is enabled

Table 6-27 shows the effect for RWE and RW on the comparison conditions. These bits are ignored if INST is set, because matches based on opcodes reaching the execution stage are data independent.

Table 6-27. Read or Write Comparison Logic Table

RWE Bit	RW Bit	RW Signal	Comment
0	x	0	RW not used in comparison
0	x	1	RW not used in comparison
1	0	0	Write match
1	0	1	No match
1	1	0	No match
1	1	1	Read match

This register can be accessed with a byte resolution, whereby DBGCDM0, DBGCDM1, DBGCDM2, DBGCDM3 map to DBGCDM[31:0] respectively.

XGATE data accesses have a maximum width of 16-bits and are mapped to DBGCDM[15:0].

Table 6-38. DBGCDM Field Descriptions

Field	Description
31–16 Bits[31:16] (DBGCDM0, DBGCDM1)	Comparator Data Mask Bits — These bits control whether the comparator compares the data bus bits to the corresponding comparator data compare bits. 0 Do not compare corresponding data bit 1 Compare corresponding data bit
15–0 Bits[15:0] (DBGCDM2, DBGCDM3)	Comparator Data Mask Bits — These bits control whether the comparator compares the data bus bits to the corresponding comparator data compare bits. 0 Do not compare corresponding data bit 1 Compare corresponding data bit

6.3.2.22 Debug Comparator D Control Register (DBGDCTL)

Address: 0x0140

Figure 6-24. Debug Comparator D Control Register

Read: Anytime.

Write: If DBG not armed and PTACT is clear.

Table 6-39. DBGDCTL Field Descriptions

Field ⁽¹⁾	Description
5 INST	Instruction Select — This bit configures the comparator to compare PC or data access addresses. 0 Comparator compares addresses of data accesses 1 Comparator compares PC address
3 RW	Read/Write Comparator Value Bit — The RW bit controls whether read or write is used in compare for the associated comparator. The RW bit is ignored if RWE is clear or INST is set. 0 Write cycle is matched 1 Read cycle is matched
2 RWE	Read/Write Enable Bit — The RWE bit controls whether read or write comparison is enabled for the associated comparator. This bit is ignored if INST is set. 0 Read/Write is not used in comparison 1 Read/Write is used in comparison
0 COMPE	Enable Bit — Determines if comparator is enabled 0 The comparator is not enabled 1 The comparator is enabled

1. If the CDCM field selects range mode comparisons, then DBGCCCTL bits configure the comparison, DBGDCTL is ignored.

Table 6-40 shows the effect for RWE and RW on the comparison conditions. These bits are ignored if INST is set, because matches based on opcodes reaching the execution stage are data independent.

Table 6-40. Read or Write Comparison Logic Table

RWE Bit	RW Bit	RW Signal	Comment
0	x	0	RW not used in comparison
0	x	1	RW not used in comparison
1	0	0	Write match
1	0	1	No match
1	1	0	No match
1	1	1	Read match

6.4 Functional Description

This section provides a complete functional description of the DBG module.

6.4.1 DBG Operation

The DBG module operation is enabled by setting ARM in DBGDC1. When armed it supports storing of data in the trace buffer and can be used to generate breakpoints to the CPU. The DBG module is made up of comparators, control logic, the trace buffer, and the state sequencer, [Figure 6-1](#).

The comparators monitor the bus activity of the CPU. Comparators can be configured to monitor opcode addresses (effectively the PC address) or data accesses. Comparators can be configured during data accesses to mask out individual data bus bits and to use R/W access qualification in the comparison. Comparators can be configured to monitor a range of addresses.

When configured for data access comparisons, the match is generated if the address (and optionally data) of a data access matches the comparator value.

Configured for monitoring opcode addresses, the match is generated when the associated opcode reaches the execution stage of the instruction queue, but before execution of that opcode.

When a match with a comparator register value occurs, the associated control logic can force the state sequencer to another state (see [Figure 6-26](#)).

The state sequencer can transition freely between the states 1, 2 and 3. On transition to Final State bus tracing can be triggered. On completion of tracing the state sequencer enters State0. If tracing is disabled or End aligned tracing is enabled then the state sequencer transitions immediately from Final State to State0. The transition to State0 generates breakpoints if breakpoints are enabled.

Independent of the comparators, state sequencer transitions can be forced by the external event input or by writing to the TRIG bit in the DBGDC1 control register.

The trace buffer is visible through a 2-byte window in the register address map and can be read out using standard 16-bit word reads.

6.4.2 Comparator Modes

The DBG contains four comparators, A, B, C, and D. Each comparator compares the address stored in DBGXAH, DBGXAM, and DBGXAL with the PC (opcode addresses) or selected address bus (data

accesses). Furthermore, comparators A and C can compare the data buses to values stored in DBGXD3-0 and allow data bit masking.

The comparators can monitor the buses for an exact address or an address range. The comparator configuration is controlled by the control register contents and the range control by the DBGCR2 contents.

The comparator control register also allows the type of data access to be included in the comparison through the use of the RWE and RW bits. The RWE bit controls whether the access type is compared for the associated comparator and the RW bit selects either a read or write access for a valid match.

The INST bit in each comparator control register is used to determine the matching condition. By setting INST, the comparator matches opcode addresses, whereby the databus, data mask, RW and RWE bits are ignored. The comparator register must be loaded with the exact opcode address.

The comparator can be configured to match memory access addresses by clearing the INST bit.

Each comparator match can force a transition to another state sequencer state (see [Section 6.4.3](#)”).

Once a successful comparator match has occurred, the condition that caused the original match is not verified again on subsequent matches. Thus if a particular data value is matched at a given address, this address may not contain that data value when a subsequent match occurs.

Comparators C and D can also be used to select an address range to trace from, when tracing CPU accesses in Detail mode. This is determined by the TRANGE bits in the DBGTCRH register. The TRANGE encoding is shown in [Table 6-10](#). If the TRANGE bits select a range definition using comparator D and the COMPE bit is clear, then comparator D is configured for trace range definition. By setting the COMPE bit the comparator is configured for address bus comparisons, the TRANGE bits are ignored and the tracing range function is disabled. Similarly if the TRANGE bits select a range definition using comparator C and the COMPE bit is clear, then comparator C is configured for trace range definition.

Match[0, 1, 2, 3] map directly to Comparators [A, B, C, D] respectively, except in range modes (see [Section 6.3.2.2](#)”). Comparator priority rules are described in the event priority section ([Section 6.4.3.5](#)”).

6.4.2.1 Exact Address Comparator Match

With range comparisons disabled, the match condition is an exact equivalence of address bus with the value stored in the comparator address registers. Qualification of the type of access (R/W) is also possible.

Code may contain various access forms of the same address, for example a 16-bit access of ADDR[n] or byte access of ADDR[n+1] both access n+1. The comparators ensure that any access of the address defined by the comparator address register generates a match, as shown in the example of [Table 6-42](#). Thus if the comparator address register contains ADDR[n+1] any access of ADDR[n+1] matches. This means that a 16-bit access of ADDR[n] or 32-bit access of ADDR[n-1] also match because they also access ADDR[n+1]. The right hand columns show the contents of DBGxA that would match for each access.

Table 6-42. Comparator Address Bus Matches

Access	Address	ADDR[n]	ADDR[n+1]	ADDR[n+2]	ADDR[n+3]
32-bit	ADDR[n]	Match	Match	Match	Match
16-bit	ADDR[n]	Match	Match	No Match	No Match
16-bit	ADDR[n+1]	No Match	Match	Match	No Match

Table 6-42. Comparator Address Bus Matches

Access	Address	ADDR[n]	ADDR[n+1]	ADDR[n+2]	ADDR[n+3]
8-bit	ADDR[n]	Match	No Match	No Match	No Match

If the comparator INST bit is set, the comparator address register contents are compared with the PC, the data register contents and access type bits are ignored. The comparator address register must be loaded with the address of the first opcode byte.

6.4.2.2 Address and Data Comparator Match

Comparators A and C feature data comparators, for data access comparisons. The comparators do not evaluate if accessed data is valid. Accesses across aligned 32-bit boundaries are split internally into consecutive accesses. The data comparator mapping to accessed addresses for the CPU is shown in Table 6-43, whereby the Address column refers to the lowest 2 bits of the lowest accessed address. This corresponds to the most significant data byte.

Table 6-43. Comparator Data Byte Alignment

Address[1:0]	Data Comparator
00	DBGxD0
01	DBGxD1
10	DBGxD2
11	DBGxD3

The fixed mapping of data comparator bytes to addresses within a 32-bit data field ensures data matches independent of access size. To compare a single data byte within the 32-bit field, the other bytes within that field must be masked using the corresponding data mask registers. This ensures that any access of that byte (32-bit, 16-bit or 8-bit) with matching data causes a match. If no bytes are masked then the data comparator always compares all 32-bits and can only generate a match on a 32-bit access with correct 32-bit data value. In this case, 8-bit or 16-bit accesses within the 32-bit field cannot generate a match even if the contents of the addressed bytes match because all 32-bits must match. In Table 6-44 the Access Address column refers to the address bits[1:0] of the lowest accessed address (most significant data byte).

Table 6-44. Data Register Use Dependency On CPU Access Type

Case	Access Address	Access Size	Memory Address[2:0]						
			000	001	010	011	100	101	110
1	00	32-bit	DBGxD0	DBGxD1	DBGxD2	DBGxD3			
2	01	32-bit		DBGxD1	DBGxD2	DBGxD3	DBGxD0		
3	10	32-bit			DBGxD2	DBGxD3	DBGxD0	DBGxD1	
4	11	32-bit				DBGxD3	DBGxD0	DBGxD1	DBGxD2
5	00	16-bit	DBGxD0	DBGxD1					
6	01	16-bit		DBGxD1	DBGxD2				
7	10	16-bit			DBGxD2	DBGxD3			

Case	Access Address	Access Size	Memory Address[2:0]						
			000	001	010	011	100	101	110
8	11	16-bit				DBGxD3	DBGxD0		
9	00	8-bit	DBGxD0						
10	01	8-bit		DBGxD1					
11	10	8-bit			DBGxD2				
12	11	8-bit				DBGxD3			
13	00	8-bit					DBGxD0		
				Denotes byte that is not accessed.					

For a match of a 32-bit access with data compare, the address comparator must be loaded with the address of the lowest accessed byte. For Case1 [Table 6-44](#) this corresponds to 000, for Case2 it corresponds to 001. To compare all 32-bits, it is required that no bits are masked.

6.4.2.3 Data Bus Comparison NDB Dependency

The NDB control bit allows data bus comparators to be configured to either match on equivalence or on difference. This allows monitoring of a difference in the contents of an address location from an expected value.

When matching on an equivalence (NDB=0), each individual data bus bit position can be masked out by clearing the corresponding mask bit, so that it is ignored in the comparison. A match occurs when all data bus bits with corresponding mask bits set are equivalent. If all mask register bits are clear, then a match is based on the address bus only, the data bus is ignored.

When matching on a difference, mask bits can be cleared to ignore bit positions. A match occurs when any data bus bit with corresponding mask bit set is different. Clearing all mask bits, causes all bits to be ignored and prevents a match because no difference can be detected. In this case address bus equivalence does not cause a match. Bytes that are not accessed are ignored. Thus when monitoring a multi byte field for a difference, partial accesses of the field only return a match if a difference is detected in the accessed bytes.

Table 6-45. NDB and MASK bit dependency

NDB	DBGADM	Comment
0	0	Do not compare data bus bit.
0	1	Compare data bus bit. Match on equivalence.
1	0	Do not compare data bus bit.
1	1	Compare data bus bit. Match on difference.

6.4.2.4 Range Comparisons

Range comparisons are accurate to byte boundaries. Thus for data access comparisons a match occurs if at least one byte of the access is in the range (inside range) or outside the range (outside range). For opcode comparisons only the address of the first opcode byte is compared with the range.

When using the AB comparator pair for a range comparison, the data bus can be used for qualification by using the comparator A data and data mask registers. Similarly when using the CD comparator pair for a range comparison, the data bus can be used for qualification by using the comparator C data and data mask registers. The DBGACTL/DBGCCCTL RW and RWE bits can be used to qualify the range comparison on either a read or a write access. The corresponding DBGBCTL/DBGDCTL bits are ignored. The DBGACTL/DBGCCCTL COMPE/INST bits are used for range comparisons. The DBGBCTL/DBGDCTL COMPE/INST bits are ignored in range modes.

6.4.2.4.1 Inside Range (CompAC_Addr ≤ address ≤ CompBD_Addr)

In the Inside Range comparator mode, either comparator pair A and B or comparator pair C and D can be configured for range comparisons by the control register (DBGCC2). The match condition requires a simultaneous valid match for both comparators. A match condition on only one comparator is not valid.

6.4.2.4.2 Outside Range (address < CompAC_Addr or address > CompBD_Addr)

In the Outside Range comparator mode, either comparator pair A and B or comparator pair C and D can be configured for range comparisons. A single match condition on either of the comparators is recognized as valid. Outside range mode in combination with opcode address matches can be used to detect if opcodes are from an unexpected range.

NOTE

When configured for data access matches, an outside range match would typically occur at any interrupt vector fetch or register access. This can be avoided by setting the upper or lower range limit to \$FFFFFF or \$000000 respectively. Interrupt vector fetches do not cause opcode address matches.

6.4.3 Events

Events are used as qualifiers for a state sequencer change of state. The state control register for the current state determines the next state for each event. An event can immediately initiate a transition to the next state sequencer state whereby the corresponding flag in DBGSR is set.

6.4.3.1 Comparator Match Events

6.4.3.1.1 Opcode Address Comparator Match

The comparator is loaded with the address of the selected instruction and the comparator control register INST bit is set. When the opcode reaches the execution stage of the instruction queue a match occurs just before the instruction executes, allowing a breakpoint immediately before the instruction boundary. The comparator address register must contain the address of the first opcode byte for the match to occur. Opcode address matches are data independent thus the RWE and RW bits are ignored. CPU compares are disabled when BDM becomes active.

6.4.3.1.2 Data Access Comparator Match

Data access matches are generated when an access occurs at the address contained in the comparator address register. The match can be qualified by the access data and by the access type (read/write). The breakpoint occurs a maximum of 2 instructions after the access in the CPU flow. Note, if a COF occurs between access and breakpoint, the opcode address of the breakpoint can be elsewhere in the memory map.

Opcode fetches are not classed as data accesses. Thus data access matches are not possible on opcode fetches.

6.4.3.2 External Event

The DBGEEV input signal can force a state sequencer transition, independent of internal comparator matches. The DBGEEV is an input signal mapped directly to a device pin and configured by the EEVE field in DBGC1. The external events can change the state sequencer state, or force a trace buffer entry, or gate trace buffer entries.

If configured to change the state sequencer state, then the external match is mapped to DBGSCRx bits C3SC[1:0]. In this configuration, internal comparator channel3 is de-coupled from the state sequencer but can still be used for timestamps. The DBGEFR bit EEVF is set when an external event occurs.

6.4.3.3 Setting The TRIG Bit

Independent of comparator matches it is possible to initiate a tracing session and/or breakpoint by writing the TRIG bit in DBGC1 to a logic “1”. This forces the state sequencer into the Final State. If configured for End aligned tracing or for no tracing, the transition to Final State is followed immediately by a transition to State0. If configured for Begin- or Mid Aligned tracing, the state sequencer remains in Final State until tracing is complete, then it transitions to State0.

Breakpoints, if enabled, are issued on the transition to State0.

6.4.3.4 Profiling Trace Buffer Overflow Event

During code profiling a trace buffer overflow forces the state sequencer into the disarmed State0 and, if breakpoints are enabled, issues a breakpoint request to the CPU.

6.4.3.5 Event Priorities

If simultaneous events occur, the priority is resolved according to [Table 6-46](#). Lower priority events are suppressed. It is thus possible to miss a lower priority event if it occurs simultaneously with an event of a higher priority. The event priorities dictate that in the case of simultaneous matches, the match on the higher comparator channel number (3,2,1,0) has priority.

If a write access to DBGC1 with the ARM bit position set occurs simultaneously to a hardware disarm from an internal event, then the ARM bit is cleared due to the hardware disarm.

Table 6-46. Event Priorities

Priority	Source	Action
Highest	TB Overflow	Immediate force to state 0, generate breakpoint and terminate tracing

Table 6-46. Event Priorities

	TRIG	Force immediately to final state
	DBGEEV	Force to next state as defined by state control registers (EEVE=2'b10)
	Match3	Force to next state as defined by state control registers
	Match2	Force to next state as defined by state control registers
	Match1	Force to next state as defined by state control registers
Lowest	Match0	Force to next state as defined by state control registers

6.4.4 State Sequence Control

Figure 6-26. State Sequencer Diagram

The state sequencer allows a defined sequence of events to provide a breakpoint and/or a trigger point for tracing of data in the trace buffer. When the DBG module is armed by setting the ARM bit in the DBGCR1 register, the state sequencer enters State1. Further transitions between the states are controlled by the state control registers and depend upon event occurrences (see [Section 6.4.3](#)). From Final State the only permitted transition is back to the disarmed State0. Transition between the states 1 to 3 is not restricted. Each transition updates the SSF[2:0] flags in DBGSR accordingly to indicate the current state. If breakpoints are enabled, then an event based transition to State0 generates the breakpoint request. A transition to State0 resulting from writing “0” to the ARM bit does not generate a breakpoint request.

6.4.4.1 Final State

On entering Final State a trigger may be issued to the trace buffer according to the trigger position control as defined by the TALIGN field (see [Section 6.3.2.3](#)”).

If tracing is enabled and either Begin or Mid aligned triggering is selected, the state sequencer remains in Final State until completion of the trace. On completion of the trace the state sequencer returns to State0 and the debug module is disarmed; if breakpoints are enabled, a breakpoint request is generated.

If tracing is disabled or End aligned triggering is selected, then when the Final State is reached the state sequencer returns to State0 immediately and the debug module is disarmed. If breakpoints are enabled, a breakpoint request is generated on transitions to State0.

6.4.5 Trace Buffer Operation

The trace buffer is a 64 lines deep by 64-bits wide RAM array. If the TSOURCE bit is set the DBG module can store trace information in the RAM array in a circular buffer format. Data is stored in mode dependent formats, as described in the following sections. After each trace buffer entry, the counter register DBGCNT is incremented. Trace buffer rollover is possible when configured for End- or Mid-Aligned tracing, such that older entries are replaced by newer entries. Tracing of CPU activity is disabled when the BDC is active.

The RAM array can be accessed through the register DBGTB using 16-bit wide word accesses. After each read, the internal RAM pointer is incremented so that the next read will receive fresh information. Reading the trace buffer whilst the DBG is armed returns invalid data and the trace buffer pointer is not incremented.

In Detail mode the address range for CPU access tracing can be limited to a range specified by the TRANGE bits in DBGTCRH. This function uses comparators C and D to define an address range inside which accesses should be traced. Thus traced accesses can be restricted, for example, to particular register or RAM range accesses.

The external event pin can be configured to force trace buffer entries in Normal or Loop1 trace modes. All tracing modes support trace buffer gating. In Pure PC and Detail modes external events do not force trace buffer entries.

If the external event pin is configured to gate trace buffer entries then any trace mode is valid.

6.4.5.1 Trace Trigger Alignment

Using the TALIGN bits (see [Section 6.3.2.3](#)) it is possible to align the trigger with the end, the middle, or the beginning of a tracing session.

If End or Mid-Alignment is selected, tracing begins when the ARM bit in DBGC1 is set and State1 is entered. The transition to Final State if End-Alignment is selected, ends the tracing session. The transition to Final State if Mid-Alignment is selected signals that another 32 lines are traced before ending the tracing session. Tracing with Begin-Alignment starts at the trigger and ends when the trace buffer is full.

Table 6-47. Tracing Alignment

TALIGN	Tracing Begin	Tracing End
00	On arming	At trigger
01	At trigger	When trace buffer is full
10	On arming	When 32 trace buffer lines have been filled after trigger
11	Reserved	

6.4.5.1.1 Storing with Begin-Alignment

Storing with Begin-Alignment, data is not stored in the trace buffer until the Final State is entered. Once the trigger condition is met the DBG module remains armed until 64 lines are stored in the trace buffer.

Using Begin-Alignment together with opcode address comparisons, if the instruction is about to be executed then the trace is started. If the trigger is at the address of a COF instruction, whilst tracing COF addresses, then that COF address is stored to the trace buffer. If breakpoints are enabled, the breakpoint is generated upon entry into State0 on completion of the tracing session; thus the breakpoint does not occur at the instruction boundary.

6.4.5.1.2 Storing with Mid-Alignment

Storing with Mid-Alignment, data is stored in the trace buffer as soon as the DBG module is armed. When the trigger condition is met, another 32 lines are traced before ending the tracing session, irrespective of the number of lines stored before the trigger occurred, then the DBG module is disarmed and no more data is stored. Using Mid-Alignment with opcode address triggers, if the instruction is about to be executed then the trace is continued for another 32 lines. If breakpoints are enabled, the breakpoint is generated upon entry into State0 on completion of the tracing session; thus the breakpoint does not occur at the instruction boundary. When configured for Compressed Pure-PC tracing, the MAT info bit is set to indicate the last PC entry before a trigger event.

6.4.5.1.3 Storing with End-Alignment

Storing with End-Alignment, data is stored in the trace buffer until the Final State is entered. Following this trigger, the DBG module immediately transitions to State0. If the trigger is at the address of a COF instruction the trigger event is not stored in the trace buffer.

6.4.5.2 Trace Modes

The DBG module can operate in four trace modes. The mode is selected using the TRCMOD bits in the DBGTCRH register. Normal, Loop1 and Detail modes can be configured to store a timestamp with each entry, by setting the STAMP bit. The modes are described in the following subsections.

In addition to the listed trace modes it is also possible to use code profiling to fill the trace buffer with a highly compressed COF format. This can be subsequently read out in the same fashion as the listed trace modes (see [Section 6.4.6](#)).

6.4.5.2.1 Normal Mode

In Normal Mode, change of flow (COF) program counter (PC) addresses are stored.

CPU COF addresses are defined as follows:

- Source address of taken conditional branches (bit-conditional, and loop primitives)
- Destination address of indexed JMP and JSR instructions
- Destination address of RTI and RTS instructions.
- Vector address of interrupts

BRA, BSR, BGND as well as non-indexed JMP and JSR instructions are not classified as change of flow and are not stored in the trace buffer.

COF addresses stored include the full address bus of CPU and an information byte, which contains bits to indicate whether the stored address was a source, destination or vector address.

NOTE

When a CPU indexed jump instruction is executed, the destination address is stored to the trace buffer on instruction completion, indicating the COF has taken place. If an interrupt occurs simultaneously then the next instruction carried out is actually from the interrupt service routine. The instruction at the destination address of the original program flow gets executed after the interrupt service routine.

In the following example an IRQ interrupt occurs during execution of the indexed JMP at address MARK1. The NOP at the destination (SUB_1) is not executed until after the IRQ service routine but the destination address is entered into the trace buffer to indicate that the indexed JMP COF has taken place.

```

LD      X, #SUB_1
MARK1:  JMP      (0,X)          ; IRQ interrupt occurs during execution of this
MARK2:  NOP
;
SUB_1:  NOP                    ; JMP Destination address TRACE BUFFER ENTRY 1
; RTI Destination address TRACE BUFFER ENTRY 3
NOP
;
ADDR1:  DBNE    D0, PART5      ; Source address TRACE BUFFER ENTRY 4
;
IRQ_ISR: LD     D1, #$F0        ; IRQ Vector $FFF2 = TRACE BUFFER ENTRY 2
ST      D1, VAR_C1
RTI

```

The execution flow taking into account the IRQ is as follows

```

LD      X, #SUB_1
MARK1:  JMP      (0,X)          ;
IRQ_ISR: LD     D1, #$F0        ;
ST      D1, VAR_C1
RTI
;
SUB_1:  NOP                    ;
NOP
;
ADDR1:  DBNE    D0, PART5      ;

```

The Normal Mode trace buffer format is shown in the following tables. Whilst tracing in Normal or Loop1 modes each array line contains 2 data entries, thus in this case the DBG CNT[0] is incremented after each separate entry. Information byte bits indicate if an entry is a source, destination or vector address.

The external event input can force trace buffer entries independent of COF occurrences, in which case the EEVI bit is set and the PC value of the last instruction is stored to the trace buffer. If the external event coincides with a COF buffer entry a single entry is made with the EEVI bit set.

Normal mode profiling with timestamp is possible when tracing from a single source by setting the STAMP bit in DBGTCRL. This results in a different format (see [Table 6-49](#)).

Table 6-48. Normal and Loop1 Mode Trace Buffer Format without Timestamp

10	Source address of COF opcode
11	Destination address of COF opcode

6.4.5.2.2 Loop1 Mode

Loop1 Mode, similarly to Normal Mode also stores only COF address information to the trace buffer, it however allows the filtering out of redundant information.

The intent of Loop1 Mode is to prevent the trace buffer from being filled entirely with duplicate information from a looping construct such as delays using the DBNE instruction. The DBG monitors trace buffer entries and prevents consecutive duplicate address entries resulting from repeated branches.

Loop1 Mode only inhibits consecutive duplicate source address entries that would typically be stored in most tight looping constructs. It does not inhibit repeated entries of destination addresses or vector addresses, since repeated entries of these could indicate a bug in application code that the DBG module is designed to help find.

The trace buffer format for Loop1 Mode is the same as that of Normal Mode.

6.4.5.2.3 Detail Mode

When tracing CPU activity in Detail Mode, address and data of data and vector accesses are traced. The information byte indicates the size of access and the type of access (read or write).

ADRH, ADRM, ADRL denote address high, middle and low byte respectively. The numerical suffix indicates which tracing step. DBGCNT increments by 2 for each line completed.

If timestamps are enabled then each CPU entry can span 2 trace buffer lines, whereby the second line includes the timestamp. If a valid PC occurs in the same cycle as the timestamp, it is also stored to the trace buffer and the PC bit is set. The second line featuring the timestamp is only stored if no further data access occurs in the following cycle. This is shown in [Table 6-53](#), where data accesses 2 and 3 occur in consecutive cycles, suppressing the entry2 timestamp. If 2 lines are used for an entry, then DBGCNT increments by 4. A timestamp line is indicated by bit1 in the TSINF byte. The timestamp counter is only reset each time a timestamp line entry is made. It is not reset when the data and address trace buffer line entry is made.

Table 6-52. Detail Mode Trace Buffer Format without Timestamp

Figure 6-28. Information Bytes CINF and XINF

When tracing in Detail Mode, CINF provides information about the type of CPU access being made.

TSINF provides information about a timestamp. Bit1 indicates if the byte is a TSINF byte.

Table 6-55. CINF Field Descriptions

Field	Description
7–6 CSZ	Access Type Indicator — This field indicates the CPU access size. 00 8-bit Access 01 16-bit Access 10 24-bit Access 11 32-bit Access
5 CRW	Read/Write Indicator — Indicates if the corresponding stored address corresponds to a read or write access. 0 Write Access 1 Read Access

Table 6-56. TSINF Field Descriptions

Field	Description
3 CTI	Comparator Timestamp Indicator — This bit indicates if the trace buffer entry corresponds to a comparator timestamp. 0 Trace buffer entry initiated by trace mode specification conditions or timestamp counter overflow 1 Trace buffer entry initiated by comparator D match
2 PC	Program Counter Valid Indicator — Indicates if the PC entry is valid on the timestamp line. 0 Trace buffer entry does not include PC value 1 Trace buffer entry includes PC value
0 TOVF	Timestamp Overflow Indicator — Indicates if the trace buffer entry corresponds to a timestamp overflow 0 Trace buffer entry not initiated by a timestamp overflow 1 Trace buffer entry initiated by a timestamp overflow

6.4.5.2.4 Pure PC Mode

In Pure PC Mode, the PC addresses of all opcodes loaded into the execution stage, including illegal opcodes, are stored.

Tracing from a single source, compression is implemented to increase the effective trace depth. A compressed entry consists of the lowest PC byte only. A full entry consists of all PC bytes. If the PC remains in the same 256 byte range, then a compressed entry is made, otherwise a full entry is made. The full entry is always the last entry of a record.

Each trace buffer line consists of 7 payload bytes, PLB0-6, containing full or compressed CPU PC addresses and 1 information byte to indicate the type of entry (compressed or base address) for each payload byte.

Each trace buffer line is filled from right to left. The final entry on each line is always a base address, used as a reference for the previous entries on the same line. Whilst tracing, a base address is typically stored

in bytes[6:4], the other payload bytes may be compressed or complete addresses as indicated by the info byte bits.

Table 6-57. Pure PC Mode Trace Buffer Format Single Source

Mode	8-Byte Wide Trace Buffer Line							
	7	6	5	4	3	2	1	0
CPU	CXINF	BASE	BASE	BASE	PLB3	PLB2	PLB1	PLB0

If the info bit for byte3 indicates a full CPU PC address, whereby bytes[5:3] are used, then the info bit mapped to byte[4] is redundant and the byte[6] is unused because a line overflow has occurred. Similarly a base address stored in bytes[4:2] causes line overflow, so bytes[6:5] are unused.

CXINF[6:4] indicate how many bytes in a line contain valid data, since tracing may terminate before a complete line has been filled.

CXINF Information Byte Source Tracing

Figure 6-29. Pure PC Mode CXINF

Table 6-58. CXINF Field Descriptions

Field	Description
MAT	Mid Aligned Trigger — This bit indicates a mid aligned trigger position. When a mid aligned trigger occurs, the next trace buffer entry is a base address and the counter is incremented to a new line, independent of the number of bytes used on the current line. The MAT bit is set on the current line, to indicate the position of the trigger. When configured for begin or end aligned trigger, this bit has no meaning. NOTE: In the case when ARM and TRIG are simultaneously set together in the same cycle that a new PC value is registered, then this PC is stored to the same trace buffer line and MAT set. 0 Line filled without mid aligned trigger occurrence 1 Line last entry is the last PC entry before a mid aligned trigger
PLEC[2:0]	Payload Entry Count — This field indicates the number of valid bytes in the trace buffer line. Binary encoding is used to indicate up to 7 valid bytes.
NBx	Payload Compression Indicator — This field indicates if the corresponding payload byte is the lowest byte of a base PC entry 0 Corresponding payload byte is a not the lowest byte of a base PC entry 1 Corresponding payload byte is the lowest byte of a base PC entry

Pure PC mode tracing does not support timestamps or external event entries.

6.4.5.3 Timestamp

When set, the STAMP bit in DBGTCRL configures the DBG to add a timestamp to trace buffer entries in Normal, Loop1 and Detail trace buffer modes. The timestamp is generated from a 16-bit counter and is stored to the trace buffer line each time a trace buffer entry is made.

The number of core clock cycles since the last entry equals the timestamp + 1. The core clock runs at twice the frequency of the bus clock. The timestamp of the first trace buffer entry is 0x0000. With timestamps enabled trace buffer entries are initiated in the following ways:

- according to the trace mode specification, for example COF PC addresses in Normal mode
- on a timestamp counter overflow
If the timestamp counter reaches 0xFFFF then a trace buffer entry is made, with timestamp=0xFFFF and the timestamp overflow bit TOVF is set.
- on a match of comparator D
If STAMP and DSTAMP are set then comparator D is used for forcing trace buffer entries with timestamps. The state control register settings determine if comparator D is also used to trigger the state sequencer. Thus if the state control register configuration does not use comparator D, then it is used solely for the timestamp function. If comparator D initiates a timestamp then the CTI bit is set in the INFO byte. This can be used in Normal/Loop1 mode to indicate when a particular data access occurs relative to the PC flow. For example when the timing of an access may be unclear due to the use of indexes.

NOTE

If comparator D is configured to match a PC address then associated timestamps trigger a trace buffer entry during execution of the previous instruction. Thus the PC stored to the trace buffer is that of the previous instruction. The comparator must contain the PC address of the instruction's first opcode byte

Timestamps are disabled in Pure PC mode.

6.4.5.4 Reading Data from Trace Buffer

The data stored in the trace buffer can be read using either the background debug controller (BDC) module or the CPU provided the DBG module is not armed and is configured for tracing by TSOURCE. When the ARM bit is set the trace buffer is locked to prevent reading. The trace buffer can only be unlocked for reading by an aligned word write to DBGTB when the module is disarmed. The trace buffer can only be read through the DBGTB register using aligned word reads. Reading the trace buffer while the DBG module is armed, or trace buffer locked returns 0xEE and no shifting of the RAM pointer occurs. Any byte or misaligned reads return 0xEE and do not cause the trace buffer pointer to increment to the next trace buffer address.

Reading the trace buffer is prevented by internal hardware whilst profiling is active because the RAM pointer is used to indicate the next row to be transmitted. Thus attempted reads of DBGTB do not return valid data when the PTACT bit is set. To initialize the pointer and read profiling data, the PTACT bit must be cleared and remain cleared.

The trace buffer data is read out first-in first-out. By reading CNT in DBGCNT the number of valid 64-bit lines can be determined. DBGCNT does not decrement as data is read.

Whilst reading, an internal pointer is used to determine the next line to be read. After a tracing session, the pointer points to the oldest data entry, thus if no overflow has occurred, the pointer points to line0. The

pointer is initialized by each aligned write to DBGTB to point to the oldest data again. This enables an interrupted trace buffer read sequence to be easily restarted from the oldest data entry. After reading all trace buffer lines, the next read wraps around and returns the contents of line0.

The least significant word of each 64-bit wide array line is read out first. All bytes, including those containing invalid information are read out.

6.4.5.5 Trace Buffer Reset State

The trace buffer contents are not initialized by a system reset. Thus should a system reset occur, the trace session information from immediately before the reset occurred can be read out. The DBGCNT bits are not cleared by a system reset. Thus should a reset occur, the number of valid lines in the trace buffer is indicated by DBGCNT. The internal pointer is cleared by a system reset. It can be initialized by an aligned word write to DBGTB following a reset during debugging, so that it points to the oldest valid data again. Debugging occurrences of system resets is best handled using mid or end trigger alignment since the reset may occur before the trace trigger, which in the begin trigger alignment case means no information would be stored in the trace buffer.

6.4.6 Code Profiling

6.4.6.1 Code Profiling Overview

Code profiling supplies encoded COF information on the PDO pin and the reference clock on the PDOCLK pin. If the TSOURCE bit is set then code profiling is enabled by setting the PROFILE bit. The associated device pin is configured for code profiling by setting the PDOE bit. Once enabled, code profiling is activated by arming the DBG. During profiling, if PDOE is set, the PDO operates as an output pin at a half the internal bus frequency, driving both high and low.

Independent of PDOE status, profiling data is stored to the trace buffer and can be read out in the usual manner when the debug session ends and the PTACT bit has been cleared.

The external debugger uses both edges of the clock output to strobe the data on PDO. The first PDOCLK edge is used to sample the first data bit on PDO.

Figure 6-30. Profiling Output Interface

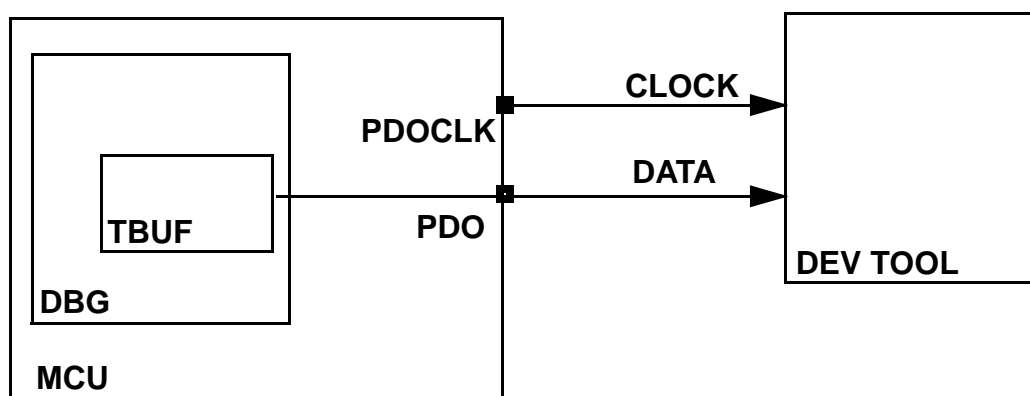

Figure 6-31 shows the profiling clock, PDOCLK, whose edges are offset from the bus clock, to ease setup and hold time requirements relative to PDO, which is synchronous to the bus clock.

The trace buffer is used as a temporary storage medium to store COF information before it is transmitted. COF information can be transmitted whilst new information is written to the trace buffer. The trace buffer data is transmitted at PDO least significant bit first. After the first trace buffer entry is made, transmission begins in the first clock period in which no further data is written to the trace buffer.

If a trace buffer line transmission completes before the next trace buffer line is ready, then the clock output is held at a constant level until the line is ready for transfer.

6.4.6.2 Profiling Configuration, Alignment and Mode Dependencies

The PROFILE bit must be set and the DBG armed to enable profiling. Furthermore the PDOE bit must be set to configure the PDO and PDOCLK pins for profiling.

If TALIGN is configured for Begin-aligned tracing, then profiling begins when the state sequencer enters Final State. If PREND is clear then profiling entries continue until a software disarm or trace buffer overflow occurs. If PREND is set then, when the trace buffer is full, the profiling session is terminated, the PTBOVF bit is set and the ARM bit is cleared. This prevents rollover from overwriting the initial PTS entry and thus allows the trace buffer contents, containing the start address, to be read out by a debugger.

Mid-Align tracing is not supported whilst profiling; if the TALIGN bits are configured for Mid-Align tracing when PROFILE is set, then the alignment defaults to end alignment.

If TALIGN is configured for End-Aligned tracing then profiling begins as soon as the module is armed. If PREND is clear then profiling entries continue until either a trace buffer overflow occurs or the DBG is disarmed by a state machine transition to State0. If PREND is set then, when the trace buffer is full, the profiling session is terminated, the PTBOVF bit is set and the ARM bit is cleared.

The profiling output transmission continues, even after disarming, until all trace buffer entries have been transmitted. The PTACT bit indicates if a profiling transmission is still active. The PTBOVF indicates if a trace buffer overflow has occurred.

The profiling timestamp feature is used only for the PTVB and PTW formats, thus differing from timestamps offered in other modes.

Profiling does not support trace buffer gating. The external pin gating feature is ignored during profiling.

When the DBG module is disarmed but profiling transmission is ongoing, register write accesses are suppressed and reading from the DBGTB returns the code 0xEEEEE.

6.4.6.3 Code Profiling Internal Data Storage Format

When profiling starts, the first trace buffer entry is made to provide the start address. This uses a 4 byte format (PTS), including the INFO byte and a 3-byte PC start address. In order to avoid trace buffer overflow a fully compressed format is used for direct (conditional branch) COF information.

Table 6-59. Profiling Trace buffer line format

Format	8-Byte Wide Trace Buffer Line							
	7	6	5	4	3	2	1	0
PTS					PC Start Address			INFO
PTIB	Indirect	Indirect	Indirect	Direct	Direct	Direct	Direct	INFO
PTHF			0	Direct	Direct	Direct	Direct	INFO
PTVB	Timestamp	Timestamp	Vector	Direct	Direct	Direct	Direct	INFO
PTW	Timestamp	Timestamp	0	Direct	Direct	Direct	Direct	INFO

The INFO byte indicates the line format used. Up to 4 bytes of each line are dedicated to branch COFs. Further bytes are used for storing indirect COF information (indexed jumps and interrupt vectors). Indexed jumps force a full line entry with the PTIB format and require 3-bytes for the full 24-bit destination address. Interrupts force a full line entry with the PTVB format, whereby vectors are stored as a single byte and a 16-bit timestamp value is stored simultaneously to indicate the number of core clock cycles relative to the previous COF. At each trace buffer entry the 16-bit timestamp counter is cleared. The device vectors use address[8:0] whereby address[1:0] are constant zero for vectors. Thus the value stored to the PTVB vector byte is equivalent to (Vector Address[8:1]).

After the PTS entry, the pointer increments and the DBG begins to fill the next line with direct COF information. This continues until the direct COF field is full or an indirect COF occurs, then the INFO byte and, if needed, indirect COF information are entered on that line and the pointer increments to the next line.

If a timestamp overflow occurs, indicating a 65536 bus clock cycles without COF, then an entry is made with the TSOVF bit set, INFO[6] (Table 6-60) and profiling continues.

If a trace buffer overflow occurs, a final entry is made with the TBOVF bit set, profiling is terminated and the DBG is disarmed. Trace buffer overflow occurs when the trace buffer contains 64 lines pending transmission.

Whenever the DBG is disarmed during profiling, a final entry is made with the TERM bit set to indicate the final entry.

When a final entry is made then by default the PTW line format is used, except if a COF occurs in the same cycle in which case the corresponding PTIB/PTVB/PTHF format is used. Since the development tool receives the INFO byte first, it can determine in advance the format of data it is about to receive. The

transmission of the INFO byte starts when a line is complete. Whole bytes are always transmitted. The grey shaded bytes of [Table 6-59](#) are not transmitted.

Figure 6-32. INFO byte encoding

Table 6-60. Profiling Format Encoding

INFO[3:0]	Line Format	Source	Description
0000	PTS	CPU	Initial CPU entry
0001	PTIB	CPU	Indexed jump with up to 31 direct COFs
0010	PTHF	CPU	31 direct COFs without indirect COF
0011	PTVB	CPU	Vector with up to 31 direct COFs
0111	PTW	CPU	Error (Error codes in INFO[7:4])
Others	Reserved	CPU	Reserved
INFO[7:4]	Bit Name		Description
INFO[7]	Reserved	CPU	Reserved
INFO[6]	TSOVF	CPU	Timestamp Overflow
INFO[5]	TBOVF	CPU	Trace Buffer Overflow
INFO[4]	TERM	CPU	Profiling terminated by disarming
Vector[7:0]	Vector[7:0]	CPU	Device Interrupt Vector Address [8:1]

6.4.6.4 Direct COF Compression

Each branch COF is stored to the trace buffer as a single bit (0=branch not taken, 1=branch taken) until an indirect COF (indexed jump, return, or interrupt) occurs. The branch COF entries are stored in the byte fields labelled “Direct” in [Table 6-59](#). These entries start at byte1[0] and continue through to byte4[7], or until an indirect COF occurs, whichever occurs sooner. The entries use a format whereby the left most asserted bit is always the stop bit, which indicates that the bit to its right is the first direct COF and byte1[0] is the last COF that occurred before the indirect COF. This is shown in [Table 6-61](#), whereby the Bytes 4 to 1 of the trace buffer are shown for 3 different cases. The stop bit field for each line is shaded.

In line0, the left most asserted bit is Byte4[7]. This indicates that all remaining 31 bits in the 4-byte field contain valid direct COF information, whereby each 1 represents branch taken and each 0 represents branch not taken. The stop bit of line1 indicates that all 30 bits to its right are valid, after the 30th direct COF entry, an indirect COF occurred, that is stored in bytes 7 to 5. In this case the bit to the left of the stop bit is redundant. Line2 indicates that an indirect COF occurred after 8 direct COF entries. The indirect COF address is stored in bytes 7 to 5. All bits to the left of the stop bit are redundant.

Line	Byte4								Byte3								Byte2								Byte1							
Line0	1	0	0	1	0	0	1	0	0	1	0	1	1	0	0	1	0	0	1	0	0	0	0	1	1	0	0	0	0	1	1	0
Line1	0	1	1	0	0	1	0	1	1	0	0	1	0	0	1	0	1	1	0	0	1	0	0	1	0	1	1	0	0	1	0	0
Line2	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0	0	0	1

Table 6-61. Profiling Direct COF Format

6.4.7 Breakpoints

Breakpoints can be generated by state sequencer transitions to State0. Transitions to State0 are forced by the following events

- Through comparator matches via Final State.
- Through software writing to the TRIG bit in the DBGIC1 register via Final State.
- Through the external event input (DBGEEV) via Final State.
- Through a profiling trace buffer overflow event.

Breakpoints are not generated by software writes to DBGIC1 that clear the ARM bit.

6.4.7.1 Breakpoints From Comparator Matches or External Events

Breakpoints can be generated when the state sequencer transitions to State0 following a comparator match or an external event.

If a tracing session is selected by TSOURCE, the transition to State0 occurs when the tracing session has completed, thus if Begin or Mid aligned triggering is selected, the breakpoint is requested only on completion of the subsequent trace. If End aligned tracing or no tracing session is selected, the transition to State0 and associated breakpoints are immediate.

6.4.7.2 Breakpoints Generated Via The TRIG Bit

When TRIG is written to “1”, the Final State is entered. If a tracing session is selected by TSOURCE, State0 is entered and breakpoints are requested only when the tracing session has completed, thus if Begin or Mid aligned triggering is selected, the breakpoint is requested only on completion of the subsequent trace. If no tracing session is selected, the state sequencer enters State0 immediately and breakpoints are requested. TRIG breakpoints are possible even if the DBG module is disarmed.

6.4.7.3 DBG Breakpoint Priorities

If a TRIG occurs after Begin or Mid aligned tracing has already been triggered by a comparator instigated transition to Final State, then TRIG no longer has an effect. When the associated tracing session is complete, the breakpoint occurs. Similarly if a TRIG is followed by a subsequent comparator match, it has no effect, since tracing has already started.

6.4.7.3.1 DBG Breakpoint Priorities And BDC Interfacing

Breakpoint operation is dependent on the state of the S12ZBDC module. BDM cannot be entered from a breakpoint unless the BDC is enabled (ENBDC bit is set in the BDC). If BDM is already active, breakpoints are disabled. In addition, while executing a BDC STEP1 command, breakpoints are disabled.

When the DBG breakpoints are mapped to BDM (BDMBP set), then if a breakpoint request, either from a BDC BACKGROUND command or a DBG event, coincides with an SWI instruction in application code, (i.e. the DBG requests a breakpoint at the next instruction boundary and the next instruction is an SWI) then the CPU gives priority to the BDM request over the SWI request.

On returning from BDM, the SWI from user code gets executed. Breakpoint generation control is summarized in [Table 6-62](#).

Table 6-62. Breakpoint Mapping Summary

BRKCPU	BDMBP Bit (DBGC1[4])	BDC Enabled	BDM Active	Breakpoint Mapping
0	X	X	X	No Breakpoint
1	0	X	0	Breakpoint to SWI
1	0	1	1	No Breakpoint
1	1	0	X	No Breakpoint
1	1	1	0	Breakpoint to BDM
1	1	1	1	No Breakpoint

6.5 Application Information

6.5.1 Avoiding Unintended Breakpoint Re-triggering

Returning from an instruction address breakpoint using an RTI or BDC GO command without PC modification, returns to the instruction that generated the breakpoint. If an active breakpoint or trigger still exists at that address, this can re-trigger, disarming the DBG. If configured for BDM breakpoints, the user must apply the BDC STEP1 command to increment the PC past the current instruction.

If configured for SWI breakpoints, the DBG can be re configured in the SWI routine. If a comparator match occurs at an SWI vector address then a code SWI and DBG breakpoint SWI could occur simultaneously. In this case the SWI routine is executed twice before returning.

6.5.2 Debugging Through Reset

To debug through reset, the debugger can recognize a reset occurrence and pull the device BKGD pin low. This forces the device to leave reset in special single chip (SSC) mode, because the BKGD pin is used as the MODC signal in the reset phase. When the device leaves reset in SSC mode, CPU execution is halted and the device is in active BDM. Thus the debugger can configure the DBG for tracing and breakpoints before returning to application code execution. In this way it is possible to analyze the sequence of events emerging from reset. The recommended handling of the internal reset scenario is as follows:

- When a reset occurs the debugger pulls BKGD low until the reset ends, forcing SSC mode entry.
- Then the debugger reads the reset flags to determine the cause of reset.
- If required, the debugger can read the trace buffer to see what happened just before reset. Since the trace buffer and DBGCNT register are not affected by resets other than POR.
- The debugger configures and arms the DBG to start tracing on returning to application code.
- The debugger then sets the PC according to the reset flags.
- Then the debugger returns to user code with GO or STEP1.

6.5.3 Breakpoints from other S12Z sources

The DBG is neither affected by CPU BGND instructions, nor by BDC BACKGROUND commands.

6.5.4 Code Profiling

The code profiling data output pin PDO is mapped to a device pin that can also be used as GPIO in an application. If profiling is required and all pins are required in the application, it is recommended to use the device pin for a simple output function in the application, without feedback to the chip. In this way the application can still be profiled, since the pin has no effect on code flow.

The PDO provides a simple bit stream that must be strobed at both edges of the profiling clock when profiling. The external development tool activates profiling by setting the DBG ARM bit, with PROFILE and PDOE already set. Thereafter the first bit of the profiling bit stream is valid at the first rising edge of the profiling clock. No start bit is provided. The external development tool must detect this first rising edge after arming the DBG. To detect the end of profiling, the DBG ARM bit can be monitored using the BDC.

Chapter 7

ECC Generation Module (SRAM_ECCV1)

Table 7-1. Revision History Table

Rev. No. (Item No.)	Date	Sections Affected	Substantial Change(s)
V01.00	15-Oct-13	all	Initial Module Version
V01.10	19-March-15	7.3.1	add feature description for S12ZVMC256 in case of non-aligned write to memory data word containing a double bit ECC error

7.1 Introduction

The purpose of ECC logic is to detect and correct as much as possible memory data bit errors. These soft errors, mainly generated by alpha radiation, can occur randomly during operation. "Soft error" means that only the information inside the memory cell is corrupt; the memory cell itself is not damaged. A write access with correct data solves the issue. If the ECC algorithm is able to correct the data, then the system can use this corrected data without any issues. If the ECC algorithm is able to detect, but not correct the error, then the system is able to ignore the memory read data to avoid system malfunction.

The ECC value is calculated based on an aligned 2 byte memory data word. The ECC algorithm is able to detect and correct single bit ECC errors. Double bit ECC errors will be detected but the system is not able to correct these errors. This kind of ECC code is called SECDED code. This ECC code requires 6 additional parity bits for each 2 byte data word.

7.1.1 Features

The SRAM_ECC module provides the ECC logic for the system memory based on a SECDED algorithm. The SRAM_ECC module includes the following features:

- SECDED ECC code
 - Single bit error detection and correction per 2 byte data word
 - Double bit error detection per 2 byte data word
- Memory initialization function
- Byte wide system memory write access
- Automatic single bit ECC error correction for read and write accesses
- Debug logic to read and write raw use data and ECC values

7.2 Memory Map and Register Definition

This section provides a detailed description of all memory and registers for the SRAM_ECC module.

7.2.1 Register Summary

[Figure 7-1](#) shows the summary of all implemented registers inside the SRAM_ECC module.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 ECCSTAT	R	0	0	0	0	0	0	0	RDY
	W								
0x0001 ECCIE	R	0	0	0	0	0	0	0	SBEEIE
	W								
0x0002 ECCIF	R	0	0	0	0	0	0	0	SBEEIF
	W								
0x0003 - 0x0006 Reserved	R	0	0	0	0	0	0	0	0
	W								
0x0007 ECCDPTRH	R	DPTR[23:16]							
	W

Figure 7-1. SRAM_ECC Register Summary

7.2.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field functions follow the register diagrams, in bit order.

7.2.2.1 ECC Status Register (ECCSTAT)

Module Base + 0x00000				Access: User read only ⁽¹⁾				
	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	RDY
W								
Reset	0	0	0	0	0	0	0	0

1. Read: Anytime
Write: Never

Figure 7-2. ECC Status Register (ECCSTAT)

Table 7-2. ECCSTAT Field Description

Field	Description
0 RDY	ECC Ready— Shows the status of the ECC module. 0 Internal SRAM initialization is ongoing, access to the SRAM is disabled 1 Internal SRAM initialization is done, access to the SRAM is enabled

7.2.2.2 ECC Interrupt Enable Register (ECCIE)

Module Base + 0x00001				Access: User read/write ⁽¹⁾				
	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	SBEEIE
W								
Reset	0	0	0	0	0	0	0	0

Table 7-3. ECCIE Field Description

Field	Description
0 SBEEIE	Single bit ECC Error Interrupt Enable — Enables Single ECC Error interrupt. 0 Interrupt request is disabled 1 Interrupt will be requested whenever SBEEIF is set

7.2.2.3 ECC Interrupt Flag Register (ECCIF)

1. Read: Anytime
Write: Anytime, write 1 to clear

Figure 7-4. ECC Interrupt Flag Register (ECCIF)

Table 7-4. ECCIF Field Description

Field	Description
0 SBEEIF	Single bit ECC Error Interrupt Flag — The flag is set to 1 when a single bit ECC error occurs. 0 No occurrences of single bit ECC error since the last clearing of the flag 1 Single bit ECC error has occurred since the last clearing of the flag

7.2.2.4 ECC Debug Pointer Register (ECCDPTRH, ECCDPTRM, ECCDPTRL)

Figure 7-5. ECC Debug Pointer Register (ECCDPTRH, ECCDPTRM, ECCDPTRL)

1. Read: Anytime
Write: Anytime

Table 7-5. ECCDPTR Register Field Descriptions

Field	Description
DPTR [23:0]	ECC Debug Pointer — This register contains the system memory address which will be used for a debug access. Address bits not relevant for SRAM address space are not writeable, so the software should read back the pointer value to make sure the register contains the intended memory address. It is possible to write an address value to this register which points outside the system memory. There is no additional monitoring of the register content; therefore, the software must make sure that the address value points to the system memory space.

7.2.2.5 ECC Debug Data (ECCDDH, ECCDDL)

Figure 7-6. ECC Debug Data (ECCDDH, ECCDDL)

1. Read: Anytime
Write: Anytime

Table 7-6. ECCDD Register Field Descriptions

Field	Description
DDATA [23:0]	ECC Debug Raw Data — This register contains the raw data which will be written into the system memory during a debug write command or the read data from the debug read command.

7.2.2.6 ECC Debug ECC (ECCDE)

1. Read: Anytime
Write: Anytime

Figure 7-7. ECC Debug ECC (ECCDE)

Table 7-7. ECCDE Field Description

Field	Description
5:0 DECC[5:0]	ECC Debug ECC — This register contains the raw ECC value which will be written into the system memory during a debug write command or the ECC read value from the debug read command.

7.2.2.7 ECC Debug Command (ECCDCMD)

- 1. Read: Anytime
- Write: Anytime, in special mode only

Figure 7-8. ECC Debug Command (ECCDCMD)

Table 7-8. ECCDCMD Field Description

Field	Description
7 ECCDRR	ECC Disable Read Repair Function— Writing one to this register bit will disable the automatic single bit ECC error repair function during read access; see also chapter 7.3.7, “ECC Debug Behavior”. 0 Automatic single ECC error repair function is enabled 1 Automatic single ECC error repair function is disabled
1 ECCDW	ECC Debug Write Command — Writing one to this register bit will perform a debug write access, to the system memory. During this access the debug data word (DDATA) and the debug ECC value (DECC) will be written to the system memory address defined by DPTR. If the debug write access is done, this bit is cleared. Writing 0 has no effect. It is not possible to set this bit if the previous debug access is ongoing (ECCDW or ECCDR bit set).
0 ECCDR	ECC Debug Read Command — Writing one to this register bit will perform a debug read access from the system memory address defined by DPTR. If the debug read access is done, this bit is cleared and the raw memory read data are available in register DDATA and the raw ECC value is available in register DECC. Writing 0 has no effect. If the ECCDW and ECCDR bit are set at the same time, then only the ECCDW bit is set and the Debug Write Command is performed. It is not possible to set this bit if the previous debug access is ongoing (ECCDW or ECCDR bit set).

7.3 Functional Description

The bus system allows 1, 2, 3 and 4 byte write access to a 4 byte aligned memory address, but the ECC value is generated based on an aligned 2 byte data word. Depending on the access type, the access is separated into different access cycles. Table 7-9 shows the different access types with the expected number of access cycles and the performed internal operations.

Table 7-9. Memory access cycles

Access type	ECC error	access cycle	Internal operation	Memory content	Error indication
2 and 4 byte aligned write access	—	1	write to memory	new data	—

Table 7-9. Memory access cycles

Access type	ECC error	access cycle	Internal operation	Memory content	Error indication
1 or 3 byte write, non-aligned 2 byte write	no	2	read data from the memory	old + new data	—
			write old + new data to the memory		
	single bit	2	read data from the memory	corrected + new data	SBEEIF
			write corrected + new data to the memory		
	double bit	2	read data from the memory	unchanged ¹	initiator module is informed
			ignore write data ¹		
read access	no	1	read from memory	unchanged	-
	single bit	1	read data from the memory	corrected data	SBEEIF
			write corrected data back to memory		
	double bit	1	read from memory	unchanged	data mark as invalid

The single bit ECC error generates an interrupt when enabled. The double bit ECC errors are reported by the SRAM_ECC module, but handled at MCU level. For more information, see the MMC description.

7.3.1 Non-aligned Memory Write Access

Non-aligned write accesses are separated into a read-modify-write operation. During the first cycle, the logic reads the data from the memory and performs an ECC check. If no ECC errors were detected then the logic generates the new ECC value based on the read and write data and writes the new data word together with the new ECC value into the memory. If required both 2 byte data words are updated.

If the module detects a single bit ECC error during the read cycle, then the logic generates the new ECC value based on the corrected read and new write read. In the next cycle, the new data word and the new ECC value are written into the memory. If required both 2 byte data words are updated. The SBEEIF bit is set. Hence, the single bit ECC error was corrected by the write access. [Figure 7-9](#) shows an example of a 2 byte non-aligned memory write access.

If the module detects a double bit ECC error during the read cycle, then the write access to the memory is blocked and the initiator module is informed about the error¹.

1. On S12ZVMC256 device only, the data are written into the memory even if a double bit ECC error was detected. The data word written to the memory is undefined due to the correction based on a double bit ECC error signature. The written data word is ECC clean.

Figure 7-9. 2 byte non-aligned write access

7.3.2 Aligned 2 and 4 Byte Memory Write Access

During an aligned 2 or 4 byte memory write access, no ECC check is performed. The internal ECC logic generates the new ECC value based on the write data and writes the data words together with the generated ECC values into the memory.

7.3.3 Memory Read Access

During each memory read access an ECC check is performed. If the logic detects a single bit ECC error, then the module corrects the data, so that the access initiator module receives correct data. In parallel, the logic writes the corrected data back to the memory, so that this read access repairs the single bit ECC error. This automatic ECC read repair function is disabled by setting the ECCDRR bit.

If a single bit ECC error was detected, then the SBEEIF flag is set.

If the logic detects a double bit ECC error, then the data word is flagged as invalid, so that the access initiator module can ignore the data.

7.3.4 Memory Initialization

To avoid spurious ECC error reporting, memory operations that allow a read before a first write (like the read-modify-write operation of the non-aligned access) require that the memory contains valid ECC values before the first read-modify-write access is performed. The ECC module provides logic to initialize the complete memory content with zero during the power up phase. During the initialization process the access to the SRAM is disabled and the RDY status bit is cleared. If the initialization process is done, SRAM access is possible and the RDY status bit is set.

7.3.5 Interrupt Handling

This section describes the interrupts generated by the SRAM_ECC module and their individual sources. Vector addresses and interrupt priority are defined at the MCU level.

Table 7-10. SRAM_ECC Interrupt Sources

Module Interrupt Sources	Local Enable
Single bit ECC error	ECCIE[SBEEIE]

7.3.6 ECC Algorithm

The table below shows the equation for each ECC bit based on the 16 bit data word.

Table 7-11. ECC Calculation

ECC bit	Use data
ECC[0]	$\sim (\wedge (\text{data}[15:0] \& 0x443F))$
ECC[1]	$\sim (\wedge (\text{data}[15:0] \& 0x13C7))$
ECC[2]	$\sim (\wedge (\text{data}[15:0] \& 0xE1D1))$
ECC[3]	$\sim (\wedge (\text{data}[15:0] \& 0xEE60))$
ECC[4]	$\sim (\wedge (\text{data}[15:0] \& 0x3E8A))$
ECC[5]	$\sim (\wedge (\text{data}[15:0] \& 0x993C))$

7.3.7 ECC Debug Behavior

For debug purposes, it is possible to read and write the uncorrected use data and the raw ECC value directly from the memory. For these debug accesses a register interface is available. The debug access is performed with the lowest priority; other memory accesses must be done before the debug access starts. If a debug access is requested during an ongoing memory initialization process, then the debug access is performed if the memory initialization process is done.

If the ECCDRR bit is set, then the automatic single bit ECC error repair function for all read accesses is disabled. In this case a read access from a system memory location with single bit ECC error will produce correct data and the single bit ECC error is flagged by the SBEEIF, but the data inside the system memory are unchanged.

By writing wrong ECC values into the system memory the debug access can be used to force single and double bit ECC errors to check the software error handling .

It is not possible to set the ECCDW or ECCDR bit if the previous debug access is ongoing (ECCDW or ECCDR bit active). This ensures that the ECCDD and ECCDE registers contains consistent data. The software should read out the status of the ECCDW and ECCDR register bit before a new debug access is requested.

7.3.7.1 ECC Debug Memory Write Access

Writing one to the ECCDW bit performs a debug write access to the memory address defined by register DPTR. During this access, the raw data DDATA and the ECC value DECC are written directly into the system memory. If the debug write access is done, the ECCDW register bit is cleared. The debug write access is always a 2 byte aligned memory access, so that no ECC check is performed and no single or double bit ECC error indication is activated.

7.3.7.2 ECC Debug Memory Read Access

Writing one to the ECCDR bit performs a debug read access from the memory address defined by register DPTR. If the ECCDR bit is cleared then the register DDATA contains the uncorrected read data from the memory. The register DECC contains the ECC value read from the memory. Independent of the ECCDRR register bit setting, the debug read access will not perform an automatic ECC repair during read access. During the debug read access no ECC check is performed, so that no single or double bit ECC error indication is activated.

If the ECCDW and the ECCDR bits are set at the same time, then only the debug write access is performed.

8.1 Introduction

This specification describes the function of the Clock, Reset and Power Management Unit (S12_CPMU_UHV_V10 and S12CPMU_UHV_V6).

- The Pierce oscillator (XOSCLCP) provides a robust, low-noise and low-power external clock source. It is designed for optimal start-up margin with typical crystal oscillators.
- The Voltage regulator (VREGAUTO) operates from the range 6V to 18V. It provides all the required chip internal voltages and voltage monitors.
- The Phase Locked Loop (PLL) provides a highly accurate frequency multiplier with internal filter.
- The Internal Reference Clock (IRC1M) provides a 1MHz internal clock.

8.1.1 Differences between S12CPMU_UHV_V10 and S12CPMU_UHV_V6

- The following device pins exist only in V10:
VDDS1, VDDS2, BCTLS1, BCTLS2, SNPS1, SNPS2,
- The feature of switching VDDS1/2 to VRH1/2 (which connects to ADC) exists only in V10
- The following register and bits exist only in V10:
CPMUVREGCTL register: Bits VRH2EN, VRH1EN, EXTS1ON, EXTS2ON
CPMULVCTL register: Bit VDDSIIE
CPMUVDDS register
- The VDDS Integrity Interrupt only exists in V10

8.1.2 Features

The Pierce Oscillator (XOSCLCP) contains circuitry to dynamically control current gain in the output amplitude. This ensures a signal with low harmonic distortion, low power and good noise immunity.

- Supports crystals or resonators from 4MHz to 20MHz.
- High noise immunity due to input hysteresis and spike filtering.
- Low RF emissions with peak-to-peak swing limited dynamically
- Transconductance (gm) sized for optimum start-up margin for typical crystals
- Dynamic gain control eliminates the need for external current limiting resistor
- Integrated resistor eliminates the need for external bias resistor
- Low power consumption: Operates from internal 1.8V (nominal) supply, Amplitude control limits power
- Optional oscillator clock monitor reset
- Optional full swing mode for higher immunity against noise injection on the cost of higher power consumption and increased emission

The Voltage Regulator (VREGAUTO) has the following features:

- Input voltage range from 6 to 18V (nominal operating range)
- Low-voltage detect (LVD) with low-voltage interrupt (LVI)
- Power-on reset (POR)
- Low-voltage reset (LVR)
- On Chip Temperature Sensor and Bandgap Voltage measurement via internal ADC channel.
- Voltage Regulator providing Full Performance Mode (FPM) and Reduced Performance Mode (RPM)
- External ballast device support to reduce internal power dissipation
- Capable of supplying both the MCU internally plus external components
- Over-temperature interrupt

The Phase Locked Loop (PLL) has the following features:

- Highly accurate and phase locked frequency multiplier
- Configurable internal filter for best stability and lock time
- Frequency modulation for defined jitter and reduced emission
- Automatic frequency lock detector
- Interrupt request on entry or exit from locked condition
- PLL clock monitor reset
- Reference clock either external (crystal) or internal square wave (1MHz IRC1M) based.
- PLL stability is sufficient for LIN communication in slave mode, even if using IRC1M as reference clock

The Internal Reference Clock (IRC1M) has the following features:

- Frequency trimming
(A factory trim value for 1MHz is loaded from Flash Memory into the IRCTRIM register after reset, which can be overwritten by application if required)
- Temperature Coefficient (TC) trimming.
(A factory trim value is loaded from Flash Memory into the IRCTRIM register to turn off TC trimming after reset. Application can trim the TC if required by overwriting the IRCTRIM register).

Other features of the S12CPMU_UHV_V10_V6 include

- Oscillator clock monitor to detect loss of crystal
- Autonomous periodical interrupt (API)
- Bus Clock Generator
 - Clock switch to select either PLLCLK or external crystal/resonator based Bus Clock
 - PLLCLK divider to adjust system speed
- System Reset generation from the following possible sources:
 - Power-on reset (POR)
 - Low-voltage reset (LVR)
 - COP system watchdog, COP reset on time-out, windowed COP
 - Loss of oscillation (Oscillator clock monitor fail)
 - Loss of PLL clock (PLL clock monitor fail)
 - External pin $\overline{\text{RESET}}$

8.1.3 Modes of Operation

This subsection lists and briefly describes all operating modes supported by the S12CPMU_UHV_V10_V6.

8.1.3.1 Run Mode

The voltage regulator is in Full Performance Mode (FPM).

NOTE

The voltage regulator is active, providing the nominal supply voltages with full current sourcing capability (see also Appendix for VREG electrical parameters). The features ACLK clock source, Low Voltage Interrupt (LVI), Low Voltage Reset (LVR) and Power-On Reset (POR) are available.

The Phase Locked Loop (PLL) is on.

The Internal Reference Clock (IRC1M) is on.

The API is available.

- PLL Engaged Internal (PEI)
 - This is the default mode after System Reset and Power-On Reset.
 - The Bus Clock is based on the PLLCLK.
 - After reset the PLL is configured for 50MHz VCOCLK operation. Post divider is 0x03, so PLLCLK is VCOCLK divided by 4, that is 12.5MHz and Bus Clock is 6.25MHz. The PLL can be re-configured for other bus frequencies.
 - The reference clock for the PLL (REFCLK) is based on internal reference clock IRC1M.
- PLL Engaged External (PEE)
 - The Bus Clock is based on the PLLCLK.
 - This mode can be entered from default mode PEI by performing the following steps:
 - Configure the PLL for desired bus frequency.
 - Program the reference divider (REFDIV[3:0] bits) to divide down oscillator frequency if necessary.
 - Enable the external oscillator (OSCE bit).
 - Wait for oscillator to start up (UPOSC=1) and PLL to lock (LOCK=1).
- PLL Bypassed External (PBE)
 - The Bus Clock is based on the Oscillator Clock (OSCCLK).
 - The PLLCLK is always on to qualify the external oscillator clock. Therefore it is necessary to make sure a valid PLL configuration is used for the selected oscillator frequency.
 - This mode can be entered from default mode PEI by performing the following steps:

- Make sure the PLL configuration is valid for the selected oscillator frequency.
- Enable the external oscillator (OSCE bit).
- Wait for oscillator to start up (UPOSC=1).
- Select the Oscillator Clock (OSCCLK) as source of the Bus Clock (PLLSEL=0).
- The PLLCLK is on and used to qualify the external oscillator clock.

8.1.3.2 Wait Mode

For S12CPMU_UHV_V10_V6 Wait Mode is the same as Run Mode.

8.1.3.3 Stop Mode

This mode is entered by executing the CPU STOP instruction.

The voltage regulator is in Reduced Performance Mode (RPM).

NOTE

The voltage regulator output voltage may degrade to a lower value than in Full Performance Mode (FPM), additionally the current sourcing capability is substantially reduced (see also Appendix for VREG electrical parameters). Only clock source ACLK is available and the Power On Reset (POR) circuitry is functional. The Low Voltage Interrupt (LVI) and Low Voltage Reset (LVR) are disabled.

The API is available.

The Phase Locked Loop (PLL) is off.

The Internal Reference Clock (IRC1M) is off.

Core Clock and Bus Clock are stopped.

Depending on the setting of the PSTP and the OSCE bit, Stop Mode can be differentiated between Full Stop Mode (PSTP = 0 or OSCE=0) and Pseudo Stop Mode (PSTP = 1 and OSCE=1). In addition, the behavior of the COP in each mode will change based on the clocking method selected by COPOSCSEL[1:0].

- **Full Stop Mode (PSTP = 0 or OSCE=0)**

External oscillator (XOSCLCP) is disabled.

- If COPOSCSEL1=0:

The COP and RTI counters halt during Full Stop Mode.

After wake-up from Full Stop Mode the Core Clock and Bus Clock are running on PLLCLK (PLLSEL=1). COP and RTI are running on IRCCLK (COPOSCSEL0=0, RTIOSCSEL=0).

- If COPOSCSEL1=1:

The clock for the COP is derived from ACLK (trimmable internal RC-Oscillator clock). During Full Stop Mode the ACLK for the COP can be stopped (COP static) or running (COP active) depending on the setting of bit CSAD. When bit CSAD is set the ACLK clock source for the

COP is stopped during Full Stop Mode and COP continues to operate after exit from Full Stop Mode. For this COP configuration (ACLK clock source, CSAD set) a latency time (please refer to CSAD bit description for details) occurs when entering or exiting (Full, Pseudo) Stop Mode. When bit CSAD is clear the ACLK clock source is on for the COP during Full Stop Mode and COP is operating.

During Full Stop Mode the RTI counter halts.

After wake-up from Full Stop Mode the Core Clock and Bus Clock are running on PLLCLK (PLLSEL=1). The COP runs on ACLK and RTI is running on IRCCLK (COPOSCSEL0=0, RTIOSCSEL=0).

- **Pseudo Stop Mode (PSTP = 1 and OSCE=1)**

External oscillator (XOSCLCP) continues to run.

- If COPOSCSEL1=0:

If the respective enable bits are set (PCE=1 and PRE=1) the COP and RTI will continue to run with a clock derived from the oscillator clock.

The clock configuration bits PLLSEL, COPOSCSEL0, RTIOSCSEL are unchanged.

- If COPOSCSEL1=1:

If the respective enable bit for the RTI is set (PRE=1) the RTI will continue to run with a clock derived from the oscillator clock.

The clock for the COP is derived from ACLK (trimmable internal RC-Oscillator clock). During Pseudo Stop Mode the ACLK for the COP can be stopped (COP static) or running (COP active) depending on the setting of bit CSAD. When bit CSAD is set the ACLK for the COP is stopped during Pseudo Stop Mode and COP continues to operate after exit from Pseudo Stop Mode.

For this COP configuration (ACLK clock source, CSAD set) a latency time (please refer to CSAD bit description for details) occurs when entering or exiting (Pseudo, Full) Stop Mode. When bit CSAD is clear the ACLK clock source is on for the COP during Pseudo Stop Mode and COP is operating.

The clock configuration bits PLLSEL, COPOSCSEL0, RTIOSCSEL are unchanged.

NOTE

When starting up the external oscillator (either by programming OSCE bit to 1 or on exit from Full Stop Mode with OSCE bit already 1) the software must wait for a minimum time equivalent to the startup-time of the external oscillator t_{UPOSC} before entering Pseudo Stop Mode.

8.1.3.4 Freeze Mode (BDM active)

For S12CPMU_UHV_V10_V6 Freeze Mode is the same as Run Mode except for RTI and COP which can be frozen in Active BDM Mode with the RSBCK bit in the CPMUCOP register. After exiting BDM Mode RTI and COP will resume its operations starting from this frozen status.

Additionally the COP can be forced to the maximum time-out period in Active BDM Mode. For details please see also the RSBCK and CR[2:0] bit description field of [Table 8-14](#) in [Section 8.3.2.12](#), “S12CPMU_UHV_V10_V6 COP Control Register (CPMUCOP)”

8.1.4 S12CPMU_UHV_V10_V6 Block Diagram

Figure 8-1. Block diagram of S12CPMU_UHV_V10_V6

Figure 8-2 shows a block diagram of the XOSCLCP.

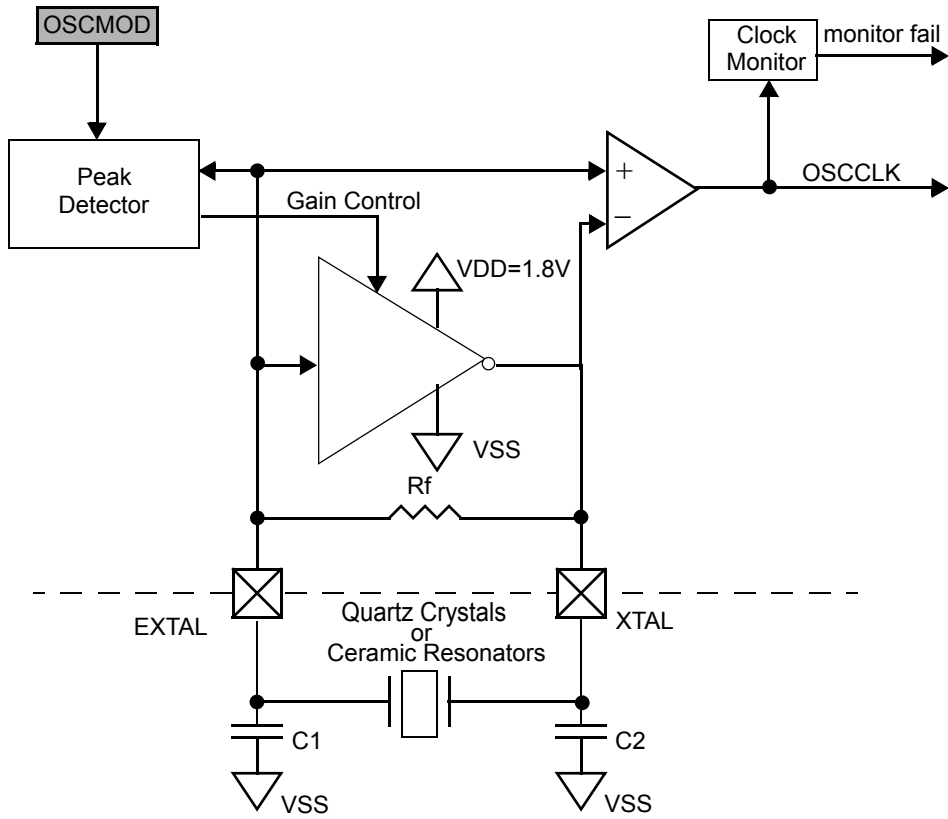

Figure 8-2. XOSCLCP Block Diagram

8.2 Signal Description

This section lists and describes the signals that connect off chip as well as internal supply nodes and special signals.

8.2.1 $\overline{\text{RESET}}$

Pin $\overline{\text{RESET}}$ is an active-low bidirectional pin. As an input it initializes the MCU asynchronously to a known start-up state. As an open-drain output it indicates that an MCU-internal reset has been triggered.

8.2.2 EXTAL and XTAL

These pins provide the interface for a crystal to control the internal clock generator circuitry. EXTAL is the input to the crystal oscillator amplifier. XTAL is the output of the crystal oscillator amplifier. If XOSCLCP is enabled, the MCU internal OSCCLK_LCP is derived from the EXTAL input frequency. If OSCE=0, the EXTAL pin is pulled down by an internal resistor of approximately 200 k Ω and the XTAL pin is pulled down by an internal resistor of approximately 700 k Ω .

NOTE

NXP recommends an evaluation of the application board and chosen resonator or crystal by the resonator or crystal supplier.
The loop controlled circuit (XOSCLCP) is not suited for overtone resonators and crystals.

8.2.3 VSUP — Regulator Power Input Pin

Pin VSUP is the power input of VREGAUTO. All currents sourced into the regulator loads flow through this pin.

A suitable reverse battery protection network can be used to connect VSUP to the car battery supply network.

8.2.4 VDDA, VSSA — Regulator Reference Supply Pins

Pins VDDA and VSSA are used to supply the analog parts of the regulator. Internal precision reference circuits are supplied from these signals.

An off-chip decoupling capacitor (220 nF(X7R ceramic)) between VDDA and VSSA is required and can improve the quality of this supply.

VDDA has to be connected externally to VDDX.

8.2.5 VDDX, VSSX— Pad Supply Pins

VDDX is the supply domain for the digital Pads.

An off-chip decoupling capacitor (10 μ F plus 220 nF(X7R ceramic)) between VDDX and VSSX is required.

This supply domain is monitored by the Low Voltage Reset circuit.

VDDX has to be connected externally to VDDA.

8.2.6 VDDC— CAN Supply Pin

VDDC is the supply domain for the CAN module.

An off-chip decoupling capacitor (10 μ F plus 220 nF(X7R ceramic)) between VDDC and VSSX is required.

This supply domain is monitored by the Low Voltage Reset circuit.

8.2.7 VDDS1— Sensor Supply1 Pin

VDDS1 is a short circuit protected supply domain which is suitable for sensors (which connect externally to the PCB).

An off-chip decoupling capacitor (4.7 μ F plus 220 nF(X7R ceramic)) between VDDS1 and VSSX is required.

This supply domain is monitored by a Low Voltage Detect (LVDS1) circuit.

8.2.8 VDDS2— Sensor Supply2 Pin

VDDS2 is a short circuit protected supply domain which is suitable for sensors (which connect externally to the PCB).

An off-chip decoupling capacitor (4.7 μ F plus 220 nF(X7R ceramic)) between VDDS2 and VSSX is required.

This supply domain is monitored by a Low Voltage Detect (LVDS2) circuit.

8.2.9 BCTL— Base Control Pin for external PNP

BCTL is the ballast connection for the on chip voltage regulator. It provides the base current of an external BJT (PNP) of the VDDX and VDDA supplies. An additional 1K Ω resistor between emitter and base of the BJT is required.

Figure 8-3 shows an application example for the external BCTL pin.

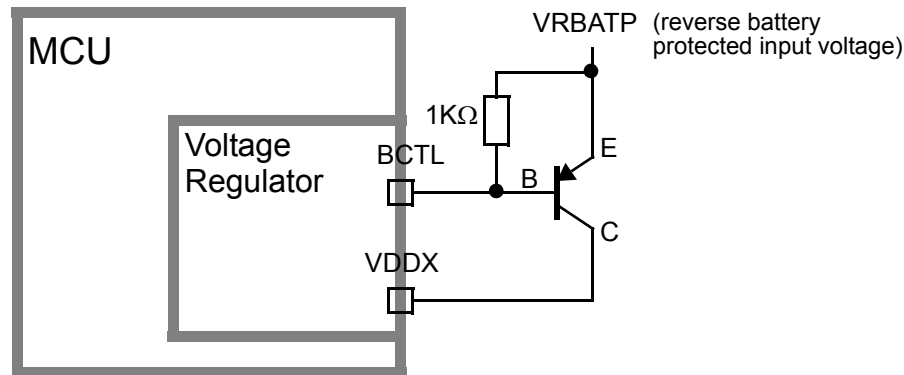

Figure 8-3. BCTL application example

8.2.10 BCTLC — Base Control Pin for external PNP for VDDC power domain

BCTLC is the ballast connection for the on chip voltage regulator for the VDDC power domain. It provides the base current of an external BJT (PNP) of the VDDC supply. An additional 1KΩ resistor between emitter and base of the BJT is required.

8.2.11 BCTLS1 — Base Control Pin for external PNP for VDDS1 power domain

BCTLS1 is the ballast connection for the on chip voltage regulator for the VDDS1 power domain. It provides the base current of an external BJT (PNP) of the VDDS1 supply. An additional 1KΩ resistor between emitter and base of the BJT is required.

Figure 8-4 shows an application example for the external BCTLS1 pin.

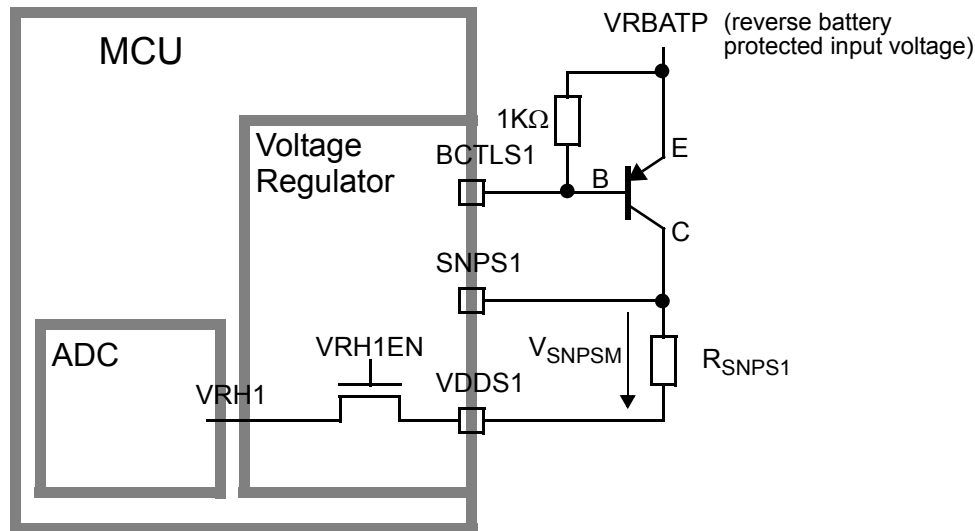

Figure 8-4. BCTLS1 application example

8.2.12 BCTLS2 — Base Control Pin for external PNP for VDDSD2 power domain

BCTLS2 is the ballast connection for the on chip voltage regulator for the VDDSD2 power domain. It provides the base current of an external BJT (PNP) of the VDDSD2 supply. An additional 1KΩ resistor between emitter and base of the BJT is required.

8.2.13 SNPS1 — Sense Pin for VDDSD1 power domain

SNPS1 is the sense input associated with the VDDSD1 power domain regulator. The voltage regulator uses it to detect a short circuit or over current condition and subsequently limits the current to avoid damage.

$$R_{SNPS1} = V_{SNPSM} / (\text{desired max current flowing})$$

8.2.14 SNPS2 — Sense Pin for VDDSD2 power domain

SNPS2 is the sense input associated with the VDDSD2 power domain regulator. The voltage regulator uses it to detect a short circuit or over current condition and subsequently limits the current to avoid damage.

$$R_{SNPS2} = V_{SNPSM} / (\text{desired max current flowing})$$

8.2.15 VSS1,2 — Core Ground Pins

VSS1,2 are the core logic supply return pins. They must be grounded.

8.2.16 VDD— Core Logic Supply Pin

VDD is the supply domain for the core logic.

An off-chip decoupling capacitor (220 nF(X7R ceramic)) between VDD and VSS is required and can improve the quality of this supply.

This supply domain is monitored by the Low Voltage Reset circuit and The Power On Reset circuit.

8.2.17 VDDF— NVM Logic Supply Pin

VDDF is the supply domain for the NVM logic.

An off-chip decoupling capacitor (220 nF(X7R ceramic)) between VDDF and VSS is required and can improve the quality of this supply.

This supply domain is monitored by the Low Voltage Reset circuit.

8.2.18 API_EXTCLK — API external clock output pin

This pin provides the signal selected via APIES and is enabled with APIEA bit. See the device specification if this clock output is available on this device and to which pin it might be connected.

8.2.19 TEMPSENSE — Internal Temperature Sensor Output Voltage

Depending on the VSEL setting either the voltage level generated by the temperature sensor or the VREG bandgap voltage is driven to a special channel input of the ADC Converter. See device level specification for connectivity of ADC special channels.

8.3 Memory Map and Registers

This section provides a detailed description of all registers accessible in the S12CPMU_UHV_V10_V6.

8.3.1 Module Memory Map

The S12CPMU_UHV_V10_V6 registers are shown in [Figure 8-5](#).

Address Offset	Register Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 8-5. CPMU Register Summary

8.3.2 Register Descriptions

This section describes all the S12CPMU_UHV_V10_V6 registers and their individual bits.

Address order is as listed in [Figure 8-5](#)

8.3.2.1 Reserved Register CPMUVREGTRIM0

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in Special Mode can alter the S12CPMU_UHV_V10_V6’s functionality.

Module Base + 0x0001

	7	6	5	4	3	2	1	0
R	0	0	0	0	U			
W								
Reset	0	0	0	0	F	F	F	F
Power on Reset	0	0	0	0	0	0	0	0

Note: After de-assert of System Reset a value is automatically loaded from the Flash memory.

Figure 8-6. Reserved Register (CPMUVREGTRIM0)

Read: Anytime

Write: Only in Special Mode

8.3.2.2 Reserved Register CPMUVREGTRIM1

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in Special Mode can alter the S12CPMU_UHV_V10_V6’s functionality.

Module Base + 0x0002

	7	6	5	4	3	2	1	0
R	0	0	U	U	U	0	0	0
W								
Reset	0	0	F	F	F	0	0	0
Power on Reset	0	0	0	0	0	0	0	0

Note: After de-assert of System Reset a value is automatically loaded from the Flash memory.

Figure 8-7. Reserved Register (CPMUVREGTRIM1)

Read: Anytime

Write: Only in Special Mode

8.3.2.3 S12CPMU_UHV_V10_V6 Reset Flags Register (CPMURFLG)

This register provides S12CPMU_UHV_V10_V6 reset flags.

Module Base + 0x0003

	7	6	5	4	3	2	1	0
R	0			0		0		
W		PORF	LVRF		COPRF		OMRF	PMRF
Reset	0	Note 1	Note 2	0	Note 3	0	Note 4	Note 5

1. PORF is set to 1 when a power on reset occurs. Unaffected by System Reset.
2. LVRF is set to 1 when a low voltage reset occurs. Unaffected by System Reset. Set by power on reset.
3. COPRF is set to 1 when COP reset occurs. Unaffected by System Reset. Cleared by power on reset.
4. OMRF is set to 1 when an oscillator clock monitor reset occurs. Unaffected by System Reset. Cleared by power on reset.
5. PMRF is set to 1 when a PLL clock monitor reset occurs. Unaffected by System Reset. Cleared by power on reset.

 = Unimplemented or Reserved

Figure 8-8. S12CPMU_UHV_V10_V6 Flags Register (CPMURFLG)

Read: Anytime

Write: Refer to each bit for individual write conditions

Table 8-2. CPMURFLG Field Descriptions

Field	Description
6 PORF	Power on Reset Flag — PORF is set to 1 when a power on reset occurs. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 Power on reset has not occurred. 1 Power on reset has occurred.
5 LVRF	Low Voltage Reset Flag — LVRF is set to 1 when a low voltage reset occurs on the VDD, VDDF or VDDX domain. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 Low voltage reset has not occurred. 1 Low voltage reset has occurred.
3 COPRF	COP Reset Flag — COPRF is set to 1 when a COP (Computer Operating Properly) reset occurs. Refer to 8.5.5, “Computer Operating Properly Watchdog (COP) Reset and 8.3.2.12, “S12CPMU_UHV_V10_V6 COP Control Register (CPMUCOP) for details. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 COP reset has not occurred. 1 COP reset has occurred.
1 OMRF	Oscillator Clock Monitor Reset Flag — OMRF is set to 1 when a loss of oscillator (crystal) clock occurs. Refer to 8.5.3, “Oscillator Clock Monitor Reset for details. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 Loss of oscillator clock reset has not occurred. 1 Loss of oscillator clock reset has occurred.
0 PMRF	PLL Clock Monitor Reset Flag — PMRF is set to 1 when a loss of PLL clock occurs. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 Loss of PLL clock reset has not occurred. 1 Loss of PLL clock reset has occurred.

8.3.2.4 S12CPMU_UHV_V10_V6 Synthesizer Register (CPMUSYNR)

The CPMUSYNR register controls the multiplication factor of the PLL and selects the VCO frequency range.

Module Base + 0x0004

Figure 8-9. S12CPMU_UHV_V10_V6 Synthesizer Register (CPMUSYNR)

Read: Anytime

Write: If PROT=0 (CPMUPROT register) and PLLSEL=1 (CPMUCLKS register), then write anytime. Else write has no effect.

NOTE

Writing to this register clears the LOCK and UPOSC status bits.

If PLL has locked (LOCK=1) $f_{VCO} = 2 \times f_{REF} \times (SYNDIV + 1)$

NOTE

f_{VCO} must be within the specified VCO frequency lock range. Bus frequency f_{bus} must not exceed the specified maximum.

The VCOFRQ[1:0] bits are used to configure the VCO gain for optimal stability and lock time. For correct PLL operation the VCOFRQ[1:0] bits have to be selected according to the actual target VCOCLK frequency as shown in Table 8-3. Setting the VCOFRQ[1:0] bits incorrectly can result in a non functional PLL (no locking and/or insufficient stability).

Table 8-3. VCO Clock Frequency Selection

VCOCLK Frequency Ranges	VCOFRQ[1:0]
32MHz <= f_{VCO} <= 48MHz	00
48MHz < f_{VCO} <= 80MHz	01
Reserved	10
80MHz < f_{VCO} <= 100MHz	11

8.3.2.5 S12CPMU_UHV_V10_V6 Reference Divider Register (CPMUREFDIV)

The CPMUREFDIV register provides a finer granularity for the PLL multiplier steps when using the external oscillator as reference.

Module Base + 0x0005

Figure 8-10. S12CPMU_UHV_V10_V6 Reference Divider Register (CPMUREFDIV)

Read: Anytime

Write: If PROT=0 (CPMUPROT register) and PLLSEL=1 (CPMUCLKS register), then write anytime. Else write has no effect.

NOTE

Write to this register clears the LOCK and UPOSC status bits.

$$\text{If XOSCLCP is enabled (OSCE=1)} \quad f_{\text{REF}} = \frac{f_{\text{OSC}}}{(\text{REFDIV} + 1)}$$

$$\text{If XOSCLCP is disabled (OSCE=0)} \quad f_{\text{REF}} = f_{\text{IRC1M}}$$

The REFFRQ[1:0] bits are used to configure the internal PLL filter for optimal stability and lock time. For correct PLL operation the REFFRQ[1:0] bits have to be selected according to the actual REFCLK frequency as shown in [Table 8-4](#).

If IRC1M is selected as REFCLK (OSCE=0) the PLL filter is fixed configured for the $1\text{MHz} \leq f_{\text{REF}} \leq 2\text{MHz}$ range. The bits can still be written but will have no effect on the PLL filter configuration.

For OSCE=1, setting the REFFRQ[1:0] bits incorrectly can result in a non functional PLL (no locking and/or insufficient stability).

Table 8-4. Reference Clock Frequency Selection if OSC_LCP is enabled

REFCLK Frequency Ranges (OSCE=1)	REFFRQ[1:0]
$1\text{MHz} \leq f_{\text{REF}} \leq 2\text{MHz}$	00
$2\text{MHz} < f_{\text{REF}} \leq 6\text{MHz}$	01
$6\text{MHz} < f_{\text{REF}} \leq 12\text{MHz}$	10
$f_{\text{REF}} > 12\text{MHz}$	11

8.3.2.6 S12CPMU_UHV_V10_V6 Post Divider Register (CPMUPOSTDIV)

The POSTDIV register controls the frequency ratio between the VCOCLK and the PLLCLK.

Module Base + 0x0006

Figure 8-11. S12CPMU_UHV_V10_V6 Post Divider Register (CPMUPOSTDIV)

Read: Anytime

Write: If PLLSEL=1 write anytime, else write has no effect

$$\text{If PLL is locked (LOCK=1)} \quad f_{\text{PLL}} = \frac{f_{\text{VCO}}}{(\text{POSTDIV} + 1)}$$

$$\text{If PLL is not locked (LOCK=0)} \quad f_{\text{PLL}} = \frac{f_{\text{VCO}}}{4}$$

$$\text{If PLL is selected (PLLSEL=1)} \quad f_{\text{bus}} = \frac{f_{\text{PLL}}}{2}$$

When changing the POSTDIV[4:0] value or PLL transitions to locked stated (lock=1), it takes up to 32 Bus Clock cycles until f_{PLL} is at the desired target frequency. This is because the post divider gradually changes (increases or decreases) f_{PLL} in order to avoid sudden load changes for the on-chip voltage regulator.

8.3.2.7 S12CPMU_UHV_V10_V6 Interrupt Flags Register (CPMUIFLG)

This register provides S12CPMU_UHV_V10_V6 status bits and interrupt flags.

Module Base + 0x0007

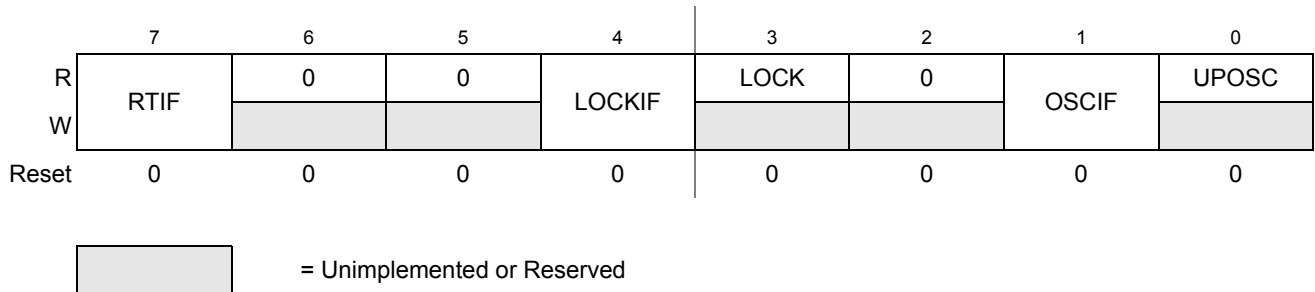

Figure 8-12. S12CPMU_UHV_V10_V6 Flags Register (CPMUIFLG)

Read: Anytime

Write: Refer to each bit for individual write conditions

Table 8-5. CPMUIFLG Field Descriptions

Field	Description
7 RTIF	<p>Real Time Interrupt Flag — RTIF is set to 1 at the end of the RTI period. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (RTIE=1), RTIF causes an interrupt request.</p> <p>0 RTI time-out has not yet occurred. 1 RTI time-out has occurred.</p>
4 LOCKIF	<p>PLL Lock Interrupt Flag — LOCKIF is set to 1 when LOCK status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LOCKIE=1), LOCKIF causes an interrupt request.</p> <p>0 No change in LOCK bit. 1 LOCK bit has changed.</p>
3 LOCK	<p>Lock Status Bit — LOCK reflects the current state of PLL lock condition. Writes have no effect. While PLL is unlocked (LOCK=0) f_{PLL} is $f_{VCO} / 4$ to protect the system from high core clock frequencies during the PLL stabilization time t_{lock}.</p> <p>0 VCOCLK is not within the desired tolerance of the target frequency. $f_{PLL} = f_{VCO}/4$. 1 VCOCLK is within the desired tolerance of the target frequency. $f_{PLL} = f_{VCO}/(POSTDIV+1)$.</p>
1 OSCIF	<p>Oscillator Interrupt Flag — OSCIF is set to 1 when UPOSC status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (OSCIE=1), OSCIF causes an interrupt request.</p> <p>0 No change in UPOSC bit. 1 UPOSC bit has changed.</p>
0 UPOSC	<p>Oscillator Status Bit — UPOSC reflects the status of the oscillator. Writes have no effect. Entering Full Stop Mode UPOSC is cleared.</p> <p>0 The oscillator is off or oscillation is not qualified by the PLL. 1 The oscillator is qualified by the PLL.</p>

8.3.2.8 S12CPMU_UHV_V10_V6 Interrupt Enable Register (CPMUINT)

This register enables S12CPMU_UHV_V10_V6 interrupt requests.

Module Base + 0x0008

Figure 8-13. S12CPMU_UHV_V10_V6 Interrupt Enable Register (CPMUINT)

Read: Anytime

Write: Anytime

Table 8-6. CPMUINT Field Descriptions

Field	Description
7 RTIE	Real Time Interrupt Enable Bit 0 Interrupt requests from RTI are disabled. 1 Interrupt will be requested whenever RTIF is set.
4 LOCKIE	PLL Lock Interrupt Enable Bit 0 PLL LOCK interrupt requests are disabled. 1 Interrupt will be requested whenever LOCKIF is set.
1 OSCIE	Oscillator Corrupt Interrupt Enable Bit 0 Oscillator Corrupt interrupt requests are disabled. 1 Interrupt will be requested whenever OSCIF is set.

8.3.2.9 S12CPMU_UHV_V10_V6 Clock Select Register (CPMUCLKS)

This register controls S12CPMU_UHV_V10_V6 clock selection.

Module Base + 0x0009

Figure 8-14. S12CPMU_UHV_V10_V6 Clock Select Register (CPMUCLKS)

Read: Anytime

Write:

- Only possible if PROT=0 (CPMUPROT register) in all MCU Modes (Normal and Special Mode).
- All bits in Special Mode (if PROT=0).
- PLLSEL, PSTP, PRE, PCE, RTIOSCSEL: In Normal Mode (if PROT=0).
- CSAD: In Normal Mode (if PROT=0) until CPMUCOP write once has taken place.
- COPOSCSEL0: In Normal Mode (if PROT=0) until CPMUCOP write once has taken place. If COPOSCSEL0 was cleared by UPOSC=0 (entering Full Stop Mode with COPOSCSEL0=1 or insufficient OSCCLK quality), then COPOSCSEL0 can be set once again.
- COPOSCSEL1: In Normal Mode (if PROT=0) until CPMUCOP write once has taken place. COPOSCSEL1 will not be cleared by UPOSC=0 (entering Full Stop Mode with COPOSCSEL1=1 or insufficient OSCCLK quality if OSCCLK is used as clock source for other clock domains: for instance core clock etc.).

NOTE

After writing CPMUCLKS register, it is strongly recommended to read back CPMUCLKS register to make sure that write of PLLSEL, RTIOSCSEL and COPOSCSEL was successful. This is because under certain circumstances writes have no effect or bits are automatically changed (see CPMUCLKS register and bit descriptions).

NOTE

When using the oscillator clock as system clock (write PLLSEL = 0) it is highly recommended to enable the oscillator clock monitor reset feature (write OMRE = 1 in CPMUOSC2 register). If the oscillator monitor reset feature is disabled (OMRE = 0) and the oscillator clock is used as system clock, the system will stall in case of loss of oscillation.

Table 8-7. CPMUCLKS Descriptions

Field	Description
7 PLLSEL	<p>PLL Select Bit</p> <p>This bit selects the PLLCLK as source of the System Clocks (Core Clock and Bus Clock). PLLSEL can only be set to 0, if UPOSC=1. UPOSC= 0 sets the PLLSEL bit. Entering Full Stop Mode sets the PLLSEL bit.</p> <p>0 System clocks are derived from OSCCLK if oscillator is up (UPOSC=1, $f_{bus} = f_{osc} / 2$).</p> <p>1 System clocks are derived from PLLCLK, $f_{bus} = f_{PLL} / 2$.</p>
6 PSTP	<p>Pseudo Stop Bit</p> <p>This bit controls the functionality of the oscillator during Stop Mode.</p> <p>0 Oscillator is disabled in Stop Mode (Full Stop Mode).</p> <p>1 Oscillator continues to run in Stop Mode (Pseudo Stop Mode), option to run RTI and COP.</p> <p>Note: Pseudo Stop Mode allows for faster STOP recovery and reduces the mechanical stress and aging of the resonator in case of frequent STOP conditions at the expense of a slightly increased power consumption.</p> <p>Note: When starting up the external oscillator (either by programming OSCE bit to 1 or on exit from Full Stop Mode with OSCE bit already 1) the software must wait for a minimum time equivalent to the startup-time of the external oscillator t_{UPOSC} before entering Pseudo Stop Mode.</p>
5 CSAD	<p>COP in Stop Mode ACLK Disable — If this bit is set the ACLK for the COP in Stop Mode is disabled. Hence the COP is static while in Stop Mode and continues to operate after exit from Stop Mode.</p> <p>For CSAD = 1 and COP is running on ACLK (COPOSCSEL1 = 1) the following applies: Due to clock domain crossing synchronization there is a latency time of 2 ACLK cycles to enter Stop Mode. After exit from STOP mode (when interrupt service routine is entered) the software has to wait for 2 ACLK cycles before it is allowed to enter Stop mode again (STOP instruction). It is absolutely forbidden to enter Stop Mode before this time of 2 ACLK cycles has elapsed.</p> <p>0 COP running in Stop Mode (ACLK for COP enabled in Stop Mode).</p> <p>1 COP stopped in Stop Mode (ACLK for COP disabled in Stop Mode)</p>
4 COP OSCSSEL1	<p>COP Clock Select 1 — COPOSCSEL0 and COPOSCSEL1 combined determine the clock source to the COP (see also Table 8-8).</p> <p>If COPOSCSEL1 = 1, COPOSCSEL0 has no effect regarding clock select and changing the COPOSCSEL0 bit does not re-start the COP time-out period.</p> <p>COPOSCSEL1 selects the clock source to the COP to be either ACLK (derived from trimmable internal RC-Oscillator) or clock selected via COPOSCSEL0 (IRCCLK or OSCCLK).</p> <p>Changing the COPOSCSEL1 bit re-starts the COP time-out period.</p> <p>COPOSCSEL1 can be set independent from value of UPOSC.</p> <p>UPOSC= 0 does not clear the COPOSCSEL1 bit.</p> <p>0 COP clock source defined by COPOSCSEL0</p> <p>1 COP clock source is ACLK derived from a trimmable internal RC-Oscillator</p>
3 PRE	<p>RTI Enable During Pseudo Stop Bit — PRE enables the RTI during Pseudo Stop Mode.</p> <p>0 RTI stops running during Pseudo Stop Mode.</p> <p>1 RTI continues running during Pseudo Stop Mode if RTIOSCSSEL=1.</p> <p>Note: If PRE=0 or RTIOSCSSEL=0 then the RTI will go static while Stop Mode is active. The RTI counter will <u>not</u> be reset.</p>
2 PCE	<p>COP Enable During Pseudo Stop Bit — PCE enables the COP during Pseudo Stop Mode.</p> <p>0 COP stops running during Pseudo Stop Mode</p> <p>1 COP continues running during Pseudo Stop Mode if COPOSCSEL=1</p> <p>Note: If PCE=0 or COPOSCSEL=0 then the COP will go static while Stop Mode is active. The COP counter will <u>not</u> be reset.</p>

Table 8-7. CPMUCLKS Descriptions (continued)

Field	Description
1 RTIOSCSEL	<p>RTI Clock Select— RTIOSCSEL selects the clock source to the RTI. Either IRCCLK or OSCCLK. Changing the RTIOSCSEL bit re-starts the RTI time-out period.</p> <p>RTIOSCSEL can only be set to 1, if UPOSC=1.</p> <p>UPOSC= 0 clears the RTIOSCSEL bit.</p> <p>0 RTI clock source is IRCCLK.</p> <p>1 RTI clock source is OSCCLK.</p>
0 COP OSCSEL0	<p>COP Clock Select 0 — COPOSCSEL0 and COPOSCSEL1 combined determine the clock source to the COP (see also Table 8-8)</p> <p>If COPOSCSEL1 = 1, COPOSCSEL0 has no effect regarding clock select and changing the COPOSCSEL0 bit does not re-start the COP time-out period.</p> <p>When COPOSCSEL1=0,COPOSCSEL0 selects the clock source to the COP to be either IRCCLK or OSCCLK. Changing the COPOSCSEL0 bit re-starts the COP time-out period.</p> <p>COPOSCSEL0 can only be set to 1, if UPOSC=1.</p> <p>UPOSC= 0 clears the COPOSCSEL0 bit.</p> <p>0 COP clock source is IRCCLK.</p> <p>1 COP clock source is OSCCLK.</p>

Table 8-8. COPOSCSEL1, COPOSCSEL0 clock source select description

COPOSCSEL1	COPOSCSEL0	COP clock source
0	0	IRCCLK
0	1	OSCCLK
1	x	ACLK

8.3.2.10 S12CPMU_UHV_V10_V6 PLL Control Register (CPMUPLL)

This register controls the PLL functionality.

Module Base + 0x000A

Figure 8-15. S12CPMU_UHV_V10_V6 PLL Control Register (CPMUPLL)

Read: Anytime

Write: Anytime if PROT=0 (CPMUPROT register) and PLLSEL=1 (CPMUCLKS register). Else write has no effect.

NOTE

Write to this register clears the LOCK and UPOSC status bits.

NOTE

Care should be taken to ensure that the bus frequency does not exceed the specified maximum when frequency modulation is enabled.

Table 8-9. CPMUPLL Field Descriptions

Field	Description
5, 4 FM1, FM0	PLL Frequency Modulation Enable Bits — FM1 and FM0 enable frequency modulation on the VCOCLK. This is to reduce noise emission. The modulation frequency is f_{ref} divided by 16. See Table 8-10 for coding.

Table 8-10. FM Amplitude selection

FM1	FM0	FM Amplitude / f_{VCO} Variation
0	0	FM off
0	1	±1%
1	0	±2%
1	1	±4%

8.3.2.11 S12CPMU_UHV_V10_V6 RTI Control Register (CPMURTI)

This register selects the time-out period for the Real Time Interrupt.

The clock source for the RTI is either IRCCLK or OSCCLK depending on the setting of the RTIOSCSEL bit. In Stop Mode with PSTP=1 (Pseudo Stop Mode) and RTIOSCSEL=1 the RTI continues to run, else the RTI counter halts in Stop Mode.

Module Base + 0x000B

Figure 8-16. S12CPMU_UHV_V10_V6 RTI Control Register (CPMURTI)

Read: Anytime

Write: Anytime

NOTE

A write to this register starts the RTI time-out period. A change of the RTIOSCSEL bit (writing a different value or loosing UPOSC status) re-starts the RTI time-out period.

Table 8-11. CPMURTI Field Descriptions

Field	Description
7 RTDEC	Decimal or Binary Divider Select Bit — RTDEC selects decimal or binary based prescaler values. 0 Binary based divider value. See Table 8-12 1 Decimal based divider value. See Table 8-13
6–4 RTR[6:4]	Real Time Interrupt Prescale Rate Select Bits — These bits select the prescale rate for the RTI. See Table 8-12 and Table 8-13 .
3–0 RTR[3:0]	Real Time Interrupt Modulus Counter Select Bits — These bits select the modulus counter target value to provide additional granularity. Table 8-12 and Table 8-13 show all possible divide values selectable by the CPMURTI register.

Table 8-12. RTI Frequency Divide Rates for RTDEC = 0

8.3.2.12 S12CPMU_UHV_V10_V6 COP Control Register (CPMUCOP)

This register controls the COP (Computer Operating Properly) watchdog.

The clock source for the COP is either ACLK, IRCCLK or OSCCLK depending on the setting of the COPOSCSEL0 and COPOSCSEL1 bit (see also [Table 8-8](#)).

In Stop Mode with PSTP=1 (Pseudo Stop Mode), COPOSCSEL0=1 and COPOSCSEL1=0 and PCE=1 the COP continues to run, else the COP counter halts in Stop Mode with COPOSCSEL1 =0.

In Full Stop Mode and Pseudo Stop Mode with COPOSCSEL1=1 the COP continues to run.

Module Base + 0x000C

	7	6	5	4	3	2	1	0
R	WCOP	RSBCK	0	0	0	CR2	CR1	CR0
W			WRTMASK					
Reset	F	0	0	0	0	F	F	F

After de-assert of System Reset the values are automatically loaded from the Flash memory. See Device specification for details.

 = Unimplemented or Reserved

Figure 8-17. S12CPMU_UHV_V10_V6 COP Control Register (CPMUCOP)

Read: Anytime

Write:

1. RSBCK: Anytime in Special Mode; write to “1” but not to “0” in Normal Mode
2. WCOP, CR2, CR1, CR0:
 - Anytime in Special Mode, when WRTMASK is 0, otherwise it has no effect
 - Write once in Normal Mode, when WRTMASK is 0, otherwise it has no effect.
 - Writing CR[2:0] to “000” has no effect, but counts for the “write once” condition.
 - Writing WCOP to “0” has no effect, but counts for the “write once” condition.

When a non-zero value is loaded from Flash to CR[2:0] the COP time-out period is started.

A change of the COPOSCSEL0 or COPOSCSEL1 bit (writing a different value) or loosing UPOSC status while COPOSCSEL1 is clear and COPOSCSEL0 is set, re-starts the COP time-out period.

In Normal Mode the COP time-out period is restarted if either of these conditions is true:

1. Writing a non-zero value to CR[2:0] (anytime in special mode, once in normal mode) with WRTMASK = 0.
2. Writing WCOP bit (anytime in Special Mode, once in Normal Mode) with WRTMASK = 0.
3. Changing RSBCK bit from “0” to “1”.

In Special Mode, any write access to CPMUCOP register restarts the COP time-out period.

Table 8-14. CPMUCOP Field Descriptions

Field	Description
7 WCOP	<p>Window COP Mode Bit — When set, a write to the CPMUARMCOP register must occur in the last 25% of the selected period. A write during the first 75% of the selected period generates a COP reset. As long as all writes occur during this window, \$55 can be written as often as desired. Once \$AA is written after the \$55, the time-out logic restarts and the user must wait until the next window before writing to CPMUARMCOP. Table 8-15 shows the duration of this window for the seven available COP rates.</p> <p>0 Normal COP operation 1 Window COP operation</p>
6 RSBCK	<p>COP and RTI Stop in Active BDM Mode Bit</p> <p>0 Allows the COP and RTI to keep running in Active BDM mode. 1 Stops the COP and RTI counters whenever the part is in Active BDM mode.</p>
5 WRTMASK	<p>Write Mask for WCOP and CR[2:0] Bit — This write-only bit serves as a mask for the WCOP and CR[2:0] bits while writing the CPMUCOP register. It is intended for BDM writing the RSBCK without changing the content of WCOP and CR[2:0].</p> <p>0 Write of WCOP and CR[2:0] has an effect with this write of CPMUCOP 1 Write of WCOP and CR[2:0] has no effect with this write of CPMUCOP. (Does not count for “write once”.)</p>
2–0 CR[2:0]	<p>COP Watchdog Timer Rate Select — These bits select the COP time-out rate (see Table 8-15 and Table 8-16). Writing a nonzero value to CR[2:0] enables the COP counter and starts the time-out period. A COP counter time-out causes a System Reset. This can be avoided by periodically (before time-out) initializing the COP counter via the CPMUARMCOP register.</p> <p>While all of the following four conditions are true the CR[2:0], WCOP bits are ignored and the COP operates at highest time-out period (2^{24} cycles) in normal COP mode (Window COP mode disabled):</p> <ol style="list-style-type: none"> 1) COP is enabled (CR[2:0] is not 000) 2) BDM mode active 3) RSBCK = 0 4) Operation in Special Mode

Table 8-15. COP Watchdog Rates if COPOSCSEL1=0.
(default out of reset)

CR2	CR1	CR0	COPCLK Cycles to time-out (COPCLK is either IRCCLK or OSCCLK depending on the COPOSCSEL0 bit)
0	0	0	COP disabled
0	0	1	2^{14}
0	1	0	2^{16}
0	1	1	2^{18}
1	0	0	2^{20}
1	0	1	2^{22}
1	1	0	2^{23}
1	1	1	2^{24}

Table 8-16. COP Watchdog Rates if COPOSCSEL1=1.

CR2	CR1	CR0	COPCLK Cycles to time-out (COPCLK is ACLK divided by 2)
0	0	0	COP disabled
0	0	1	2^7
0	1	0	2^9
0	1	1	2^{11}
1	0	0	2^{13}
1	0	1	2^{15}
1	1	0	2^{16}
1	1	1	2^{17}

8.3.2.13 Reserved Register CPMUTEST0

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in Special Mode can alter the S12CPMU_UHV_V10_V6's functionality.

Module Base + 0x000D

Figure 8-18. Reserved Register (CPMUTEST0)

Read: Anytime

Write: Only in Special Mode

8.3.2.14 Reserved Register CPMUTEST1

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in Special Mode can alter the S12CPMU_UHV_V10_V6's functionality.

Module Base + 0x000E

Figure 8-19. Reserved Register (CPMUTEST1)

Read: Anytime

Write: Only in Special Mode

8.3.2.15 S12CPMU_UHV_V10_V6 COP Timer Arm/Reset Register (CPMUARMCOP)

This register is used to restart the COP time-out period.

Module Base + 0x000F

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W	ARMCOP-Bit 7	ARMCOP-Bit 6	ARMCOP-Bit 5	ARMCOP-Bit 4	ARMCOP-Bit 3	ARMCOP-Bit 2	ARMCOP-Bit 1	ARMCOP-Bit 0
Reset	0	0	0	0	0	0	0	0

Figure 8-20. S12CPMU_UHV_V10_V6 CPMUARMCOP Register

Read: Always reads \$00

Write: Anytime

When the COP is disabled (CR[2:0] = “000”) writing to this register has no effect.

When the COP is enabled by setting CR[2:0] nonzero, the following applies:

Writing any value other than \$55 or \$AA causes a COP reset. To restart the COP time-out period write \$55 followed by a write of \$AA. These writes do not need to occur back-to-back, but the sequence (\$55, \$AA) must be completed prior to COP end of time-out period to avoid a COP reset. Sequences of \$55 writes are allowed. When the WCOP bit is set, \$55 and \$AA writes must be done in the last 25% of the selected time-out period; writing any value in the first 75% of the selected period will cause a COP reset.

8.3.2.16 High Temperature Control Register (CPMUHTCTL)

The CPMUHTCTL register configures the temperature sense features.

Module Base + 0x0010

	7	6	5	4	3	2	1	0
R	Reserved	0	VSEL	0	HTE	HTDS	HTIE	HTIF
W								
Reset	0	0	0	0	0	0	0	0

 = Unimplemented or Reserved

Figure 8-21. High Temperature Control Register (CPMUHTCTL)

Read: Anytime

Write: VSEL, HTE, HTIE and HTIF are write anytime, HTDS is read only

Table 8-17. CPMUHTCTL Field Descriptions

Field	Description
5 VSEL	Voltage Access Select Bit — If set, the bandgap reference voltage V_{BG} can be accessed internally (i.e. multiplexed to an internal Analog to Digital Converter channel). If not set, the die temperature proportional voltage V_{HT} of the temperature sensor can be accessed internally. See device level specification for connectivity. For any of these access the HTE bit must be set. 0 An internal temperature proportional voltage V_{HT} can be accessed internally. 1 Bandgap reference voltage V_{BG} can be accessed internally.
3 HTE	High Temperature Sensor/Bandgap Voltage Enable Bit — This bit enables the high temperature sensor and bandgap voltage amplifier. 0 The temperature sensor and bandgap voltage amplifier is disabled. 1 The temperature sensor and bandgap voltage amplifier is enabled.
2 HTDS	High Temperature Detect Status Bit — This read-only status bit reflects the temperature status. Writes have no effect. 0 Junction Temperature is below level T_{HTID} or RPM. 1 Junction Temperature is above level T_{HTIA} and FPM.
1 HTIE	High Temperature Interrupt Enable Bit 0 Interrupt request is disabled. 1 Interrupt will be requested whenever HTIF is set.
0 HTIF	High Temperature Interrupt Flag — HTIF is set to 1 when HTDS status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (HTIE=1), HTIF causes an interrupt request. 0 No change in HTDS bit. 1 HTDS bit has changed.

NOTE

The voltage at the temperature sensor can be computed as follows:

$$V_{HT(temp)} = V_{HT(150)} - (150 - temp) * dV_{HT}$$

Figure 8-22. Voltage Access Select

8.3.2.17 Low Voltage Control Register (CPMULVCTL)

The CPMULVCTL register allows the configuration of the low-voltage detect features.

Module Base + 0x0011

	7	6	5	4	3	2	1	0
R	0	0	0	0	VDDSIE ⁽¹⁾	LVDS	LVIE	LVIF
W								
Reset	0	0	0	0	0	U	0	U

The Reset state of LVDS and LVIF depends on the external supplied VDDA level

 = Unimplemented or Reserved

Figure 8-23. Low Voltage Control Register (CPMULVCTL)

1. Only available in V10

Read: Anytime

Write: LVIE and LVIF are write anytime, LVDS is read only

Table 8-18. CPMULVCTL Field Descriptions

Field	Description
3 VDDSIE	VDDS Integrity Interrupt Enable Bit 0 Interrupt request is disabled. 1 Interrupt will be requested on VDDS integrity fails, that means whenever one of the following flags in CPMUVDDS register is set: SCS2IF, SCS1IF, LVS2IF, LVS1IF.
2 LVDS	Low-Voltage Detect Status Bit — This read-only status bit reflects the voltage level on VDDA. Writes have no effect. 0 Input voltage VDDA is above level V_{LVID} or RPM. 1 Input voltage VDDA is below level V_{LVIA} and FPM.
1 LVIE	Low-Voltage Interrupt Enable Bit 0 Interrupt request is disabled. 1 Interrupt will be requested whenever LVIF is set.
0 LVIF	Low-Voltage Interrupt Flag — LVIF is set to 1 when LVDS status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LVIE = 1), LVIF causes an interrupt request. 0 No change in LVDS bit. 1 LVDS bit has changed.

8.3.2.18 Autonomous Periodical Interrupt Control Register (CPMUAPICTL)

The CPMUAPICTL register allows the configuration of the autonomous periodical interrupt features.

Module Base + 0x0012

Figure 8-24. Autonomous Periodical Interrupt Control Register (CPMUAPICTL)

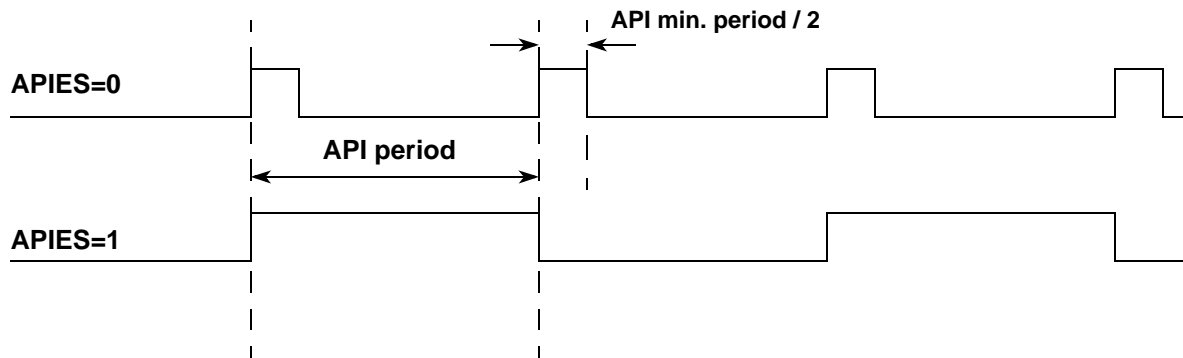

Read: Anytime

Write: Anytime

Table 8-19. CPMUAPICTL Field Descriptions

Field	Description
7 APICLK	Autonomous Periodical Interrupt Clock Select Bit — Selects the clock source for the API. Writable only if APIFE = 0. APICLK cannot be changed if APIFE is set by the same write operation. 0 Autonomous Clock (ACLK) used as source. 1 Bus Clock used as source.
4 APIES	Autonomous Periodical Interrupt External Select Bit — Selects the waveform at the external pin API_EXTCLK as shown in Figure 8-25 . See device level specification for connectivity of API_EXTCLK pin. 0 If APIEA and APIFE are set, at the external pin API_EXTCLK periodic high pulses are visible at the end of every selected period with the size of half of the minimum period (APIR=0x0000 in Table 8-23). 1 If APIEA and APIFE are set, at the external pin API_EXTCLK a clock is visible with 2 times the selected API Period.
3 APIEA	Autonomous Periodical Interrupt External Access Enable Bit — If set, the waveform selected by bit APIES can be accessed externally. See device level specification for connectivity. 0 Waveform selected by APIES can not be accessed externally. 1 Waveform selected by APIES can be accessed externally, if APIFE is set.
2 APIFE	Autonomous Periodical Interrupt Feature Enable Bit — Enables the API feature and starts the API timer when set. 0 Autonomous periodical interrupt is disabled. 1 Autonomous periodical interrupt is enabled and timer starts running.
1 APIE	Autonomous Periodical Interrupt Enable Bit 0 API interrupt request is disabled. 1 API interrupt will be requested whenever APIF is set.
0 APIF	Autonomous Periodical Interrupt Flag — APIF is set to 1 when the in the API configured time has elapsed. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (APIE = 1), APIF causes an interrupt request. 0 API time-out has not yet occurred. 1 API time-out has occurred.

Figure 8-25. Waveform selected on API_EXTCLK pin (APIEA=1, APIFE=1)

8.3.2.19 Autonomous Clock Trimming Register (CPMUACKTR)

The CPMUACKTR register configures the trimming of the Autonomous Clock (ACLK - trimmable internal RC-Oscillator) which can be selected as clock source for some CPMU features.

Module Base + 0x0013

After de-assert of System Reset a value is automatically loaded from the Flash memory.

Figure 8-26. Autonomous Clock Trimming Register (CPMUACKTR)

Read: Anytime

Write: Anytime

Table 8-20. CPMUACKTR Field Descriptions

Field	Description
7–2 ACLKTR[5:0]	Autonomous Clock Period Trimming Bits — See Table 8-21 for trimming effects. The ACLKTR[5:0] value represents a signed number influencing the ACLK period time.

Table 8-21. Trimming Effect of ACLKTR[5:0]

ACLKTR[5:0]	Decimal	ACLK frequency
100000	-32	lowest
100001	-31	increasing
....		
111111	-1	
000000	0	mid
000001	+1	increasing
....		
011110	+30	
011111	+31	highest

8.3.2.20 Autonomous Periodical Interrupt Rate High and Low Register (CPMUAPIRH / CPMUAPIRL)

The CPMUAPIRH and CPMUAPIRL registers allow the configuration of the autonomous periodical interrupt rate.

Module Base + 0x0014

Figure 8-27. Autonomous Periodical Interrupt Rate High Register (CPMUAPIRH)

Module Base + 0x0015

Figure 8-28. Autonomous Periodical Interrupt Rate Low Register (CPMUAPIRL)

Read: Anytime

Write: Anytime if APIFE=0, Else writes have no effect.

Table 8-22. CPMUAPIRH / CPMUAPIRL Field Descriptions

Field	Description
15-0 APIR[15:0]	Autonomous Periodical Interrupt Rate Bits — These bits define the time-out period of the API. See Table 8-23 for details of the effect of the autonomous periodical interrupt rate bits.

The period can be calculated as follows depending on logical value of the APICLK bit:

APICLK=0: Period = $2 * (APIR[15:0] + 1) * (ACLK \text{ Clock Period} * 2)$

APICLK=1: Period = $2 * (APIR[15:0] + 1) * \text{Bus Clock Period}$

NOTE

For APICLK bit clear the first time-out period of the API will show a latency time between two to three f_{ACLK} cycles due to synchronous clock gate release when the API feature gets enabled (APIFE bit set).

Table 8-23. Selectable Autonomous Periodical Interrupt Periods

APICLK	APIR[15:0]	Selected Period

Write: Only in Special Mode

8.3.2.22 High Temperature Trimming Register (CPMUHTTR)

The CPMUHTTR register configures the trimming of the S12CPMU_UHV_V10_V6 temperature sense.

Module Base + 0x0017

After de-assert of System Reset a trim value is automatically loaded from the Flash memory. See Device specification for details.

 = Unimplemented or Reserved

Figure 8-30. High Temperature Trimming Register (CPMUHTTR)

8.3.2.23 S12CPMU_UHV_V10_V6 IRC1M Trim Registers (CPMUIRTRIMH / CPMUIRTRIML)

Module Base + 0x0018

After de-assert of System Reset a factory programmed trim value is automatically loaded from the Flash memory to provide trimmed Internal Reference Frequency f_{IRC1M_TRIM} .

Figure 8-31. S12CPMU_UHV_V10_V6 IRC1M Trim High Register (CPMUIRTRIMH)

Module Base + 0x0019

After de-assert of System Reset a factory programmed trim value is automatically loaded from the Flash memory to provide trimmed Internal Reference Frequency f_{IRC1M_TRIM} .

Figure 8-32. S12CPMU_UHV_V10_V6 IRC1M Trim Low Register (CPMUIRTRIML)

Read: Anytime

Write: Anytime if PROT=0 (CPMUPROT register). Else write has no effect

NOTE

Writes to these registers while PLLSEL=1 clears the LOCK and UPOSC status bits.

Table 8-27. CPMUIRTRIMH/L Field Descriptions

Field	Description
15-11 TCTRIM[4:0]	IRC1M temperature coefficient Trim Bits Trim bits for the Temperature Coefficient (TC) of the IRC1M frequency. Table 8-28 shows the influence of the bits TCTRIM[4:0] on the relationship between frequency and temperature. Figure 8-34 shows an approximate TC variation, relative to the nominal TC of the IRC1M (i.e. for TCTRIM[4:0]=0x00000 or 0x10000).
9-0 IRCTRIM[9:0]	IRC1M Frequency Trim Bits — Trim bits for Internal Reference Clock After System Reset the factory programmed trim value is automatically loaded into these registers, resulting in a Internal Reference Frequency f_{IRC1M_TRIM} . See device electrical characteristics for value of f_{IRC1M_TRIM} . The frequency trimming consists of two different trimming methods: A rough trimming controlled by bits IRCTRIM[9:6] can be done with frequency leaps of about 6% in average. A fine trimming controlled by bits IRCTRIM[5:0] can be done with frequency leaps of about 0.3% (this trimming determines the precision of the frequency setting of 0.15%, i.e. 0.3% is the distance between two trimming values). Figure 8-33 shows the relationship between the trim bits and the resulting IRC1M frequency.

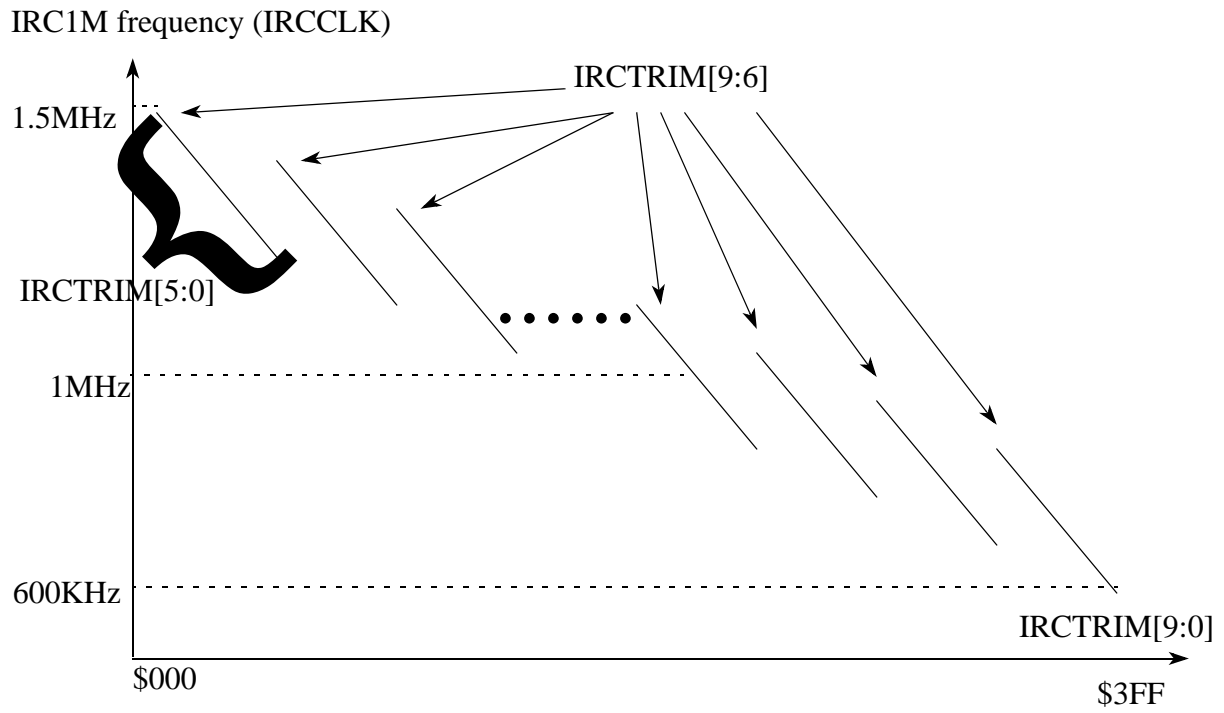

Figure 8-33. IRC1M Frequency Trimming Diagram

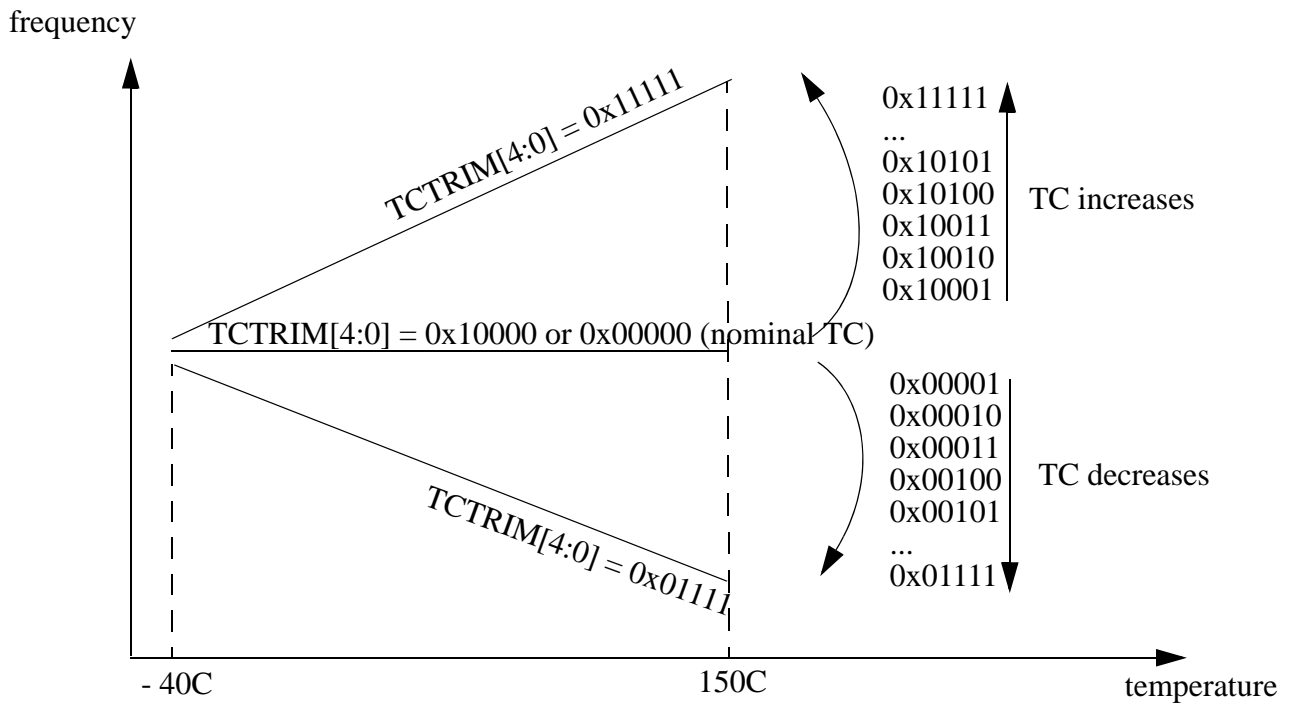

Figure 8-34. Influence of TCTRIM[4:0] on the Temperature Coefficient

NOTE

The frequency is not necessarily linear with the temperature (in most cases it will not be). The above diagram is meant only to give the direction (positive or negative) of the variation of the TC, relative to the nominal TC.

Setting TCTRIM[4:0] at 0x00000 or 0x10000 does not mean that the temperature coefficient will be zero. These two combinations basically switch off the TC compensation module, which results in the nominal TC of the IRC1M.

Table 8-28. TC trimming of the frequency of the IRC1M at ambient temperature

TCTRIM[4:0]	IRC1M Indicative relative TC variation	IRC1M indicative frequency drift for relative TC variation
00000	0 (nominal TC of the IRC)	0%
00001	-0.27%	-0.5%
00010	-0.54%	-0.9%
00011	-0.81%	-1.3%
00100	-1.08%	-1.7%
00101	-1.35%	-2.0%
00110	-1.63%	-2.2%
00111	-1.9%	-2.5%
01000	-2.20%	-3.0%
01001	-2.47%	-3.4%
01010	-2.77%	-3.9%
01011	-3.04%	-4.3%
01100	-3.33%	-4.7%
01101	-3.6%	-5.1%
01110	-3.91%	-5.6%
01111	-4.18%	-5.9%
10000	0 (nominal TC of the IRC)	0%
10001	+0.27%	+0.5%
10010	+0.54%	+0.9%
10011	+0.81%	+1.3%
10100	+1.07%	+1.7%
10101	+1.34%	+2.0%
10110	+1.59%	+2.2%
10111	+1.86%	+2.5%
11000	+2.11%	+3.0%
11001	+2.38%	+3.4%
11010	+2.62%	+3.9%
11011	+2.89%	+4.3%
11100	+3.12%	+4.7%
11101	+3.39%	+5.1%
11110	+3.62%	+5.6%
11111	+3.89%	+5.9%

NOTE

Since the IRC1M frequency is not a linear function of the temperature, but more like a parabola, the above relative variation is only an indication and should be considered with care.

Be aware that the output frequency varies with the TC trimming. A frequency trimming correction is therefore necessary. The values provided in [Table 8-28](#) are typical values at ambient temperature which can vary from device to device.

8.3.2.24 S12CPMU_UHV_V10_V6 Oscillator Register (CPMUOSC)

This registers configures the external oscillator (XOSCLCP).

Module Base + 0x001A

Figure 8-35. S12CPMU_UHV_V10_V6 Oscillator Register (CPMUOSC)

Read: Anytime

Write: Anytime if PROT=0 (CPMUPROT register) and PLLSEL=1 (CPMUCLKS register). Else write has no effect.

NOTE.

Write to this register clears the LOCK and UPOSC status bits.

Table 8-29. CPMUOSC Field Descriptions

Field	Description
7 OSCE	<p>Oscillator Enable Bit — This bit enables the external oscillator (XOSCLCP). The UPOSC status bit in the CPMIUFLG register indicates when the oscillation is stable and when OSCCLK can be selected as source of the Bus Clock or source of the COP or RTI. If the oscillator clock monitor reset is enabled (OMRE = 1 in CPMUOSC2 register), then a loss of oscillation will lead to an oscillator clock monitor reset.</p> <p>0 External oscillator is disabled. REFCLK for PLL is IRCCLK.</p> <p>1 External oscillator is enabled. Oscillator clock monitor is enabled. External oscillator is qualified by PLLCLK. REFCLK for PLL is the external oscillator clock divided by REFDIV.</p> <p>If OSCE bit has been set (write “1”) the EXTAL and XTAL pins are exclusively reserved for the oscillator and they can not be used anymore as general purpose I/O until the next system reset.</p> <p>Note: When starting up the external oscillator (either by programming OSCE bit to 1 or on exit from Full Stop Mode with OSCE bit already 1) the software must wait for a minimum time equivalent to the startup-time of the external oscillator t_{UPOSC} before entering Pseudo Stop Mode.</p>

8.3.2.25 S12CPMU_UHV_V10_V6 Protection Register (CPMUPROT)

This register protects the clock configuration registers from accidental overwrite:

CPMUSYNR, CPMUREFDIV, CPMUCLKS, CPMUPLL, CPMUIRCTRIMH/L, CPMUOSC and CPMUOSC2

Module Base + 0x001B

0 OSCMOD	This bit selects the mode of the external oscillator (XOSCLCP) If OSCE bit in CPMUOSC register is 1, then the OSCMOD bit can not be changed (writes will have no effect). 0 External oscillator configured for loop controlled mode (reduced amplitude on EXTAL and XTAL) 1 External oscillator configured for full swing mode (full swing amplitude on EXTAL and XTAL)

8.3.2.29 VDDS Status Register (CPMUVDDS)

This register is only available in V10.

The CPMUVDDS register contains the status and flag bits for VDDS1 and VDDS2 to indicate integrity fails. Monitoring of VDDS1 and VDDS2 domain is only active in full performance mode (FPM) and if the respective supply is enabled in CPMUVREGCTL register. It is disabled in reduced performance mode (RPM).

Module Base + 0x001F

The Reset state of LVDS and LVIF depends on the external supplied VDDA level

“U” = Unknown, either 0 or 1

 = Unimplemented or Reserved

Figure 8-40. VDDS Status Register (CPMUVDDS)

Read: Anytime

Write: SCS2IF, SCS1IF, LVS2IF and LVS1IF are write anytime,
SCS2, SCS, LVS2 and LVS1 are read only

Table 8-33. CPMUVDDS Field Descriptions

Field	Description
7 SCS2	Short circuit on VDDS2 Status Bit —This read-only status bit reflects short circuit status on VDDS2 supply. This feature only makes sense if the VDDS2 supply is enabled (EXT2SON=1). 0 VRH2EN=0 or RPM or VDDS2 voltage level is less than or equal to VDDA supply. 1 VRH2EN=1and FPM and the voltage level on VDDS2 is greater than on VDDA supply.
6 SCS1	Short circuit on VDDS1 Status Bit —This read-only status bit reflects short circuit status on VDDS1 supply. This feature only makes sense if the VDDS1 supply is enabled (EXT1SON=1). 0 VRH1EN=0 or RPM or VDDS1 voltage level is less than or equal to VDDA supply. 1 VRH1EN=1and FPM and the voltage level on VDDS1 is greater than on VDDA supply.
5 LVDS2	Low Voltage on VDDS2 Status Bit —This read-only status bit reflects the voltage level on VDDS2 supply. If VDDS2 is enabled (EXTS2ON=1 in CPMUVREGCTL register), it is monitored that VDDS2 does not drop below a voltage threshold V_{DDSM} . 0 VDDS2 voltage is above V_{DDSM} threshold or VDDS2 is disabled or RPM. 1 EXTS2ON =1 and VDDS2 voltage is below V_{DDSM} threshold and FPM.
4 LVDS1	Low Voltage on VDDS1 Status Bit —This read-only status bit reflects the voltage level on VDDS1 supply. If VDDS1 is enabled (EXTS1ON=1 in CPMUVREGCTL register), it is monitored that VDDS1 does not drop below a voltage threshold V_{DDSM} . 0 VDDS1 voltage is above V_{DDSM} threshold or VDDS1 is disabled or RPM. 1 EXTS1ON =1 and VDDS1 voltage is below V_{DDSM} threshold and FPM.

Table 8-33. CPMUVDDS Field Descriptions (continued)

Field	Description
3 SCS2IF	Short circuit VDDS2 Interrupt Flag — SCS2IF is set to 1 when SCS2 status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (VDDSIIE = 1), SCS2IF causes an interrupt request. 0 No change in SCS2 bit. 1 SCS2 bit has changed.
2 SCS1IF	Short circuit VDDS1 Interrupt Flag — SCS1IF is set to 1 when SCS1 status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (VDDSIIE = 1), SCS1IF causes an interrupt request. 0 No change in SCS1 bit. 1 SCS1 bit has changed.
1 LVS2IF	Low-Voltage VDDS2 Interrupt Flag — LVS2IF is set to 1 when LVDS2 status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (VDDSIIE = 1), LVS2IF causes an interrupt request. 0 No change in LVDS2 bit. 1 LVDS2 bit has changed.
0 LVS1IF	Low-Voltage VDDS1 Interrupt Flag — LVS1IF is set to 1 when LVDS1 status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (VDDSIIE = 1), LVS1IF causes an interrupt request. 0 No change in LVDS1 bit. 1 LVDS1 bit has changed.

8.4 Functional Description

8.4.1 Phase Locked Loop with Internal Filter (PLL)

The PLL is used to generate a high speed PLLCLK based on a low frequency REFCLK.

The REFCLK is by default the IRCCLK which is trimmed to $f_{\text{IRC1M_TRIM}}=1\text{MHz}$.

If using the oscillator (OSCE=1) REFCLK will be based on OSCCLK. For increased flexibility, OSCCLK can be divided in a range of 1 to 16 to generate the reference frequency REFCLK using the REFDIV[3:0] bits. Based on the SYNDIV[5:0] bits the PLL generates the VCOCLK by multiplying the reference clock by a 2, 4, 6,... 126, 128. Based on the POSTDIV[4:0] bits the VCOCLK can be divided in a range of 1,2, 3, 4, 5, 6,... to 32 to generate the PLLCLK.

$$\text{If oscillator is enabled (OSCE=1)} \quad f_{\text{REF}} = \frac{f_{\text{OSC}}}{(\text{REFDIV} + 1)}$$

$$\text{If oscillator is disabled (OSCE=0)} \quad f_{\text{REF}} = f_{\text{IRC1M}}$$

$$f_{\text{VCO}} = 2 \times f_{\text{REF}} \times (\text{SYNDIV} + 1)$$

$$\text{If PLL is locked (LOCK=1)} \quad f_{\text{PLL}} = \frac{f_{\text{VCO}}}{(\text{POSTDIV} + 1)}$$

$$\text{If PLL is not locked (LOCK=0)} \quad f_{\text{PLL}} = \frac{f_{\text{VCO}}}{4}$$

$$\text{If PLL is selected (PLLSEL=1)} \quad f_{\text{bus}} = \frac{f_{\text{PLL}}}{2}$$

NOTE

Although it is possible to set the dividers to command a very high clock frequency, do not exceed the specified bus frequency limit for the MCU.

Several examples of PLL divider settings are shown in Table 8-34. The following rules help to achieve optimum stability and shortest lock time:

- Use lowest possible f_{VCO} / f_{REF} ratio (SYNDIV value).
- Use highest possible REFCLK frequency f_{REF} .

Table 8-34. Examples of PLL Divider Settings

f_{osc}	REFDIV[3:0]	f_{REF}	REFFRQ[1:0]	SYNDIV[5:0]	f_{VCO}	VCOFRQ[1:0]	POSTDIV[4:0]	f_{PLL}	f_{bus}
off	\$00	1MHz	00	\$18	50MHz	01	\$03	12.5MHz	6.25MHz
off	\$00	1MHz	00	\$18	50MHz	01	\$00	50MHz	25MHz
4MHz	\$00	4MHz	01	\$05	48MHz	00	\$00	48MHz	24MHz

The phase detector inside the PLL compares the feedback clock ($FBCLK = VCOCLK / (SYNDIV + 1)$) with the reference clock ($REFCLK = (IRC1M \text{ or } OSCCLK) / (REFDIV + 1)$). Correction pulses are generated based on the phase difference between the two signals. The loop filter alters the DC voltage on the internal filter capacitor, based on the width and direction of the correction pulse which leads to a higher or lower VCO frequency.

The user must select the range of the REFCLK frequency (REFFRQ[1:0] bits) and the range of the VCOCLK frequency (VCOFRQ[1:0] bits) to ensure that the correct PLL loop bandwidth is set.

The lock detector compares the frequencies of the FBCLK and the REFCLK. Therefore the speed of the lock detector is directly proportional to the reference clock frequency. The circuit determines the lock condition based on this comparison. So e.g. a failure in the reference clock will cause the PLL not to lock.

If PLL LOCK interrupt requests are enabled, the software can wait for an interrupt request and for instance check the LOCK bit. If interrupt requests are disabled, software can poll the LOCK bit continuously (during PLL start-up) or at periodic intervals. In either case, only when the LOCK bit is set, the VCOCLK will have stabilized to the programmed frequency.

- The LOCK bit is a read-only indicator of the locked state of the PLL.
- The LOCK bit is set when the VCO frequency is within the tolerance, Δ_{Lock} , and is cleared when the VCO frequency is out of the tolerance, Δ_{unl} .

Interrupt requests can occur if enabled (LOCKIE = 1) when the lock condition changes, toggling the LOCK bit. In case of loss of reference clock (e.g. IRCCLK) the PLL will not lock or if already locked, then it will unlock. The frequency of the VCOCLK will be very low and will depend on the value of the VCOFRQ[1:0] bits.

8.4.2 Startup from Reset

An example for startup of the clock system from Reset is given in [Figure 8-41](#).

Figure 8-41. Startup of clock system after Reset

8.4.3 Stop Mode using PLLCLK as source of the Bus Clock

An example of what happens going into Stop Mode and exiting Stop Mode after an interrupt is shown in [Figure 8-42](#). Disable PLL Lock interrupt (LOCKIE=0) before going into Stop Mode.

Figure 8-42. Stop Mode using PLLCLK as source of the Bus Clock

Depending on the COP configuration there might be an additional significant latency time until COP is active again after exit from Stop Mode due to clock domain crossing synchronization. This latency time occurs if COP clock source is ACLK and the CSAD bit is set (please refer to CSAD bit description for details).

8.4.4 Full Stop Mode using Oscillator Clock as source of the Bus Clock

An example of what happens going into Full Stop Mode and exiting Full Stop Mode after an interrupt is shown in [Figure 8-43](#).

Disable PLL Lock interrupt (LOCKIE=0) and oscillator status change interrupt (OSCIE=0) before going into Full Stop Mode.

Figure 8-43. Full Stop Mode using Oscillator Clock as source of the Bus Clock

Depending on the COP configuration there might be a significant latency time until COP is active again after exit from Stop Mode due to clock domain crossing synchronization. This latency time occurs if COP clock source is ACLK and the CSAD bit is set (please refer to CSAD bit description for details).

8.4.5 External Oscillator

8.4.5.1 Enabling the External Oscillator

An example of how to use the oscillator as source of the Bus Clock is shown in [Figure 8-44](#).

Figure 8-44. Enabling the external oscillator

8.4.6 System Clock Configurations

8.4.6.1 PLL Engaged Internal Mode (PEI)

This mode is the default mode after System Reset or Power-On Reset.

The Bus Clock is based on the PLLCLK, the reference clock for the PLL is internally generated (IRC1M). The PLL is configured to 50 MHz VCOCLK with POSTDIV set to 0x03. If locked (LOCK=1) this results in a PLLCLK of 12.5 MHz and a Bus Clock of 6.25 MHz. The PLL can be re-configured to other bus frequencies.

The clock sources for COP and RTI can be based on the internal reference clock generator (IRC1M) or the RC-Oscillator (ACLK).

8.4.6.2 PLL Engaged External Mode (PEE)

In this mode, the Bus Clock is based on the PLLCLK as well (like PEI). The reference clock for the PLL is based on the external oscillator.

The clock sources for COP and RTI can be based on the internal reference clock generator or on the external oscillator clock or the RC-Oscillator (ACLK).

This mode can be entered from default mode PEI by performing the following steps:

1. Configure the PLL for desired bus frequency.
2. Enable the external Oscillator (OSCE bit).
3. Wait for oscillator to start-up and the PLL being locked (LOCK = 1) and (UPOSC =1).
4. Clear all flags in the CPMUIFLG register to be able to detect any future status bit change.
5. Optionally status interrupts can be enabled (CPMUINT register).

Loosing PLL lock status (LOCK=0) means loosing the oscillator status information as well (UPOSC=0).

The impact of loosing the oscillator status (UPOSC=0) in PEE mode is as follows:

- The PLLCLK is derived from the VCO clock (with its actual frequency) divided by four until the PLL locks again.

Application software needs to be prepared to deal with the impact of loosing the oscillator status at any time.

8.4.6.3 PLL Bypassed External Mode (PBE)

In this mode, the Bus Clock is based on the external oscillator clock. The reference clock for the PLL is based on the external oscillator.

The clock sources for COP and RTI can be based on the internal reference clock generator or on the external oscillator clock or the RC-Oscillator (ACLK).

This mode can be entered from default mode PEI by performing the following steps:

1. Make sure the PLL configuration is valid.
2. Enable the external Oscillator (OSCE bit)
3. Wait for the oscillator to start-up and the PLL being locked (LOCK = 1) and (UPOSC =1)
4. Clear all flags in the CPMUIFLG register to be able to detect any status bit change.
5. Optionally status interrupts can be enabled (CPMUINT register).
6. Select the Oscillator clock as source of the Bus clock (PLLSEL=0)

Loosing PLL lock status (LOCK=0) means loosing the oscillator status information as well (UPOSC=0).

The impact of loosing the oscillator status (UPOSC=0) in PBE mode is as follows:

- PLLSEL is set automatically and the Bus clock source is switched back to the PLL clock.
- The PLLCLK is derived from the VCO clock (with its actual frequency) divided by four until the PLL locks again.

NOTE Application software needs to be prepared to deal with the impact of loosing the oscillator status at any time.

When using the oscillator clock as system clock (write PLLSEL = 0) it is highly recommended to enable the oscillator clock monitor reset feature (write OMRE = 1 in CPMUOSC2 register). If the oscillator monitor reset feature is disabled (OMRE = 0) and the oscillator clock is used as system clock, the system might stall in case of loss of oscillation.

8.5 Resets

8.5.1 General

All reset sources are listed in [Table 8-35](#). There is only one reset vector for all these reset sources. Refer to MCU specification for reset vector address.

Table 8-35. Reset Summary

Reset Source	Local Enable
Power-On Reset (POR)	None
Low Voltage Reset (LVR)	None
External pin $\overline{\text{RESET}}$	None
PLL Clock Monitor Reset	None

Table 8-35. Reset Summary

Reset Source	Local Enable
Oscillator Clock Monitor Reset	OSCE Bit in CPMUOSC register and OMRE Bit in CPMUOSC2 register
COP Reset	CR[2:0] in CPMUCOP register

8.5.2 Description of Reset Operation

Upon detection of any reset of [Table 8-35](#), an internal circuit drives the $\overline{\text{RESET}}$ pin low for 512 PLLCLK cycles. After 512 PLLCLK cycles the $\overline{\text{RESET}}$ pin is released. The internal reset of the MCU remains asserted while the reset generator completes the 768 PLLCLK cycles long reset sequence. In case the $\overline{\text{RESET}}$ pin is externally driven low for more than these 768 PLLCLK cycles (External Reset), the internal reset remains asserted longer.

NOTE

While System Reset is asserted the PLLCLK runs with the frequency f_{VCRST} .

Figure 8-45. RESET Timing

8.5.3 Oscillator Clock Monitor Reset

If the external oscillator is enabled (OSCE=1) and the oscillator clock monitor reset is enabled (OMRE=1), then in case of loss of oscillation or the oscillator frequency drops below the failure assert frequency f_{CMFA} (see device electrical characteristics for values), the S12CPMU_UHV_V10_V6 generates an Oscillator Clock Monitor Reset. In Full Stop Mode the external oscillator and the oscillator clock monitor are disabled.

8.5.4 PLL Clock Monitor Reset

In case of loss of PLL clock oscillation or the PLL clock frequency is below the failure assert frequency f_{PMFA} (see device electrical characteristics for values), the S12CPMU_UHV_V10_V6 generates a PLL Clock Monitor Reset. In Full Stop Mode the PLL and the PLL clock monitor are disabled.

8.5.5 Computer Operating Properly Watchdog (COP) Reset

The COP (free running watchdog timer) enables the user to check that a program is running and sequencing properly. When the COP is being used, software is responsible for keeping the COP from timing out. If the COP times out it is an indication that the software is no longer being executed in the intended sequence; thus COP reset is generated.

The clock source for the COP is either ACLK, IRCCLK or OSCCLK depending on the setting of the COPOSCSEL0 and COPOSCSEL1 bit.

Depending on the COP configuration there might be a significant latency time until COP is active again after exit from Stop Mode due to clock domain crossing synchronization. This latency time occurs if COP clock source is ACLK and the CSAD bit is set (please refer to CSAD bit description for details).

Table 8-36 gives an overview of the COP condition (run, static) in Stop Mode depending on legal configuration and status bit settings:

Table 8-36. COP condition (run, static) in Stop Mode

COPOSCSEL1	CSAD	PSTP	PCE	COPOSCSEL0	OSCE	UPOSC	COP counter behavior in Stop Mode (clock source)
1	0	x	x	x	x	x	Run (ACLK)
1	1	x	x	x	x	x	Static (ACLK)
0	x	1	1	1	1	1	Run (OSCCLK)
0	x	1	1	0	0	x	Static (IRCCLK)
0	x	1	1	0	1	x	Static (IRCCLK)
0	x	1	0	0	x	x	Static (IRCCLK)
0	x	1	0	1	1	1	Static (OSCCLK)
0	x	0	1	1	1	1	Static (OSCCLK)
0	x	0	1	0	1	x	Static (IRCCLK)
0	x	0	1	0	0	0	Static (IRCCLK)
0	x	0	0	1	1	1	Static (OSCCLK)
0	x	0	0	0	1	1	Static (IRCCLK)
0	x	0	0	0	1	0	Static (IRCCLK)
0	x	0	0	0	0	0	Static (IRCCLK)

Three control bits in the CPMUCOP register allow selection of seven COP time-out periods.

When COP is enabled, the program must write \$55 and \$AA (in this order) to the CPMUARMCOP register during the selected time-out period. Once this is done, the COP time-out period is restarted. If the program fails to do this and the COP times out, a COP reset is generated. Also, if any value other than \$55 or \$AA is written, a COP reset is generated.

Windowed COP operation is enabled by setting WCOP in the CPMUCOP register. In this mode, writes to the CPMUARMCOP register to clear the COP timer must occur in the last 25% of the selected time-out period. A premature write will immediately reset the part.

In MCU Normal Mode the COP time-out period (CR[2:0]) and COP window (WCOP) setting can be automatically pre-loaded at reset release from NVM memory (if values are defined in the NVM by the application). By default the COP is off and no window COP feature is enabled after reset release via NVM memory. The COP control register CPMUCOP can be written once in an application in MCU Normal Mode to update the COP time-out period (CR[2:0]) and COP window (WCOP) setting loaded from NVM memory at reset release. Any value for the new COP time-out period and COP window setting is allowed except COP off value if the COP was enabled during pre-load via NVM memory.

The COP clock source select bits can not be pre-loaded via NVM memory at reset release. The IRC clock is the default COP clock source out of reset.

The COP clock source select bits (COPOSCSEL0/1) and ACLK clock control bit in Stop Mode (CSAD) can be modified until the CPMUCOP register write once has taken place. Therefore these control bits should be modified before the final COP time-out period and window COP setting is written.

The CPMUCOP register access to modify the COP time-out period and window COP setting in MCU Normal Mode after reset release must be done with the WRTMASK bit cleared otherwise the update is ignored and this access does not count as the write once.

8.5.6 Power-On Reset (POR)

The on-chip POR circuitry detects when the internal supply VDD drops below an appropriate voltage level. The POR is deasserted, if the internal supply VDD exceeds an appropriate voltage level (voltage levels not specified, because the internal supply can not be monitored externally). The POR circuitry is always active. It acts as LVR in Stop Mode.

8.5.7 Low-Voltage Reset (LVR)

The on-chip LVR circuitry detects when one of the supply voltages VDD, VDDX and VDDF drops below an appropriate voltage level. If LVR is deasserted the MCU is fully operational at the specified maximum speed. The LVR assert and deassert levels for the supply voltage VDDX are V_{LVRXA} and V_{LVRXD} and are specified in the device Reference Manual. The LVR circuitry is active in Run- and Wait Mode.

8.6 Interrupts

The interrupt vectors requested by the S12CPMU_UHV_V10_V6 are listed in [Table 8-37](#). Refer to MCU specification for related vector addresses and priorities.

Table 8-37. S12CPMU_UHV_V10_V6 Interrupt Vectors

Interrupt Source	CCR Mask	Local Enable
RTI time-out interrupt	I bit	CPMUINT (RTIE)
PLL lock interrupt	I bit	CPMUINT (LOCKIE)
Oscillator status interrupt	I bit	CPMUINT (OSCIE)
Low voltage interrupt	I bit	CPMULVCTL (LVIE)
VDDS integrity interrupt ⁽¹⁾	I bit	CPMULVCTL (VDDISIE)
High temperature interrupt	I bit	CPMUHTCTL (HTIE)
Autonomous Periodical Interrupt	I bit	CPMUAPICTL (APIE)

1. Only available in V10

8.6.1 Description of Interrupt Operation

8.6.1.1 Real Time Interrupt (RTI)

The clock source for the RTI is either IRCCLK or OSCCLK depending on the setting of the RTIOSCSEL bit. In Stop Mode with PSTP=1 (Pseudo Stop Mode), RTIOSCSEL=1 and PRE=1 the RTI continues to run, else the RTI counter halts in Stop Mode.

The RTI can be used to generate hardware interrupts at a fixed periodic rate. If enabled (by setting RTIE=1), this interrupt will occur at the rate selected by the CPMURTI register. At the end of the RTI time-out period the RTIF flag is set to one and a new RTI time-out period starts immediately.

A write to the CPMURTI register restarts the RTI time-out period.

8.6.1.2 PLL Lock Interrupt

The S12CPMU_UHV_V10_V6 generates a PLL Lock interrupt when the lock condition (LOCK status bit) of the PLL changes, either from a locked state to an unlocked state or vice versa. Lock interrupts are locally disabled by setting the LOCKIE bit to zero. The PLL Lock interrupt flag (LOCKIF) is set to 1 when the lock condition has changed, and is cleared to 0 by writing a 1 to the LOCKIF bit.

8.6.1.3 Oscillator Status Interrupt

When the OSCE bit is 0, then UPOSC stays 0. When OSCE=1 the UPOSC bit is set after the LOCK bit is set.

Upon detection of a status change (UPOSC) the OSCIF flag is set. Going into Full Stop Mode or disabling the oscillator can also cause a status change of UPOSC.

Any change in PLL configuration or any other event which causes the PLL lock status to be cleared leads to a loss of the oscillator status information as well (UPOSC=0).

Oscillator status change interrupts are locally enabled with the OSCIE bit.

NOTE

Loosing the oscillator status (UPOSC=0) affects the clock configuration of the system¹. This needs to be dealt with in application software.

8.6.1.4 Low-Voltage Interrupt (LVI)

In FPM the input voltage VDDA is monitored. Whenever VDDA drops below level V_{LVIA} , the status bit LVDS is set to 1. When VDDA rises above level V_{LVID} the status bit LVDS is cleared to 0. An interrupt, indicated by flag LVIF = 1, is triggered by any change of the status bit LVDS if interrupt enable bit LVIE = 1.

8.6.1.5 VDDS Integrity Interrupt

This interrupt is only available in V10.

In FPM the input voltages VDDS1 and VSS2 are monitored for integrity. The flags in CPMUVDDS register indicate such a failing condition. When one the status bits changes, the respective flag is set in CPMUVDDS register. If interrupt is enabled (VDDSIE = 1) an interrupt is triggered by any of these flags.

See CPMUVDDS register description for details.

8.6.1.6 HTI - High Temperature Interrupt

In FPM the junction temperature T_J is monitored. Whenever T_J exceeds level T_{HTIA} the status bit HTDS is set to 1. Vice versa, HTDS is reset to 0 when T_J get below level T_{HTID} . An interrupt, indicated by flag HTIF = 1, is triggered by any change of the status bit HTDS, if interrupt enable bit HTIE = 1.

8.6.1.7 Autonomous Periodical Interrupt (API)

The API sub-block can generate periodical interrupts independent of the clock source of the MCU. To enable the timer, the bit APIFE needs to be set.

The API timer is either clocked by the Autonomous Clock (ACLK - trimmable internal RC oscillator) or the Bus Clock. Timer operation will freeze when MCU clock source is selected and Bus Clock is turned off. The clock source can be selected with bit APICLK. APICLK can only be written when APIFE is not set.

The APIR[15:0] bits determine the interrupt period. APIR[15:0] can only be written when APIFE is cleared. As soon as APIFE is set, the timer starts running for the period selected by APIR[15:0] bits. When the configured time has elapsed, the flag APIF is set. An interrupt, indicated by flag APIF = 1, is triggered if interrupt enable bit APIE = 1. The timer is re-started automatically again after it has set APIF.

1. For details please refer to "8.4.6 System Clock Configurations"

The procedure to change APICLK or APIR[15:0] is first to clear APIFE, then write to APICLK or APIR[15:0], and afterwards set APIFE.

The API Trimming bits ACLKTR[5:0] must be set so the minimum period equals 0.2 ms if stable frequency is desired.

See [Table 8-21](#) for the trimming effect of ACLKTR[5:0].

NOTE

The first period after enabling the counter by APIFE might be reduced by API start up delay t_{sdel} .

It is possible to generate with the API a waveform at the external pin API_EXTCLK by setting APIFE and enabling the external access with setting APIEA.

8.7 Initialization/Application Information

8.7.1 General Initialization Information

Usually applications run in MCU Normal Mode.

It is recommended to write the CPMUCOP register in any case from the application program initialization routine after reset no matter if the COP is used in the application or not, even if a configuration is loaded via the flash memory after reset. By doing a “controlled” write access in MCU Normal Mode (with the right value for the application) the write once for the COP configuration bits (WCOP,CR[2:0]) takes place which protects these bits from further accidental change. In case of a program sequencing issue (code runaway) the COP configuration can not be accidentally modified anymore.

8.7.2 Application information for COP and API usage

In many applications the COP is used to check that the program is running and sequencing properly. Often the COP is kept running during Stop Mode and periodic wake-up events are needed to service the COP on time and maybe to check the system status.

For such an application it is recommended to use the ACLK as clock source for both COP and API. This guarantees lowest possible IDD current during Stop Mode. Additionally it eases software implementation using the same clock source for both, COP and API.

The Interrupt Service Routine (ISR) of the Autonomous Periodic Interrupt API should contain the write instruction to the CPMUARMCOP register. The value (byte) written is derived from the “main routine” (alternating sequence of \$55 and \$AA) of the application software.

Using this method, then in the case of a runtime or program sequencing issue the application “main routine” is not executed properly anymore and the alternating values are not provided properly. Hence the COP is written at the correct time (due to independent API interrupt request) but the wrong value is written (alternating sequence of \$55 and \$AA is no longer maintained) which causes a COP reset.

If the COP is stopped during any Stop Mode it is recommended to service the COP shortly before Stop Mode is entered.

8.7.3 Application Information for PLL and Oscillator Startup

The following C-code example shows a recommended way of setting up the system clock system using the PLL and Oscillator:

```

/* Procedure proposed by to setup PLL and Oscillator */
/* example for OSC = 4 MHz and Bus Clock = 25MHz, That is VCOCLK = 50MHz */

/* Initialize */
/* PLL Clock = 50 MHz, divide by one */
CPMUPOSTDIV = 0x00;

/* Generally: Whenever changing PLL reference clock (REFCLK) frequency to a higher value */
/* it is recommended to write CPMUSYNR = 0x00 in order to stay within specified */
/* maximum frequency of the MCU */
CPMUSYNR = 0x00;

/* configure PLL reference clock (REFCLK) for usage with Oscillator */
/* OSC=4MHz divide by 4 (3+1) = 1MHz, REFCLK range 1MHz to 2 MHz (REFFRQ[1:0] = 00) */
CPMUREFDIV = 0x03;

/* enable external Oscillator, switch PLL reference clock (REFCLK) to OSC */
CPMUOSC = 0x80;

/* multiply REFCLK = 1MHz by 2*(24+1)*1MHz = 50MHz */
/* VCO range 48 to 80 MHz (VCOFRQ[1:0] = 01) */
CPMUSYNR = 0x58;

/* clear all flags, especially LOCKIF and OSCIF */
CPMUIFLG = 0xFF;

/* put your code to loop and wait for the LOCKIF and OSCIF or */
/* poll CPMUIFLG register until both UPOSC and LOCK status are "1" */
/* that is CPMUIFLG == 0x1B */

/*.....continue to your main code execution here.....*/

/* in case later in your code you want to disable the Oscillator and use the */
/* 1MHz IRCCLK as PLL reference clock */

/* Generally: Whenever changing PLL reference clock (REFCLK) frequency to a higher value */
/* it is recommended to write CPMUSYNR = 0x00 in order to stay within specified */
/* maximum frequency of the MCU */
CPMUSYNR = 0x00;

/* disable OSC and switch PLL reference clock to IRC */
CPMUOSC = 0x00;

/* multiply REFCLK = 1MHz by 2*(24+1)*1MHz = 50MHz */
/* VCO range 48 to 80 MHz (VCOFRQ[1:0] = 01) */
CPMUSYNR = 0x58;

/* clear all flags, especially LOCKIF and OSCIF */
CPMUIFLG = 0xFF;

```

```
/* put your code to loop and wait for the LOCKIF or */  
/* poll CPMUIFLG register until both LOCK status is "1" */  
/* that is CPMUIFLG == 0x18 */  
  
/*.....continue to your main code execution here.....*/
```

Chapter 9

Analog-to-Digital Converter (ADC12B_LBA)

Table 9-1. Revision History

Revision Number	Revision Date	Sections Affected	Description of Changes
V1.37	19. Apr 2013	-	Updates from review of reference manual to fix typos etc.
V1.38	30. Apr 2013	9.5.2.13/9-389	Provided more detailed information regarding captured information in bits RIDX_IMD[5:0] for different scenarios of Sequence Abort Event execution.
V1.39	02. Jul 2013	9.5.2.6/9-378	Update of: Timing considerations for Restart Mode
V1.40	02. Oct 2013	entire document	Updated formatting and wording correction for entire document (for technical publications).
V2.00	14. Oct. 2014	9.3/9-363 , 9.5.2.15/9-392 , 9.5.2.17/9-397 , Figure 9-2./9-367 ,	Added option bits to conversion command for top level SoC specific feature/function implementation option.
V3.00	27. Feb. 2015	9.5.2.16/9-395 , 9.1/9-361	Changed ADCCMD_1 VRH_SEL, VRL_SEL Single document for all versions (V1,V2,V3)
V3.01	15. Oct 2015	9.5.2.16/9-395	Added clarification: CMD{EIF not set for internal channels

9.1 Differences ADC12B_LBA V1 vs V2 vs V3

NOTE

Device reference manuals specify which module version is integrated on the device. Some reference manuals support families of devices, with device dependent module versions. This chapter describes the superset. The feature differences are listed in [Table 9-2](#).

Table 9-2. Comparison of ADC12B_LBA Module Versions

Feature	V1	V2	V3
ADC Command Register 0 (ADCCMD_0), ADC Command Register 2 (ADCCMD_2): OPT[3:0] bits	No	Yes	Yes
ADC Command Register 1 (ADCCMD_1):VRH_SEL[1:0]	No	No	Yes
ADC Command Register 1 (ADCCMD_1):VRH_SEL,VRL_SEL	Yes	Yes	No

9.2 Introduction

The ADC12B_LBA is an n-channel multiplexed input successive approximation analog-to-digital converter. Refer to device electrical specifications for ADC parameters and accuracy.

The List Based Architecture (LBA) provides flexible conversion sequence definition as well as flexible oversampling. The order of channels to be converted can be freely defined. Also, multiple instantiations of the module can be triggered simultaneously (matching sampling point across multiple module instantiations).

There are four register bits which control the conversion flow (please refer to the description of register ADCFLWCTL).

The four conversion flow control bits of register ADCFLWCTL can be modified in two different ways:

- Via data bus accesses
- Via internal interface Signals (Trigger, Restart, LoadOK, and Seq_Abort; see also [Figure 9-2](#)). Each Interface Signal is associated with one conversion flow control bit.

For information regarding internal interface connectivity related to the conversion flow control please refer to the device overview of the reference manual.

The ADCFLWCTL register can be controlled via internal interface only or via data bus only or by both depending on the register access configuration bits ACC_CFG[1:0].

The four bits of register ADCFLWCTL reflect the captured request and status of the four internal interface Signals (LoadOK, Trigger, Restart, and Seq_abort; see also [Figure 9-2](#)) if access configuration is set accordingly and indicate event progress (when an event is processed and when it is finished).

Conversion flow error situations are captured by corresponding interrupt flags in the ADCEIF register.

There are two conversion flow control modes (Restart Mode, Trigger Mode). Each mode causes a certain behavior of the conversion flow control bits which can be selected according to the application needs.

Please refer to [Section 9.5.2.1, “ADC Control Register 0 \(ADCCTL_0\)”](#) and [Section 9.6.3.2.4, “The two conversion flow control Mode Configurations”](#) for more information regarding conversion flow control.

Because internal components of the ADC are turned on/off with bit ADC_EN, the ADC requires a recovery time period (t_{REC}) after ADC is enabled until the first conversion can be launched via a trigger.

When bit ADC_EN gets cleared (transition from 1'b1 to 1'b0) any ongoing conversion sequence will be aborted and pending results, or the result of current conversion, gets discarded (not stored). The ADC cannot be re-enabled before any pending action or action in process is finished respectively aborted, which could take up to a maximum latency time of $t_{DISABLE}$ (see device level specification for more details).

9.3 Key Features

- Programmer's Model with List Based Architecture for conversion command and result value organization
- Selectable resolution of 8-bit, 10-bit, or 12-bit
- Channel select control for n external analog input channels
- Provides up to eight device internal channels (please see the device reference manual for connectivity information and [Figure 9-2](#))
- Programmable sample time
- A sample buffer amplifier for channel sampling (improved performance in view to influence of channel input path resistance versus conversion accuracy)
- Left/right justified result data
- Individual selectable VRH_0/1 and VRL_0/1 inputs (ADC12B_LBA V1 and V2) or VRH_0/1/2 inputs (ADC12B_LBA V3) on a conversion command basis (please see [Figure 9-2](#), [Table 9-2](#))
- Special conversions for selected VRH_0/1 (V1 and V2) or VRH_0/1/2 (V3), VRL_0/1 (V1 and V2) or VRL_0 (V3), $(VRL_0/1 + VRH_0/1) / 2$ (V1 and V2) or $(VRL_0 + VRH_0/1/2) / 2$ (V3) (please see [Table 9-2](#))
- 15 conversion interrupts with flexible interrupt organization per conversion result
- One dedicated interrupt for "End Of List" type commands
- Command Sequence List (CSL) with a maximum number of 64 command entries
- Provides conversion sequence abort
- Restart from top of active Command Sequence List (CSL)
- The Command Sequence List and Result Value List are implemented in double buffered manner (two lists in parallel for each function)
- Conversion Command (CSL) loading possible from System RAM or NVM
- Single conversion flow control register with software selectable access path
- Two conversion flow control modes optimized to different application use cases
- Four option bits in the conversion command for top level SoC specific feature/function implementation option (Please refer to the device reference manual for details of the top level feature/function if implemented)

9.3.1 Modes of Operation

9.3.1.1 Conversion Modes

This architecture provides **single**, **multiple**, or **continuous conversion** on a **single channel** or on **multiple channels based on the Command Sequence List**.

9.3.1.2 MCU Operating Modes

- **MCU Stop Mode**

Before issuing an MCU Stop Mode request the ADC should be idle (no conversion or conversion sequence or Command Sequence List ongoing).

If a conversion, conversion sequence, or CSL is in progress when an MCU Stop Mode request is issued, a Sequence Abort Event occurs automatically and any ongoing conversion finish. After the Sequence Abort Event finishes, if the STR_SEQA bit is set (STR_SEQA=1), then the conversion result is stored and the corresponding flags are set. If the STR_SEQA bit is cleared (STR_SEQA=0), then the conversion result is not stored and the corresponding flags are not set. The microcontroller then enters MCU Stop Mode without SEQAD_IF being set.

Alternatively, the Sequence Abort Event can be issued by software before an MCU Stop Mode request. As soon as flag SEQAD_IF is set the MCU Stop Mode request can be issued.

With the occurrence of the MCU Stop Mode Request until exit from Stop Mode all flow control signals (RSTA, SEQA, LDOK, TRIG) are cleared.

After exiting MCU Stop Mode, the following happens in the order given with expected event(s) depending on the conversion flow control mode:

- In ADC conversion flow control mode “Trigger Mode” a Restart Event is expected to simultaneously set bits TRIG and RSTA, causing the ADC to execute the Restart Event (CMD_IDX and RVL_IDX cleared) followed by the Trigger Event. The Restart Event can be generated automatically after exit from MCU Stop Mode if bit AUT_RSTA is set.
- In ADC conversion flow control mode “Restart Mode”, a Restart Event is expected to set bit RSTA only (ADC already aborted at MCU Stop Mode entry hence bit SEQA must not be set simultaneously) causing the ADC to execute the Restart Event (CDM_IDX and RVL_IDX cleared). The Restart Event can be generated automatically after exit from MCU Stop Mode if bit AUT_RSTA is set.
- The RVL buffer select (RVL_SEL) is not changed if a CSL is in process at MCU Stop Mode request. Hence the same buffer will be used after exit from Stop Mode that was used when the Stop Mode request occurred.

- **MCU Wait Mode**

Depending on the ADC Wait Mode configuration bit SWAI, the ADC either continues conversion in MCU Wait Mode or freezes conversion at the next conversion boundary before MCU Wait Mode is entered.

ADC behavior for configuration SWAI = 1'b0:

The ADC continues conversion during Wait Mode according to the conversion flow control sequence. It is assumed that the conversion flow control sequence is continued (conversion flow control bits TRIG, RSTA, SEQA, and LDOK are serviced accordingly).

ADC behavior for configuration SWAI = 1'b1:

At MCU Wait Mode request the ADC should be idle (no conversion or conversion sequence or Command Sequence List ongoing).

If a conversion, conversion sequence, or CSL is in progress when an MCU Wait Mode request is issued, a Sequence Abort Event occurs automatically and any ongoing conversion finish. After the Sequence Abort Event finishes, if the STR_SEQA bit is set (STR_SEQA=1), then the conversion result is stored and the corresponding flags are set. If the STR_SEQA bit is cleared (STR_SEQA=0), then the conversion result is not stored and the corresponding flags are not set. Alternatively the Sequence Abort Event can be issued by software before MCU Wait Mode request. As soon as flag SEQAD_IF is set, the MCU Wait Mode request can be issued.

With the occurrence of the MCU Wait Mode request until exit from Wait Mode all flow control signals (RSTA, SEQA, LDOK, TRIG) are cleared.

After exiting MCU Wait Mode, the following happens in the order given with expected event(s) depending on the conversion flow control mode:

- In ADC conversion flow control mode “Trigger Mode”, a Restart Event is expected to occur. This simultaneously sets bit TRIG and RSTA causing the ADC to execute the Restart Event (CMD_IDX and RVL_IDX cleared) followed by the Trigger Event. The Restart Event can be generated automatically after exit from MCU Wait Mode if bit AUT_RSTA is set.
- In ADC conversion flow control mode “Restart Mode”, a Restart Event is expected to set bit RSTA only (ADC already aborted at MCU Wait Mode entry hence bit SEQA must not be set simultaneously) causing the ADC to execute the Restart Event (CMD_IDX and RVL_IDX cleared). The Restart Event can be generated automatically after exit from MCU Wait Mode if bit AUT_RSTA is set.
- The RVL buffer select (RVL_SEL) is not changed if a CSL is in process at MCU Wait Mode request. Hence the same RVL buffer will be used after exit from Wait Mode that was used when Wait Mode request occurred.

NOTE

In principle, the MCU could stay in Wait Mode for a shorter period of time than the ADC needs to abort an ongoing conversion (range of $\mu\mu\mu\mu\mu\mu\text{s}$). Therefore in case a Sequence Abort Event is issued automatically due to MCU Wait Mode request a following Restart Event after exit from MCU Wait Mode can not be executed before ADC has finished this Sequence Abort Event. The Restart Event is detected but it is pending. This applies in case MCU Wait Mode is exited before ADC has finished the Sequence Abort Event and a Restart Event is issued immediately after exit from MCU Wait Mode. Bit READY can be used by software to detect when the Restart Event can be issued without latency time in processing the event (see also Figure 9-1).

Figure 9-1. Conversion Flow Control Diagram - Wait Mode (SWAI=1'b1, AUT_RSTA=1'b0)

- **MCU Freeze Mode**

Depending on the ADC Freeze Mode configuration bit FRZ_MOD, the ADC either continues conversion in Freeze Mode or freezes conversion at next conversion boundary before the MCU Freeze Mode is entered. After exit from MCU Freeze Mode with previously frozen conversion sequence the ADC continues the conversion with the next conversion command and all ADC interrupt flags are unchanged during MCU Freeze Mode.

9.3.2 Block Diagram

Figure 9-2. ADC12B_LBA Block Diagram

9.4 Signal Description

This section lists all inputs to the ADC12B_LBA block.

9.4.1 Detailed Signal Descriptions

9.4.1.1 AN x ($x = n, \dots, 2, 1, 0$)

This pin serves as the analog input Channel x . The maximum input channel number is n . Please refer to the device reference manual for the maximum number of input channels.

9.4.1.2 VRH_0, VRH_1, VRH_2, VRL_0, VRL_1

VRH_0/1/2 are the high reference voltages, VRL0/1 are the low reference voltages for a ADC conversion selectable on a conversion command basis. Please refer to the device overview information for availability and connectivity of these pins.

VRH_2 is only available on ADC12B_LBA V3.

VRL_1 is only available on ADC12B_LBA V1 and V2.

See also [Table 9-2](#).

9.4.1.3 VDDA, VSSA

These pins are the power supplies for the analog circuitry of the ADC12B_LBA block.

9.5 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the ADC12B_LBA.

9.5.1 Module Memory Map

Figure 9-3 gives an overview of all ADC12B_LBA registers.

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address	Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000	ADCCTL_0	R W	ADC_EN	ADC_SR	FRZ_MOD	SWAI	ACC_CFG[1:0]		STR_SEQ A	MOD_CFG
0x0001	ADCCTL_1	R W	CSL_BMO D	RVL_BMO D	SMOD_AC C	AUT_RST A	0	0	0	0
0x0002	ADCSTS	R W	CSL_SEL	RVL_SEL	DBECC_E RR	Reserved	READY	0	0	0
0x0003	ADCTIM	R W	0	PRS[6:0]						
0x0004	ADCFMT	R W	DJM	0	0	0	0	SRES[2:0]

9.5.2 Register Descriptions

This section describes in address order all the ADC12B_LBA registers and their individual bits.

9.5.2.1 ADC Control Register 0 (ADCCTL_0)

Module Base + 0x0000

Figure 9-4. ADC Control Register 0 (ADCCTL_0)

Read: Anytime

Write:

- Bits ADC_EN, ADC_SR, FRZ_MOD and SWAI writable anytime
- Bits MOD_CFG, STR_SEQA and ACC_CFG[1:0] writable if bit ADC_EN clear or bit SMOD_ACC set

Table 9-3. ADCCTL_0 Field Descriptions

Field	Description
15 ADC_EN	ADC Enable Bit — This bit enables the ADC (e.g. sample buffer amplifier etc.) and controls accessibility of ADC register bits. When this bit gets cleared any ongoing conversion sequence will be aborted and pending results or the result of current conversion gets discarded (not stored). The ADC cannot be re-enabled before any pending action or action in process is finished or aborted, which could take up to a maximum latency time of $t_{DISABLE}$ (see device reference manual for more details). Because internal components of the ADC are turned on/off with this bit, the ADC requires a recovery time period (t_{REC}) after ADC is enabled until the first conversion can be launched via a trigger. 0 ADC disabled. 1 ADC enabled.
14 ADC_SR	ADC Soft-Reset — This bit causes an ADC Soft-Reset if set after a severe error occurred (see list of severe errors in Section 9.5.2.9, “ADC Error Interrupt Flag Register (ADCEIF)” that causes the ADC to cease operation). It clears all overrun flags and error flags and forces the ADC state machine to its idle state. It also clears the Command Index Register, the Result Index Register, and the CSL_SEL and RVL_SEL bits (to be ready for a new control sequence to load new command and start execution again from top of selected CSL). A severe error occurs if an error flag is set which cause the ADC to cease operation. In order to make the ADC operational again an ADC Soft-Reset must be issued. Once this bit is set it can not be cleared by writing any value. It is cleared only by ADC hardware after the Soft-Reset has been executed. 0 No ADC Soft-Reset issued. 1 Issue ADC Soft-Reset.
13 FRZ_MOD	Freeze Mode Configuration — This bit influences conversion flow during Freeze Mode. 0 ADC continues conversion in Freeze Mode. 1 ADC freezes the conversion at next conversion boundary at Freeze Mode entry.
12 SWAI	Wait Mode Configuration — This bit influences conversion flow during Wait Mode. 0 ADC continues conversion in Wait Mode. 1 ADC halts the conversion at next conversion boundary at Wait Mode entry.

Table 9-3. ADCCTL_0 Field Descriptions (continued)

Field	Description
11-10 ACC_CFG[1:0]	ADCFLWCTL Register Access Configuration — These bits define if the register ADCFLWCTL is controlled via internal interface only or data bus only or both. See Table 9-4 . for more details.
9 STR_SEQA	Control Of Conversion Result Storage and RSTAR_EIF flag setting at Sequence Abort or Restart Event — This bit controls conversion result storage and RSTAR_EIF flag setting when a Sequence Abort Event or Restart Event occurs as follows: If STR_SEQA = 1'b0 and if a: <ul style="list-style-type: none"> Sequence Abort Event or Restart Event is issued during a conversion the data of this conversion is not stored and the respective conversion complete flag is not set Restart Event only is issued before the last conversion of a CSL is finished and no Sequence Abort Event is in process (SEQA clear) causes the RSTA_EIF error flag to be asserted and bit SEQA gets set by hardware If STR_SEQA = 1'b1 and if a: <ul style="list-style-type: none"> Sequence Abort Event or Restart Event is issued during a conversion the data of this conversion is stored and the respective conversion complete flag is set and Intermediate Result Information Register is updated. Restart Event only occurs during the last conversion of a CSL and no Sequence Abort Event is in process (SEQA clear) does not set the RSTA_EIF error flag Restart Event only is issued before the CSL is finished and no Sequence Abort Event is in process (SEQA clear) causes the RSTA_EIF error flag to be asserted and bit SEQA gets set by hardware
8 MOD_CFG	(Conversion Flow Control) Mode Configuration — This bit defines the conversion flow control after a Restart Event and after execution of the “End Of List” command type: - Restart Mode - Trigger Mode (For more details please see also section Section 9.6.3.2, “Introduction of the Programmer’s Model and following.) 0 “Restart Mode” selected. 1 “Trigger Mode” selected.

Table 9-4. ADCFLWCTL Register Access Configurations

ACC_CFG[1]	ACC_CFG[0]	ADCFLWCTL Access Mode
0	0	None of the access paths is enabled (default / reset configuration)
0	1	Single Access Mode - Internal Interface (ADCFLWCTL access via internal interface only)
1	0	Single Access Mode - Data Bus (ADCFLWCTL access via data bus only)
1	1	Dual Access Mode (ADCFLWCTL register access via internal interface and data bus)

NOTE

Each conversion flow control bit (SEQA, RSTA, TRIG, LDOK) must be controlled by software or internal interface according to the requirements described in [Section 9.6.3.2.4, “The two conversion flow control Mode Configurations](#) and overview summary in [Table 9-11](#).

9.5.2.2 ADC Control Register 1 (ADCCTL_1)

Module Base + 0x0001

Figure 9-5. ADC Control Register 1 (ADCCTL_1)

Read: Anytime

Write:

- Bit CSL_BMOD and RVL_BMOD writable if bit ADC_EN clear or bit SMOD_ACC set
- Bit SMOD_ACC only writable in MCU Special Mode
- Bit AUT_RSTA writable anytime

Table 9-5. ADCCTL_1 Field Descriptions

Field	Description
7 CSL_BMOD	CSL Buffer Mode Select Bit — This bit defines the CSL buffer mode. This bit is only writable if ADC_EN is clear. 0 CSL single buffer mode. 1 CSL double buffer mode.
6 RVL_BMOD	RVL Buffer Mode Select Bit — This bit defines the RVL buffer mode. 0 RVL single buffer mode 1 RVL double buffer mode
5 SMOD_ACC	Special Mode Access Control Bit — This bit controls register access rights in MCU Special Mode. This bit is automatically cleared when leaving MCU Special Mode. Note: When this bit is set also the ADCCMD register is writeable via the data bus to allow modification of the current command for debugging purpose. But this is only possible if the current command is not already processed (conversion not started). Please see access details given for each register. Care must be taken when modifying ADC registers while bit SMOD_ACC is set to not corrupt a possible ongoing conversion. 0 Normal user access - Register write restrictions exist as specified for each bit. 1 Special access - Register write restrictions are lifted.
4 AUT_RSTA	Automatic Restart Event after exit from MCU Stop and Wait Mode (SWAI set) — This bit controls if a Restart Event is automatically generated after exit from MCU Stop Mode or Wait Mode with bit SWAI set. It can be configured for ADC conversion flow control mode “Trigger Mode” and “Restart Mode” (anytime during application runtime). 0 No automatic Restart Event after exit from MCU Stop Mode. 1 Automatic Restart Event occurs after exit from MCU Stop Mode.

9.5.2.3 ADC Status Register (ADCSTS)

It is important to note that if flag DBECC_ERR is set the ADC ceases operation. In order to make the ADC operational again an ADC Soft-Reset must be issued. An ADC Soft-Reset clears bits CSL_SEL and RVL_SEL.

Module Base + 0x0002

Figure 9-6. ADC Status Register (ADCSTS)

Read: Anytime

Write:

- Bits CSL_SEL and RVL_SEL anytime if bit ADC_EN is clear or bit SMOD_ACC is set
- Bits DBECC_ERR and READY not writable

Table 9-6. ADCSTS Field Descriptions

Field	Description
7 CSL_SEL	Command Sequence List Select bit — This bit controls and indicates which ADC Command List is active. This bit can only be written if ADC_EN bit is clear. This bit toggles in CSL double buffer mode when no conversion or conversion sequence is ongoing and bit LDOK is set and bit RSTA is set. In CSL single buffer mode this bit is forced to 1'b0 by bit CSL_BMOD. 0 ADC Command List 0 is active. 1 ADC Command List 1 is active.
6 RVL_SEL	Result Value List Select Bit — This bit controls and indicates which ADC Result List is active. This bit can only be written if bit ADC_EN is clear. After storage of the initial Result Value List this bit toggles in RVL double buffer mode whenever the conversion result of the first conversion of the current CSL is stored or a CSL got aborted. In RVL single buffer mode this bit is forced to 1'b0 by bit RVL_BMOD. Please see also Section 9.3.1.2, "MCU Operating Modes" for information regarding Result List usage in case of Stop or Wait Mode. 0 ADC Result List 0 is active. 1 ADC Result List 1 is active.
5 DBECC_ERR	Double Bit ECC Error Flag — This flag indicates that a double bit ECC error occurred during conversion command load or result storage and ADC ceases operation. In order to make the ADC operational again an ADC Soft-Reset must be issued. This bit is cleared if bit ADC_EN is clear. 0 No double bit ECC error occurred. 1 A double bit ECC error occurred.
3 READY	Ready For Restart Event Flag — This flag indicates that ADC is in its idle state and ready for a Restart Event. It can be used to verify after exit from Wait Mode if a Restart Event can be issued and processed immediately without any latency time due to an ongoing Sequence Abort Event after exit from MCU Wait Mode (see also the Note in Section 9.3.1.2, "MCU Operating Modes"). 0 ADC not in idle state. 1 ADC is in idle state.

9.5.2.4 ADC Timing Register (ADCTIM)

Module Base + 0x0003

Figure 9-7. ADC Timing Register (ADCTIM)

Read: Anytime

Write: These bits are writable if bit ADC_EN is clear or bit SMOD_ACC is set

Table 9-7. ADCTIM Field Descriptions

Field	Description
6-0 PRS[6:0]	<p>ADC Clock Prescaler — These 7bits are the binary prescaler value PRS. The ADC conversion clock frequency is calculated as follows:</p> $f_{ATDCLK} = \frac{f_{BUS}}{2^X(PRS + 1)}$ <p>Refer to Device Specification for allowed frequency range of f_{ATDCLK}.</p>

9.5.2.5 ADC Format Register (ADCFMT)

Module Base + 0x0004

Figure 9-8. ADC Format Register (ADCFMT)

Read: Anytime

Write: Bits DJM and SRES[2:0] are writable if bit ADC_EN clear or bit SMOD_ACC set

Table 9-8. ADCFMT Field Descriptions

Field	Description
7 DJM	Result Register Data Justification — Conversion result data format is always unsigned. This bit controls justification of conversion result data in the conversion result list. 0 Left justified data in the conversion result list. 1 Right justified data in the conversion result list.
2-0 SRES[2:0]	ADC Resolution Select — These bits select the resolution of conversion results. See Table 9-9 for coding.

Table 9-9. Selectable Conversion Resolution

SRES[2]	SRES[1]	SRES[0]	ADC Resolution
0	0	0	8-bit data
0	0	1	Reserved ^{1.}
0	1	0	10-bit data
0	1	1	Reserved ^{1.}
1	0	0	12-bit data
1	x	x	Reserved ⁽¹⁾

1. Reserved settings cause a severe error at ADC conversion start whereby the CMD_EIF flag is set and ADC ceases operation

9.5.2.6 ADC Conversion Flow Control Register (ADCFLWCTL)

Bit set and bit clear instructions should not be used to access this register.

When the ADC is enabled the bits of ADCFLWCTL register can be modified after a latency time of three Bus Clock cycles.

All bits are cleared if bit ADC_EN is clear or via ADC soft-reset.

Module Base + 0x0005

Figure 9-9. ADC Conversion Flow Control Register (ADCFLWCTL)

Read: Anytime

Write:

- Bits SEQA, TRIG, RSTA, LDOK can only be set if bit ADC_EN is set.
- Writing 1'b0 to any of these bits does not have an effect

Timing considerations (Trigger Event - channel sample start) depending on ADC mode configuration:

- **Restart Mode**
When the Restart Event has been processed (initial command of current CSL is loaded) it takes two Bus Clock cycles plus two ADC conversion clock cycles (pump phase) from the Trigger Event (bit TRIG set) until the select channel starts to sample.
During a conversion sequence (back to back conversions) it takes five Bus Clock cycles plus two ADC conversion clock cycles (pump phase) from current conversion period end until the newly selected channel is sampled in the following conversion period.
- **Trigger Mode**
When a Restart Event occurs a Trigger Event is issued simultaneously. The time required to process the Restart Event is mainly defined by the internal read data bus availability and therefore can vary. In this mode the Trigger Event is processed immediately after the Restart Event is finished and both conversion flow control bits are cleared simultaneously. From de-assert of bit TRIG until sampling begins five Bus Clock cycles are required. Hence from occurrence of a Restart Event until channel sampling it takes five Bus Clock cycles plus an uncertainty of a few Bus Clock cycles.

For more details regarding the sample phase please refer to [Section 9.6.2.2, "Sample and Hold Machine with Sample Buffer Amplifier."](#)

Table 9-10. ADCFLWCTL Field Descriptions

Field	Description
7 SEQA	<p>Conversion Sequence Abort Event — This bit indicates that a conversion sequence abort event is in progress. When this bit is set the ongoing conversion sequence and current CSL will be aborted at the next conversion boundary. This bit gets cleared when the ongoing conversion sequence is aborted and ADC is idle. This bit can only be set if bit ADC_EN is set. This bit is cleared if bit ADC_EN is clear.</p> <p>Data Bus Control: This bit can be controlled via the data bus if access control is configured accordingly via ACC_CFG[1:0]. Writing a value of 1'b0 does not clear the flag. Writing a one to this bit does not clear it but causes an overrun if the bit has already been set. See Section 9.6.3.2.6, “Conversion flow control in case of conversion sequence control bit overrun scenarios for more details.</p> <p>Internal Interface Control: This bit can be controlled via the internal interface Signal “Seq_Abort” if access control is configured accordingly via ACC_CFG[1:0]. After being set an additional request via the internal interface Signal “Seq_Abort” causes an overrun. See also conversion flow control in case of overrun situations.</p> <p>General: In both conversion flow control modes (Restart Mode and Trigger Mode) when bit RSTA gets set automatically bit SEQA gets set when the ADC has not reached one of the following scenarios: - A Sequence Abort request is about to be executed or has been executed. - “End Of List” command type has been executed or is about to be executed In case bit SEQA is set automatically the Restart error flag RSTA_EIF is set to indicate an unexpected Restart Request. 0 No conversion sequence abort request. 1 Conversion sequence abort request.</p>
6 TRIG	<p>Conversion Sequence Trigger Bit — This bit starts a conversion sequence if set and no conversion or conversion sequence is ongoing. This bit is cleared when the first conversion of a sequence starts to sample. This bit can only be set if bit ADC_EN is set. This bit is cleared if bit ADC_EN is clear.</p> <p>Data Bus Control: This bit can be controlled via the data bus if access control is configured accordingly via ACC_CFG[1:0]. Writing a value of 1'b0 does not clear the flag. After being set this bit can not be cleared by writing a value of 1'b1 instead the error flag TRIG_EIF is set. See also Section 9.6.3.2.6, “Conversion flow control in case of conversion sequence control bit overrun scenarios for more details.</p> <p>Internal Interface Control: This bit can be controlled via the internal interface Signal “Trigger” if access control is configured accordingly via ACC_CFG[1:0]. After being set an additional request via internal interface Signal “Trigger” causes the flag TRIG_EIF to be set. 0 No conversion sequence trigger. 1 Trigger to start conversion sequence.</p>

Table 9-10. ADCFLWCTL Field Descriptions (continued)

Field	Description
5 RSTA	<p>Restart Event (Restart from Top of Command Sequence List) — This bit indicates that a Restart Event is executed. The ADC loads the conversion command from top of the active Sequence Command List when no conversion or conversion sequence is ongoing. This bit is cleared when the first conversion command of the sequence from top of active Sequence Command List has been loaded into the ADCCMD register.</p> <p>This bit can only be set if bit ADC_EN is set. This bit is cleared if bit ADC_EN is clear.</p> <p>Data Bus Control: This bit can be controlled via the data bus if access control is configured accordingly via ACC_CFG[1:0]. Writing a value of 1'b0 does not clear the flag. Writing a one to this bit does not clear it but causes an overrun if the bit has already been set. See also Section 9.6.3.2.6, “Conversion flow control in case of conversion sequence control bit overrun scenarios for more details.</p> <p>Internal Interface Control: This bit can be controlled via the internal interface Signal “Restart” if access control is configured accordingly via ACC_CFG[1:0]. After being set an additional request via internal interface Signal “Restart” causes an overrun. See conversion flow control in case of overrun situations for more details.</p> <p>General: In conversion flow control mode “Trigger Mode” when bit RSTA gets set bit TRIG is set simultaneously if one of the following has been executed:</p> <ul style="list-style-type: none"> - “End Of List” command type has been executed or is about to be executed - Sequence Abort Event <p>0 Continue with commands from active Sequence Command List. 1 Restart from top of active Sequence Command List.</p>
4 LDOK	<p>Load OK for alternative Command Sequence List — This bit indicates if the preparation of the alternative Sequence Command List is done and Command Sequence List must be swapped with the Restart Event. This bit is cleared when bit RSTA is set (Restart Event executed) and the Command Sequence List got swapped.</p> <p>This bit can only be set if bit ADC_EN is set. This bit is cleared if bit ADC_EN is clear. This bit is forced to zero if bit CSL_BMOD is clear.</p> <p>Data Bus Control: This bit can be controlled via the data bus if access control is configured accordingly via ACC_CFG[1:0]. Writing a value of 1'b0 does not clear the flag. To set bit LDOK the bits LDOK and RSTA must be written simultaneously. After being set this bit can not be cleared by writing a value of 1'b1. See also Section 9.6.3.2.6, “Conversion flow control in case of conversion sequence control bit overrun scenarios for more details.</p> <p>Internal Interface Control: This bit can be controlled via the internal interface Signal “LoadOK” and “Restart” if access control is configured accordingly via ACC_CFG[1:0]. With the assertion of Interface Signal “Restart” the interface Signal “LoadOK” is evaluated and bit LDOK set accordingly (bit LDOK set if Interface Signal “LoadOK” asserted when Interface Signal “Restart” asserts).</p> <p>General: Only in “Restart Mode” if a Restart Event occurs without bit LDOK being set the error flag LDOK_EIF is set except when the respective Restart Request occurred after or simultaneously with a Sequence Abort Request. The LDOK_EIF error flag is also not set in “Restart Mode” if the first Restart Event occurs after:</p> <ul style="list-style-type: none"> - ADC got enabled - Exit from Stop Mode - ADC Soft-Reset <p>0 Load of alternative list done. 1 Load alternative list.</p>

Table 9-11. Summary of Conversion Flow Control Bit Scenarios

RSTA	TRIG	SEQA	LDOK	Conversion Flow Control Mode	Conversion Flow Control Scenario
0	0	0	0	Both Modes	Valid
0	0	0	1	Both Modes	Can Not Occur
0	0	1	0	Both Modes	Valid ^{5.}
0	0	1	1	Both Modes	Can Not Occur
0	1	0	0	Both Modes	Valid ^{2.}
0	1	0	1	Both Modes	Can Not Occur
0	1	1	0	Both Modes	Can Not Occur
0	1	1	1	Both Modes	Can Not Occur
1	0	0	0	Both Modes	Valid ^{4.}
1	0	0	1	Both Modes	Valid ^{1. 4.}
1	0	1	0	Both Modes	Valid ^{3. 4. 5.}
1	0	1	1	Both Modes	Valid ^{1. 3. 4. 5.}
1	1	0	0	"Restart Mode"	Error flag TRIG_EIF set
				"Trigger Mode"	Valid ^{2. 4. 6.}
1	1	0	1	"Restart Mode"	Error flag TRIG_EIF set
				"Trigger Mode"	Valid ^{1. 2. 4. 6.}
1	1	1	0	"Restart Mode"	Error flag TRIG_EIF set
				"Trigger Mode"	Valid ^{2. 3. 4. 5. 6.}
1	1	1	1	"Restart Mode"	Error flag TRIG_EIF set
				"Trigger Mode"	Valid ^{(1) (2) (3) (4) (5) (6)}

1. Swap CSL buffer
2. Start conversion sequence
3. Prevent RSTA_EIF and LDOK_EIF
4. Load conversion command from top of CSL
5. Abort any ongoing conversion, conversion sequence and CSL
6. Bit TRIG set automatically in Trigger Mode

For a detailed description of all conversion flow control bit scenarios please see also [Section 9.6.3.2.4, "The two conversion flow control Mode Configurations](#), [Section 9.6.3.2.5, "The four ADC conversion flow control bits](#) and [Section 9.6.3.2.6, "Conversion flow control in case of conversion sequence control bit overrun scenarios](#)

9.5.2.7 ADC Error Interrupt Enable Register (ADCEIE)

Module Base + 0x0006

Figure 9-10. ADC Error Interrupt Enable Register (ADCEIE)

Read: Anytime

Write: Anytime

Table 9-12. ADCEIE Field Descriptions

Field	Description
7 IA_EIE	Illegal Access Error Interrupt Enable Bit — This bit enables the illegal access error interrupt. 0 Illegal access error interrupt disabled. 1 Illegal access error interrupt enabled.
6 CMD_EIE	Command Value Error Interrupt Enable Bit — This bit enables the command value error interrupt. 0 Command value interrupt disabled. 1 Command value interrupt enabled.
5 EOL_EIE	“End Of List” Error Interrupt Enable Bit — This bit enables the “End Of List” error interrupt. 0 “End Of List” error interrupt disabled. 1 “End Of List” error interrupt enabled.
3 TRIG_EIE	Conversion Sequence Trigger Error Interrupt Enable Bit — This bit enables the conversion sequence trigger error interrupt. 0 Conversion sequence trigger error interrupt disabled. 1 Conversion sequence trigger error interrupt enabled.
2 RSTAR_EIE	Restart Request Error Interrupt Enable Bit — This bit enables the restart request error interrupt. 0 Restart Request error interrupt disabled. 1 Restart Request error interrupt enabled.
1 LDOK_EIE	Load OK Error Interrupt Enable Bit — This bit enables the Load OK error interrupt. 0 Load OK error interrupt disabled. 1 Load OK error interrupt enabled.

9.5.2.8 ADC Interrupt Enable Register (ADCIE)

Module Base + 0x0007

Figure 9-11. ADC Interrupt Enable Register (ADCIE)

Read: Anytime

Write: Anytime

Table 9-13. ADCIE Field Descriptions

Field	Description
7 SEQAD_IE	Conversion Sequence Abort Done Interrupt Enable Bit — This bit enables the conversion sequence abort event done interrupt. 0 Conversion sequence abort event done interrupt disabled. 1 Conversion sequence abort event done interrupt enabled.
6 CONIF_OIE	ADCCONIF Register Flags Overrun Interrupt Enable — This bit enables the flag which indicates if an overrun situation occurred for one of the CON_IF[15:1] flags or for the EOL_IF flag. 0 No ADCCONIF Register Flag overrun occurred. 1 ADCCONIF Register Flag overrun occurred.

9.5.2.9 ADC Error Interrupt Flag Register (ADCEIF)

If one of the following error flags is set the ADC ceases operation:

- IA_EIF
- CMD_EIF
- EOL_EIF
- TRIG_EIF

In order to make the ADC operational again an ADC Soft-Reset must be issued which clears above listed error interrupt flags.

The error interrupt flags RSTAR_EIF and LDOK_EIF do not cause the ADC to cease operation. If set the ADC continues operation. Each of the two bits can be cleared by writing a value of 1'b1. Both bits are also cleared if an ADC Soft-Reset is issued.

All bits are cleared if bit ADC_EN is clear. Writing any flag with value 1'b0 does not clear a flag. Writing any flag with value 1'b1 does not set the flag.

Module Base + 0x0008

Figure 9-12. ADC Error Interrupt Flag Register (ADCEIF)

Read: Anytime

Write:

- Bits RSTAR_EIF and LDOK_EIF are writable anytime
- Bits IA_EIF, CMD_EIF, EOL_EIF and TRIG_EIF are not writable

Table 9-14. ADCEIF Field Descriptions

Field	Description
7 IA_EIF	Illegal Access Error Interrupt Flag — This flag indicates that storing the conversion result caused an illegal access error or conversion command loading from outside system RAM or NVM area occurred. The ADC ceases operation if this error flag is set (issue of type severe). 0 No illegal access error occurred. 1 An illegal access error occurred.
6 CMD_EIF	Command Value Error Interrupt Flag — This flag indicates that an invalid command is loaded (Any command that contains reserved bit settings) or illegal format setting selected (reserved SRES[2:0] bit settings). The ADC ceases operation if this error flag is set (issue of type severe). 0 Valid conversion command loaded. 1 Invalid conversion command loaded.
5 EOL_EIF	“End Of List” Error Interrupt Flag — This flag indicates a missing “End Of List” command type in current executed CSL. The ADC ceases operation if this error flag is set (issue of type severe). 0 No “End Of List” error. 1 “End Of List” command type missing in current executed CSL.

Table 9-14. ADCEIF Field Descriptions (continued)

Field	Description
3 TRIG{EIF	<p>Trigger Error Interrupt Flag — This flag indicates that a trigger error occurred.</p> <p>This flag is set in “Restart” Mode when a conversion sequence got aborted and no Restart Event occurred before the Trigger Event or if the Trigger Event occurred before the Restart Event was finished (conversion command has been loaded).</p> <p>This flag is set in “Trigger” Mode when a Trigger Event occurs before the Restart Event is issued to start conversion of the initial Command Sequence List. In “Trigger” Mode only a Restart Event is required to start conversion of the initial Command Sequence List.</p> <p>This flag is set when a Trigger Event occurs before a conversion sequence got finished.</p> <p>This flag is also set if a Trigger occurs while a Trigger Event is just processed - first conversion command of a sequence is beginning to sample (see also Section 9.6.3.2.6, “Conversion flow control in case of conversion sequence control bit overrun scenarios”).</p> <p>This flag is also set if the Trigger Event occurs automatically generated by hardware in “Trigger Mode” due to a Restart Event and simultaneously a Trigger Event is generated via data bus or internal interface.</p> <p>The ADC ceases operation if this error flag is set (issue of type severe).</p> <p>0 No trigger error occurred. 1 A trigger error occurred.</p>
2 RSTAR{EIF	<p>Restart Request Error Interrupt Flag — This flag indicates a flow control issue. It is set when a Restart Request occurs after a Trigger Event and before one of the following conditions was reached:</p> <ul style="list-style-type: none"> - The “End Of List” command type has been executed - Depending on bit STR_SEQA if the “End Of List” command type is about to be executed - The current CSL has been aborted or is about to be aborted due to a Sequence Abort Request. <p>The ADC continues operation if this error flag is set.</p> <p>This flag is not set for Restart Request overrun scenarios (see also Section 9.6.3.2.6, “Conversion flow control in case of conversion sequence control bit overrun scenarios”).</p> <p>0 No Restart request error situation occurred. 1 Restart request error situation occurred.</p>
1 LDOK{EIF	<p>Load OK Error Interrupt Flag — This flag can only be set in “Restart Mode”. It indicates that a Restart Request occurred without LDOK. This flag is not set if a Sequence Abort Event is already in process (bit SEQA set) when the Restart Request occurs or a Sequence Abort Request occurs simultaneously with the Restart Request.</p> <p>The LDOK{EIF error flag is also not set in “Restart Mode” if the first Restart Event occurs after:</p> <ul style="list-style-type: none"> - ADC got enabled - Exit from Stop Mode - ADC Soft-Reset - ADC used in CSL single buffer mode <p>The ADC continues operation if this error flag is set.</p> <p>0 No Load OK error situation occurred. 1 Load OK error situation occurred.</p>

9.5.2.10 ADC Interrupt Flag Register (ADCIF)

After being set any of these bits can be cleared by writing a value of 1'b1 or via ADC soft-reset (bit ADC_SR). All bits are cleared if bit ADC_EN is clear. Writing any flag with value 1'b0 does not clear the flag. Writing any flag with value 1'b1 does not set the flag.

Module Base + 0x0009

Figure 9-13. ADC Interrupt Flag Register (ADCIF)

Read: Anytime

Write: Anytime

Table 9-15. ADCIF Field Descriptions

Field	Description
7 SEQAD_IF	<p>Conversion Sequence Abort Done Interrupt Flag — This flag is set when the Sequence Abort Event has been executed except the Sequence Abort Event occurred by hardware in order to be able to enter MCU Stop Mode or Wait Mode with bit SWAI set. This flag is also not set if the Sequence Abort request occurs during execution of the last conversion command of a CSL and bit STR_SEQA being set.</p> <p>0 No conversion sequence abort request occurred. 1 A conversion sequence abort request occurred.</p>
6 CONIF_OIF	<p>ADCCONIF Register Flags Overrun Interrupt Flag — This flag indicates if an overrun situation occurred for one of the CON_IF[15:1] flags or for the EOL_IF flag. In RVL single buffer mode (RVL_BMOD clear) an overrun of the EOL_IF flag is not indicated (For more information please see Note below).</p> <p>0 No ADCCONIF Register Flag overrun occurred. 1 ADCCONIF Register Flag overrun occurred.</p>

NOTE

In RVL double buffer mode a conversion interrupt flag (CON_IF[15:1]) or End Of List interrupt flag (EOL_IF) overrun is detected if one of these bits is set when it should be set again due to conversion command execution.

In RVL single buffer mode a conversion interrupt flag (CON_IF[15:1]) overrun is detected only. The overrun is detected if any of the conversion interrupt flags (CON_IF[15:1]) is set while the first conversion result of a CSL is stored (result of first conversion from top of CSL is stored).

9.5.2.11 ADC Conversion Interrupt Enable Register (ADCCONIE)

Module Base + 0x000A

Figure 9-14. ADC Conversion Interrupt Enable Register (ADCCONIE)

Read: Anytime

Write: Anytime

Table 9-16. ADCCONIE Field Descriptions

Field	Description
15-1 CON_IE[15:1]	Conversion Interrupt Enable Bits — These bits enable the individual interrupts which can be triggered via interrupt flags CON_IF[15:1]. 0 ADC conversion interrupt disabled. 1 ADC conversion interrupt enabled.
0 EOL_IE	End Of List Interrupt Enable Bit — This bit enables the end of conversion sequence list interrupt. 0 End of list interrupt disabled. 1 End of list interrupt enabled.

9.5.2.12 ADC Conversion Interrupt Flag Register (ADCCONIF)

After being set any of these bits can be cleared by writing a value of 1'b1. All bits are cleared if bit ADC_EN is clear or via ADC soft-reset (bit ADC_SR set). Writing any flag with value 1'b0 does not clear the flag. Writing any flag with value 1'b1 does not set the flag.

Figure 9-15. ADC Conversion Interrupt Flag Register (ADCCONIF)

Read: Anytime

Write: Anytime

Table 9-17. ADCCONIF Field Descriptions

Field	Description
15-1 CON_IF[15:1]	Conversion Interrupt Flags — These bits could be set by the binary coded interrupt select bits INTFLG_SEL[3:0] when the corresponding conversion command has been processed and related data has been stored to RAM. See also notes below.
0 EOL_IF	End Of List Interrupt Flag — This bit is set by the binary coded conversion command type select bits CMD_SEL[1:0] for “end of list” type of commands and after such a command has been processed and the related data has been stored RAM. See also second note below

NOTE

These bits can be used to indicate if a certain packet of conversion results is available. Clearing a flag indicates that conversion results have been retrieved by software and the flag can be used again (see also [Section 9.9.6, “RVL swapping in RVL double buffer mode and related registers ADCIMDRI and ADCEOLRI.](#)

NOTE

Overflow situation of a flag CON_IF[15:1] and EOL_IF are indicated by flag CONIF_OIF.

9.5.2.13 ADC Intermediate Result Information Register (ADCIMDRI)

This register is cleared when bit ADC_SR is set or bit ADC_EN is clear.

Module Base + 0x000E

Figure 9-16. ADC Intermediate Result Information Register (ADCIMDRI)

Read: Anytime

Write: Never

Table 9-18. ADCIMDRI Field Descriptions

Field	Description
15 CSL_IMD	<p>Active CSL At Intermediate Event — This bit indicates the active (used) CSL at the occurrence of a conversion interrupt flag (CON_IF[15:1]) (occurrence of an intermediate result buffer fill event) or when a Sequence Abort Event gets executed.</p> <p>0 CSL_0 active (used) when a conversion interrupt flag (CON_IF[15:1]) got set. 1 CSL_1 active (used) when a conversion interrupt flag (CON_IF[15:1]) got set.</p>
14 RVL_IMD	<p>Active RVL At Intermediate Event — This bit indicates the active (used) RVL buffer at the occurrence of a conversion interrupt flag (CON_IF[15:1]) (occurrence of an intermediate result buffer fill event) or when a Sequence Abort Event gets executed.</p> <p>0 RVL_0 active (used) when a conversion interrupt flag (CON_IF[15:1]) got set. 1 RVL_1 active (used) when a conversion interrupt flag (CON_IF[15:1]) got set.</p>
5-0 RIDX_IMD[5:0]	<p>RES_IDX Value At Intermediate Event — These bits indicate the result index (RES_IDX) value at the occurrence of a conversion interrupt flag (CON_IF[15:1]) (occurrence of an intermediate result buffer fill event) or occurrence of EOL_IF flag or when a Sequence Abort Event gets executed to abort an ongoing conversion (the result index RES_IDX is captured at the occurrence of a result data store).</p> <p>When a Sequence Abort Event has been processed flag SEQAD_IF is set and the RES_IDX value of the last stored result is provided. Hence in case an ongoing conversion is aborted the RES_IDX value captured in RIDX_IMD bits depends on bit STORE_SEQA:</p> <ul style="list-style-type: none"> - STORE_SEQA =1: The result index of the aborted conversion is provided - STORE_SEQA =0: The result index of the last stored result at abort execution time is provided <p>In case a CSL is aborted while no conversion is ongoing (ADC waiting for a Trigger Event) the last captured result index is provided.</p> <p>In case a Sequence Abort Event was initiated by hardware due to MCU entering Stop Mode or Wait Mode with bit SWAI set, the result index of the last stored result is captured by bits RIDX_IMD but flag SEQAD_IF is not set.</p>

NOTE

The register ADCIMDRI is updated and simultaneously a conversion interrupt flag CON_IF[15:1] occurs when the corresponding conversion command (conversion command with INTFLG_SEL[3:0] set) has been processed and related data has been stored to RAM.

9.5.2.14 ADC End Of List Result Information Register (ADCEOLRI)

This register is cleared when bit ADC_SR is set or bit ADC_EN is clear.

Module Base + 0x0010

Figure 9-17. ADC End Of List Result Information Register (ADCEOLRI)

Read: Anytime

Write: Never

Table 9-19. ADCEOLRI Field Descriptions

Field	Description
7 CSL_EOL	Active CSL When “End Of List” Command Type Executed — This bit indicates the active (used) CSL when a “End Of List” command type has been executed and related data has been stored to RAM. 0 CSL_0 active when “End Of List” command type executed. 1 CSL_1 active when “End Of List” command type executed.
6 RVL_EOL	Active RVL When “End Of List” Command Type Executed — This bit indicates the active (used) RVL when a “End Of List” command type has been executed and related data has been stored to RAM. 0 RVL_0 active when “End Of List” command type executed. 1 RVL_1 active when “End Of List” command type executed.

NOTE

The conversion interrupt EOL_IF occurs and simultaneously the register ADCEOLRI is updated when the “End Of List” conversion command type has been processed and related data has been stored to RAM.

9.5.2.15 ADC Command Register 0 (ADCCMD_0)

Module Base + 0x0014

Field	Description
6-0 CMDRES_OFF1 [6:0]	ADC Result Address Offset Value — These bits represent the conversion command and result offset value relative to the conversion command base pointer address and result base pointer address in the memory map to refer to CSL_1 and RVL_1. It is used to calculate the address inside the system RAM to which the result at the end of the current conversion is stored to and the area (RAM or NVM) from which the conversion commands are loaded from. These bits do not represent absolute addresses instead it is an sample offset (object size 16bit for RVL, object size 32bit for CSL)., These bits can only be modified if bit ADC_EN is clear. See also Section 9.6.3.2.2, “Introduction of the two Command Sequence Lists (CSLs) and Section 9.6.3.2.3, “Introduction of the two Result Value Lists (RVLs) for more details.

9.6 Functional Description

9.6.1 Overview

The ADC12B_LBA consists of an analog sub-block and a digital sub-block. It is a successive approximation analog-to-digital converter including a sample-and-hold mechanism and an internal charge scaled C-DAC (switched capacitor scaled digital-to-analog converter) with a comparator to realize the successive approximation algorithm.

9.6.2 Analog Sub-Block

The analog sub-block contains all analog circuits (sample and hold, C-DAC, analog Comparator, and so on) required to perform a single conversion. Separate power supplies VDDA and VSSA allow noise from the MCU circuitry to be isolated from the analog sub-block for improved accuracy.

9.6.2.1 Analog Input Multiplexer

The analog input multiplexers connect one of the external or internal analog input channels to the sample and hold storage node.

9.6.2.2 Sample and Hold Machine with Sample Buffer Amplifier

The Sample and Hold Machine controls the storage and charge of the storage node (sample capacitor) to the voltage level of the analog signal at the selected ADC input channel. This architecture employs the advantage of reduced crosstalk between channels.

The sample buffer amplifier is used to raise the effective input impedance of the A/D machine, so that external components (higher bandwidth or higher impedance connected as specified) are less significant to accuracy degradation.

During the sample phase, the analog input connects first via a sample buffer amplifier with the storage node always for two ADC clock cycles (“Buffer” sample time). For the remaining sample time (“Final” sample time) the storage node is directly connected to the analog input source. Please see also [Figure 9-28](#) for illustration and the Appendix of the device reference manual for more details.

The input analog signals are unipolar and must be within the potential range of VSSA to VDDA. During the hold process, the analog input is disconnected from the storage node.

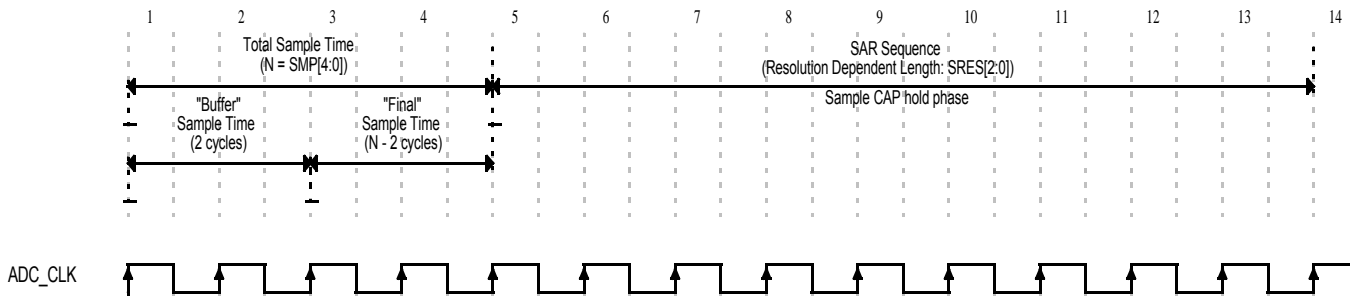

Figure 9-28. Sampling and Conversion Timing Example (8-bit Resolution, 4 Cycle Sampling)

Please note that there is always a pump phase of two ADC_CLK cycles before the sample phase begins, hence glitches during the pump phase could impact the conversion accuracy for short sample times.

9.6.3 Digital Sub-Block

The digital sub-block contains a list-based programmer's model and the control logic for the analog sub-block circuits.

9.6.3.1 Analog-to-Digital (A/D) Machine

The A/D machine performs the analog-to-digital conversion. The resolution is program selectable to be either 8- or 10- or 12 bits. The A/D machine uses a successive approximation architecture. It functions by comparing the sampled and stored analog voltage with a series of binary coded discrete voltages.

By following a binary search algorithm, the A/D machine identifies the discrete voltage that is nearest to the sampled and stored voltage.

Only analog input signals within the potential range of VRL_0/1 to VRH_0/1/3 (availability of VRL_1 and VRH_2 see [Table 9-2](#)) (A/D reference potentials) will result in a non-railed digital output code.

9.6.3.2 Introduction of the Programmer's Model

The ADC_LBA provides a programmer's model that uses a system memory list-based architecture for definition of the conversion command sequence and conversion result handling.

The Command Sequence List (CSL) and Result Value List (RVL) are implemented in double buffered manner and the buffer mode is user selectable for each list (bits CSL_BMOD, RVL_BMOD). The 32-bit wide conversion command is double buffered and the currently active command is visible in the ADC register map at ADCCMD register space.

9.6.3.2.1 Introduction of The Command Sequence List (CSL) Format

A Command Sequence List (CSL) contains up to 64 conversion commands. A user selectable number of successive conversion commands in the CSL can be grouped as a command sequence. This sequence of conversion commands is successively executed by the ADC at the occurrence of a Trigger Event. The commands of a sequence are successively executed until an “End Of Sequence” or “End Of List” command type identifier in a command is detected (command type is coded via bits CMD_SEL[1:0]). The number of successive conversion commands that belong to a command sequence and the number of command sequences inside the CSL can be freely defined by the user and is limited by the 64 conversion commands a CSL can contain. A CSL must contain at least one conversion command and one “end of list” command type identifier. The minimum number of command sequences inside a CSL is zero and the maximum number of command sequences is 63. A command sequence is defined with bits CMD_SEL[1:0] in the register ADCCMD_M by defining the end of a conversion sequence. The Figure 9-29 and Figure 9-30 provides examples of a CSL.

Figure 9-29. Example CSL with sequences and an “End Of List” command type identifier

Figure 9-30. Example CSL for continues conversion

9.6.3.2.2 Introduction of the two Command Sequence Lists (CSLs)

The two Command Sequence Lists (CSLs) can be referred to via the Command Base Pointer Register plus the Command and Result Offset Registers plus the Command Index Register (ADCCBP, ADCCROFF_0/1, ADCCIDX).

The final address for conversion command loading is calculated by the sum of these registers (e.g.: ADCCBP+ADCCROFF_0+ADCCIDX or ADCCBP+ADCCROFF_1+ADCCIDX).

Bit CSL_BMOD selects if the CSL is used in double buffer or single buffer mode. In double buffer mode, the CSL can be swapped by flow control bits LDOK and RSTA. For detailed information about when and how the CSL is swapped, please refer to [Section 9.6.3.2.5, “The four ADC conversion flow control bits - description of Restart Event + CSL Swap](#), [Section 9.9.7.1, “Initial Start of a Command Sequence List](#) and [Section 9.9.7.3, “Restart CSL execution with new/other CSL \(alternative CSL becomes active CSL\) — CSL swapping](#)

Which list is actively used for ADC command loading is indicated by bit CSL_SEL. The register to define the CSL start addresses (ADCCBP) can be set to any even location of the system RAM or NVM area. It is the user’s responsibility to make sure that the different ADC lists do not overlap or exceed the system RAM or the NVM area, respectively. The error flag IA_EIF will be set for accesses to ranges outside system RAM area and cause an error interrupt if enabled.

Note: Address register names in () are not absolute addresses instead they are a sample offset or sample index

Figure 9-31. Command Sequence List Schema in Double Buffer Mode

Note: Address register names in () are not absolute addresses instead they are a sample offset or sample index

Figure 9-32. Command Sequence List Schema in Single Buffer Mode

While the ADC is enabled, one CSL is active (indicated by bit CSL_SEL) and the corresponding list should not be modified anymore. At the same time the alternative CSL can be modified to prepare the ADC for new conversion sequences in CSL double buffered mode. When the ADC is enabled, the command address registers (ADCCBP, ADCCROFF_0/2, ADCCIDX) are read only and register ADCCIDX is under control of the ADC.

9.6.3.2.3 Introduction of the two Result Value Lists (RVLs)

The same list-based architecture as described above for the CSL has been implemented for the Result Value List (RVL) with corresponding address registers (ADCRBP, ADCCROFF_0/1, ADCRIDX).

The final address for conversion result storage is calculated by the sum of these registers (e.g.: ADCRBP+ADCCROFF_0+ADCRIDX or ADCRBP+ADCCROFF_1+ADCRIDX).

The RVL_BMOD bit selects if the RVL is used in double buffer or single buffer mode. In double buffer mode the RVL is swapped:

- Each time an “End Of List” command type got executed followed by the first conversion from top of the next CSL and related (first) result is about to be stored
- A CSL got aborted (bit SEQA=1'b1) and ADC enters idle state (becomes ready for new flow control events)

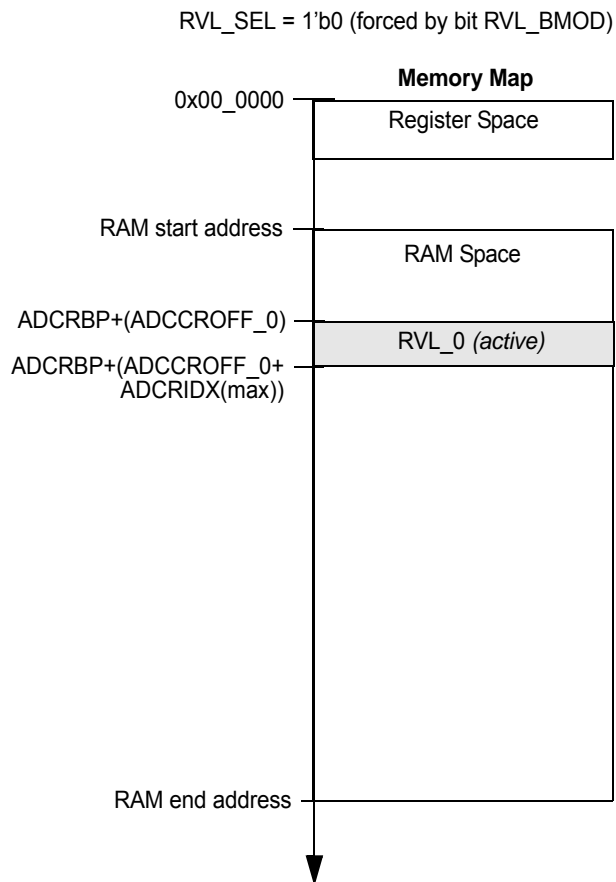

Using the RVL in double buffer mode the RVL is not swapped after exit from Stop Mode or Wait Mode with bit SWAI set. Hence the RVL used before entry of Stop or Wait Mode with bit SWAI set is overwritten after exit from the MCU Operating Mode (see also [Section 9.3.1.2, “MCU Operating Modes](#)).

Which list is actively used for the ADC conversion result storage is indicated by bit RVL_SEL. The register to define the RVL start addresses (ADCRBP) can be set to any even location of the system RAM area. It is the user’s responsibility to make sure that the different ADC lists do not overlap or exceed the system RAM area. The error flag IA_EIF will be set for accesses to ranges outside system RAM area and cause an error interrupt if enabled.

Note: Address register names in () are not absolute addresses instead they are a sample offset or sample index

Figure 9-33. Result Value List Schema in Double Buffer Mode

Note: Address register names in () are not absolute addresses instead they are a sample offset or sample index

Figure 9-34. Result Value List Schema in Single Buffer Mode

While ADC is enabled, one Result Value List is active (indicated by bit RVL_SEL). The conversion Result Value List can be read anytime. When the ADC is enabled the conversion result address registers (ADCRBP, ADCCROFF_0/1, ADCRIDX) are read only and register ADCRIDX is under control of the ADC.

A conversion result is always stored as 16bit entity in unsigned data representation. Left and right justification inside the entity is selected via the DJM control bit. Unused bits inside an entity are stored zero.

Table 9-33. Conversion Result Justification Overview

Conversion Resolution (SRES[1:0])	Left Justified Result (DJM = 1'b0)	Right Justified Result (DJM = 1'b1)
8 bit	{Result[7:0],8'b00000000}	{8'b00000000,Result[7:0]}
10 bit	{Result[9:0],6'b000000}	{6'b000000,Result[9:0]}
12 bit	{Result[11:0],4'b0000}	{4'b0000,Result[11:0]}

9.6.3.2.4 The two conversion flow control Mode Configurations

The ADC provides two modes (“Trigger Mode” and “Restart Mode”) which are different in the conversion control flow. The “Restart Mode” provides precise timing control about the sample start point but is more complex from the flow control perspective, while the “Trigger Mode” is more simple from flow control point of view but is less controllable regarding conversion sample start.

Following are the key differences:

In “Trigger Mode” configuration, when conversion flow control bit RSTA gets set the bit TRIG gets set automatically. Hence in “Trigger Mode” the applications should not set the bit TRIG and bit RSTA simultaneously (via data bus or internal interface), because it is a flow control failure and the ADC will cease operation.

In “Trigger Mode” configuration, after the execution of the initial Restart Event the current CSL can be executed and controlled via Trigger Events only. Hence, if the “End Of List” command is reached a restart of conversion flow from top of current CSL does not require to set bit RSTA because returning to the top of current CSL is done automatically. Therefore the current CSL can be executed again after the “End Of List” command type is executed by a Trigger Event only.

In “Restart Mode” configuration, the execution of a CSL is controlled via Trigger Events and Restart Events. After execution of the “End Of List” command the conversion flow must be continued by a Restart Event followed by a Trigger Event and the Trigger Event must not occur before the Restart Event has finished.

For more details and examples regarding flow control and application use cases please see following section and [Section 9.9.7, “Conversion flow control application information.](#)

9.6.3.2.5 The four ADC conversion flow control bits

There are four bits to control conversion flow (execution of a CSL and CSL exchange in double buffer mode). Each bit is controllable via the data bus and internal interface depending on the setting of ACC_CFG[1:0] bits (see also [Figure 9-2](#)). In the following the conversion control event to control the conversion flow is given with the related internal interface signal and corresponding register bit name together with information regarding:

- Function of the conversion control event
- How to request the event
- When is the event finished
- Mandatory requirements to executed the event

A summary of all event combinations is provided by [Table 9-11](#).

- **Trigger Event**
Internal Interface Signal: Trigger
Corresponding Bit Name: TRIG

- *Function:*
Start the first conversion of a conversion sequence which is defined in the active Command Sequence List
 - *Requested by:*
 - Positive edge of internal interface signal Trigger
 - Write Access via data bus to set control bit TRIG
 - *When finished:*
This bit is cleared by the ADC when the first conversion of the sequence is beginning to sample
 - *Mandatory Requirements:*
 - In all ADC conversion flow control modes bit TRIG is only set (Trigger Event executed) if the Trigger Event occurs while no conversion or conversion sequence is ongoing (ADC idle)
 - In ADC conversion flow control mode “Restart Mode” with a Restart Event in progress it is not allowed that a Trigger Event occurs before the background command load phase has finished (Restart Event has been executed) else the error flag TRIG{EIF is set
 - In ADC conversion flow control mode “Trigger Mode” a Restart Event causes bit TRIG being set automatically. Bit TRIG is set when no conversion or conversion sequence is ongoing (ADC idle) and the RVL done condition is reached by one of the following:
 - * A “End Of List” command type has been executed
 - * A Sequence Abort Event is in progress or has been executed
The ADC executes the Restart Event followed by the Trigger Event.
 - In ADC conversion flow control mode “Trigger Mode” a Restart Event and a simultaneous Trigger Event via internal interface or data bus causes the TRIG{EIF bit being set and ADC cease operation.
- **Restart Event** (with current active CSL)
Internal Interface Signal: Restart
Corresponding Bit Name: RSTA
 - *Function:*
 - Go to top of active CSL (clear index register for CSL)
 - Load one background command register and wait for Trigger (CSL offset register is not switched independent of bit CSL_BMOD)
 - Set error flag RSTA{EIF when a Restart Request occurs before one of the following conditions was reached:
 - * The "End Of List" command type has been executed
 - * Depending on bit STR_SEQA if the "End Of List" command type is about to be executed
 - * The current CSL has been aborted or is about to be aborted due to a Sequence Abort Request.
 - *Requested by:*
 - Positive edge of internal interface signal Restart
 - Write Access via data bus to set control bit RSTA

- *When finished:*
This bit is cleared when the first conversion command of the sequence from top of active Sequence Command List is loaded
- *Mandatory Requirement:*
 - In all ADC conversion flow control modes a Restart Event causes bit RSTA to be set. Bit SEQA is set simultaneously by ADC hardware if:
 - * ADC not idle (a conversion or conversion sequence is ongoing and current CSL not finished) and no Sequence Abort Event in progress (bit SEQA not already set or set simultaneously via internal interface or data bus)
 - * ADC idle but RVL done condition not reached
 The RVL done condition is reached by one of the following:
 - * A “End Of List” command type has been executed
 - * A Sequence Abort Event is in progress or has been executed (bit SEQA already set or set simultaneously via internal interface or data bus)
 The ADC executes the Sequence Abort Event followed by the Restart Event for the conditions described before or only a Restart Event.
 - In ADC conversion flow control mode “Trigger Mode” a Restart Event causes bit TRIG being set automatically. Bit TRIG is set when no conversion or conversion sequence is ongoing (ADC idle) and the RVL done condition is reached by one of the following:
 - * A “End Of List” command type has been executed
 - * A Sequence Abort Event is in progress or has been executed
 The ADC executes the Restart Event followed by the Trigger Event.
 - In ADC conversion flow control mode “Trigger Mode” a Restart Event and a simultaneous Trigger Event via internal interface or data bus causes the TRIG_EIF bit being set and ADC cease operation.
- **Restart Event + CSL Exchange (Swap)**
Internal Interface Signals: Restart + LoadOK
Corresponding Bit Names: RSTA + LDOK
 - *Function:*
Go to top of active CSL (clear index register for CSL) and switch to other offset register for address calculation if configured for double buffer mode (exchange the CSL list)
Requested by:
 - Internal interface with the assertion of Interface Signal Restart the interface Signal LoadOK is evaluated and bit LDOK is set accordingly (bit LDOK set if Interface Signal LoadOK asserted when Interface Signal Restart asserts).
 - Write Access via data bus to set control bit RSTA simultaneously with bit LDOK.
 - *When finished:*
Bit LDOK can only be cleared if it was set as described before and both bits (LDOK, RSTA) are cleared when the first conversion command from top of active Sequence Command List is loaded
 - *Mandatory Requirement:*
No ongoing conversion or conversion sequence
Details if using the internal interface:

If signal Restart is asserted before signal LoadOK is set the conversion starts from top of currently active CSL at the next Trigger Event (no exchange of CSL list).

If signal Restart is asserted after or simultaneously with signal LoadOK the conversion starts from top of the other CSL at the next Trigger Event (CSL is switched) if CSL is configured for double buffer mode.

- **Sequence Abort Event**

Internal Interface Signal: Seq_Abort

Corresponding Bit Name: SEQA

- *Function:*
Abort any possible ongoing conversion at next conversion boundary and abort current conversion sequence and active CSL
- *Requested by:*
 - Positive edge of internal interface signal Seq_Abort
 - Write Access via data bus to set control bit SEQA
- *When finished:*
This bit gets cleared when an ongoing conversion is finished and the result is stored and/or an ongoing conversion sequence is aborted and current active CSL is aborted (ADC idle, RVL done)
- *Mandatory Requirement:*
 - In all ADC conversion flow control modes bit SEQA can only be set if:
 - * ADC not idle (a conversion or conversion sequence is ongoing)
 - * ADC idle but RVL done condition not reached
 The RVL done condition is not reached if:
 - * An “End Of List” command type has not been executed
 - * A Sequence Abort Event has not been executed (bit SEQA not already set)
 - In all ADC conversion flow control modes a Sequence Abort Event can be issued at any time
 - In ADC conversion flow control mode “Restart Mode” after a conversion sequence abort request has been executed it is mandatory to set bit RSTA. If a Trigger Event occurs before a Restart Event is executed (bit RSTA set and cleared by hardware), bit TRIG is set, error flag TRIG_EIF is set, and the ADC can only be continued by a Soft-Reset. After the Restart Event the ADC accepts new Trigger Events (bit TRIG set) and begins conversion from top of the currently active CSL.
 - In ADC conversion flow control mode “Restart Mode” after a Sequence Abort Event has been executed, a Restart Event causes only the RSTA bit being set. The ADC executes a Restart Event only.
- In both conversion flow control modes (“Restart Mode” and “Trigger Mode”) when conversion flow control bit RSTA gets set automatically bit SEQA gets set when the ADC has not reached one of the following scenarios:
 - * An “End Of List” command type has been executed or is about to be executed
 - * A Sequence Abort request is about to be executed or has been executed.
 In case bit SEQA is set automatically the Restart error flag RSTA_EIF is set to indicate an unexpected Restart Request.

9.6.3.2.6 Conversion flow control in case of conversion sequence control bit overrun scenarios

Restart Request Overrun:

If a legal Restart Request is detected and no Restart Event is in progress, the RSTA bit is set due to the request. The set RSTA bit indicates that a Restart Request was detected and the Restart Event is in process. In case further Restart Requests occur while the RSTA bit is set, this is defined as an overrun situation. This scenario is likely to occur when bit STR_SEQA is set or when a Restart Event causes a Sequence Abort Event. The request overrun is captured in a background register that always stores the last detected overrun request. Hence if the overrun situation occurs more than once while a Restart Event is in progress, only the latest overrun request is pending. When the RSTA bit is cleared, the latest overrun request is processed and RSTA is set again one cycle later.

LoadOK Overrun:

Simultaneously at any Restart Request overrun situation the LoadOK input is evaluated and the status is captured in a background register which is alternated anytime a Restart Request Overrun occurs while Load OK Request is asserted. The Load OK background register is cleared as soon as the pending Restart Request gets processed.

Trigger Overrun:

If a Trigger occurs whilst bit TRIG is already set, this is defined as a Trigger overrun situation and causes the ADC to cease conversion at the next conversion boundary and to set bit TRIG_EIF. An overrun is also detected if the Trigger Event occurs automatically generated by hardware in “Trigger Mode” due to a Restart Event and simultaneously a Trigger Event is generated via data bus or internal interface. In this case the ADC ceases operation before conversion begins to sample. In “Trigger Mode” a Restart Request Overrun does not cause a Trigger Overrun (bit TRIG_EIF not set).

Sequence Abort Request Overrun:

If a Sequence Abort Request occurs whilst bit SEQA is already set, this is defined as a Sequence Abort Request Overrun situation and the overrun request is ignored.

9.6.3.3 ADC List Usage and Conversion/Conversion Sequence Flow Description

It is the user's responsibility to make sure that the different lists do not overlap or exceed the system RAM area respectively the CSL does not exceed the NVM area if located in the NVM. The error flag IA_EIF will be set for accesses done outside the system RAM area and will cause an error interrupt if enabled for lists that are located in the system RAM.

Generic flow for ADC register load at conversion sequence start/restart:

- It is mandatory that the ADC is idle (no ongoing conversion or conversion sequence).
- It is mandatory to have at least one CSL with valid entries. See also [Section 9.9.7.2, "Restart CSL execution with currently active CSL"](#) or [Section 9.9.7.3, "Restart CSL execution with new/other CSL \(alternative CSL becomes active CSL\) — CSL swapping"](#) for more details on possible scenarios.
- A Restart Event occurs, which causes the index registers to be cleared (register ADCCIDX and ADCRIDX are cleared) and to point to the top of the corresponding lists (top of active RVL and CSL).
- Load conversion command to background conversion command register 1.
- The control bit(s) RSTA (and LDOK if set) are cleared.
- Wait for Trigger Event to start conversion.

Generic flow for ADC register load during conversion:

- The index registers ADCCIDX is incremented.
- The inactive background command register is loaded with a new conversion command.

Generic flow for ADC result storage at end of conversion:

- Index register ADCRIDX is incremented and the conversion result is stored in system RAM. As soon as the result is successfully stored, any conversion interrupt flags are set accordingly.
- At the conversion boundary the other background command register becomes active and visible in the ADC register map.
- If the last executed conversion command was of type "End Of Sequence", the ADC waits for the Trigger Event.
- If the last executed conversion command was of type "End Of List" and the ADC is configured in "Restart Mode", the ADC sets all related flags and stays idle awaiting a Restart Event to continue.
- If the last executed conversion command was of type "End Of List" and the ADC is configured in "Trigger Mode", the ADC sets all related flags and automatically returns to top of current CSL and is awaiting a Trigger Event to continue.
- If the last executed conversion command was of type "Normal Conversion" the ADC continues command execution in the order of the current CSL (continues conversion).

9.7 Resets

At reset the ADC12B_LBA is disabled and in a power down state. The reset state of each individual bit is listed within [Section 9.5.2, “Register Descriptions”](#) which details the registers and their bit-fields.

9.8 Interrupts

The ADC supports three types of interrupts:

- Conversion Interrupt
- Sequence Abort Interrupt
- Error and Conversion Flow Control Issue Interrupt

Each of the interrupt types is associated with individual interrupt enable bits and interrupt flags.

9.8.1 ADC Conversion Interrupt

The ADC provides one conversion interrupt associated to 16 interrupt enable bits with dedicated interrupt flags. The 16 interrupt flags consist of:

- 15 conversion interrupt flags which can be associated to any conversion completion.
- One additional interrupt flag which is fixed to the “End Of List” conversion command type within the active CSL.

The association of the conversion number with the interrupt flag number is done in the conversion command.

9.8.2 ADC Sequence Abort Done Interrupt

The ADC provides one sequence abort done interrupt associated with the sequence abort request for conversion flow control. Hence, there is only one dedicated interrupt flag and interrupt enable bit for conversion sequence abort and it occurs when the sequence abort is done.

9.8.3 ADC Error and Conversion Flow Control Issue Interrupt

The ADC provides one error interrupt for four error classes related to conversion interrupt overflow, command validness, DMA access status and Conversion Flow Control issues, and CSL failure. The following error interrupt flags belong to the group of severe issues which cause an error interrupt if enabled and cease ADC operation:

- IA{EIF
- CMD{EIF
- EOL{EIF
- TRIG{EIF

In order to make the ADC operational again, an ADC Soft-Reset must be issued which clears the above listed error interrupt flags.

NOTE

It is important to note that if flag DBECC_ERR is set, the ADC ceases operation as well, but does not cause an ADC error interrupt. Instead, a machine exception is issued. In order to make the ADC operational again an ADC Soft-Reset must be issued.

Remaining error interrupt flags cause an error interrupt if enabled, but ADC continues operation. The related interrupt flags are:

- RSTAR{EIF
- LDOK{EIF
- CONIF_OIF

9.9 Use Cases and Application Information

9.9.1 List Usage — CSL single buffer mode and RVL single buffer mode

In this use case both list types are configured for single buffer mode (CSL_BMOD=1'b0 and RVL_BMOD=1'b0, CSL_SEL and RVL_SEL are forced to 1'b0). The index register for the CSL and RVL are cleared to start from the top of the list with next conversion command and result storage in the following cases:

- The conversion flow reaches the command containing the “End-of-List” command type identifier
- A Restart Request occurs at a sequence boundary
- After an aborted conversion or conversion sequence

Figure 9-35. CSL Single Buffer Mode — RVL Single Buffer Mode Diagram

9.9.2 List Usage — CSL single buffer mode and RVL double buffer mode

In this use case the CSL is configured for single buffer mode (CSL_BMOD=1'b0) and the RVL is configured for double buffer mode (RVL_BMOD=1'b1). In this buffer configuration only the result list RVL is switched when the first conversion result of a CSL is stored after a CSL was successfully finished or a CSL got aborted.

Figure 9-36. CSL Single Buffer Mode — RVL Single Buffer Mode Diagram

The last entirely filled RVL (an RVL where the corresponding CSL has been executed including the “End Of List “ command type) is shown by register ADCEOLRI.

The CSL is used in single buffer mode and bit CSL_SEL is forced to 1'b0.

9.9.3 List Usage — CSL double buffer mode and RVL double buffer mode

In this use case both list types are configured for double buffer mode (CSL_BMOD=1'b1 and RVL_BMOD=1'b1) and whenever a Command Sequence List (CSL) is finished or aborted the command Sequence List is swapped by the simultaneous assertion of bits LDOK and RSTA.

Figure 9-37. CSL Double Buffer Mode — RVL Double Buffer Mode Diagram

This use case can be used if the channel order or CSL length varies very frequently in an application.

9.9.4 List Usage — CSL double buffer mode and RVL single buffer mode

In this use case the CSL is configured for double buffer mode (CSL_BMOD=1'b1) and the RVL is configured for single buffer mode (RVL_BMOD=1'b0).

The two command lists can be different sizes and the allocated result list memory area in the RAM must be able to hold as many entries as the larger of the two command lists. Each time when the end of a Command Sequence List is reached, if bits LDOK and RSTA are set, the commands list is swapped.

Figure 9-38. CSL Double Buffer Mode — RVL Single Buffer Mode Diagram

9.9.5 List Usage — CSL double buffer mode and RVL double buffer mode

In this use case both list types are configured for double buffer mode (CSL_BMOD=1'b1) and RVL_BMOD=1'b1).

This setup is the same as [Section 9.9.3, “List Usage — CSL double buffer mode and RVL double buffer mode”](#) but at the end of a CSL the CSL is not always swapped (bit LDOK not always set with bit RSTA). The Result Value List is swapped whenever a CSL is finished or a CSL got aborted.

Figure 9-39. CSL Double Buffer Mode — RVL Double Buffer Mode Diagram

9.9.6 RVL swapping in RVL double buffer mode and related registers ADCIMDRI and ADCEOLRI

When using the RVL in double buffer mode, the registers ADCIMDRI and ADCEOLRI can be used by the application software to identify which RVL holds relevant and latest data and which CSL is related to this data. These registers are updated at the setting of one of the CON_IF[15:1] or the EOL_IF interrupt flags. As described in the register description [Section 9.5.2.13, “ADC Intermediate Result Information Register \(ADCIMDRI\)”](#) and [Section 9.5.2.14, “ADC End Of List Result Information Register \(ADCEOLRI\)”](#), the register ADCIMDRI, for instance, is always updated at the occurrence of a CON_IF[15:1] interrupt flag amongst other cases. Also each time the last conversion command of a CSL is finished and the corresponding result is stored, the related EOL_IF flag is set and register ADCEOLRI is updated. Hence application software can pick up conversion results, or groups of results, or an entire result list driven fully by interrupts. A use case example diagram is shown in [Figure 9-40](#).

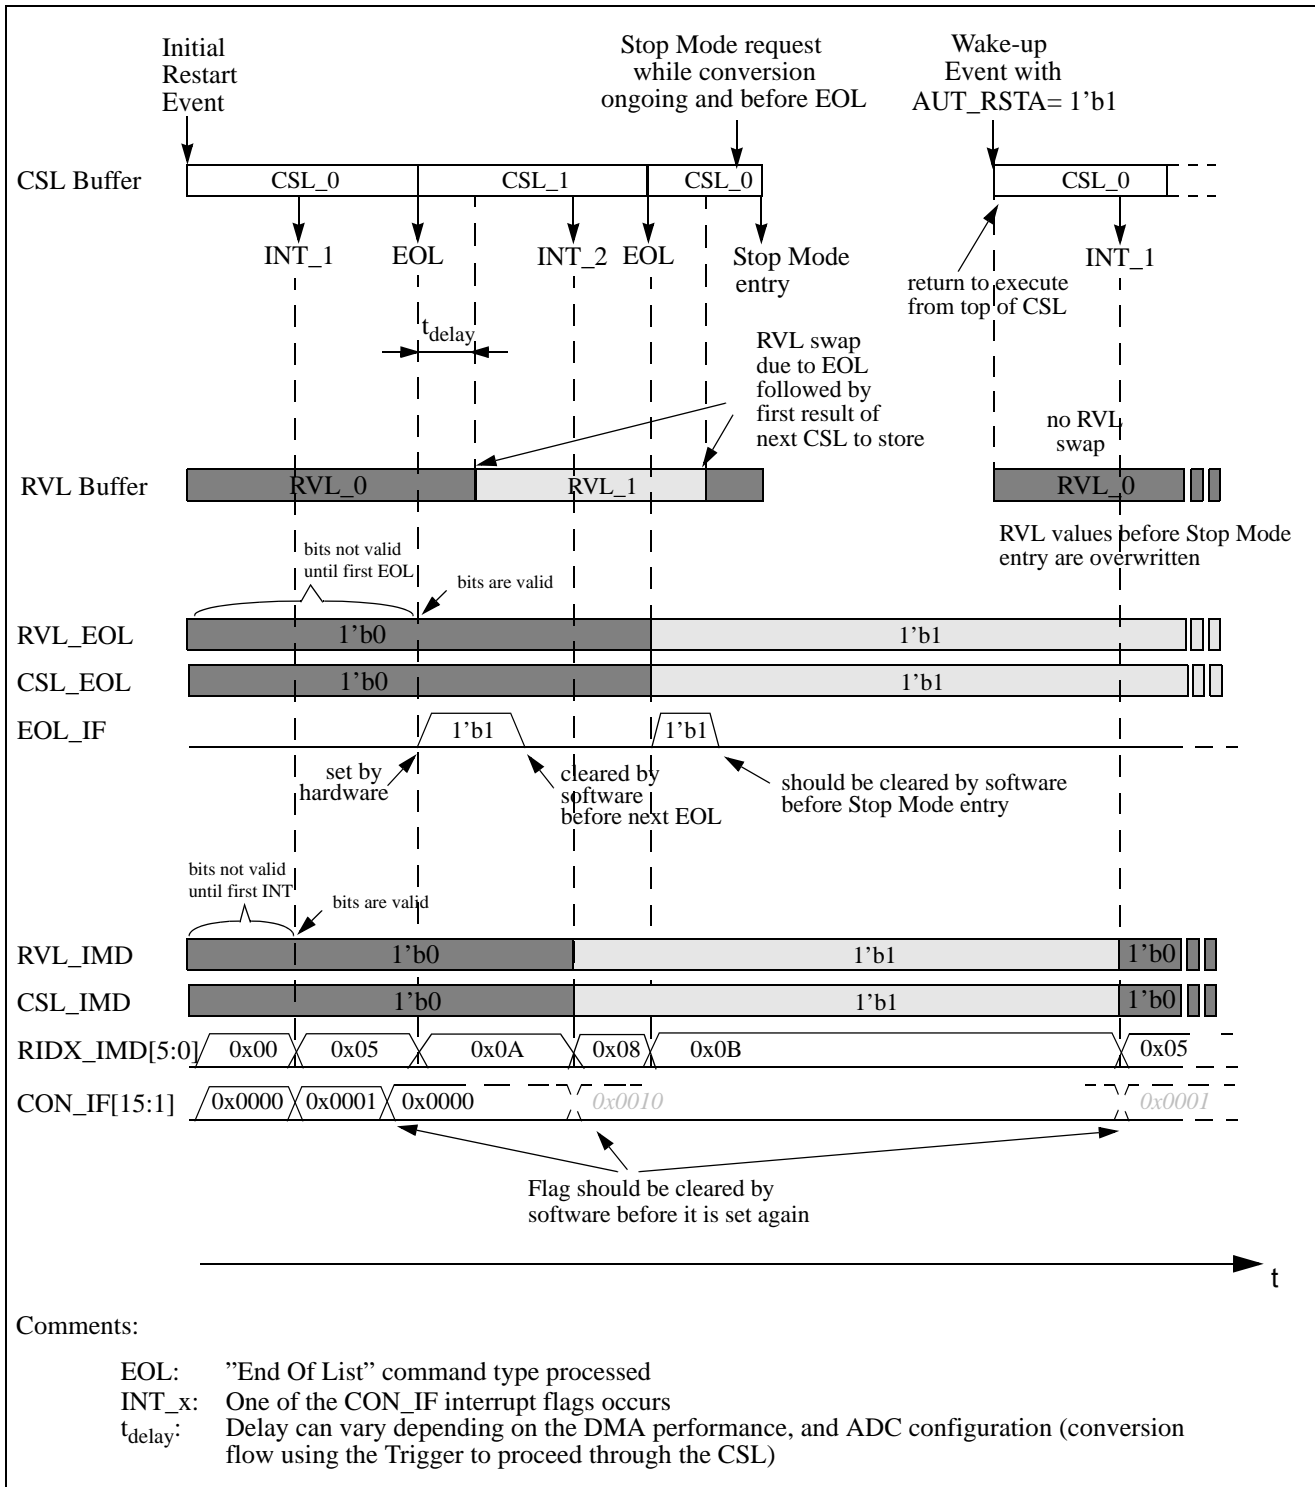

Figure 9-40. RVL Swapping — Use Case Diagram

9.9.7 Conversion flow control application information

The ADC12B_LBA provides various conversion control scenarios to the user accomplished by the following features.

The ADC conversion flow control can be realized via the data bus only, the internal interface only, or by both access methods. The method used is software configurable via bits ACC_CFG[1:0].

The conversion flow is controlled via the four conversion flow control bits: SEQA, TRIG, RSTA, and LDOK.

Two different conversion flow control modes can be configured: Trigger Mode or Restart Mode
Single or double buffer configuration of CSL and RVL.

9.9.7.1 Initial Start of a Command Sequence List

At the initial start of a Command Sequence List after device reset all entries for at least one of the two CSL must have been completed and data must be valid. Depending on if the CSL_0 or the CSL_1 should be executed at the initial start of a Command Sequence List the following conversion control sequence must be applied:

If CSL_0 should be executed at the initial conversion start after device reset:

A Restart Event and a Trigger Event must occur (depending to the selected conversion flow control mode the events must occur one after the other or simultaneously) which causes the ADC to start conversion with commands loaded from CSL_0.

If CSL_1 should be executed at the initial conversion start after device reset:

Bit LDOK must be set simultaneously with the Restart Event followed by a Trigger Event (depending on the selected conversion flow control mode the Trigger events must occur simultaneously or after the Restart Event is finished). As soon as the Trigger Event gets executed the ADC starts conversion with commands loaded from CSL_1.

As soon as a new valid Restart Event occurs the flow for ADC register load at conversion sequence start as described in [Section 9.6.3.3, “ADC List Usage and Conversion/Conversion Sequence Flow Description](#) applies.

9.9.7.2 Restart CSL execution with currently active CSL

To restart a Command Sequence List execution it is mandatory that the ADC is idle (no conversion or conversion sequence is ongoing).

If necessary, a possible ongoing conversion sequence can be aborted by the Sequence Abort Event (setting bit SEQA). As soon as bit SEQA is cleared by the ADC, the current conversion sequence has been aborted and the ADC is idle (no conversion sequence or conversion ongoing).

After a conversion sequence abort is executed it is mandatory to request a Restart Event (bit RSTA set). After the Restart Event is finished (bit RSTA is cleared), the ADC accepts a new Trigger Event (bit TRIG can be set) and begins conversion from the top of the currently active CSL. In conversion flow control

mode “Trigger Mode” only a Restart Event is necessary if ADC is idle to restart Conversion Sequence List execution (the Trigger Event occurs automatically).

It is possible to set bit RSTA and SEQA simultaneously, causing a Sequence Abort Event followed by a Restart Event. In this case the error flags behave differently depending on the selected conversion flow control mode:

- Setting both flow control bits simultaneously in conversion flow control mode “Restart Mode” prevents the error flags RSTA_EIF and LDOK_EIF from occurring.
- Setting both flow control bits simultaneously in conversion flow control mode “Trigger Mode” prevents the error flag RSTA_EIF from occurring.

If only a Restart Event occurs while ADC is not idle and bit SEQA is not set already (Sequence Abort Event in progress) a Sequence Abort Event is issued automatically and bit RSTAR_EIF is set.

Please see also the detailed conversion flow control bit mandatory requirements and execution information for bit RSTA and SEQA described in [Section 9.6.3.2.5, “The four ADC conversion flow control bits.”](#)

9.9.7.3 Restart CSL execution with new/other CSL (alternative CSL becomes active CSL) — CSL swapping

After all alternative conversion command list entries are finished the bit LDOK can be set simultaneously with the next Restart Event to swap command buffers.

To start conversion command list execution it is mandatory that the ADC is idle (no conversion or conversion sequence is ongoing).

If necessary, a possible ongoing conversion sequence can be aborted by the Sequence Abort Event (setting bit SEQA). As soon as bit SEQA is cleared by the ADC, the current conversion sequence has been aborted and the ADC is idle (no conversion sequence or conversion ongoing).

After a conversion sequence abort is executed it is mandatory to request a Restart Event (bit RSTA set) and simultaneously set bit LDOK to swap the CSL buffer. After the Restart Event is finished (bit RSTA and LDOK are cleared), the ADC accepts a new Trigger Event (bit TRIG can be set) and begins conversion from the top of the newly selected CSL buffer. In conversion flow control mode “Trigger Mode” only a Restart Event (simultaneously with bit LDOK being set) is necessary to restart conversion command list execution with the newly selected CSL buffer (the Trigger Event occurs automatically).

It is possible to set bits RSTA, LDOK and SEQA simultaneously, causing a Sequence Abort Event followed by a Restart Event. In this case the error flags behave differently depending on the selected conversion flow control mode:

- Setting these three flow control bits simultaneously in “Restart Mode” prevents the error flags RSTA_EIF and LDOK_EIF from occurring.
- Setting these three flow control bits simultaneously in “Trigger Mode” prevents the error flag RSTA_EIF from occurring.

If only a Restart Event occurs while ADC is not idle and bit SEQA is not set already (Sequence Abort Event in progress) a Sequence Abort Event is issued automatically and bit RSTAR_EIF is set.

Please see also the detailed conversion flow control bit mandatory requirements and execution information for bit RSTA and SEQA described in [Section 9.6.3.2.5](#), “The four ADC conversion flow control bits.

9.9.8 Continuous Conversion

Applications that only need to continuously convert a list of channels, without the need for timing control or the ability to perform different sequences of conversions (grouped number of different channels to convert) can make use of the following simple setup:

- “Trigger Mode” configuration
- Single buffer CSL
- Depending on data transfer rate either use single or double buffer RVL configuration
- Define a list of conversion commands which only contains the “End Of List” command with automatic wrap to top of CSL

After finishing the configuration and enabling the ADC an initial Restart Event is sufficient to launch the continuous conversion until next device reset or low power mode.

In case a Low Power Mode is used:

If bit AUT_RSTA is set before Low Power Mode is entered the conversion continues automatically as soon as a low power mode (Stop Mode or Wait Mode with bit SWAI set) is exited.

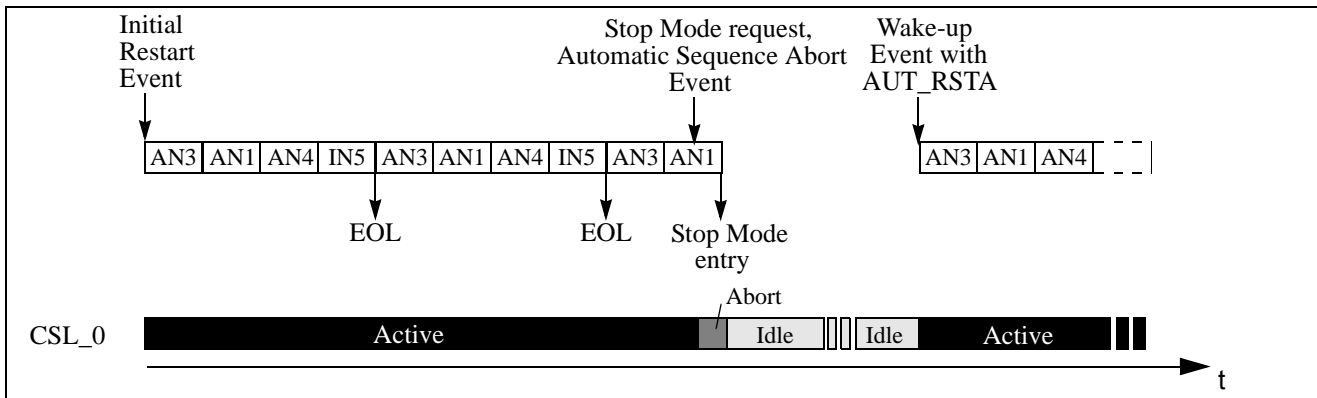

Figure 9-41. Conversion Flow Control Diagram — Continuous Conversion (with Stop Mode)

9.9.9 Triggered Conversion — Single CSL

Applications that require the conversion of one or more groups of different channels in a periodic and timed manner can make use of a configuration in “Trigger Mode” with a single CSL containing a list of sequences. This means the CSL consists of several sequences each separated by an “End of Sequence” command. The last command of the CSL uses the “End Of List” command with wrap to top of CSL and waiting for a Trigger (CMD_SEL[1:0] = 2'b11). Hence after the initial Restart Event each sequence can be launched via a Trigger Event and repetition of the CSL can be launched via a Trigger after execution of the “End Of List” command.

Figure 9-42. Conversion Flow Control Diagram — Triggered Conversion (CSL Repetition)

Figure 9-43. Conversion Flow Control Diagram — Triggered Conversion (with Stop Mode)

In case a Low Power Mode is used:

If bit AUT_RSTA is set before Low Power Mode is entered, the conversion continues automatically as soon as a low power mode (Stop Mode or Wait Mode with bit SWAI set) is exited.

9.9.10 Fully Timing Controlled Conversion

As described previously, in “Trigger Mode” a Restart Event automatically causes a trigger. To have full and precise timing control of the beginning of any conversion/sequence the “Restart Mode” is available. In “Restart Mode” a Restart Event does not cause a Trigger automatically; instead, the Trigger must be issued separately and with correct timing, which means the Trigger is not allowed before the Restart Event (conversion command loading) is finished (bit RSTA=1'b0 again). The time required from Trigger until sampling phase starts is given (refer to [Section 9.5.2.6, “ADC Conversion Flow Control Register \(ADCFLWCTL\), Timing considerations](#)) and hence timing is fully controllable by the application. Additionally, if a Trigger occurs before a Restart Event is finished, this causes the TRIG_EIF flag being set. This allows detection of false flow control sequences.

Figure 9-44. Conversion Flow Control Diagram — Fully Timing Controlled Conversion (with Stop Mode)

Unlike the Stop Mode entry shown in [Figure 9-43](#) and [Figure 9-44](#) it is recommended to issue the Stop Mode at sequence boundaries (when ADC is idle and no conversion/conversion sequence is ongoing).

Any of the Conversion flow control application use cases described above (Continuous, Triggered, or Fully Timing Controlled Conversion) can be used with CSL single buffer mode or with CSL double buffer mode. If using CSL double buffer mode, CSL swapping is performed by issuing a Restart Event with bit LDOK set.

Chapter 10

Supply Voltage Sensor - (BATSV3)

Table 10-1. Revision History Table

Rev. No. (Item No.)	Data	Sections Affected	Substantial Change(s)
V01.00	15 Dec 2010	all	Initial Version
V02.00	16 Mar 2011	10.3.2.1 10.4.2.1	- added BVLS[1] to support four voltage level - moved BVHS to register bit 6
V03.00	26 Apr 2011	all	- removed Vsense
V03.10	04 Oct 2011	10.4.2.1 and 10.4.2.2	- removed BSESE

10.1 Introduction

The BATS module provides the functionality to measure the voltage of the chip supply pin VSUP.

10.1.1 Features

The VSUP pin can be routed via an internal divider to the internal Analog to Digital Converter. Independent of the routing to the Analog to Digital Converter, it is possible to route this voltage to a comparator to generate a low or a high voltage interrupt to alert the MCU.

10.1.2 Modes of Operation

The BATS module behaves as follows in the system power modes:

1. Run mode

The activation of the VSUP Level Sense Enable (BSUSE=1) or ADC connection Enable (BSUAE=1) closes the path from VSUP pin through the resistor chain to ground and enables the associated features if selected.

2. Stop mode

During stop mode operation the path from the VSUP pin through the resistor chain to ground is opened and the low and high voltage sense features are disabled.

The content of the configuration register is unchanged.

10.1.3 Block Diagram

Figure 10-1 shows a block diagram of the BATS module. See device guide for connectivity to ADC channel.

Figure 10-1. BATS Block Diagram

1 automatically closed if BSUSE and/or BSUAE is active, open during Stop mode

10.2 External Signal Description

This section lists the name and description of all external ports.

10.2.1 VSUP — Voltage Supply Pin

This pin is the chip supply. It can be internally connected for voltage measurement. The voltage present at this input is scaled down by an internal voltage divider, and can be routed to the internal ADC or to a comparator.

10.3 Memory Map and Register Definition

This section provides the detailed information of all registers for the BATS module.

10.3.1 Register Summary

Figure 10-2 shows the summary of all implemented registers inside the BATS module.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 BATE	R	0	BVHS	BVLS[1:0]		BSUAE	BSUSE	0	0
	W								
0x0001 BATSr	R	0	0	0	0	0	0	BVHC	BVLC
	W								
0x0002 BATIE	R	0	0	0	0	0	0	BVHIE	BVLIE
	W								
0x0003 BATIF	R	0	0	0	0	0	0	BVHIF	BVLIF
	W

Figure 10-2. BATS Register Summary

10.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order. Unused bits read back zero.

10.3.2.1 BATS Module Enable Register (BATE)

Figure 10-3. BATS Module Enable Register (BATE)

1. Read: Anytime
Write: Anytime

Table 10-2. BATE Field Description

Field	Description
6 BVHS	<p>BATS Voltage High Select — This bit selects the trigger level for the Voltage Level High Condition (BVHC).</p> <p>0 Voltage level V_{HB11} is selected 1 Voltage level V_{HB12} is selected</p>
5:4 BVLS[1:0]	<p>BATS Voltage Low Select — This bit selects the trigger level for the Voltage Level Low Condition (BVLC).</p> <p>00 Voltage level V_{LB11} is selected 01 Voltage level V_{LB12} is selected 10 Voltage level V_{LB13} is selected 11 Voltage level V_{LB14} is selected</p>
3 BSUAE	<p>BATS VSUP ADC Connection Enable — This bit connects the VSUP pin through the resistor chain to ground and connects the ADC channel to the divided down voltage.</p> <p>0 ADC Channel is disconnected 1 ADC Channel is connected</p>
2 BSUSE	<p>BATS VSUP Level Sense Enable — This bit connects the VSUP pin through the resistor chain to ground and enables the Voltage Level Sense features measuring BVLC and BVHC.</p> <p>0 Level Sense features disabled 1 Level Sense features enabled</p>

NOTE

When opening the resistors path to ground by changing BSUSE or BSUAE then for a time T_{EN_UNC} + two bus cycles the measured value is invalid. This is to let internal nodes be charged to correct value. BVHIE, BVLIE might be cleared for this time period to avoid false interrupts.

10.3.2.2 BATS Module Status Register (BATSR)

Figure 10-4. BATS Module Status Register (BATSR)

0 BVLIE	BATS Interrupt Enable Low — Enables Low Voltage Interrupt . 0 No interrupt will be requested whenever BVLIF flag is set . 1 Interrupt will be requested whenever BVLIF flag is set .

10.3.2.4 BATS Interrupt Flag Register (BATIF)

Figure 10-7. BATS Interrupt Flag Register (BATIF)

1. Read: Anytime
Write: Anytime, write 1 to clear

Table 10-5. BATIF Register Field Descriptions

Field	Description
1 BVHIF	BATS Interrupt Flag High Detect — The flag is set to 1 when BVHC status bit changes. 0 No change of the BVHC status bit since the last clearing of the flag. 1 BVHC status bit has changed since the last clearing of the flag.
0 BVLIF	BATS Interrupt Flag Low Detect — The flag is set to 1 when BVLC status bit changes. 0 No change of the BVLC status bit since the last clearing of the flag. 1 BVLC status bit has changed since the last clearing of the flag.

10.3.2.5 Reserved Register

Figure 10-8. Reserved Register

1. Read: Anytime
Write: Only in special mode

NOTE

These reserved registers are designed for factory test purposes only and are not intended for general user access. Writing to these registers when in special mode can alter the module's functionality.

10.4 Functional Description

10.4.1 General

The BATS module allows measuring the voltage on the VSUP pin. The voltage at the VSUP pin can be routed via an internal voltage divider to an internal Analog to Digital Converter Channel. Also the BATS module can be configured to generate a low and high voltage interrupt based on VSUP. The trigger level of the high and low interrupt are selectable.

10.4.2 Interrupts

This section describes the interrupt generated by the BATS module. The interrupt is only available in CPU run mode. Entering and exiting CPU stop mode has no effect on the interrupt flags.

To make sure the interrupt generation works properly the bus clock frequency must be higher than the Voltage Warning Low Pass Filter frequency (f_{VWLP_filter}).

The comparator outputs BVLC and BVHC are forced to zero if the comparator is disabled (configuration bit BSUSE is cleared). If the software disables the comparator during a high or low Voltage condition (BVHC or BVLC active), then an additional interrupt is generated. To avoid this behavior the software must disable the interrupt generation before disabling the comparator.

The BATS interrupt vector is named in [Table 10-6](#). Vector addresses and interrupt priorities are defined at MCU level.

The module internal interrupt sources are combined into one module interrupt signal.

Table 10-6. BATS Interrupt Sources

Module Interrupt Source	Module Internal Interrupt Source	Local Enable
BATS Interrupt (BATI)	BATS Voltage Low Condition Interrupt (BVLI)	BVLIE = 1
	BATS Voltage High Condition Interrupt (BVHI)	BVHIE = 1

10.4.2.1 BATS Voltage Low Condition Interrupt (BVLI)

To use the Voltage Low Interrupt the Level Sensing must be enabled (BSUSE = 1).

If measured when

- a) V_{LBI1} selected with $BVLS[1:0] = 0x0$
 $V_{measure} < V_{LBI1_A}$ (falling edge) or $V_{measure} < V_{LBI1_D}$ (rising edge)

or when

- b) V_{LBI2} selected with $BVLS[1:0] = 0x1$ at pin VSUP
 $V_{measure} < V_{LBI2_A}$ (falling edge) or $V_{measure} < V_{LBI2_D}$ (rising edge)

or when

- c) V_{LBI3} selected with $BVLS[1:0] = 0x2$
 $V_{measure} < V_{LBI3_A}$ (falling edge) or $V_{measure} < V_{LBI3_D}$ (rising edge)

or when

- d) V_{LBI4} selected with $BVLS[1:0] = 0x3$
 $V_{measure} < V_{LBI4_A}$ (falling edge) or $V_{measure} < V_{LBI4_D}$ (rising edge)

then BVLC is set. BVLC status bit indicates that a low voltage at pin VSUP is present. The Low Voltage Interrupt flag (BVLIF) is set to 1 when the Voltage Low Condition (BVLC) changes state. The Interrupt flag BVLIF can only be cleared by writing a 1. If the interrupt is enabled by bit BVLIE the module requests an interrupt to MCU (BATI).

10.4.2.2 BATS Voltage High Condition Interrupt (BVHI)

To use the Voltage High Interrupt the Level Sensing must be enabled (BSUSE=1).

If measured when

- a) V_{HBI1} selected with $\text{BVHS} = 0$
 $V_{\text{measure}} \geq V_{\text{HBI1_A}}$ (rising edge) or $V_{\text{measure}} \geq V_{\text{HBI1_D}}$ (falling edge)

or when

- a) V_{HBI2} selected with $\text{BVHS} = 1$
 $V_{\text{measure}} \geq V_{\text{HBI2_A}}$ (rising edge) or $V_{\text{measure}} \geq V_{\text{HBI2_D}}$ (falling edge)

then BVHC is set. BVHC status bit indicates that a high voltage at pin VSUP is present. The High Voltage Interrupt flag (BVHIF) is set to 1 when a Voltage High Condition (BVHC) changes state. The Interrupt flag BVHIF can only be cleared by writing a 1. If the interrupt is enabled by bit BVHIE the module requests an interrupt to MCU (BATI).

Chapter 11

Timer Module (TIM16B4CV3) Block Description

Table 11-1. Revision History

V03.03	Jan,14,2013		-single source generate different channel guide
--------	-------------	--	---

11.1 Introduction

The basic scalable timer consists of a 16-bit, software-programmable counter driven by a flexible programmable prescaler.

This timer can be used for many purposes, including input waveform measurements while simultaneously generating an output waveform.

This timer could contain up to 4 input capture/output compare channels . The input capture function is used to detect a selected transition edge and record the time. The output compare function is used for generating output signals or for timer software delays.

A full access for the counter registers or the input capture/output compare registers should take place in one clock cycle. Accessing high byte and low byte separately for all of these registers may not yield the same result as accessing them in one word.

11.1.1 Features

The TIM16B4CV3 includes these distinctive features:

- Up to 4 channels available. (refer to device specification for exact number)
- All channels have same input capture/output compare functionality.
- Clock prescaling.
- 16-bit counter.

11.1.2 Modes of Operation

Stop: Timer is off because clocks are stopped.

Freeze: Timer counter keeps on running, unless TSFRZ in TSCR1 is set to 1.

Wait: Counters keeps on running, unless TSWAI in TSCR1 is set to 1.

Normal: Timer counter keep on running, unless TEN in TSCR1 is cleared to 0.

11.1.3 Block Diagrams

Figure 11-1. TIM16B4CV3 Block Diagram

Figure 11-2. Interrupt Flag Setting

11.2 External Signal Description

The TIM16B4CV3 module has a selected number of external pins. Refer to device specification for exact number.

11.2.1 IOC3 - IOC0 — Input Capture and Output Compare Channel 3-0

Those pins serve as input capture or output compare for TIM16B4CV3 channel .

NOTE

For the description of interrupts see [Section 11.6, “Interrupts”](#).

11.3 Memory Map and Register Definition

This section provides a detailed description of all memory and registers.

11.3.1 Module Memory Map

The memory map for the TIM16B4CV3 module is given below in [Figure 11-3](#). The address listed for each register is the address offset. The total address for each register is the sum of the base address for the TIM16B4CV3 module and the address offset for each register.

11.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Only bits related to implemented channels are valid.

Figure 11-6. Timer Count Register High (TCNTH)

Module Base + 0x0005

Figure 11-7. Timer Count Register Low (TCNTL)

The 16-bit main timer is an up counter.

A full access for the counter register should take place in one clock cycle. A separate read/write for high byte and low byte will give a different result than accessing them as a word.

Read: Anytime

Write: Has no meaning or effect in the normal mode; only writable in special mode.

The period of the first count after a write to the TCNT registers may be a different size because the write is not synchronized with the prescaler clock.

11.3.2.4 Timer System Control Register 1 (TSCR1)

Module Base + 0x0006

Figure 11-8. Timer System Control Register 1 (TSCR1)

Read: Anytime

Write: Anytime

Table 11-4. TSCR1 Field Descriptions

Field	Description
7 TEN	Timer Enable 0 Disables the main timer, including the counter. Can be used for reducing power consumption. 1 Allows the timer to function normally. If for any reason the timer is not active, there is no ÷64 clock for the pulse accumulator because the ÷64 is generated by the timer prescaler.
6 TSWAI	Timer Module Stops While in Wait 0 Allows the timer module to continue running during wait. 1 Disables the timer module when the MCU is in the wait mode. Timer interrupts cannot be used to get the MCU out of wait. TSWAI also affects pulse accumulator.

Table 11-4. TSCR1 Field Descriptions (continued)

Field	Description
5 TSFRZ	Timer Stops While in Freeze Mode 0 Allows the timer counter to continue running while in freeze mode. 1 Disables the timer counter whenever the MCU is in freeze mode. This is useful for emulation. TSFRZ does not stop the pulse accumulator.
4 TFFCA	Timer Fast Flag Clear All 0 Allows the timer flag clearing to function normally. 1 For TFLG1(0x000E), a read from an input capture or a write to the output compare channel (0x0010–0x001F) causes the corresponding channel flag, CnF, to be cleared. For TFLG2 (0x000F), any access to the TCNT register (0x0004, 0x0005) clears the TOF flag. This has the advantage of eliminating software overhead in a separate clear sequence. Extra care is required to avoid accidental flag clearing due to unintended accesses.
3 PRNT	Precision Timer 0 Enables legacy timer. PR0, PR1, and PR2 bits of the TSCR2 register are used for timer counter prescaler selection. 1 Enables precision timer. All bits of the PTPSR register are used for Precision Timer Prescaler Selection, and all bits. This bit is writable only once out of reset.

11.3.2.5 Timer Toggle On Overflow Register 1 (TTOV)

Module Base + 0x0007

Figure 11-9. Timer Toggle On Overflow Register 1 (TTOV)

 0x0013 = TC1L 0x001B=RESERVD
 0x0015 =TC2L 0x001D=RESERVD
 0x0017=TC3L 0x001F=RESERVD

Figure 11-19. Timer Input Capture/Output Compare Register x Low (TCxL)

¹ This register is available only when the corresponding channel exists and is reserved if that channel does not exist. Writes to a reserved register have no functional effect. Reads from a reserved register return zeroes.

Depending on the TIOS bit for the corresponding channel, these registers are used to latch the value of the free-running counter when a defined transition is sensed by the corresponding input capture edge detector or to trigger an output action for output compare.

Read: Anytime

Write: Anytime for output compare function. Writes to these registers have no meaning or effect during input capture. All timer input capture/output compare registers are reset to 0x0000.

NOTE

Read/Write access in byte mode for high byte should take place before low byte otherwise it will give a different result.

11.3.2.13 Output Compare Pin Disconnect Register(OCPD)

Module Base + 0x002C

Figure 11-20. Output Compare Pin Disconnect Register (OCPD)

Read: Anytime

Write: Anytime

All bits reset to zero.

Table 11-15. OCPD Field Description

Note: Writing to unavailable bits has no effect. Reading from unavailable bits return a zero.

Field	Description
3:0 OCPD[3:0]	Output Compare Pin Disconnect Bits 0 Enables the timer channel port. Output Compare action will occur on the channel pin. These bits do not affect the input capture . 1 Disables the timer channel port. Output Compare action will not occur on the channel pin, but the output compare flag still become set.

11.3.2.14 Precision Timer Prescaler Select Register (PTPSR)

Module Base + 0x002E

Figure 11-21. Precision Timer Prescaler Select Register (PTPSR)

Read: Anytime

Write: Anytime

All bits reset to zero.

Table 11-16. PTPSR Field Descriptions

Field	Description
7:0 PTPS[7:0]	Precision Timer Prescaler Select Bits — These eight bits specify the division rate of the main Timer prescaler. These are effective only when the PRNT bit of TSCR1 is set to 1. Table 11-17 shows some selection examples in this case. The newly selected prescale factor will not take effect until the next synchronized edge where all prescale counter stages equal zero.

The Prescaler can be calculated as follows depending on logical value of the PTPS[7:0] and PRNT bit:

$$\text{PRNT} = 1 : \text{Prescaler} = \text{PTPS}[7:0] + 1$$

Table 11-17. Precision Timer Prescaler Selection Examples when PRNT = 1

PTPS7	PTPS6	PTPS5	PTPS4	PTPS3	PTPS2	PTPS1	PTPS0	Prescale Factor
0	0	0	0	0	0	0	0	1

1	1	1	1	1	1	1	1	256

11.4 Functional Description

This section provides a complete functional description of the timer TIM16B4CV3 block. Please refer to the detailed timer block diagram in [Figure 11-22](#) as necessary.

Figure 11-22. Detailed Timer Block Diagram

11.4.1 Prescaler

The prescaler divides the Bus clock by 1, 2, 4, 8, 16, 32, 64 or 128. The prescaler select bits, PR[2:0], select the prescaler divisor. PR[2:0] are in timer system control register 2 (TSCR2).

The prescaler divides the Bus clock by a prescaler value. Prescaler select bits PR[2:0] of in timer system control register 2 (TSCR2) are set to define a prescaler value that generates a divide by 1, 2, 4, 8, 16, 32, 64 and 128 when the PRNT bit in TSCR1 is disabled.

By enabling the PRNT bit of the TSCR1 register, the performance of the timer can be enhanced. In this case, it is possible to set additional prescaler settings for the main timer counter in the present timer by using PTPSR[7:0] bits of PTPSR register generating divide by 1, 2, 3, 4,....20, 21, 22, 23,.....255, or 256.

11.4.2 Input Capture

Clearing the I/O (input/output) select bit, IOS_x, configures channel x as an input capture channel. The input capture function captures the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the timer transfers the value in the timer counter into the timer channel registers, TC_x.

The minimum pulse width for the input capture input is greater than two Bus clocks.

An input capture on channel x sets the CxF flag. The CxI bit enables the CxF flag to generate interrupt requests. Timer module must stay enabled (TEN bit of TSCR1 register must be set to one) while clearing CxF (writing one to CxF).

11.4.3 Output Compare

Setting the I/O select bit, IOS_x, configures channel x when available as an output compare channel. The output compare function can generate a periodic pulse with a programmable polarity, duration, and frequency. When the timer counter reaches the value in the channel registers of an output compare channel, the timer can set, clear, or toggle the channel pin if the corresponding OCPD_x bit is set to zero. An output compare on channel x sets the CxF flag. The CxI bit enables the CxF flag to generate interrupt requests. Timer module must stay enabled (TEN bit of TSCR1 register must be set to one) while clearing CxF (writing one to CxF).

The output mode and level bits, OM_x and OL_x, select set, clear, toggle on output compare. Clearing both OM_x and OL_x results in no output compare action on the output compare channel pin.

Setting a force output compare bit, FOC_x, causes an output compare on channel x. A forced output compare does not set the channel flag.

Writing to the timer port bit of an output compare pin does not affect the pin state. The value written is stored in an internal latch. When the pin becomes available for general-purpose output, the last value written to the bit appears at the pin.

11.4.3.1 OC Channel Initialization

The internal register whose output drives OC_x can be programmed before the timer drives OC_x. The desired state can be programmed to this internal register by writing a one to CFORC_x bit with TIOS_x, OCPD_x and TEN bits set to one.

Set OC_x: Write a 1 to FOC_x while TEN=1, IOS_x=1, OM_x=1, OL_x=1 and OCPD_x=1

Clear OC_x: Write a 1 to FOC_x while TEN=1, IOS_x=1, OM_x=1, OL_x=0 and OCPD_x=1

Setting OCPD_x to zero allows the internal register to drive the programmed state to OC_x. This allows a glitch free switch over of port from general purpose I/O to timer output once the OCPD_x bit is set to zero.

11.5 Resets

The reset state of each individual bit is listed within [Section 11.3, “Memory Map and Register Definition”](#) which details the registers and their bit fields

11.6 Interrupts

This section describes interrupts originated by the TIM16B4CV3 block. [Table 11-18](#) lists the interrupts generated by the TIM16B4CV3 to communicate with the MCU.

Table 11-18. TIM16B4CV3 Interrupts

Interrupt	Offset	Vector	Priority	Source	Description
C[3:0]F	—	—	—	Timer Channel 3–0	Active high timer channel interrupts 3–0
TOF	—	—	—	Timer Overflow	Timer Overflow interrupt

The TIM16B4CV3 could use up to 5 interrupt vectors. The interrupt vector offsets and interrupt numbers are chip dependent.

11.6.1 Channel [3:0] Interrupt (C[3:0]F)

This active high outputs will be asserted by the module to request a timer channel 7 – 0 interrupt. The TIM block only generates the interrupt and does not service it. Only bits related to implemented channels are valid.

11.6.2 Timer Overflow Interrupt (TOF)

This active high output will be asserted by the module to request a timer overflow interrupt. The TIM block only generates the interrupt and does not service it.

Chapter 12

Timer Module (TIM16B2CV3) Block Description

Table 12-1. Revision History

V03.03	Jan,14,2013		-single source generate different channel guide
--------	-------------	--	---

12.1 Introduction

The basic scalable timer consists of a 16-bit, software-programmable counter driven by a flexible programmable prescaler.

This timer can be used for many purposes, including input waveform measurements while simultaneously generating an output waveform.

This timer could contain up to 2 input capture/output compare channels . The input capture function is used to detect a selected transition edge and record the time. The output compare function is used for generating output signals or for timer software delays.

A full access for the counter registers or the input capture/output compare registers should take place in one clock cycle. Accessing high byte and low byte separately for all of these registers may not yield the same result as accessing them in one word.

12.1.1 Features

The TIM16B2CV3 includes these distinctive features:

- Up to 2 channels available. (refer to device specification for exact number)
- All channels have same input capture/output compare functionality.
- Clock prescaling.
- 16-bit counter.

12.1.2 Modes of Operation

Stop: Timer is off because clocks are stopped.

Freeze: Timer counter keeps on running, unless TSFRZ in TSCR1 is set to 1.

Wait: Counters keeps on running, unless TSWAI in TSCR1 is set to 1.

Normal: Timer counter keep on running, unless TEN in TSCR1 is cleared to 0.

12.1.3 Block Diagrams

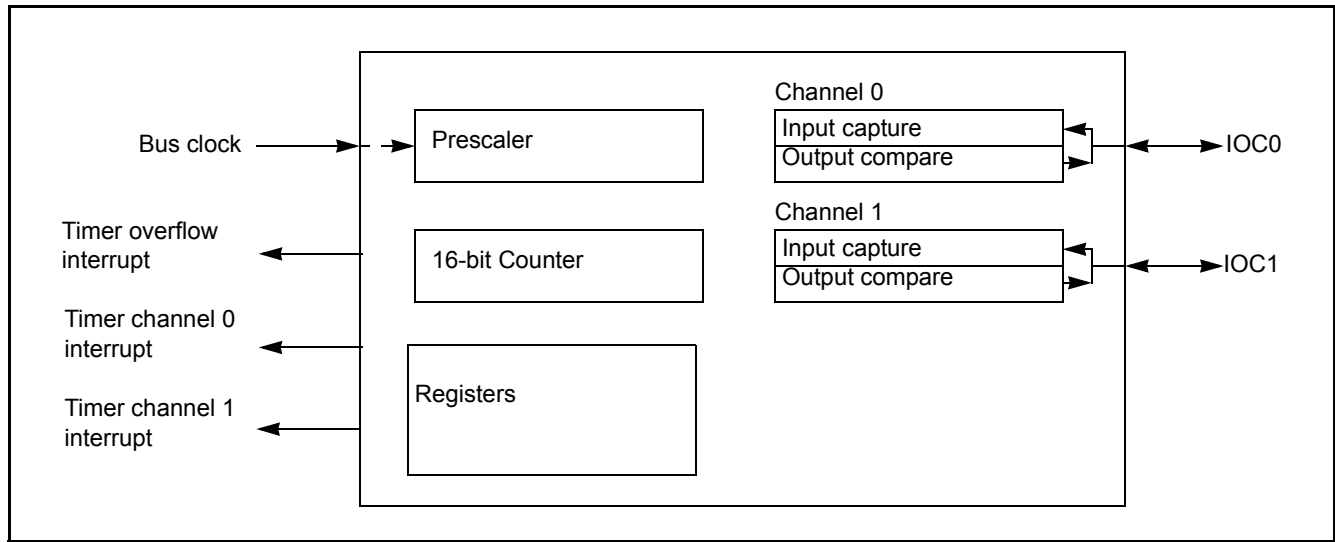

Figure 12-1. TIM16B2CV3 Block Diagram

Figure 12-2. Interrupt Flag Setting

12.2 External Signal Description

The TIM16B2CV3 module has a selected number of external pins. Refer to device specification for exact number.

12.2.1 IOC1 - IOC0 — Input Capture and Output Compare Channel 1-0

Those pins serve as input capture or output compare for TIM16B2CV3 channel .

NOTE

For the description of interrupts see [Section 12.6, “Interrupts”](#).

12.3 Memory Map and Register Definition

This section provides a detailed description of all memory and registers.

12.3.1 Module Memory Map

The memory map for the TIM16B2CV3 module is given below in [Figure 12-3](#). The address listed for each register is the address offset. The total address for each register is the sum of the base address for the TIM16B2CV3 module and the address offset for each register.

12.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Only bits related to implemented channels are valid.

Figure 12-6. Timer Count Register High (TCNTH)

Module Base + 0x0005

Figure 12-7. Timer Count Register Low (TCNTL)

The 16-bit main timer is an up counter.

A full access for the counter register should take place in one clock cycle. A separate read/write for high byte and low byte will give a different result than accessing them as a word.

Read: Anytime

Write: Has no meaning or effect in the normal mode; only writable in special mode.

The period of the first count after a write to the TCNT registers may be a different size because the write is not synchronized with the prescaler clock.

12.3.2.4 Timer System Control Register 1 (TSCR1)

Module Base + 0x0006

Figure 12-8. Timer System Control Register 1 (TSCR1)

Read: Anytime

Write: Anytime

Table 12-4. TSCR1 Field Descriptions

Field	Description
7 TEN	Timer Enable 0 Disables the main timer, including the counter. Can be used for reducing power consumption. 1 Allows the timer to function normally. If for any reason the timer is not active, there is no ÷64 clock for the pulse accumulator because the ÷64 is generated by the timer prescaler.
6 TSWAI	Timer Module Stops While in Wait 0 Allows the timer module to continue running during wait. 1 Disables the timer module when the MCU is in the wait mode. Timer interrupts cannot be used to get the MCU out of wait. TSWAI also affects pulse accumulator.

Table 12-4. TSCR1 Field Descriptions (continued)

Field	Description
5 TSFRZ	Timer Stops While in Freeze Mode 0 Allows the timer counter to continue running while in freeze mode. 1 Disables the timer counter whenever the MCU is in freeze mode. This is useful for emulation. TSFRZ does not stop the pulse accumulator.
4 TFFCA	Timer Fast Flag Clear All 0 Allows the timer flag clearing to function normally. 1 For TFLG1(0x000E), a read from an input capture or a write to the output compare channel (0x0010–0x001F) causes the corresponding channel flag, CnF, to be cleared. For TFLG2 (0x000F), any access to the TCNT register (0x0004, 0x0005) clears the TOF flag. This has the advantage of eliminating software overhead in a separate clear sequence. Extra care is required to avoid accidental flag clearing due to unintended accesses.
3 PRNT	Precision Timer 0 Enables legacy timer. PR0, PR1, and PR2 bits of the TSCR2 register are used for timer counter prescaler selection. 1 Enables precision timer. All bits of the PTPSR register are used for Precision Timer Prescaler Selection, and all bits. This bit is writable only once out of reset.

12.3.2.5 Timer Toggle On Overflow Register 1 (TTOV)

Module Base + 0x0007

Figure 12-9. Timer Toggle On Overflow Register 1 (TTOV)

Read: Anytime

Write: Anytime

Table 12-5. TTOV Field Descriptions

Note: Writing to unavailable bits has no effect. Reading from unavailable bits return a zero.

Field	Description
1:0 TOV[1:0]	Toggle On Overflow Bits — TOVx toggles output compare pin on overflow. This feature only takes effect when in output compare mode. When set, it takes precedence over forced output compare 0 Toggle output compare pin on overflow feature disabled. 1 Toggle output compare pin on overflow feature enabled.

¹ This register is available only when the corresponding channel exists and is reserved if that channel does not exist. Writes to a reserved register have no functional effect. Reads from a reserved register return zeroes.

Depending on the TIOS bit for the corresponding channel, these registers are used to latch the value of the free-running counter when a defined transition is sensed by the corresponding input capture edge detector or to trigger an output action for output compare.

Read: Anytime

Write: Anytime for output compare function. Writes to these registers have no meaning or effect during input capture. All timer input capture/output compare registers are reset to 0x0000.

NOTE

Read/Write access in byte mode for high byte should take place before low byte otherwise it will give a different result.

12.3.2.13 Output Compare Pin Disconnect Register(OCPD)

Module Base + 0x002C

Read: Anytime

Write: Anytime

All bits reset to zero.

Table 12-15. OCPD Field Description

Note: Writing to unavailable bits has no effect. Reading from unavailable bits return a zero.

Field	Description
1:0 OCPD[1:0]	Output Compare Pin Disconnect Bits 0 Enables the timer channel port. Output Compare action will occur on the channel pin. These bits do not affect the input capture . 1 Disables the timer channel port. Output Compare action will not occur on the channel pin, but the output compare flag still become set.

12.3.2.14 Precision Timer Prescaler Select Register (PTPSR)

Module Base + 0x002E

Figure 12-21. Precision Timer Prescaler Select Register (PTPSR)

Read: Anytime

Write: Anytime

All bits reset to zero.

Table 12-16. PTPSR Field Descriptions

Field	Description
7:0 PTPS[7:0]	Precision Timer Prescaler Select Bits — These eight bits specify the division rate of the main Timer prescaler. These are effective only when the PRNT bit of TSCR1 is set to 1. Table 12-17 shows some selection examples in this case. The newly selected prescale factor will not take effect until the next synchronized edge where all prescale counter stages equal zero.

The Prescaler can be calculated as follows depending on logical value of the PTPS[7:0] and PRNT bit:

$$\text{PRNT} = 1 : \text{Prescaler} = \text{PTPS}[7:0] + 1$$

Table 12-17. Precision Timer Prescaler Selection Examples when PRNT = 1

12.4 Functional Description

This section provides a complete functional description of the timer TIM16B2CV3 block. Please refer to the detailed timer block diagram in [Figure 12-22](#) as necessary.

Figure 12-22. Detailed Timer Block Diagram

12.4.1 Prescaler

The prescaler divides the Bus clock by 1, 2, 4, 8, 16, 32, 64 or 128. The prescaler select bits, PR[2:0], select the prescaler divisor. PR[2:0] are in timer system control register 2 (TSCR2).

The prescaler divides the Bus clock by a prescaler value. Prescaler select bits PR[2:0] of in timer system control register 2 (TSCR2) are set to define a prescaler value that generates a divide by 1, 2, 4, 8, 16, 32, 64 and 128 when the PRNT bit in TSCR1 is disabled.

By enabling the PRNT bit of the TSCR1 register, the performance of the timer can be enhanced. In this case, it is possible to set additional prescaler settings for the main timer counter in the present timer by using PTPSR[7:0] bits of PTPSR register generating divide by 1, 2, 3, 4,....20, 21, 22, 23,.....255, or 256.

12.4.2 Input Capture

Clearing the I/O (input/output) select bit, IOS_x, configures channel x as an input capture channel. The input capture function captures the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the timer transfers the value in the timer counter into the timer channel registers, TC_x.

The minimum pulse width for the input capture input is greater than two Bus clocks.

An input capture on channel x sets the CxF flag. The CxI bit enables the CxF flag to generate interrupt requests. Timer module must stay enabled (TEN bit of TSCR1 register must be set to one) while clearing CxF (writing one to CxF).

12.4.3 Output Compare

Setting the I/O select bit, IOS_x, configures channel x when available as an output compare channel. The output compare function can generate a periodic pulse with a programmable polarity, duration, and frequency. When the timer counter reaches the value in the channel registers of an output compare channel, the timer can set, clear, or toggle the channel pin if the corresponding OCPD_x bit is set to zero. An output compare on channel x sets the CxF flag. The CxI bit enables the CxF flag to generate interrupt requests. Timer module must stay enabled (TEN bit of TSCR1 register must be set to one) while clearing CxF (writing one to CxF).

The output mode and level bits, OM_x and OL_x, select set, clear, toggle on output compare. Clearing both OM_x and OL_x results in no output compare action on the output compare channel pin.

Setting a force output compare bit, FOC_x, causes an output compare on channel x. A forced output compare does not set the channel flag.

Writing to the timer port bit of an output compare pin does not affect the pin state. The value written is stored in an internal latch. When the pin becomes available for general-purpose output, the last value written to the bit appears at the pin.

12.4.3.1 OC Channel Initialization

The internal register whose output drives OC_x can be programmed before the timer drives OC_x. The desired state can be programmed to this internal register by writing a one to CFORC_x bit with TIOS_x, OCPD_x and TEN bits set to one.

Set OC_x: Write a 1 to FOC_x while TEN=1, IOS_x=1, OM_x=1, OL_x=1 and OCPD_x=1

Clear OC_x: Write a 1 to FOC_x while TEN=1, IOS_x=1, OM_x=1, OL_x=0 and OCPD_x=1

Setting OCPD_x to zero allows the internal register to drive the programmed state to OC_x. This allows a glitch free switch over of port from general purpose I/O to timer output once the OCPD_x bit is set to zero.

12.5 Resets

The reset state of each individual bit is listed within [Section 12.3, “Memory Map and Register Definition”](#) which details the registers and their bit fields

12.6 Interrupts

This section describes interrupts originated by the TIM16B2CV3 block. [Table 12-18](#) lists the interrupts generated by the TIM16B2CV3 to communicate with the MCU.

Table 12-18. TIM16B2CV3 Interrupts

Interrupt	Offset	Vector	Priority	Source	Description
C[1:0]F	—	—	—	Timer Channel 1–0	Active high timer channel interrupts 1–0
TOF	—	—	—	Timer Overflow	Timer Overflow interrupt

The TIM16B2CV3 could use up to 3 interrupt vectors. The interrupt vector offsets and interrupt numbers are chip dependent.

12.6.1 Channel [1:0] Interrupt (C[1:0]F)

This active high outputs will be asserted by the module to request a timer channel 7 – 0 interrupt. The TIM block only generates the interrupt and does not service it. Only bits related to implemented channels are valid.

12.6.2 Timer Overflow Interrupt (TOF)

This active high output will be asserted by the module to request a timer overflow interrupt. The TIM block only generates the interrupt and does not service it.

13.1 Introduction

Scalable controller area network (S12MSCANV3) definition is based on the MSCAN12 definition, which is the specific implementation of the MSCAN concept targeted for the S12, S12X and S12Z microcontroller families.

The module is a communication controller implementing the CAN 2.0A/B protocol as defined in the Bosch specification dated September 1991. For users to fully understand the MSCAN specification, it is recommended that the Bosch specification be read first to familiarize the reader with the terms and concepts contained within this document.

Though not exclusively intended for automotive applications, CAN protocol is designed to meet the specific requirements of a vehicle serial data bus: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth.

MSCAN uses an advanced buffer arrangement resulting in predictable real-time behavior and simplified application software.

13.1.1 Glossary

Table 13-1. Terminology

ACK	Acknowledge of CAN message
CAN	Controller Area Network
CRC	Cyclic Redundancy Code
EOF	End of Frame
FIFO	First-In-First-Out Memory
IFS	Inter-Frame Sequence
SOF	Start of Frame
CPU bus	CPU related read/write data bus
CAN bus	CAN protocol related serial bus
oscillator clock	Direct clock from external oscillator
bus clock	CPU bus related clock
CAN clock	CAN protocol related clock

13.1.2 Block Diagram

Figure 13-1. MSCAN Block Diagram

13.1.3 Features

The basic features of the MSCAN are as follows:

- Implementation of the CAN protocol — Version 2.0A/B
 - Standard and extended data frames
 - Zero to eight bytes data length
 - Programmable bit rate up to 1 Mbps¹
 - Support for remote frames
- Five receive buffers with FIFO storage scheme
- Three transmit buffers with internal prioritization using a “local priority” concept
- Flexible maskable identifier filter supports two full-size (32-bit) extended identifier filters, or four 16-bit filters, or eight 8-bit filters
- Programmable wake-up functionality with integrated low-pass filter
- Programmable loopback mode supports self-test operation
- Programmable listen-only mode for monitoring of CAN bus
- Programmable bus-off recovery functionality
- Separate signalling and interrupt capabilities for all CAN receiver and transmitter error states (warning, error passive, bus-off)
- Programmable MSCAN clock source either bus clock or oscillator clock
- Internal timer for time-stamping of received and transmitted messages
- Three low-power modes: sleep, power down, and MSCAN enable
- Global initialization of configuration registers

13.1.4 Modes of Operation

For a description of the specific MSCAN modes and the module operation related to the system operating modes refer to [Section 13.4.4, “Modes of Operation”](#).

1. Depending on the actual bit timing and the clock jitter of the PLL.

13.2 External Signal Description

The MSCAN uses two external pins.

NOTE

On MCUs with an integrated CAN physical interface (transceiver) the MSCAN interface is connected internally to the transceiver interface. In these cases the external availability of signals TXCAN and RXCAN is optional.

13.2.1 RXCAN — CAN Receiver Input Pin

RXCAN is the MSCAN receiver input pin.

13.2.2 TXCAN — CAN Transmitter Output Pin

TXCAN is the MSCAN transmitter output pin. The TXCAN output pin represents the logic level on the CAN bus:

0 = Dominant state

1 = Recessive state

13.2.3 CAN System

A typical CAN system with MSCAN is shown in [Figure 13-2](#). Each CAN station is connected physically to the CAN bus lines through a transceiver device. The transceiver is capable of driving the large current needed for the CAN bus and has current protection against defective CAN or defective stations.

Figure 13-2. CAN System

13.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the MSCAN.

13.3.1 Module Memory Map

Figure 13-3 gives an overview on all registers and their individual bits in the MSCAN memory map. The *register address* results from the addition of *base address* and *address offset*. The *base address* is determined at the MCU level and can be found in the MCU memory map description. The *address offset* is defined at the module level.

The MSCAN occupies 64 bytes in the memory space. The base address of the MSCAN module is determined at the MCU level when the MCU is defined. The register decode map is fixed and begins at the first address of the module address offset.

The detailed register descriptions follow in the order they appear in the register map.

Register Name	Bit 7	6	5	4	3	2	1	Bit 0

Figure 13-3. MSCAN Register Summary (continued)

13.3.2 Register Descriptions

This section describes in detail all the registers and register bits in the MSCAN module. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order. All bits of all registers in this module are completely synchronous to internal clocks during a register read.

13.3.2.1 MSCAN Control Register 0 (CANCTL0)

The CANCTL0 register provides various control bits of the MSCAN module as described below.

Module Base + 0x0000

Access: User read/write⁽¹⁾

Figure 13-4. MSCAN Control Register 0 (CANCTL0)

1. Read: Anytime

Write: Anytime when out of initialization mode; exceptions are read-only RXACT and SYNCH, RXFRM (which is set by the module only), and INITRQ (which is also writable in initialization mode)

NOTE

The CANCTL0 register, except WUPE, INITRQ, and SLPRQ, is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable again as soon as the initialization mode is exited (INITRQ = 0 and INITAK = 0).

Table 13-2. CANCTL0 Register Field Descriptions

Field	Description
7 RXFRM	Received Frame Flag — This bit is read and clear only. It is set when a receiver has received a valid message correctly, independently of the filter configuration. After it is set, it remains set until cleared by software or reset. Clearing is done by writing a 1. Writing a 0 is ignored. This bit is not valid in loopback mode. 0 No valid message was received since last clearing this flag 1 A valid message was received since last clearing of this flag
6 RXACT	Receiver Active Status — This read-only flag indicates the MSCAN is receiving a message ⁽¹⁾ . The flag is controlled by the receiver front end. This bit is not valid in loopback mode. 0 MSCAN is transmitting or idle 1 MSCAN is receiving a message (including when arbitration is lost)
5 CSWAI ⁽²⁾	CAN Stops in Wait Mode — Enabling this bit allows for lower power consumption in wait mode by disabling all the clocks at the CPU bus interface to the MSCAN module. 0 The module is not affected during wait mode 1 The module ceases to be clocked during wait mode
4 SYNCH	Synchronized Status — This read-only flag indicates whether the MSCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the MSCAN. 0 MSCAN is not synchronized to the CAN bus 1 MSCAN is synchronized to the CAN bus
3 TIME	Timer Enable — This bit activates an internal 16-bit wide free running timer which is clocked by the bit clock rate. If the timer is enabled, a 16-bit time stamp will be assigned to each transmitted/received message within the active TX/RX buffer. Right after the EOF of a valid message on the CAN bus, the time stamp is written to the highest bytes (0x000E, 0x000F) in the appropriate buffer (see Section 13.3.3, “Programmer’s Model of Message Storage”). In loopback mode no receive timestamp is generated. The internal timer is reset (all bits set to 0) when disabled. This bit is held low in initialization mode. 0 Disable internal MSCAN timer 1 Enable internal MSCAN timer

Table 13-2. CANCTL0 Register Field Descriptions (continued)

Field	Description
2 WUPE ⁽³⁾	<p>Wake-Up Enable — This configuration bit allows the MSCAN to restart from sleep mode or from power down mode (entered from sleep) when traffic on CAN is detected (see Section 13.4.5.5, “MSCAN Sleep Mode”). This bit must be configured before sleep mode entry for the selected function to take effect.</p> <p>0 Wake-up disabled — The MSCAN ignores traffic on CAN</p> <p>1 Wake-up enabled — The MSCAN is able to restart</p>
1 SLPRQ ⁽⁴⁾	<p>Sleep Mode Request — This bit requests the MSCAN to enter sleep mode, which is an internal power saving mode (see Section 13.4.5.5, “MSCAN Sleep Mode”). The sleep mode request is serviced when the CAN bus is idle, i.e., the module is not receiving a message and all transmit buffers are empty. The module indicates entry to sleep mode by setting SLPK = 1 (see Section 13.3.2.2, “MSCAN Control Register 1 (CANCTL1)”). SLPRQ cannot be set while the WUIF flag is set (see Section 13.3.2.5, “MSCAN Receiver Flag Register (CANRFLG)”). Sleep mode will be active until SLPRQ is cleared by the CPU or, depending on the setting of WUPE, the MSCAN detects activity on the CAN bus and clears SLPRQ itself.</p> <p>0 Running — The MSCAN functions normally</p> <p>1 Sleep mode request — The MSCAN enters sleep mode when CAN bus idle</p>
0 INITRQ ^{(5),(6)}	<p>Initialization Mode Request — When this bit is set by the CPU, the MSCAN skips to initialization mode (see Section 13.4.4.5, “MSCAN Initialization Mode”). Any ongoing transmission or reception is aborted and synchronization to the CAN bus is lost. The module indicates entry to initialization mode by setting INITAK = 1 (Section 13.3.2.2, “MSCAN Control Register 1 (CANCTL1)”).</p> <p>The following registers enter their hard reset state and restore their default values: CANCTL0⁽⁷⁾, CANRFLG⁽⁸⁾, CANRIER⁽⁹⁾, CANTFLG, CANTIER, CANTARQ, CANTAACK, and CANTBSEL.</p> <p>The registers CANCTL1, CANBTR0, CANBTR1, CANIDAC, CANIDAR0-7, and CANIDMR0-7 can only be written by the CPU when the MSCAN is in initialization mode (INITRQ = 1 and INITAK = 1). The values of the error counters are not affected by initialization mode.</p> <p>When this bit is cleared by the CPU, the MSCAN restarts and then tries to synchronize to the CAN bus. If the MSCAN is not in bus-off state, it synchronizes after 11 consecutive recessive bits on the CAN bus; if the MSCAN is in bus-off state, it continues to wait for 128 occurrences of 11 consecutive recessive bits.</p> <p>Writing to other bits in CANCTL0, CANRFLG, CANRIER, CANTFLG, or CANTIER must be done only after initialization mode is exited, which is INITRQ = 0 and INITAK = 0.</p> <p>0 Normal operation</p> <p>1 MSCAN in initialization mode</p>

1. See the Bosch CAN 2.0A/B specification for a detailed definition of transmitter and receiver states.
2. In order to protect from accidentally violating the CAN protocol, TXCAN is immediately forced to a recessive state when the CPU enters wait (CSWAI = 1) or stop mode (see [Section 13.4.5.2, “Operation in Wait Mode”](#) and [Section 13.4.5.3, “Operation in Stop Mode”](#)).
3. The CPU has to make sure that the WUPE register and the WUIE wake-up interrupt enable register (see [Section 13.3.2.6, “MSCAN Receiver Interrupt Enable Register \(CANRIER\)”](#)) is enabled, if the recovery mechanism from stop or wait is required.
4. The CPU cannot clear SLPRQ before the MSCAN has entered sleep mode (SLPRQ = 1 and SLPK = 1).
5. The CPU cannot clear INITRQ before the MSCAN has entered initialization mode (INITRQ = 1 and INITAK = 1).
6. In order to protect from accidentally violating the CAN protocol, TXCAN is immediately forced to a recessive state when the initialization mode is requested by the CPU. Thus, the recommended procedure is to bring the MSCAN into sleep mode (SLPRQ = 1 and SLPK = 1) before requesting initialization mode.
7. Not including WUPE, INITRQ, and SLPRQ.
8. TSTAT1 and TSTAT0 are not affected by initialization mode.
9. RSTAT1 and RSTAT0 are not affected by initialization mode.

13.3.2.2 MSCAN Control Register 1 (CANCTL1)

The CANCTL1 register provides various control bits and handshake status information of the MSCAN module as described below.

Figure 13-5. MSCAN Control Register 1 (CANCTL1)

1. Read: Anytime

Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1), except CANE which is write once in normal and anytime in special system operation modes when the MSCAN is in initialization mode (INITRQ = 1 and INITAK = 1)

Table 13-3. CANCTL1 Register Field Descriptions

Field	Description
7 CANE	MSCAN Enable 0 MSCAN module is disabled 1 MSCAN module is enabled
6 CLKSRC	MSCAN Clock Source — This bit defines the clock source for the MSCAN module (only for systems with a clock generation module; Section 13.4.3.2, “Clock System,” and Section Figure 13-43., “MSCAN Clocking Scheme,”). 0 MSCAN clock source is the oscillator clock 1 MSCAN clock source is the bus clock
5 LOOPB	Loopback Self Test Mode — When this bit is set, the MSCAN performs an internal loopback which can be used for self test operation. The bit stream output of the transmitter is fed back to the receiver internally. The RXCAN input is ignored and the TXCAN output goes to the recessive state (logic 1). The MSCAN behaves as it does normally when transmitting and treats its own transmitted message as a message received from a remote node. In this state, the MSCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated. 0 Loopback self test disabled 1 Loopback self test enabled
4 LISTEN	Listen Only Mode — This bit configures the MSCAN as a CAN bus monitor. When LISTEN is set, all valid CAN messages with matching ID are received, but no acknowledgement or error frames are sent out (see Section 13.4.4.4, “Listen-Only Mode”). In addition, the error counters are frozen. Listen only mode supports applications which require “hot plugging” or throughput analysis. The MSCAN is unable to transmit any messages when listen only mode is active. 0 Normal operation 1 Listen only mode activated
3 BORM	Bus-Off Recovery Mode — This bit configures the bus-off state recovery mode of the MSCAN. Refer to Section 13.5.2, “Bus-Off Recovery,” for details. 0 Automatic bus-off recovery (see Bosch CAN 2.0A/B protocol specification) 1 Bus-off recovery upon user request

Table 13-3. CANCTL1 Register Field Descriptions (continued)

Field	Description
2 WUPM	Wake-Up Mode — If WUPE in CANCTL0 is enabled, this bit defines whether the integrated low-pass filter is applied to protect the MSCAN from spurious wake-up (see Section 13.4.5.5, “MSCAN Sleep Mode”). 0 MSCAN wakes up on any dominant level on the CAN bus 1 MSCAN wakes up only in case of a dominant pulse on the CAN bus that has a length of T_{wup}
1 SLPAK	Sleep Mode Acknowledge — This flag indicates whether the MSCAN module has entered sleep mode (see Section 13.4.5.5, “MSCAN Sleep Mode”). It is used as a handshake flag for the SLPRQ sleep mode request. Sleep mode is active when SLPRQ = 1 and SLPAK = 1. Depending on the setting of WUPE, the MSCAN will clear the flag if it detects activity on the CAN bus while in sleep mode. 0 Running — The MSCAN operates normally 1 Sleep mode active — The MSCAN has entered sleep mode
0 INITAK	Initialization Mode Acknowledge — This flag indicates whether the MSCAN module is in initialization mode (see Section 13.4.4.5, “MSCAN Initialization Mode”). It is used as a handshake flag for the INITRQ initialization mode request. Initialization mode is active when INITRQ = 1 and INITAK = 1. The registers CANCTL1, CANBTR0, CANBTR1, CANIDAC, CANIDAR0–CANIDAR7, and CANIDMR0–CANIDMR7 can be written only by the CPU when the MSCAN is in initialization mode. 0 Running — The MSCAN operates normally 1 Initialization mode active — The MSCAN has entered initialization mode

13.3.2.3 MSCAN Bus Timing Register 0 (CANBTR0)

The CANBTR0 register configures various CAN bus timing parameters of the MSCAN module.

Module Base + 0x0002

Access: User read/write⁽¹⁾

**Figure 13-6. MSCAN Bus Timing Register 0 (CANBTR0)**

1. Read: Anytime

Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

Table 13-4. CANBTR0 Register Field Descriptions

Field	Description
7-6 SJW[1:0]	Synchronization Jump Width — The synchronization jump width defines the maximum number of time quanta (T_q) clock cycles a bit can be shortened or lengthened to achieve resynchronization to data transitions on the CAN bus (see Table 13-5).
5-0 BRP[5:0]	Baud Rate Prescaler — These bits determine the time quanta (T_q) clock which is used to build up the bit timing (see Table 13-6).

Table 13-5. Synchronization Jump Width

SJW1	SJW0	Synchronization Jump Width
0	0	1 Tq clock cycle
0	1	2 Tq clock cycles
1	0	3 Tq clock cycles
1	1	4 Tq clock cycles

Table 13-6. Baud Rate Prescaler

BRP5	BRP4	BRP3	BRP2	BRP1	BRP0	Prescaler value (P)
0	0	0	0	0	0	1
0	0	0	0	0	1	2
0	0	0	0	1	0	3
0	0	0	0	1	1	4

13.3.2.4 MSCAN Bus Timing Register 1 (CANBTR1)

The CANBTR1 register configures various CAN bus timing parameters of the MSCAN module.

Module Base + 0x0003

Access: User read/write⁽¹⁾

Figure 13-7. MSCAN Bus Timing Register 1 (CANBTR1)

- 1. Read: Anytime
- Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

Table 13-7. CANBTR1 Register Field Descriptions

Field	Description
7 SAMP	<p>Sampling — This bit determines the number of CAN bus samples taken per bit time.</p> <p>0 One sample per bit.</p> <p>1 Three samples per bit⁽¹⁾.</p> <p>If SAMP = 0, the resulting bit value is equal to the value of the single bit positioned at the sample point. If SAMP = 1, the resulting bit value is determined by using majority rule on the three total samples. For higher bit rates, it is recommended that only one sample is taken per bit time (SAMP = 0).</p>

Table 13-7. CANBTR1 Register Field Descriptions (continued)

Field	Description
6-4 TSEG2[2:0]	Time Segment 2 — Time segments within the bit time fix the number of clock cycles per bit time and the location of the sample point (see Figure 13-44). Time segment 2 (TSEG2) values are programmable as shown in Table 13-8.
3-0 TSEG1[3:0]	Time Segment 1 — Time segments within the bit time fix the number of clock cycles per bit time and the location of the sample point (see Figure 13-44). Time segment 1 (TSEG1) values are programmable as shown in Table 13-9.

1. In this case, PHASE_SEG1 must be at least 2 time quanta (Tq).

Table 13-8. Time Segment 2 Values

TSEG22	TSEG21	TSEG20	Time Segment 2
0	0	0	1 Tq clock cycle ⁽¹⁾
0	0	1	2 Tq clock cycles
:	:	:	:
1	1	0	7 Tq clock cycles
1	1	1	8 Tq clock cycles

1. This setting is not valid. Please refer to Table 13-36 for valid settings.

Table 13-9. Time Segment 1 Values

TSEG13	TSEG12	TSEG11	TSEG10	Time segment 1
0	0	0	0	1 Tq clock cycle ⁽¹⁾
0	0	0	1	2 Tq clock cycles ¹
0	0	1	0	3 Tq clock cycles ¹
0	0	1	1	4 Tq clock cycles
:	:	:	:	:
1	1	1	0	15 Tq clock cycles
1	1	1	1	16 Tq clock cycles

1. This setting is not valid. Please refer to Table 13-36 for valid settings.

The bit time is determined by the oscillator frequency, the baud rate prescaler, and the number of time quanta (Tq) clock cycles per bit (as shown in Table 13-8 and Table 13-9).

Eqn. 13-1

$$\text{Bit Time} = \frac{(\text{Prescaler value})}{f_{\text{CANCLK}}} \cdot (1 + \text{TimeSegment1} + \text{TimeSegment2})$$

13.3.2.5 MSCAN Receiver Flag Register (CANRFLG)

A flag can be cleared only by software (writing a 1 to the corresponding bit position) when the condition which caused the setting is no longer valid. Every flag has an associated interrupt enable bit in the CANRIER register.

Module Base + 0x0004

Access: User read/write⁽¹⁾

Figure 13-8. MSCAN Receiver Flag Register (CANRFLG)

1. Read: Anytime

Write: Anytime when not in initialization mode, except RSTAT[1:0] and TSTAT[1:0] flags which are read-only; write of 1 clears flag; write of 0 is ignored

NOTE

The CANRFLG register is held in the reset state¹ when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable again as soon as the initialization mode is exited (INITRQ = 0 and INITAK = 0).

Table 13-10. CANRFLG Register Field Descriptions

Field	Description
7 WUPIF	<p>Wake-Up Interrupt Flag — If the MSCAN detects CAN bus activity while in sleep mode (see Section 13.4.5.5, “MSCAN Sleep Mode,”) and WUPE = 1 in CANTCTL0 (see Section 13.3.2.1, “MSCAN Control Register 0 (CANCTL0)”), the module will set WUPIF. If not masked, a wake-up interrupt is pending while this flag is set.</p> <p>0 No wake-up activity observed while in sleep mode 1 MSCAN detected activity on the CAN bus and requested wake-up</p>
6 CSCIF	<p>CAN Status Change Interrupt Flag — This flag is set when the MSCAN changes its current CAN bus status due to the actual value of the transmit error counter (TEC) and the receive error counter (REC). An additional 4-bit (RSTAT[1:0], TSTAT[1:0]) status register, which is split into separate sections for TEC/REC, informs the system on the actual CAN bus status (see Section 13.3.2.6, “MSCAN Receiver Interrupt Enable Register (CANRIER)”). If not masked, an error interrupt is pending while this flag is set. CSCIF provides a blocking interrupt. That guarantees that the receiver/transmitter status bits (RSTAT/TSTAT) are only updated when no CAN status change interrupt is pending. If the TECs/RECs change their current value after the CSCIF is asserted, which would cause an additional state change in the RSTAT/TSTAT bits, these bits keep their status until the current CSCIF interrupt is cleared again.</p> <p>0 No change in CAN bus status occurred since last interrupt 1 MSCAN changed current CAN bus status</p>

1. The RSTAT[1:0], TSTAT[1:0] bits are not affected by initialization mode.

Table 13-10. CANRFLG Register Field Descriptions (continued)

Field	Description
5-4 RSTAT[1:0]	Receiver Status Bits — The values of the error counters control the actual CAN bus status of the MSCAN. As soon as the status change interrupt flag (CSCIF) is set, these bits indicate the appropriate receiver related CAN bus status of the MSCAN. The coding for the bits RSTAT1, RSTAT0 is: 00 RxOK: 0 ≤ receive error counter < 96 01 RxWRN: 96 ≤ receive error counter < 128 10 RxERR: 128 ≤ receive error counter 11 Bus-off ⁽¹⁾ : 256 ≤ transmit error counter
3-2 TSTAT[1:0]	Transmitter Status Bits — The values of the error counters control the actual CAN bus status of the MSCAN. As soon as the status change interrupt flag (CSCIF) is set, these bits indicate the appropriate transmitter related CAN bus status of the MSCAN. The coding for the bits TSTAT1, TSTAT0 is: 00 TxOK: 0 ≤ transmit error counter < 96 01 TxWRN: 96 ≤ transmit error counter < 128 10 TxERR: 128 ≤ transmit error counter < 256 11 Bus-Off: 256 ≤ transmit error counter
1 OVRIF	Overrun Interrupt Flag — This flag is set when a data overrun condition occurs. If not masked, an error interrupt is pending while this flag is set. 0 No data overrun condition 1 A data overrun detected
0 RXF ⁽²⁾	Receive Buffer Full Flag — RXF is set by the MSCAN when a new message is shifted in the receiver FIFO. This flag indicates whether the shifted buffer is loaded with a correctly received message (matching identifier, matching cyclic redundancy code (CRC) and no other errors detected). After the CPU has read that message from the RxFG buffer in the receiver FIFO, the RXF flag must be cleared to release the buffer. A set RXF flag prohibits the shifting of the next FIFO entry into the foreground buffer (RxFG). If not masked, a receive interrupt is pending while this flag is set. 0 No new message available within the RxFG 1 The receiver FIFO is not empty. A new message is available in the RxFG

1. Redundant Information for the most critical CAN bus status which is “bus-off”. This only occurs if the Tx error counter exceeds a number of 255 errors. Bus-off affects the receiver state. As soon as the transmitter leaves its bus-off state the receiver state skips to RxOK too. Refer also to TSTAT[1:0] coding in this register.

2. To ensure data integrity, do not read the receive buffer registers while the RXF flag is cleared. For MCUs with dual CPUs, reading the receive buffer registers while the RXF flag is cleared may result in a CPU fault condition.

13.3.2.6 MSCAN Receiver Interrupt Enable Register (CANRIER)

This register contains the interrupt enable bits for the interrupt flags described in the CANRFLG register.

Module Base + 0x0005

Access: User read/write⁽¹⁾

Figure 13-9. MSCAN Receiver Interrupt Enable Register (CANRIER)

1. Read: Anytime

Write: Anytime when not in initialization mode

NOTE

The CANRIER register is held in the reset state when the initialization mode is active (INITRQ=1 and INITAK=1). This register is writable when not in initialization mode (INITRQ=0 and INITAK=0).

The RSTATE[1:0], TSTATE[1:0] bits are not affected by initialization mode.

Table 13-11. CANRIER Register Field Descriptions

Field	Description
7 WUPIE ⁽¹⁾	Wake-Up Interrupt Enable 0 No interrupt request is generated from this event. 1 A wake-up event causes a Wake-Up interrupt request.
6 CSCIE	CAN Status Change Interrupt Enable 0 No interrupt request is generated from this event. 1 A CAN Status Change event causes an error interrupt request.
5-4 RSTATE[1:0]]	Receiver Status Change Enable — These RSTAT enable bits control the sensitivity level in which receiver state changes are causing CSCIF interrupts. Independent of the chosen sensitivity level the RSTAT flags continue to indicate the actual receiver state and are only updated if no CSCIF interrupt is pending. 00 Do not generate any CSCIF interrupt caused by receiver state changes. 01 Generate CSCIF interrupt only if the receiver enters or leaves “bus-off” state. Discard other receiver state changes for generating CSCIF interrupt. 10 Generate CSCIF interrupt only if the receiver enters or leaves “RxErr” or “bus-off” ⁽²⁾ state. Discard other receiver state changes for generating CSCIF interrupt. 11 Generate CSCIF interrupt on all state changes.
3-2 TSTATE[1:0]	Transmitter Status Change Enable — These TSTAT enable bits control the sensitivity level in which transmitter state changes are causing CSCIF interrupts. Independent of the chosen sensitivity level, the TSTAT flags continue to indicate the actual transmitter state and are only updated if no CSCIF interrupt is pending. 00 Do not generate any CSCIF interrupt caused by transmitter state changes. 01 Generate CSCIF interrupt only if the transmitter enters or leaves “bus-off” state. Discard other transmitter state changes for generating CSCIF interrupt. 10 Generate CSCIF interrupt only if the transmitter enters or leaves “TxErr” or “bus-off” state. Discard other transmitter state changes for generating CSCIF interrupt. 11 Generate CSCIF interrupt on all state changes.
1 OVRIE	Overrun Interrupt Enable 0 No interrupt request is generated from this event. 1 An overrun event causes an error interrupt request.
0 RXFIE	Receiver Full Interrupt Enable 0 No interrupt request is generated from this event. 1 A receive buffer full (successful message reception) event causes a receiver interrupt request.

1. WUPIE and WUPE (see [Section 13.3.2.1, “MSCAN Control Register 0 \(CANCTL0\)”](#)) must both be enabled if the recovery mechanism from stop or wait is required.
2. Bus-off state is only defined for transmitters by the CAN standard (see Bosch CAN 2.0A/B protocol specification). Because the only possible state change for the transmitter from bus-off to TxOK also forces the receiver to skip its current state to RxOK, the coding of the RXSTAT[1:0] flags define an additional bus-off state for the receiver (see [Section 13.3.2.5, “MSCAN Receiver Flag Register \(CANRFLG\)”](#)).

13.3.2.7 MSCAN Transmitter Flag Register (CANTFLG)

The transmit buffer empty flags each have an associated interrupt enable bit in the CANTIER register.

Module Base + 0x0006

Access: User read/write⁽¹⁾

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	TXE2	TXE1	TXE0
W								
Reset:	0	0	0	0	0	1	1	1

 = Unimplemented

Figure 13-10. MSCAN Transmitter Flag Register (CANTFLG)

1. Read: Anytime

Write: Anytime when not in initialization mode; write of 1 clears flag, write of 0 is ignored

NOTE

The CANTFLG register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 13-12. CANTFLG Register Field Descriptions

Field	Description
2-0 TXE[2:0]	<p>Transmitter Buffer Empty — This flag indicates that the associated transmit message buffer is empty, and thus not scheduled for transmission. The CPU must clear the flag after a message is set up in the transmit buffer and is due for transmission. The MSCAN sets the flag after the message is sent successfully. The flag is also set by the MSCAN when the transmission request is successfully aborted due to a pending abort request (see Section 13.3.2.9, “MSCAN Transmitter Message Abort Request Register (CANTARQ)”). If not masked, a transmit interrupt is pending while this flag is set.</p> <p>Clearing a TXEx flag also clears the corresponding ABTAKx (see Section 13.3.2.10, “MSCAN Transmitter Message Abort Acknowledge Register (CANTAACK)”). When a TXEx flag is set, the corresponding ABTRQx bit is cleared (see Section 13.3.2.9, “MSCAN Transmitter Message Abort Request Register (CANTARQ)”).</p> <p>When listen-mode is active (see Section 13.3.2.2, “MSCAN Control Register 1 (CANCTL1)”) the TXEx flags cannot be cleared and no transmission is started.</p> <p>Read and write accesses to the transmit buffer will be blocked, if the corresponding TXEx bit is cleared (TXEx = 0) and the buffer is scheduled for transmission.</p> <p>0 The associated message buffer is full (loaded with a message due for transmission)</p> <p>1 The associated message buffer is empty (not scheduled)</p>

13.3.2.8 MSCAN Transmitter Interrupt Enable Register (CANTIER)

This register contains the interrupt enable bits for the transmit buffer empty interrupt flags.

Module Base + 0x0007

Access: User read/write⁽¹⁾

Figure 13-11. MSCAN Transmitter Interrupt Enable Register (CANTIER)

- 1. Read: Anytime
- Write: Anytime when not in initialization mode

NOTE

The CANTIER register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 13-13. CANTIER Register Field Descriptions

Field	Description
2-0 TXEIE[2:0]	<p>Transmitter Empty Interrupt Enable</p> <p>0 No interrupt request is generated from this event.</p> <p>1 A transmitter empty (transmit buffer available for transmission) event causes a transmitter empty interrupt request.</p>

13.3.2.9 MSCAN Transmitter Message Abort Request Register (CANTARQ)

The CANTARQ register allows abort request of queued messages as described below.

Module Base + 0x0008

Access: User read/write⁽¹⁾

Figure 13-12. MSCAN Transmitter Message Abort Request Register (CANTARQ)

- 1. Read: Anytime
- Write: Anytime when not in initialization mode

NOTE

The CANTARQ register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 13-14. CANTARQ Register Field Descriptions

Field	Description
2-0 ABTRQ[2:0]	<p>Abort Request — The CPU sets the ABTRQx bit to request that a scheduled message buffer (TXEx = 0) be aborted. The MSCAN grants the request if the message has not already started transmission, or if the transmission is not successful (lost arbitration or error). When a message is aborted, the associated TXE (see Section 13.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)”) and abort acknowledge flags (ABTAK, see Section 13.3.2.10, “MSCAN Transmitter Message Abort Acknowledge Register (CANTAACK)”) are set and a transmit interrupt occurs if enabled. The CPU cannot reset ABTRQx. ABTRQx is reset whenever the associated TXE flag is set.</p> <p>0 No abort request 1 Abort request pending</p>

13.3.2.10 MSCAN Transmitter Message Abort Acknowledge Register (CANTAACK)

The CANTAACK register indicates the successful abort of a queued message, if requested by the appropriate bits in the CANTARQ register.

Module Base + 0x0009

Access: User read/write⁽¹⁾

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	ABTAK2	ABTAK1	ABTAK0
W								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 13-13. MSCAN Transmitter Message Abort Acknowledge Register (CANTAACK)

1. Read: Anytime
Write: Unimplemented

NOTE

The CANTAACK register is held in the reset state when the initialization mode is active (INTRQ = 1 and INITAK = 1).

Table 13-15. CANTAACK Register Field Descriptions

Field	Description
2-0 ABTAK[2:0]	<p>Abort Acknowledge — This flag acknowledges that a message was aborted due to a pending abort request from the CPU. After a particular message buffer is flagged empty, this flag can be used by the application software to identify whether the message was aborted successfully or was sent anyway. The ABTAKx flag is cleared whenever the corresponding TXE flag is cleared.</p> <p>0 The message was not aborted. 1 The message was aborted.</p>

13.3.2.11 MSCAN Transmit Buffer Selection Register (CANTBSEL)

The CANTBSEL register allows the selection of the actual transmit message buffer, which then will be accessible in the CANTXFG register space.

Figure 13-14. MSCAN Transmit Buffer Selection Register (CANTBSEL)

- 1. Read: Find the lowest ordered bit set to 1, all other bits will be read as 0
- Write: Anytime when not in initialization mode

NOTE

The CANTBSEL register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK=1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 13-16. CANTBSEL Register Field Descriptions

Field	Description
2-0 TX[2:0]	<p>Transmit Buffer Select — The lowest numbered bit places the respective transmit buffer in the CANTXFG register space (e.g., TX1 = 1 and TX0 = 1 selects transmit buffer TX0; TX1 = 1 and TX0 = 0 selects transmit buffer TX1). Read and write accesses to the selected transmit buffer will be blocked, if the corresponding TXEx bit is cleared and the buffer is scheduled for transmission (see Section 13.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)”).</p> <p>0 The associated message buffer is deselected</p> <p>1 The associated message buffer is selected, if lowest numbered bit</p>

The following gives a short programming example of the usage of the CANTBSEL register:

To get the next available transmit buffer, application software must read the CANTFLG register and write this value back into the CANTBSEL register. In this example Tx buffers TX1 and TX2 are available. The value read from CANTFLG is therefore 0b0000_0110. When writing this value back to CANTBSEL, the Tx buffer TX1 is selected in the CANTXFG because the lowest numbered bit set to 1 is at bit position 1. Reading back this value out of CANTBSEL results in 0b0000_0010, because only the lowest numbered bit position set to 1 is presented. This mechanism eases the application software’s selection of the next available Tx buffer.

- LDAA CANTFLG; value read is 0b0000_0110
- STAA CANTBSEL; value written is 0b0000_0110
- LDAA CANTBSEL; value read is 0b0000_0010

If all transmit message buffers are deselected, no accesses are allowed to the CANTXFG registers.

13.3.2.12 MSCAN Identifier Acceptance Control Register (CANIDAC)

The CANIDAC register is used for identifier acceptance control as described below.

Module Base + 0x000B

Access: User read/write⁽¹⁾**Figure 13-15. MSCAN Identifier Acceptance Control Register (CANIDAC)**

1. Read: Anytime

Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1), except bits IDHITx, which are read-only

Table 13-17. CANIDAC Register Field Descriptions

Field	Description
5-4 IDAM[1:0]	Identifier Acceptance Mode — The CPU sets these flags to define the identifier acceptance filter organization (see Section 13.4.3, “Identifier Acceptance Filter”). Table 13-18 summarizes the different settings. In filter closed mode, no message is accepted such that the foreground buffer is never reloaded.
2-0 IDHIT[2:0]	Identifier Acceptance Hit Indicator — The MSCAN sets these flags to indicate an identifier acceptance hit (see Section 13.4.3, “Identifier Acceptance Filter”). Table 13-19 summarizes the different settings.

Table 13-18. Identifier Acceptance Mode Settings

IDAM1	IDAM0	Identifier Acceptance Mode
0	0	Two 32-bit acceptance filters
0	1	Four 16-bit acceptance filters
1	0	Eight 8-bit acceptance filters
1	1	Filter closed

Table 13-19. Identifier Acceptance Hit Indication

IDHIT2	IDHIT1	IDHIT0	Identifier Acceptance Hit
0	0	0	Filter 0 hit
0	0	1	Filter 1 hit
0	1	0	Filter 2 hit
0	1	1	Filter 3 hit
1	0	0	Filter 4 hit
1	0	1	Filter 5 hit
1	1	0	Filter 6 hit
1	1	1	Filter 7 hit

The IDHITx indicators are always related to the message in the foreground buffer (RxFG). When a message gets shifted into the foreground buffer of the receiver FIFO the indicators are updated as well.

13.3.2.13 MSCAN Reserved Register

This register is reserved for factory testing of the MSCAN module and is not available in normal system operating modes.

Figure 13-16. MSCAN Reserved Register

- 1. Read: Always reads zero in normal system operation modes
- Write: Unimplemented in normal system operation modes

NOTE

Writing to this register when in special system operating modes can alter the MSCAN functionality.

13.3.2.14 MSCAN Miscellaneous Register (CANMISC)

This register provides additional features.

Figure 13-17. MSCAN Miscellaneous Register (CANMISC)

- 1. Read: Anytime
- Write: Anytime; write of '1' clears flag; write of '0' ignored

Table 13-20. CANMISC Register Field Descriptions

Field	Description
0 BOHOLD	<p>Bus-off State Hold Until User Request — If BORM is set in MSCAN Control Register 1 (CANCTL1), this bit indicates whether the module has entered the bus-off state. Clearing this bit requests the recovery from bus-off. Refer to Section 13.5.2, “Bus-Off Recovery,” for details.</p> <p>0 Module is not bus-off or recovery has been requested by user in bus-off state 1 Module is bus-off and holds this state until user request</p>

13.3.2.15 MSCAN Receive Error Counter (CANRXERR)

This register reflects the status of the MSCAN receive error counter.

Figure 13-18. MSCAN Receive Error Counter (CANRXERR)

1. Read: Only when in sleep mode (SLPRQ = 1 and SLPK = 1) or initialization mode (INITRQ = 1 and INITAK = 1)
Write: Unimplemented

NOTE

Reading this register when in any other mode other than sleep or initialization mode may return an incorrect value. For MCUs with dual CPUs, this may result in a CPU fault condition.

13.3.2.16 MSCAN Transmit Error Counter (CANTXERR)

This register reflects the status of the MSCAN transmit error counter.

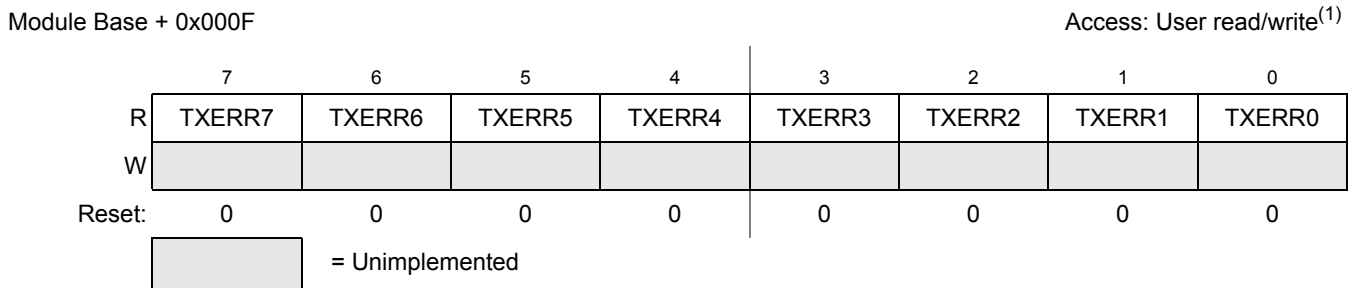

Figure 13-19. MSCAN Transmit Error Counter (CANTXERR)

- 1. Read: Only when in sleep mode (SLPRQ = 1 and SLPAK = 1) or initialization mode (INITRQ = 1 and INITAK = 1)
- Write: Unimplemented

NOTE

Reading this register when in any other mode other than sleep or initialization mode, may return an incorrect value. For MCUs with dual CPUs, this may result in a CPU fault condition.

13.3.2.17 MSCAN Identifier Acceptance Registers (CANIDAR0-7)

On reception, each message is written into the background receive buffer. The CPU is only signalled to read the message if it passes the criteria in the identifier acceptance and identifier mask registers (accepted); otherwise, the message is overwritten by the next message (dropped).

The acceptance registers of the MSCAN are applied on the IDR0–IDR3 registers (see [Section 13.3.3.1, “Identifier Registers \(IDR0–IDR3\)”](#)) of incoming messages in a bit by bit manner (see [Section 13.4.3, “Identifier Acceptance Filter”](#)).

For extended identifiers, all four acceptance and mask registers are applied. For standard identifiers, only the first two (CANIDAR0/1, CANIDMR0/1) are applied.

Figure 13-20. MSCAN Identifier Acceptance Registers (First Bank) — CANIDAR0–CANIDAR3

- 1. Read: Anytime
- Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

Table 13-21. CANIDAR0–CANIDAR3 Register Field Descriptions

Field	Description
7-0 AC[7:0]	Acceptance Code Bits — AC[7:0] comprise a user-defined sequence of bits with which the corresponding bits of the related identifier register (IDRn) of the receive message buffer are compared. The result of this comparison is then masked with the corresponding identifier mask register.

Module Base + 0x0018 to Module Base + 0x001B

Access: User read/write⁽¹⁾**Figure 13-21. MSCAN Identifier Acceptance Registers (Second Bank) — CANIDAR4–CANIDAR7**

1. Read: Anytime

Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

Table 13-22. CANIDAR4–CANIDAR7 Register Field Descriptions

Field	Description
7-0 AC[7:0]	Acceptance Code Bits — AC[7:0] comprise a user-defined sequence of bits with which the corresponding bits of the related identifier register (IDRn) of the receive message buffer are compared. The result of this comparison is then masked with the corresponding identifier mask register.

13.3.2.18 MSCAN Identifier Mask Registers (CANIDMR0–CANIDMR7)

The identifier mask register specifies which of the corresponding bits in the identifier acceptance register are relevant for acceptance filtering. To receive standard identifiers in 32 bit filter mode, it is required to program the last three bits (AM[2:0]) in the mask registers CANIDMR1 and CANIDMR5 to “don’t care.” To receive standard identifiers in 16 bit filter mode, it is required to program the last three bits (AM[2:0]) in the mask registers CANIDMR1, CANIDMR3, CANIDMR5, and CANIDMR7 to “don’t care.”

Module Base + 0x0014 to Module Base + 0x0017

Access: User read/write⁽¹⁾**Figure 13-22. MSCAN Identifier Mask Registers (First Bank) — CANIDMR0–CANIDMR3**

Table 13-24. CANIDMR4–CANIDMR7 Register Field Descriptions

Field	Description
7-0 AM[7:0]	<p>Acceptance Mask Bits — If a particular bit in this register is cleared, this indicates that the corresponding bit in the identifier acceptance register must be the same as its identifier bit before a match is detected. The message is accepted if all such bits match. If a bit is set, it indicates that the state of the corresponding bit in the identifier acceptance register does not affect whether or not the message is accepted.</p> <p>0 Match corresponding acceptance code register and identifier bits 1 Ignore corresponding acceptance code register bit</p>

13.3.3 Programmer's Model of Message Storage

The following section details the organization of the receive and transmit message buffers and the associated control registers.

To simplify the programmer interface, the receive and transmit message buffers have the same outline. Each message buffer allocates 16 bytes in the memory map containing a 13 byte data structure.

An additional transmit buffer priority register (TBPR) is defined for the transmit buffers. Within the last two bytes of this memory map, the MSCAN stores a special 16-bit time stamp, which is sampled from an internal timer after successful transmission or reception of a message. This feature is only available for transmit and receiver buffers, if the TIME bit is set (see [Section 13.3.2.1, “MSCAN Control Register 0 \(CANCTL0\)”](#)).

The time stamp register is written by the MSCAN. The CPU can only read these registers.

Table 13-25. Message Buffer Organization

Offset Address	Register	Access
0x00X0	IDR0 — Identifier Register 0	R/W
0x00X1	IDR1 — Identifier Register 1	R/W

Table 13-27. IDR1 Register Field Descriptions — Extended

Field	Description
7-5 ID[20:18]	Extended Format Identifier — The identifiers consist of 29 bits (ID[28:0]) for the extended format. ID28 is the most significant bit and is transmitted first on the CAN bus during the arbitration procedure. The priority of an identifier is defined to be highest for the smallest binary number.
4 SRR	Substitute Remote Request — This fixed recessive bit is used only in extended format. It must be set to 1 by the user for transmission buffers and is stored as received on the CAN bus for receive buffers.
3 IDE	ID Extended — This flag indicates whether the extended or standard identifier format is applied in this buffer. In the case of a receive buffer, the flag is set as received and indicates to the CPU how to process the buffer identifier registers. In the case of a transmit buffer, the flag indicates to the MSCAN what type of identifier to send. 0 Standard format (11 bit) 1 Extended format (29 bit)
2-0 ID[17:15]	Extended Format Identifier — The identifiers consist of 29 bits (ID[28:0]) for the extended format. ID28 is the most significant bit and is transmitted first on the CAN bus during the arbitration procedure. The priority of an identifier is defined to be highest for the smallest binary number.

This register keeps the data length field of the CAN frame.

Module Base + 0x00XC

Figure 13-35. Data Length Register (DLR) — Extended Identifier Mapping

Table 13-33. DLR Register Field Descriptions

Field	Description
3-0 DLC[3:0]	Data Length Code Bits — The data length code contains the number of bytes (data byte count) of the respective message. During the transmission of a remote frame, the data length code is transmitted as programmed while the number of transmitted data bytes is always 0. The data byte count ranges from 0 to 8 for a data frame. Table 13-34 shows the effect of setting the DLC bits.

Table 13-34. Data Length Codes

Data Length Code				Data Byte Count
DLC3	DLC2	DLC1	DLC0	
0	0	0	0	0
0	0	0	1	1
0	0	1	0	2
0	0	1	1	3
0	1	0	0	4
0	1	0	1	5
0	1	1	0	6
0	1	1	1	7
1	0	0	0	8

13.3.3.4 Transmit Buffer Priority Register (TBPR)

This register defines the local priority of the associated message buffer. The local priority is used for the internal prioritization process of the MSCAN and is defined to be highest for the smallest binary number. The MSCAN implements the following internal prioritization mechanisms:

- All transmission buffers with a cleared TXEx flag participate in the prioritization immediately before the SOF (start of frame) is sent.

- The transmission buffer with the lowest local priority field wins the prioritization.

In cases of more than one buffer having the same lowest priority, the message buffer with the lower index number wins.

Figure 13-36. Transmit Buffer Priority Register (TBPR)

- Read: Anytime when TXEx flag is set (see [Section 13.3.2.7, “MSCAN Transmitter Flag Register \(CANTFLG\)”](#)) and the corresponding transmit buffer is selected in CANTBSEL (see [Section 13.3.2.11, “MSCAN Transmit Buffer Selection Register \(CANTBSEL\)”](#))
Write: Anytime when TXEx flag is set (see [Section 13.3.2.7, “MSCAN Transmitter Flag Register \(CANTFLG\)”](#)) and the corresponding transmit buffer is selected in CANTBSEL (see [Section 13.3.2.11, “MSCAN Transmit Buffer Selection Register \(CANTBSEL\)”](#))

13.3.3.5 Time Stamp Register (TSRH–TSRL)

If the TIME bit is enabled, the MSCAN will write a time stamp to the respective registers in the active transmit or receive buffer right after the EOF of a valid message on the CAN bus (see [Section 13.3.2.1, “MSCAN Control Register 0 \(CANCTL0\)”](#)). In case of a transmission, the CPU can only read the time stamp after the respective transmit buffer has been flagged empty.

The timer value, which is used for stamping, is taken from a free running internal CAN bit clock. A timer overrun is not indicated by the MSCAN. The timer is reset (all bits set to 0) during initialization mode. The CPU can only read the time stamp registers.

Figure 13-37. Time Stamp Register — High Byte (TSRH)

13.4 Functional Description

13.4.1 General

This section provides a complete functional description of the MSCAN.

13.4.2 Message Storage

Figure 13-39. User Model for Message Buffer Organization

The MSCAN facilitates a sophisticated message storage system which addresses the requirements of a broad range of network applications.

13.4.2.1 Message Transmit Background

Modern application layer software is built upon two fundamental assumptions:

- Any CAN node is able to send out a stream of scheduled messages without releasing the CAN bus between the two messages. Such nodes arbitrate for the CAN bus immediately after sending the previous message and only release the CAN bus in case of lost arbitration.
- The internal message queue within any CAN node is organized such that the highest priority message is sent out first, if more than one message is ready to be sent.

The behavior described in the bullets above cannot be achieved with a single transmit buffer. That buffer must be reloaded immediately after the previous message is sent. This loading process lasts a finite amount of time and must be completed within the inter-frame sequence (IFS) to be able to send an uninterrupted stream of messages. Even if this is feasible for limited CAN bus speeds, it requires that the CPU reacts with short latencies to the transmit interrupt.

A double buffer scheme de-couples the reloading of the transmit buffer from the actual message sending and, therefore, reduces the reactivity requirements of the CPU. Problems can arise if the sending of a message is finished while the CPU re-loads the second buffer. No buffer would then be ready for transmission, and the CAN bus would be released.

At least three transmit buffers are required to meet the first of the above requirements under all circumstances. The MSCAN has three transmit buffers.

The second requirement calls for some sort of internal prioritization which the MSCAN implements with the “local priority” concept described in [Section 13.4.2.2, “Transmit Structures.”](#)

13.4.2.2 Transmit Structures

The MSCAN triple transmit buffer scheme optimizes real-time performance by allowing multiple messages to be set up in advance. The three buffers are arranged as shown in [Figure 13-39](#).

All three buffers have a 13-byte data structure similar to the outline of the receive buffers (see [Section 13.3.3, “Programmer’s Model of Message Storage”](#)). An additional Transmit Buffer Priority Register (TBPR) contains an 8-bit local priority field (PRIO) (see [Section 13.3.3.4, “Transmit Buffer Priority Register \(TBPR\)”](#)). The remaining two bytes are used for time stamping of a message, if required (see [Section 13.3.3.5, “Time Stamp Register \(TSRH–TSRL\)”](#)).

To transmit a message, the CPU must identify an available transmit buffer, which is indicated by a set transmitter buffer empty (TXEx) flag (see [Section 13.3.2.7, “MSCAN Transmitter Flag Register \(CANTFLG\)”](#)). If a transmit buffer is available, the CPU must set a pointer to this buffer by writing to the CANTBSEL register (see [Section 13.3.2.11, “MSCAN Transmit Buffer Selection Register \(CANTBSEL\)”](#)). This makes the respective buffer accessible within the CANTXFG address space (see [Section 13.3.3, “Programmer’s Model of Message Storage”](#)). The algorithmic feature associated with the CANTBSEL register simplifies the transmit buffer selection. In addition, this scheme makes the handler

software simpler because only one address area is applicable for the transmit process, and the required address space is minimized.

The CPU then stores the identifier, the control bits, and the data content into one of the transmit buffers. Finally, the buffer is flagged as ready for transmission by clearing the associated TXE flag.

The MSCAN then schedules the message for transmission and signals the successful transmission of the buffer by setting the associated TXE flag. A transmit interrupt (see [Section 13.4.7.2, “Transmit Interrupt”](#)) is generated¹ when TXEx is set and can be used to drive the application software to re-load the buffer.

If more than one buffer is scheduled for transmission when the CAN bus becomes available for arbitration, the MSCAN uses the local priority setting of the three buffers to determine the prioritization. For this purpose, every transmit buffer has an 8-bit local priority field (PRIO). The application software programs this field when the message is set up. The local priority reflects the priority of this particular message relative to the set of messages being transmitted from this node. The lowest binary value of the PRIO field is defined to be the highest priority. The internal scheduling process takes place whenever the MSCAN arbitrates for the CAN bus. This is also the case after the occurrence of a transmission error.

When a high priority message is scheduled by the application software, it may become necessary to abort a lower priority message in one of the three transmit buffers. Because messages that are already in transmission cannot be aborted, the user must request the abort by setting the corresponding abort request bit (ABTRQ) (see [Section 13.3.2.9, “MSCAN Transmitter Message Abort Request Register \(CANTARQ\)”](#).) The MSCAN then grants the request, if possible, by:

1. Setting the corresponding abort acknowledge flag (ABTAK) in the CANTAACK register.
2. Setting the associated TXE flag to release the buffer.
3. Generating a transmit interrupt. The transmit interrupt handler software can determine from the setting of the ABTAK flag whether the message was aborted (ABTAK = 1) or sent (ABTAK = 0).

13.4.2.3 Receive Structures

The received messages are stored in a five stage input FIFO. The five message buffers are alternately mapped into a single memory area (see [Figure 13-39](#)). The background receive buffer (RxBG) is exclusively associated with the MSCAN, but the foreground receive buffer (RxFG) is addressable by the CPU (see [Figure 13-39](#)). This scheme simplifies the handler software because only one address area is applicable for the receive process.

All receive buffers have a size of 15 bytes to store the CAN control bits, the identifier (standard or extended), the data contents, and a time stamp, if enabled (see [Section 13.3.3, “Programmer’s Model of Message Storage”](#)).

The receiver full flag (RXF) (see [Section 13.3.2.5, “MSCAN Receiver Flag Register \(CANRFLG\)”](#)) signals the status of the foreground receive buffer. When the buffer contains a correctly received message with a matching identifier, this flag is set.

On reception, each message is checked to see whether it passes the filter (see [Section 13.4.3, “Identifier Acceptance Filter”](#)) and simultaneously is written into the active RxBG. After successful reception of a valid message, the MSCAN shifts the content of RxBG into the receiver FIFO, sets the RXF flag, and

1. The transmit interrupt occurs only if not masked. A polling scheme can be applied on TXEx also.

generates a receive interrupt¹ (see [Section 13.4.7.3, “Receive Interrupt”](#)) to the CPU. The user’s receive handler must read the received message from the RxFG and then reset the RXF flag to acknowledge the interrupt and to release the foreground buffer. A new message, which can follow immediately after the IFS field of the CAN frame, is received into the next available RxBG. If the MSCAN receives an invalid message in its RxBG (wrong identifier, transmission errors, etc.) the actual contents of the buffer will be over-written by the next message. The buffer will then not be shifted into the FIFO.

When the MSCAN module is transmitting, the MSCAN receives its own transmitted messages into the background receive buffer, RxBG, but does not shift it into the receiver FIFO, generate a receive interrupt, or acknowledge its own messages on the CAN bus. The exception to this rule is in loopback mode (see [Section 13.3.2.2, “MSCAN Control Register 1 \(CANCTL1\)”](#)) where the MSCAN treats its own messages exactly like all other incoming messages. The MSCAN receives its own transmitted messages in the event that it loses arbitration. If arbitration is lost, the MSCAN must be prepared to become a receiver.

An overrun condition occurs when all receive message buffers in the FIFO are filled with correctly received messages with accepted identifiers and another message is correctly received from the CAN bus with an accepted identifier. The latter message is discarded and an error interrupt with overrun indication is generated if enabled (see [Section 13.4.7.5, “Error Interrupt”](#)). The MSCAN remains able to transmit messages while the receiver FIFO is being filled, but all incoming messages are discarded. As soon as a receive buffer in the FIFO is available again, new valid messages will be accepted.

13.4.3 Identifier Acceptance Filter

The MSCAN identifier acceptance registers (see [Section 13.3.2.12, “MSCAN Identifier Acceptance Control Register \(CANIDAC\)”](#)) define the acceptable patterns of the standard or extended identifier (ID[10:0] or ID[28:0]). Any of these bits can be marked ‘don’t care’ in the MSCAN identifier mask registers (see [Section 13.3.2.18, “MSCAN Identifier Mask Registers \(CANIDMR0–CANIDMR7\)”](#)).

A filter hit is indicated to the application software by a set receive buffer full flag (RXF = 1) and three bits in the CANIDAC register (see [Section 13.3.2.12, “MSCAN Identifier Acceptance Control Register \(CANIDAC\)”](#)). These identifier hit flags (IDHIT[2:0]) clearly identify the filter section that caused the acceptance. They simplify the application software’s task to identify the cause of the receiver interrupt. If more than one hit occurs (two or more filters match), the lower hit has priority.

A very flexible programmable generic identifier acceptance filter has been introduced to reduce the CPU interrupt loading. The filter is programmable to operate in four different modes:

- Two identifier acceptance filters, each to be applied to:
 - The full 29 bits of the extended identifier and to the following bits of the CAN 2.0B frame:
 - Remote transmission request (RTR)
 - Identifier extension (IDE)
 - Substitute remote request (SRR)
 - The 11 bits of the standard identifier plus the RTR and IDE bits of the CAN 2.0A/B messages. This mode implements two filters for a full length CAN 2.0B compliant extended identifier. Although this mode can be used for standard identifiers, it is recommended to use the four or eight identifier acceptance filters.

1. The receive interrupt occurs only if not masked. A polling scheme can be applied on RXF also.

Figure 13-40 shows how the first 32-bit filter bank (CANIDAR0–CANIDAR3, CANIDMR0–CANIDMR3) produces a filter 0 hit. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces a filter 1 hit.

- Four identifier acceptance filters, each to be applied to:
 - The 14 most significant bits of the extended identifier plus the SRR and IDE bits of CAN 2.0B messages.
 - The 11 bits of the standard identifier, the RTR and IDE bits of CAN 2.0A/B messages.

Figure 13-41 shows how the first 32-bit filter bank (CANIDAR0–CANIDAR3, CANIDMR0–CANIDMR3) produces filter 0 and 1 hits. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces filter 2 and 3 hits.

- Eight identifier acceptance filters, each to be applied to the first 8 bits of the identifier. This mode implements eight independent filters for the first 8 bits of a CAN 2.0A/B compliant standard identifier or a CAN 2.0B compliant extended identifier.

Figure 13-42 shows how the first 32-bit filter bank (CANIDAR0–CANIDAR3, CANIDMR0–CANIDMR3) produces filter 0 to 3 hits. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces filter 4 to 7 hits.

- Closed filter. No CAN message is copied into the foreground buffer RxFG, and the RXF flag is never set.

Figure 13-40. 32-bit Maskable Identifier Acceptance Filter

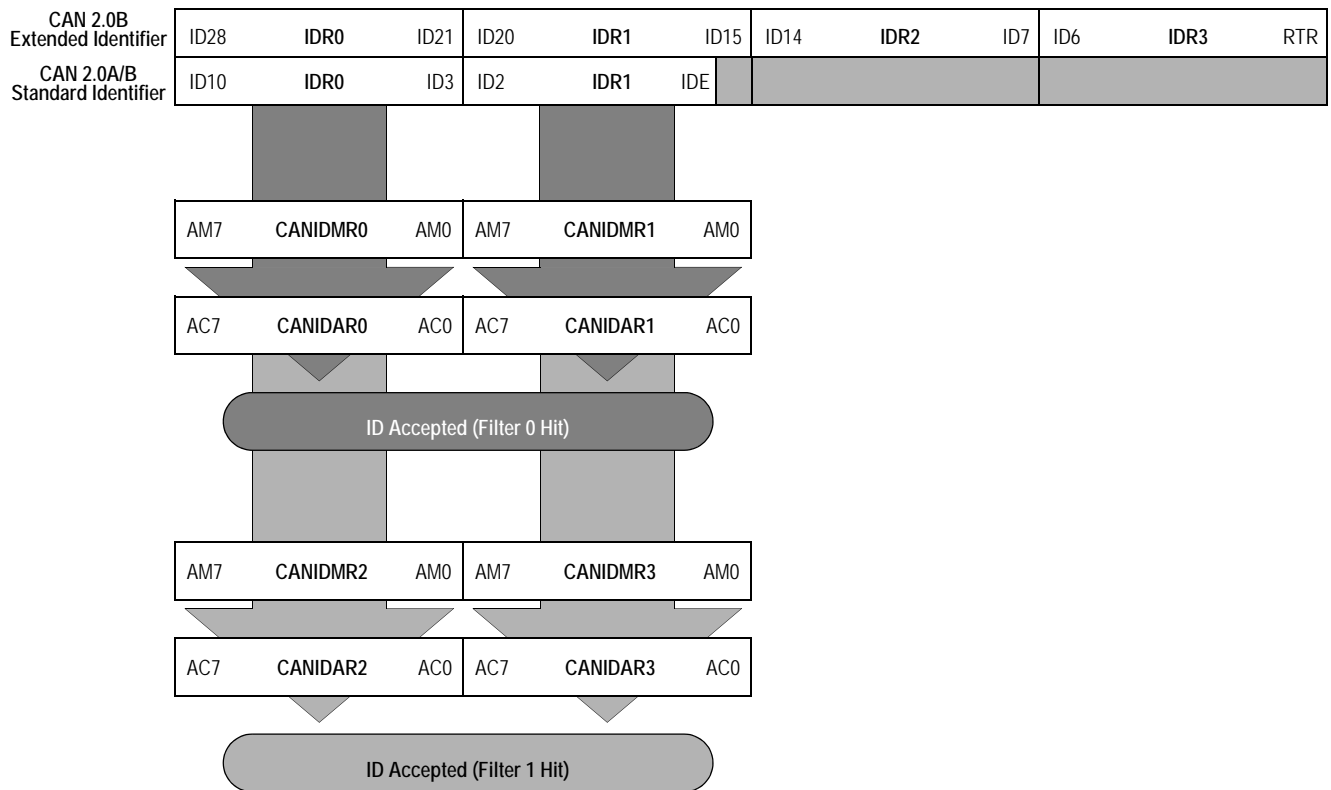

Figure 13-41. 16-bit Maskable Identifier Acceptance Filters

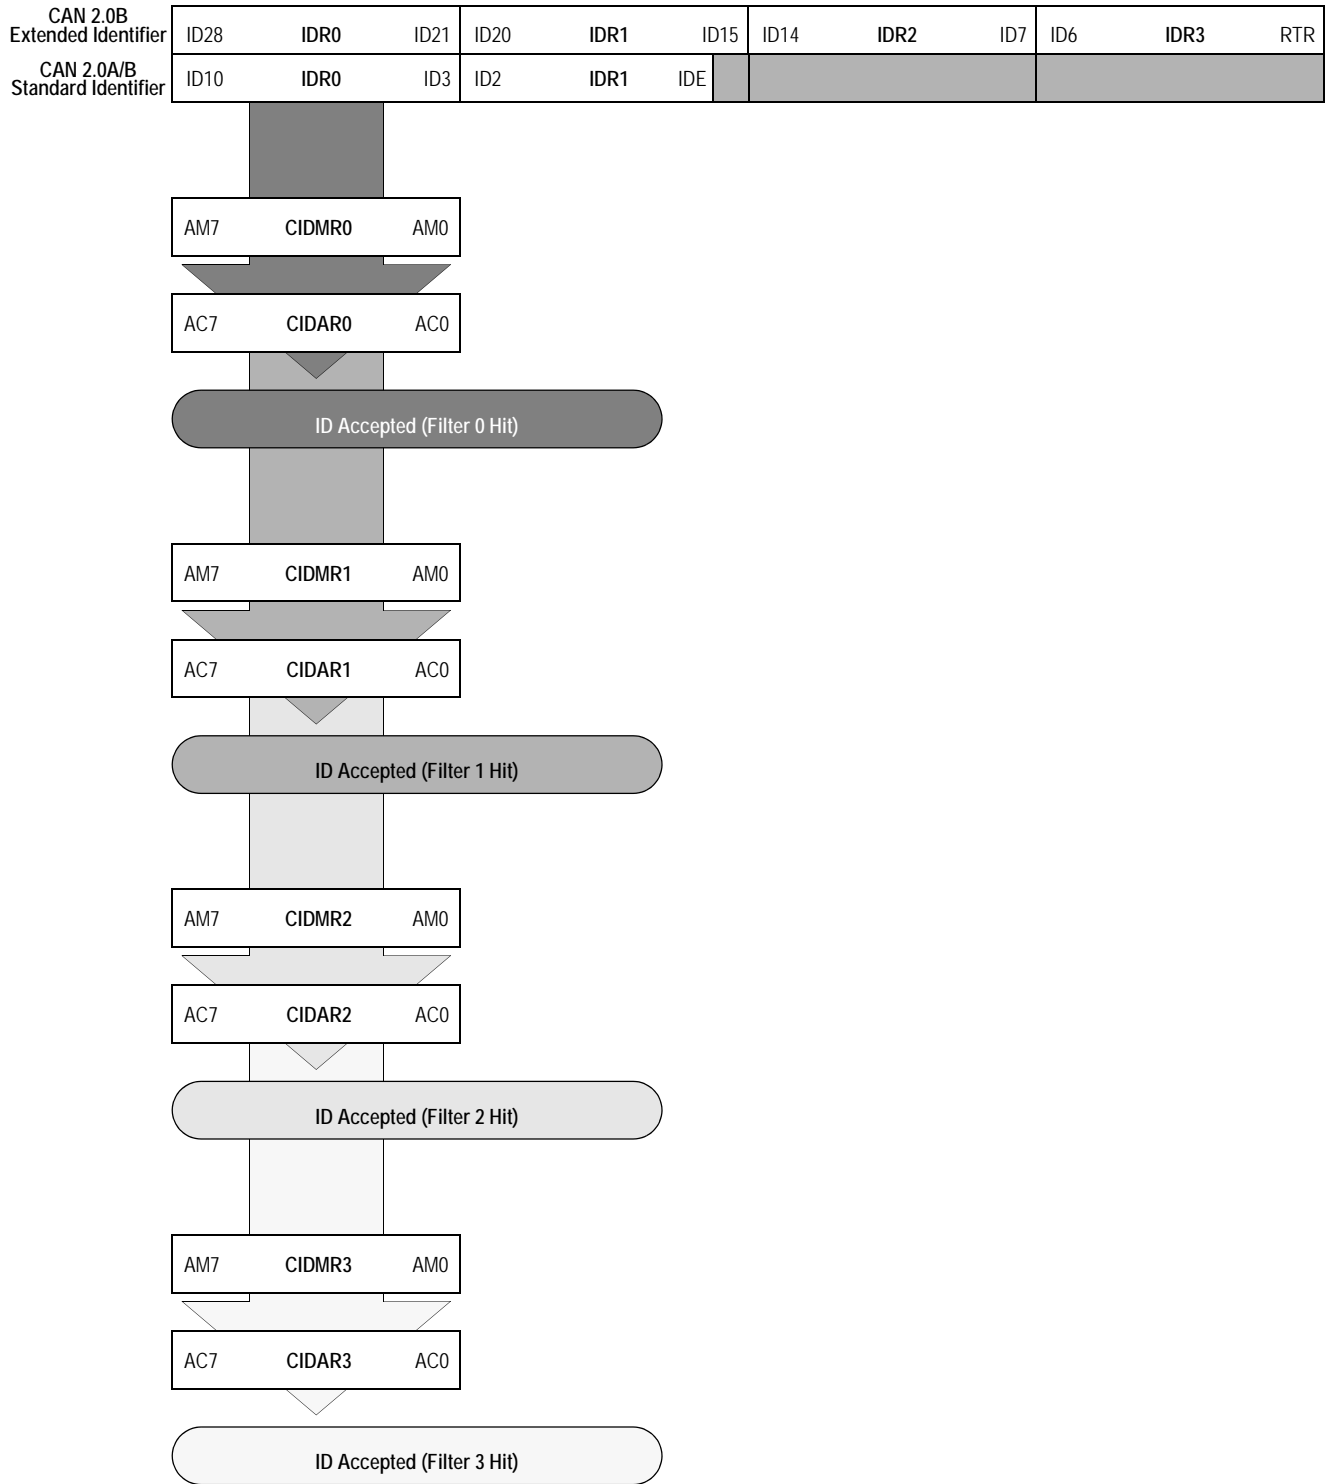

Figure 13-42. 8-bit Maskable Identifier Acceptance Filters

13.4.3.1 Protocol Violation Protection

The MSCAN protects the user from accidentally violating the CAN protocol through programming errors. The protection logic implements the following features:

- The receive and transmit error counters cannot be written or otherwise manipulated.
- All registers which control the configuration of the MSCAN cannot be modified while the MSCAN is on-line. The MSCAN has to be in Initialization Mode. The corresponding INITRQ/INITAK handshake bits in the CANCTL0/CANCTL1 registers (see [Section 13.3.2.1, “MSCAN Control Register 0 \(CANCTL0\)”](#)) serve as a lock to protect the following registers:
 - MSCAN control 1 register (CANCTL1)
 - MSCAN bus timing registers 0 and 1 (CANBTR0, CANBTR1)
 - MSCAN identifier acceptance control register (CANIDAC)
 - MSCAN identifier acceptance registers (CANIDAR0–CANIDAR7)
 - MSCAN identifier mask registers (CANIDMR0–CANIDMR7)
- The TXCAN is immediately forced to a recessive state when the MSCAN goes into the power down mode or initialization mode (see [Section 13.4.5.6, “MSCAN Power Down Mode,”](#) and [Section 13.4.4.5, “MSCAN Initialization Mode”](#)).
- The MSCAN enable bit (CANE) is writable only once in normal system operation modes, which provides further protection against inadvertently disabling the MSCAN.

13.4.3.2 Clock System

[Figure 13-43](#) shows the structure of the MSCAN clock generation circuitry.

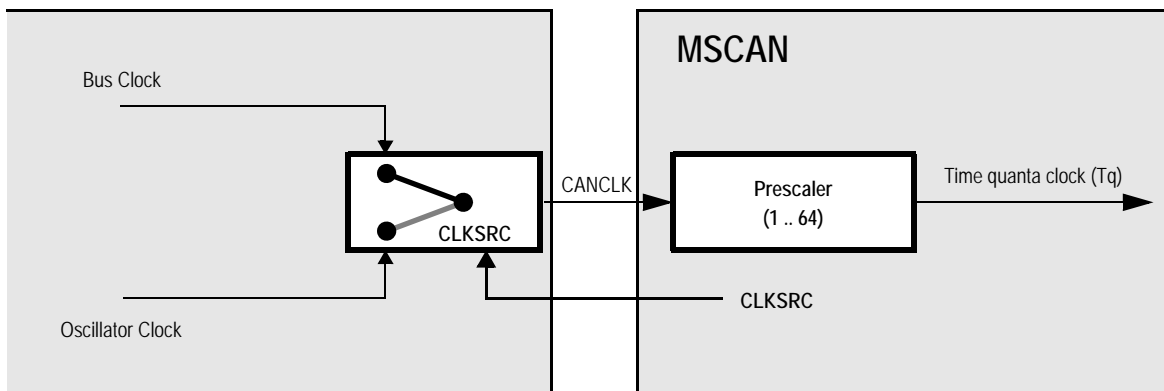

Figure 13-43. MSCAN Clocking Scheme

The clock source bit (CLKSRC) in the CANCTL1 register ([13.3.2.2/13-486](#)) defines whether the internal CANCLK is connected to the output of a crystal oscillator (oscillator clock) or to the bus clock.

The clock source has to be chosen such that the tight oscillator tolerance requirements (up to 0.4%) of the CAN protocol are met. Additionally, for high CAN bus rates (1 Mbps), a 45% to 55% duty cycle of the clock is required.

If the bus clock is generated from a PLL, it is recommended to select the oscillator clock rather than the bus clock due to jitter considerations, especially at the faster CAN bus rates.

For microcontrollers without a clock and reset generator (CRG), CANCLK is driven from the crystal oscillator (oscillator clock).

A programmable prescaler generates the time quanta (T_q) clock from CANCLK. A time quantum is the atomic unit of time handled by the MSCAN.

Eqn. 13-2

$$T_q = \frac{f_{\text{CANCLK}}}{\text{Prescaler value}}$$

A bit time is subdivided into three segments as described in the Bosch CAN 2.0A/B specification. (see [Figure 13-44](#)):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the PROP_SEG and the PHASE_SEG1 of the CAN standard. It can be programmed by setting the parameter TSEG1 to consist of 4 to 16 time quanta.
- Time Segment 2: This segment represents the PHASE_SEG2 of the CAN standard. It can be programmed by setting the TSEG2 parameter to be 2 to 8 time quanta long.

Eqn. 13-3

$$\text{Bit Rate} = \frac{f_{T_q}}{\text{(number of Time Quanta)}}$$

Figure 13-44. Segments within the Bit Time

Table 13-35. Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the CAN bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node in receive mode samples the CAN bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The synchronization jump width (see the Bosch CAN 2.0A/B specification for details) can be programmed in a range of 1 to 4 time quanta by setting the SJW parameter.

The SYNC_SEG, TSEG1, TSEG2, and SJW parameters are set by programming the MSCAN bus timing registers (CANBTR0, CANBTR1) (see [Section 13.3.2.3, “MSCAN Bus Timing Register 0 \(CANBTR0\)”](#) and [Section 13.3.2.4, “MSCAN Bus Timing Register 1 \(CANBTR1\)”](#)).

[Table 13-36](#) gives an overview of the Bosch CAN 2.0A/B specification compliant segment settings and the related parameter values.

NOTE

It is the user’s responsibility to ensure the bit time settings are in compliance with the CAN standard.

Table 13-36. Bosch CAN 2.0A/B Compliant Bit Time Segment Settings

Time Segment 1	TSEG1	Time Segment 2	TSEG2	Synchronization Jump Width	SJW
5 .. 10	4 .. 9	2	1	1 .. 2	0 .. 1
4 .. 11	3 .. 10	3	2	1 .. 3	0 .. 2
5 .. 12	4 .. 11	4	3	1 .. 4	0 .. 3
6 .. 13	5 .. 12	5	4	1 .. 4	0 .. 3
7 .. 14	6 .. 13	6	5	1 .. 4	0 .. 3
8 .. 15	7 .. 14	7	6	1 .. 4	0 .. 3
9 .. 16	8 .. 15	8	7	1 .. 4	0 .. 3

13.4.4 Modes of Operation

13.4.4.1 Normal System Operating Modes

The MSCAN module behaves as described within this specification in all normal system operating modes. Write restrictions exist for some registers.

13.4.4.2 Special System Operating Modes

The MSCAN module behaves as described within this specification in all special system operating modes. Write restrictions which exist on specific registers in normal modes are lifted for test purposes in special modes.

13.4.4.3 Emulation Modes

In all emulation modes, the MSCAN module behaves just like in normal system operating modes as described within this specification.

13.4.4.4 Listen-Only Mode

In an optional CAN bus monitoring mode (listen-only), the CAN node is able to receive valid data frames and valid remote frames, but it sends only “recessive” bits on the CAN bus. In addition, it cannot start a transmission.

If the MAC sub-layer is required to send a “dominant” bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the MAC sub-layer monitors this “dominant” bit, although the CAN bus may remain in recessive state externally.

13.4.4.5 MSCAN Initialization Mode

The MSCAN enters initialization mode when it is enabled (CANE=1).

When entering initialization mode during operation, any on-going transmission or reception is immediately aborted and synchronization to the CAN bus is lost, potentially causing CAN protocol violations. To protect the CAN bus system from fatal consequences of violations, the MSCAN immediately drives TXCAN into a recessive state.

NOTE

The user is responsible for ensuring that the MSCAN is not active when initialization mode is entered. The recommended procedure is to bring the MSCAN into sleep mode (SLPRQ = 1 and SLPK = 1) before setting the INTRQ bit in the CANCTL0 register. Otherwise, the abort of an on-going message can cause an error condition and can impact other CAN bus devices.

In initialization mode, the MSCAN is stopped. However, interface registers remain accessible. This mode is used to reset the CANCTL0, CANRFLG, CANRIER, CANTFLG, CANTIER, CANTARQ, CANTAACK, and CANTBSEL registers to their default values. In addition, the MSCAN enables the configuration of the CANBTR0, CANBTR1 bit timing registers; CANIDAC; and the CANIDAR, CANIDMR message filters. See [Section 13.3.2.1, “MSCAN Control Register 0 \(CANCTL0\),”](#) for a detailed description of the initialization mode.

Figure 13-45. Initialization Request/Acknowledge Cycle

Due to independent clock domains within the MSCAN, INITRQ must be synchronized to all domains by using a special handshake mechanism. This handshake causes additional synchronization delay (see Figure 13-45).

If there is no message transfer ongoing on the CAN bus, the minimum delay will be two additional bus clocks and three additional CAN clocks. When all parts of the MSCAN are in initialization mode, the INITAK flag is set. The application software must use INITAK as a handshake indication for the request (INITRQ) to go into initialization mode.

NOTE

The CPU cannot clear INITRQ before initialization mode (INITRQ = 1 and INITAK = 1) is active.

13.4.5 Low-Power Options

If the MSCAN is disabled (CANE = 0), the MSCAN clocks are stopped for power saving.

If the MSCAN is enabled (CANE = 1), the MSCAN has two additional modes with reduced power consumption, compared to normal mode: sleep and power down mode. In sleep mode, power consumption is reduced by stopping all clocks except those to access the registers from the CPU side. In power down mode, all clocks are stopped and no power is consumed.

Table 13-37 summarizes the combinations of MSCAN and CPU modes. A particular combination of modes is entered by the given settings on the CSWAI and SLPRQ/SLPAK bits.

Table 13-37. CPU vs. MSCAN Operating Modes

CPU Mode	MSCAN Mode			
	Normal	Reduced Power Consumption		
		Sleep	Power Down	Disabled (CANE=0)
RUN	CSWAI = X ⁽¹⁾ SLPRQ = 0 SLPAK = 0	CSWAI = X SLPRQ = 1 SLPAK = 1		CSWAI = X SLPRQ = X SLPAK = X
WAIT	CSWAI = 0 SLPRQ = 0 SLPAK = 0	CSWAI = 0 SLPRQ = 1 SLPAK = 1	CSWAI = 1 SLPRQ = X SLPAK = X	CSWAI = X SLPRQ = X SLPAK = X
STOP			CSWAI = X SLPRQ = X SLPAK = X	CSWAI = X SLPRQ = X SLPAK = X

1. 'X' means don't care.

13.4.5.1 Operation in Run Mode

As shown in [Table 13-37](#), only MSCAN sleep mode is available as low power option when the CPU is in run mode.

13.4.5.2 Operation in Wait Mode

The WAI instruction puts the MCU in a low power consumption stand-by mode. If the CSWAI bit is set, additional power can be saved in power down mode because the CPU clocks are stopped. After leaving this power down mode, the MSCAN restarts and enters normal mode again.

While the CPU is in wait mode, the MSCAN can be operated in normal mode and generate interrupts (registers can be accessed via background debug mode).

13.4.5.3 Operation in Stop Mode

The STOP instruction puts the MCU in a low power consumption stand-by mode. In stop mode, the MSCAN is set in power down mode regardless of the value of the SLPRQ/SLPAK and CSWAI bits ([Table 13-37](#)).

13.4.5.4 MSCAN Normal Mode

This is a non-power-saving mode. Enabling the MSCAN puts the module from disabled mode into normal mode. In this mode the module can either be in initialization mode or out of initialization mode. See [Section 13.4.4.5, “MSCAN Initialization Mode”](#).

13.4.5.5 MSCAN Sleep Mode

The CPU can request the MSCAN to enter this low power mode by asserting the SLPRQ bit in the CANCTL0 register. The time when the MSCAN enters sleep mode depends on a fixed synchronization delay and its current activity:

- If there are one or more message buffers scheduled for transmission (TXEx = 0), the MSCAN will continue to transmit until all transmit message buffers are empty (TXEx = 1, transmitted successfully or aborted) and then goes into sleep mode.
- If the MSCAN is receiving, it continues to receive and goes into sleep mode as soon as the CAN bus next becomes idle.
- If the MSCAN is neither transmitting nor receiving, it immediately goes into sleep mode.

Figure 13-46. Sleep Request / Acknowledge Cycle

NOTE

The application software must avoid setting up a transmission (by clearing one or more TXEx flag(s)) and immediately request sleep mode (by setting SLPRQ). Whether the MSCAN starts transmitting or goes into sleep mode directly depends on the exact sequence of operations.

If sleep mode is active, the SLPRQ and SLPK bits are set (Figure 13-46). The application software must use SLPK as a handshake indication for the request (SLPRQ) to go into sleep mode.

When in sleep mode (SLPRQ = 1 and SLPK = 1), the MSCAN stops its internal clocks. However, clocks that allow register accesses from the CPU side continue to run.

If the MSCAN is in bus-off state, it stops counting the 128 occurrences of 11 consecutive recessive bits due to the stopped clocks. TXCAN remains in a recessive state. If RXF = 1, the message can be read and RXF can be cleared. Shifting a new message into the foreground buffer of the receiver FIFO (RxFG) does not take place while in sleep mode.

It is possible to access the transmit buffers and to clear the associated TXE flags. No message abort takes place while in sleep mode.

If the WUPE bit in CANCTL0 is not asserted, the MSCAN will mask any activity it detects on CAN. RXCAN is therefore held internally in a recessive state. This locks the MSCAN in sleep mode. WUPE must be set before entering sleep mode to take effect.

The MSCAN is able to leave sleep mode (wake up) only when:

- CAN bus activity occurs and WUPE = 1
- or
- the CPU clears the SLPRQ bit

NOTE

The CPU cannot clear the SLPRQ bit before sleep mode (SLPRQ = 1 and SLPK = 1) is active.

After wake-up, the MSCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, if the MSCAN is woken-up by a CAN frame, this frame is not received.

The receive message buffers (RxFG and RxBG) contain messages if they were received before sleep mode was entered. All pending actions will be executed upon wake-up; copying of RxBG into RxFG, message aborts and message transmissions. If the MSCAN remains in bus-off state after sleep mode was exited, it continues counting the 128 occurrences of 11 consecutive recessive bits.

13.4.5.6 MSCAN Power Down Mode

The MSCAN is in power down mode ([Table 13-37](#)) when

- CPU is in stop mode
- or
- CPU is in wait mode and the CSWAI bit is set

When entering the power down mode, the MSCAN immediately stops all ongoing transmissions and receptions, potentially causing CAN protocol violations. To protect the CAN bus system from fatal consequences of violations to the above rule, the MSCAN immediately drives TXCAN into a recessive state.

NOTE

The user is responsible for ensuring that the MSCAN is not active when power down mode is entered. The recommended procedure is to bring the MSCAN into Sleep mode before the STOP or WAI instruction (if CSWAI is set) is executed. Otherwise, the abort of an ongoing message can cause an error condition and impact other CAN bus devices.

In power down mode, all clocks are stopped and no registers can be accessed. If the MSCAN was not in sleep mode before power down mode became active, the module performs an internal recovery cycle after powering up. This causes some fixed delay before the module enters normal mode again.

13.4.5.7 Disabled Mode

The MSCAN is in disabled mode out of reset (CANE=0). All module clocks are stopped for power saving, however the register map can still be accessed as specified.

13.4.5.8 Programmable Wake-Up Function

The MSCAN can be programmed to wake up from sleep or power down mode as soon as CAN bus activity is detected (see control bit WUPE in MSCAN Control Register 0 (CANCTL0). The sensitivity to existing CAN bus action can be modified by applying a low-pass filter function to the RXCAN input line (see control bit WUPM in [Section 13.3.2.2, “MSCAN Control Register 1 \(CANCTL1\)”](#)).

This feature can be used to protect the MSCAN from wake-up due to short glitches on the CAN bus lines. Such glitches can result from—for example—electromagnetic interference within noisy environments.

13.4.6 Reset Initialization

The reset state of each individual bit is listed in [Section 13.3.2, “Register Descriptions,”](#) which details all the registers and their bit-fields.

13.4.7 Interrupts

This section describes all interrupts originated by the MSCAN. It documents the enable bits and generated flags. Each interrupt is listed and described separately.

13.4.7.1 Description of Interrupt Operation

The MSCAN supports four interrupt vectors (see [Table 13-38](#)), any of which can be individually masked (for details see [Section 13.3.2.6, “MSCAN Receiver Interrupt Enable Register \(CANRIER\)”](#) to [Section 13.3.2.8, “MSCAN Transmitter Interrupt Enable Register \(CANTIER\)”](#)).

Refer to the device overview section to determine the dedicated interrupt vector addresses.

Table 13-38. Interrupt Vectors

Interrupt Source	CCR Mask	Local Enable
Wake-Up Interrupt (WUPIF)	1 bit	CANRIER (WUPIE)
Error Interrupts Interrupt (CSCIF, OVRIF)	1 bit	CANRIER (CSCIE, OVRIE)
Receive Interrupt (RXF)	1 bit	CANRIER (RXFIE)
Transmit Interrupts (TXE[2:0])	1 bit	CANTIER (TXEIE[2:0])

13.4.7.2 Transmit Interrupt

At least one of the three transmit buffers is empty (not scheduled) and can be loaded to schedule a message for transmission. The TXEx flag of the empty message buffer is set.

13.4.7.3 Receive Interrupt

A message is successfully received and shifted into the foreground buffer (RxFG) of the receiver FIFO. This interrupt is generated immediately after receiving the EOF symbol. The RXF flag is set. If there are multiple messages in the receiver FIFO, the RXF flag is set as soon as the next message is shifted to the foreground buffer.

13.4.7.4 Wake-Up Interrupt

A wake-up interrupt is generated if activity on the CAN bus occurs during MSCAN sleep or power-down mode.

NOTE

This interrupt can only occur if the MSCAN was in sleep mode (SLPRQ = 1 and SLPK = 1) before entering power down mode, the wake-up option is enabled (WUPE = 1), and the wake-up interrupt is enabled (WUPIE = 1).

13.4.7.5 Error Interrupt

An error interrupt is generated if an overrun of the receiver FIFO, error, warning, or bus-off condition occurs. MSCAN Receiver Flag Register (CANRFLG) indicates one of the following conditions:

- **Overrun** — An overrun condition of the receiver FIFO as described in [Section 13.4.2.3, “Receive Structures,”](#) occurred.
- **CAN Status Change** — The actual value of the transmit and receive error counters control the CAN bus state of the MSCAN. As soon as the error counters skip into a critical range (Tx/Rx-warning, Tx/Rx-error, bus-off) the MSCAN flags an error condition. The status change, which caused the error condition, is indicated by the TSTAT and RSTAT flags (see [Section 13.3.2.5, “MSCAN Receiver Flag Register \(CANRFLG\)”](#) and [Section 13.3.2.6, “MSCAN Receiver Interrupt Enable Register \(CANRIER\)”](#)).

13.4.7.6 Interrupt Acknowledge

Interrupts are directly associated with one or more status flags in either the MSCAN Receiver Flag Register (CANRFLG) or the MSCAN Transmitter Flag Register (CANTFLG). Interrupts are pending as long as one of the corresponding flags is set. The flags in CANRFLG and CANTFLG must be reset within the interrupt handler to handshake the interrupt. The flags are reset by writing a 1 to the corresponding bit position. A flag cannot be cleared if the respective condition prevails.

NOTE

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

13.5 Initialization/Application Information

13.5.1 MSCAN initialization

The procedure to initially start up the MSCAN module out of reset is as follows:

1. Assert CANE
2. Write to the configuration registers in initialization mode
3. Clear INTRQ to leave initialization mode

If the configuration of registers which are only writable in initialization mode shall be changed:

1. Bring the module into sleep mode by setting SLPRQ and awaiting SLPK to assert after the CAN bus becomes idle.
2. Enter initialization mode: assert INTRQ and await INITAK
3. Write to the configuration registers in initialization mode
4. Clear INTRQ to leave initialization mode and continue

13.5.2 Bus-Off Recovery

The bus-off recovery is user configurable. The bus-off state can either be left automatically or on user request.

For reasons of backwards compatibility, the MSCAN defaults to automatic recovery after reset. In this case, the MSCAN will become error active again after counting 128 occurrences of 11 consecutive recessive bits on the CAN bus (see the Bosch CAN 2.0 A/B specification for details).

If the MSCAN is configured for user request (BORM set in MSCAN Control Register 1 (CANCTL1)), the recovery from bus-off starts after both independent events have become true:

- 128 occurrences of 11 consecutive recessive bits on the CAN bus have been monitored
- BOHOLD in MSCAN Miscellaneous Register (CANMISC) has been cleared by the user

These two events may occur in any order.

Chapter 14

Programmable Trigger Unit (PTUV3)

Table 14-1. Revision History Table

Rev. No. (Item No.)	Data	Sections Affected	Substantial Change(s)
01.00	21 Oct. 2011	all	Initial Version
02.00	22. Mar. 2012	14.3.2.1, 14.3.2.7, 14.3.2.10, 14.3.2.14 - 14.3.2.17	- removed PTUWP bit (now: PTUPTR is write protected if both TGs are disabled, TGxLxIDX is write protected if the associated TG is disabled) - TGxLIST bits are writeable if associated TG is disabled - PTULDOK bit is writable if both TGs are disabled - TGxLIST swap at every reload with LDOK set
3.0	16. Jul. 2013		minor corrections

Table 14-2. Terminology

Term	Meaning
TG	Trigger Generator
EOL	End of trigger list

14.1 Introduction

In PWM driven systems it is important to schedule the acquisition of the state variables with respect to PWM cycle.

The Programmable Trigger Unit (PTU) is intended to completely avoid CPU involvement in the time acquisitions of state variables during the control cycle that can be half, full, multiple PWM cycles.

All acquisition time values are stored inside the global memory map, basically inside the system memory; see the MMC section for the supported memory area. In such cases the pre-setting of the acquisition times needs to be completed during the previous control cycle to where the actual acquisitions are to be made.

14.1.1 Features

The PTU module includes these distinctive features:

- One 16 bit counter as time base for all trigger events
- Two independent trigger generators (TG0 and TG1)
- Up to 32 trigger events per trigger generator

- Global Load OK support, to guarantee coherent update of all control loop modules
- Trigger values stored inside the global memory map, basically inside system memory
- Software generated reload event and Trigger event generation for debugging

14.1.2 Modes of Operation

The PTU module behaves as follows in the system power modes:

1. Run mode
All PTU features are available.
2. Wait mode
All PTU features are available.
3. Freeze Mode
Depends on the PTUFRZ register bit setting the internal counter is stopped and no trigger events will be generated.
4. Stop mode
The PTU is disabled and the internal counter is stopped; no trigger events will be generated. The content of the configuration register is unchanged.

14.1.3 Block Diagram

Figure 14-1 shows a block diagram of the PTU module.

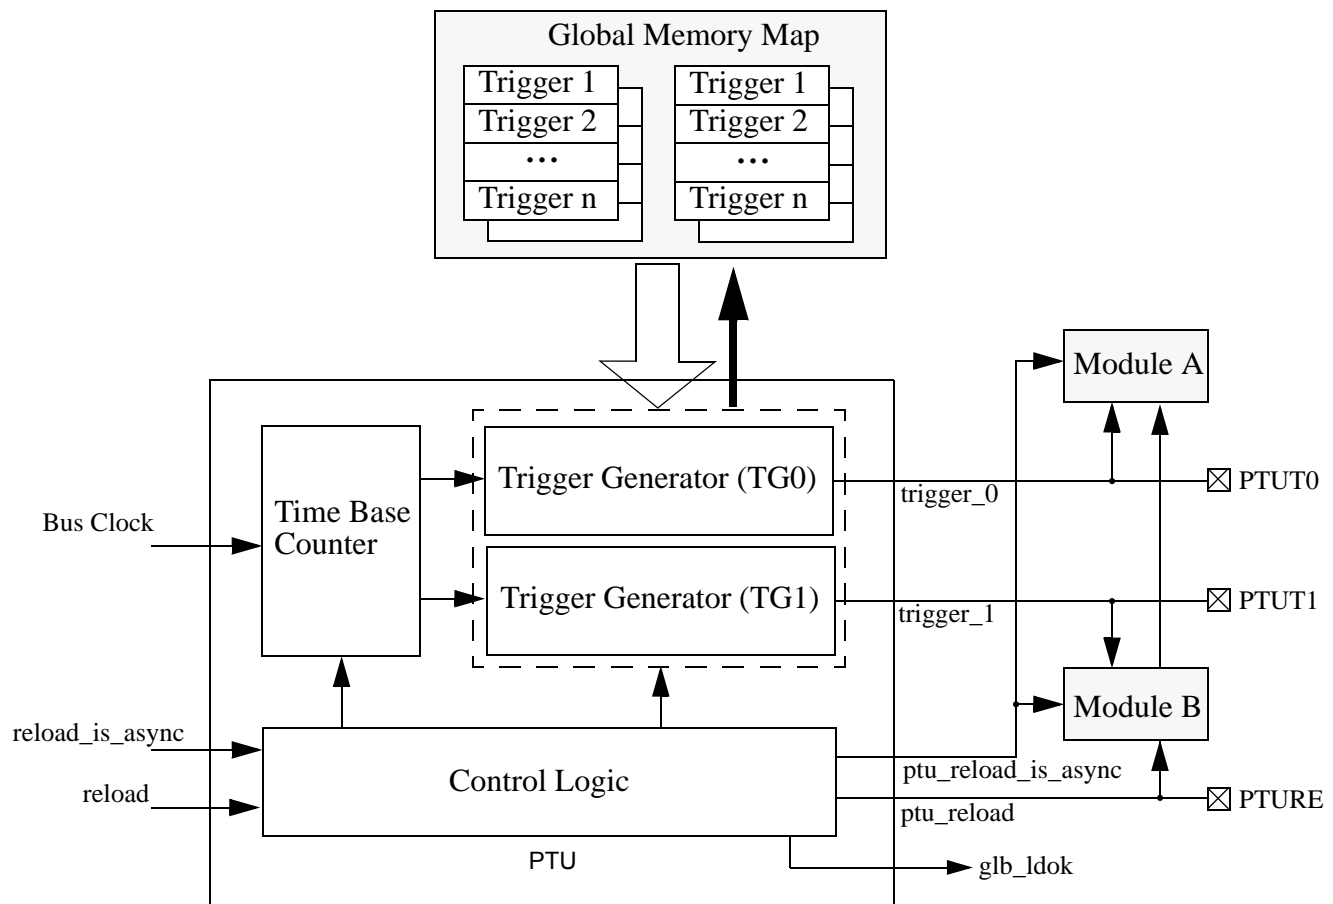

Figure 14-1. PTU Block Diagram

14.2 External Signal Description

This section lists the name and description of all external ports.

14.2.1 PTUT0 — PTU Trigger 0

If enabled (PTUT0PE is set) this pin shows the internal trigger_0 event.

14.2.2 PTUT1 — PTU Trigger 1

If enabled (PTUT1PE is set) this pin shows the internal trigger_1 event.

14.2.3 PTURE — PTUE Reload Event

If enabled (PTUREPE is set) this pin shows the internal reload event.

14.3 Memory Map and Register Definition

This section provides the detailed information of all registers for the PTU module.

14.3.1 Register Summary

Figure 14-2 shows the summary of all implemented registers inside the PTU module.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset Register Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 14-2. PTU Register Summary

14.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order. Unused bits read back zero.

14.3.2.1 PTU Module Enable Register (PTUE)

Figure 14-3. PTU Module Enable Register (PTUE)

1. Read: Anytime
Write: Anytime

Table 14-3. PTUE Register Field Description

Field	Description
6 PTUFRZ	<p>PTU Stop in Freeze Mode — In freeze mode, there is an option to disable the input clock to the PTU time base counter. If this bit is set, whenever the MCU is in freeze mode, the input clock to the time base counter is disabled. In this way, the counters can be stopped while in freeze mode so that once normal program flow is continued, the counter is re-enabled.</p> <p>0 Allow time base counter to continue while in freeze mode 1 Disable time base counter clock whenever the part is in freeze mode</p>
1 TG1EN	<p>Trigger Generator 1 Enable — This bit enables trigger generator 1.</p> <p>0 Trigger generator 1 is disabled 1 Trigger generator 1 is enabled</p>
0 TG0EN	<p>Trigger Generator 0 Enable — This bit enables trigger generator 0.</p> <p>0 Trigger generator 0 is disabled 1 Trigger generator 0 is enabled</p>

14.3.2.2 PTU Module Control Register (PTUC)

Figure 14-4. PTU Module Control Register (PTUC)

1. Read: Anytime
Write: write 1 anytime, write 0 if TG0EN and TG1EN is cleared

Table 14-4. PTUC Register Field Descriptions

Field	Description
0 PTULDOK	Load Okay — When this bit is set by the software, this allows the trigger generator to switch to the alternative list and load the trigger time values at the next reload event from the new list. If the reload event occurs when the PTULDOK bit is not set then the trigger generator generates a reload overrun event and uses the previously used list. At the next reload event this bit is cleared by control logic. Write 0 is only possible if TG0EN and TG1EN is cleared. The PTULDOK can be used by other module as global load OK (glb_ldok).

14.3.2.3 PTU Interrupt Enable Register High (PTUIEH)

Figure 14-5. PTU Interrupt Enable Register High (PTUIEH)

1. Read: Anytime
Write: Anytime

Table 14-5. PTUIEH Register Field Descriptions

Field	Description
0 PTUROIE	PTU Reload Overrun Interrupt Enable — Enables PTU reload overrun interrupt. 0 No interrupt will be requested whenever PTUROIF is set 1 Interrupt will be requested whenever PTUROIF is set

14.3.2.4 PTU Interrupt Enable Register Low (PTUIEL)

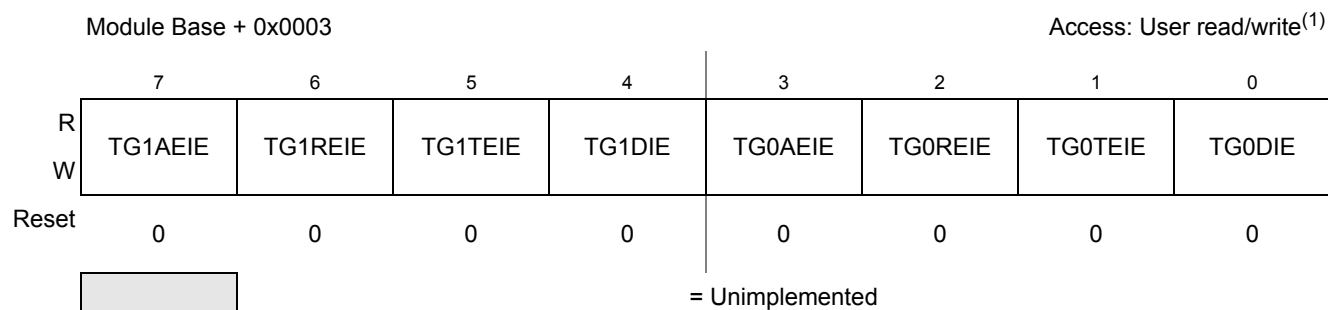

Figure 14-6. PTU Interrupt Enable Register Low (PTUIEL)

1. Read: Anytime
Write: Anytime

Table 14-6. PTUIEL Register Field Descriptions

Field	Description
7 TG1AEIE	Trigger Generator 1 Memory Access Error Interrupt Enable — Enables trigger generator memory access error interrupt. 0 No interrupt will be requested whenever TG1AEIF is set 1 Interrupt will be requested whenever TG1AEIF is set
6 TG1REIE	Trigger Generator 1 Reload Error Interrupt Enable — Enables trigger generator reload error interrupt. 0 No interrupt will be requested whenever TG1REIF is set 1 Interrupt will be requested whenever TG1REIF is set

Table 14-6. PTUIEL Register Field Descriptions

Field	Description
5 TG1TEIE	Trigger Generator 1 Timing Error Interrupt Enable — Enables trigger generator timing error interrupt. 0 No interrupt will be requested whenever TG1TEIF is set 1 Interrupt will be requested whenever TG1TEIF is set
4 TG1DIE	Trigger Generator 1 Done Interrupt Enable — Enables trigger generator done interrupt. 0 No interrupt will be requested whenever TG1DIF is set 1 Interrupt will be requested whenever TG1DIF is set
3 TG0AEIE	Trigger Generator 0 Memory Access Error Interrupt Enable — Enables trigger generator memory access error interrupt. 0 No interrupt will be requested whenever TG0AEIF is set 1 Interrupt will be requested whenever TG0AEIF is set
2 TG0REIE	Trigger Generator 0 Reload Error Interrupt Enable — Enables trigger generator reload error interrupt. 0 No interrupt will be requested whenever TG0REIF is set 1 Interrupt will be requested whenever TG0REIF is set
1 TG0TEIE	Trigger Generator 0 Timing Error Interrupt Enable — Enables trigger generator timing error interrupt. 0 No interrupt will be requested whenever TG0TEIF is set 1 Interrupt will be requested whenever TG0TEIF is set
0 TG0DIE	Trigger Generator 0 Done Interrupt Enable — Enables trigger generator done interrupt. 0 No interrupt will be requested whenever TG0DIF is set 1 Interrupt will be requested whenever TG0DIF is set

14.3.2.5 PTU Interrupt Flag Register High (PTUIFH)

Figure 14-7. PTU Interrupt Flag Register High (PTUIFH)

1. Read: Anytime
Write: Anytime, write 1 to clear

Table 14-7. PTUIFH Register Field Descriptions

Field	Description
1 PTUDEEF	PTU Double bit ECC Error Flag — This bit is set if the read data from the memory contains double bit ECC errors. While this bit is set the trigger generation of both trigger generators stops. 0 No double bit ECC error occurs 1 Double bit ECC error occurs
0 PTUROIF	PTU Reload Overrun Interrupt Flag — If reload event occurs when the PTULDOK bit is not set then this bit will be set. This bit is not set if the reload event was forced by an asynchronous commutation event. 0 No reload overrun occurs 1 Reload overrun occurs

1. Read: Anytime
Write: only in special mode

Table 14-21. PTUDEBUG Register Field Descriptions

Field	Description
6 PTUREPE	PTU Pin Enable — This bit enables the output port for pin PTURE. 0 PTURE output port are disabled 1 PTURE output port are enabled
5 PTUT1PE	PTU PTUT1 Pin Enable — This bit enables the output port for pin PTUT1. 0 PTUT1 output port are disabled 1 PTUT1 output port are enabled
4 PTUT0PE	PTU PTUT0 Pin Enable — This bit enables the output port for pin PTUT0. 0 PTUT0 output port are disabled 1 PTUT0 output port are enabled
2 PTUFRE	Force Reload event generation — If one of the TGs is enabled then writing 1 to this bit will generate a reload event. The reload event forced by PTUFRE does not set the PTUROIF interrupt flag. Also the ptu_reload signal asserts for one bus clock cyclet. Writing 0 to this bit has no effect. Always reads back as 0. This behavior is not available during stop or freeze mode.
1 TG1FTE	Trigger Generator 1 Force Trigger Event — If TG1 is enabled then writing 1 to this bit will generate a trigger event independent on the list based trigger generation. Writing 0 to this bit has no effect. Always reads back as 0. This behavior is not available during stop or freeze mode.
0 TG0FTE	Trigger Generator 0 Force Trigger Event — If TG0 is enabled then writing 1 to this bit will generate a trigger event independent on the list based trigger generation. Writing 0 to this bit has no effect. Always reads back as 0. This behavior is not available during stop or freeze mode.

14.4 Functional Description

14.4.1 General

The PTU module consists of two trigger generators (TG0 and TG1). For each TG a separate enable bit is available, so that both TGs can be enabled independently.

If both trigger generators are disabled then the PTU is disabled, the trigger generation stops and the memory accesses are disabled.

The trigger generation of the PTU module is synchronized to the incoming reload event. This reload event resets and restarts the internal time base counter and makes sure that the first trigger value from the actual trigger list is loaded. Furthermore the corresponding module is informed that a new control cycle has started.

If the counter value matches the current trigger value then a trigger event is generated. In this way, the reload event is delayed by the number of bus clock cycles defined by the current trigger value. After this, a new trigger value is loaded from the memory and the TG waits for the next match. So up to 32 trigger events per control cycle can be generated. If the trigger value is 0x0000 or 32 trigger events have been generated during this control cycle, the TGxDIF bit is set and the TG waits for the next reload event.

Figure 14-22 shows an example of the trigger generation using the trigger values shown in Figure 14-23.

Figure 14-22. TG0 trigger generation example

NOTE

If the trigger list contains less than 32 trigger values a delay between the generation of the last trigger and the assertion of the done interrupt flag will be visible. During this time the PTU loads the next trigger value from the memory to evaluate the EOL symbol.

14.4.2 Memory based trigger event list

The lists with the trigger values are located inside the global memory map. The location of the trigger lists in the memory map is configured with registers PTUPTR and TGxLxIDX. If one of the TGs is enabled then the PTUPTR register is locked. If the TG is enabled then the associated TGxLxIDX registers are locked.

The trigger values inside the trigger list are 16 bit values. Each 16 bit value defines the delay between the reload event and the trigger event in bus clock cycles. A delay value of 0x0000 will be interpreted as End Of trigger List (EOL) symbol. The list must be sorted in ascending order. If a subsequent value is smaller than the previous value or the loaded trigger value is smaller than the current counter value then the TGxTEIF error indication is generated and the trigger generation of this list is stopped until the next reload event. For more information about these error scenario see [Section 14.4.5.5, “Trigger Generator Timing Error”](#).

The module is not able to access memory area outside the 256 byte window starting at the memory address defined by PTUPTR.

Figure 14-23. Global Memory map usage

14.4.3 Reload mechanism

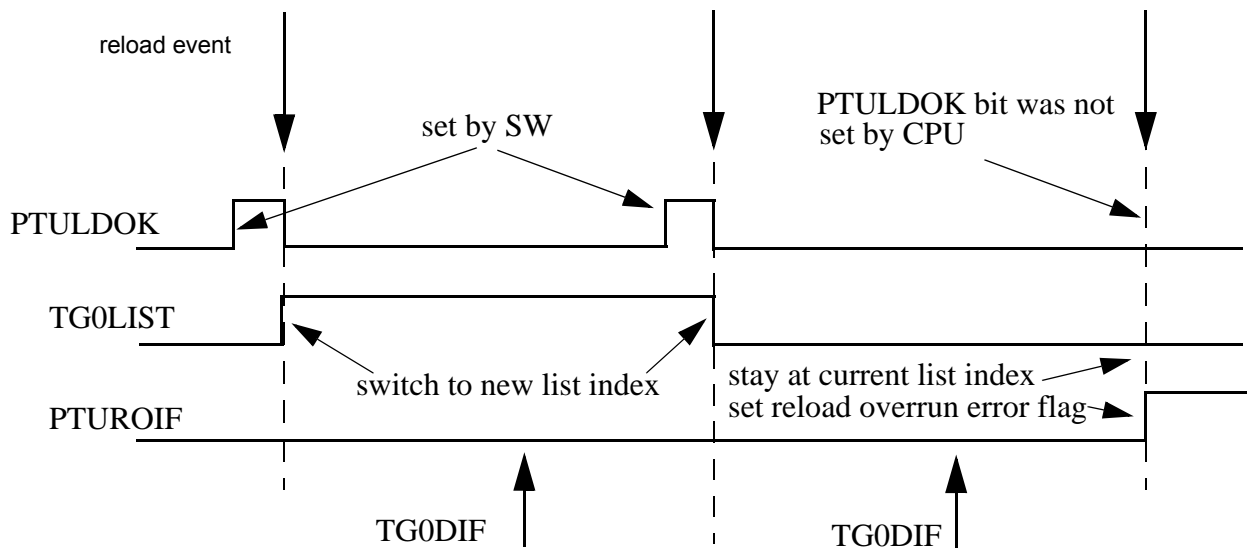

Each trigger generator uses two lists to load the trigger values from the memory. One list can be updated by the CPU while the other list is used to generate the trigger events. After enabling, the TG uses the lists in alternate order. When the update of alternate trigger list is done, the SW must set the PTULDOK bit. If the load OK bit is set at the time of reload event, the TG switches to the alternate list and loads the first trigger value from this trigger event list. The reload event clears the PTULDOK bit.

The TG0LIST and TG1LIST bits shows the currently use list number. These bits are writeable if the associated TG is disabled.

If the PTULDOK bit was not set before the reload event then the reload overrun error flag is set (PTUROIF) and both TGs do not switch to the alternative list. The current trigger list is used to load the trigger values. [Figure 14-24](#) shows an example. The PTULDOK bit can be used by other modules as `glb_ldok`.

To reduce the used memory size, it is also possible to set TG0LOIDX equal to TG0L1IDX or to set TG1LOIDX equal to TG1L1IDX. In this case the trigger generator is using only one physical list of trigger events even if the trigger generator logic is switching between both pointers. The SW must make sure, that the CPU does not update the trigger list before the execution of the trigger list is done. The time window to update the trigger list starts at the trigger generator done interrupt flag (TGxDIF) and ends with the next reload event. Even if only one physical trigger event list is used the TGxLIST shows a swap between list 0 and 1 at every reload event with set PTULDOK bit.

Figure 14-24. TG0 Reload behavior with local PTULDOK

14.4.4 Async reload event

If the reload and reload_is_async are active at the same time then an async reload event happens. The PTU behavior on an async reload event is the same like on the reload event described in [Section 14.4.3, “Reload](#)

[mechanism](#)” above. The only difference is, that during an async reload event the error interrupt flags PTUROIF and TGxREIF are not generated.

14.4.5 Interrupts and error handling

This section describes the interrupts generated by the PTU module and their individual sources, Vector addresses and interrupt priority are defined by MCU level.

Table 14-22. PTU Interrupt Sources

Module Interrupt Sources	Local Enable
PTU Reload Overrun Error	PTUIEH[PTUROIE]
TG0 Error	PTUIEL[TG0AEIE, TG0REIE, TG0TEIE]
TG1 Error	PTUIEL[TG1AEIE, TG1REIE, TG1TEIE]
TG0 Done	PTUIEL[TG0DIE]
TG1 Done	PTUIEL[TG1DIE]

14.4.5.1 PTU Double Bit ECC Error

If one trigger generator reads trigger values from the memory which contains double bit ECC errors then the PTUDEEF is set. These read data are ignored and the execution of both trigger generators is stopped until the PTUDEEF flag was cleared. To make sure the trigger generator starts in a define state it is required to execute follow sequence:

1. disable both trigger generators
2. configure the PTU if required
3. clear the PTUDEEF
4. enable the desired trigger generators

14.4.5.2 PTU Reload Overrun Error

If the PTULDOK bit is not set during the reload event then the PTUROIF bit is set. If enabled (PTUROIE is set) an interrupt is generated. For more information see [Section 14.4.3, “Reload mechanism”](#). During an async reload event the PTUROIF interrupt flag is not set.

14.4.5.3 Trigger Generator Memory Access Error

The trigger generator memory access error flag (TGxAEIF) is set if the used read address is outside the accessible memory address area; see the MMC section for the supported memory area. The loaded trigger values are ignored and the execution of this trigger list is stopped until the next reload event. If enabled (TGxAEIE is set) an interrupt will be generated.

14.4.5.4 Trigger Generator Reload Error

The trigger generator reload error flag (TGxREIF) is set if a new reload event occurs before the trigger generator reaches the EOL symbol or the maximum number of generated triggers. Independent of this

error condition the trigger generator reloads the new data from the trigger list and starts to generate the trigger. During an async reload event the TGxREIF interrupt flag is not set.

If the trigger value loaded from the memory contains double bit ECC errors (PTUDEEF flag is set) then the data is ignored and the trigger generator reload error flag (TGxREIF) is not set.

14.4.5.5 Trigger Generator Timing Error

The PTU module requires a defined number of bus clock cycle to load the next trigger value from the memory. This load time defines the minimum possible distance between consecutive trigger values within one trigger list or the distance between the reload event and the first trigger value. If a smaller distance is used then it is possible, depending on device conditions, that the TGxTEIF event is generated. To evaluate the TGxTEIF handling a distance of 1 should be used. This value will generate the TGxTEIF condition independent from the device conditions.

For the specification of this number, please see the Device Overview chapter.

The trigger generator timing error flag (TGxTEIF) is set if the loaded trigger value is smaller than the current counter value. The execution of this trigger list is stopped until the next reload event. There are different reasons for the trigger generator error condition:

- reload time exceeds time of next trigger event
- reload time exceeds the time between two consecutive trigger values
- a subsequent trigger value is smaller than the predecessor trigger value

If the trigger value loaded from the memory contains double bit ECC errors (PTUDEEF flag is set) then the data are ignored and the trigger generator timing error flag (TGxTEIF) is not set.

If enabled (TGxEIE is set) an interrupt will be generated.

14.4.5.6 Trigger Generator Done

The trigger generator done flag (TGxDIF) is set if the loaded trigger value contains 0x0000 or if the number of maximum trigger events (32) was reached. Please note, that the time which is required to load the next trigger value defines the delay between the generation of the last trigger and the assertion of the done flag. If enabled (TGxDIE is set) an interrupt is generated. If the trigger value loaded from the memory contains double bit ECC errors (PTUDEEF flag is set) then the data are ignored and the trigger generator done flag (TGxDIF) is not set.

14.4.6 Debugging

To see the internal status of the trigger generator the register TGxLIST, TGxTNUM, and TGxTV can be used. The TGxLIST register shows the number of currently used list. The TGxTNUM shows the number of generated triggers since the last reload event. If the maximum number of triggers was generated then this register shows zero. The trigger value loaded from the memory to generate the next trigger event is visible inside the TGxTV register. If the execution of the trigger list is done then these registers are unchanged until the next reload event. The next PWM reload event clears the TGxTNUM register and toggles the used trigger list if PTULDOK was set.

To generate a reload event or trigger event independent from the PWM status the debug register bits PTUFRE or TGxFTE can be used. A write one to this bits will generate the associated event. This behavior is not available during stop or freeze mode.

Glossary

Table 15-2. Glossary of Terms

Term	Definition
Set	Discrete signal is in active logic state.
Clear	A discrete signal is in inactive logic state.
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.

Table 15-2. Glossary of Terms

Term	Definition
PWM active state Normal output Positive polarity	PWM logic level high causing external power device to conduct
PWM inactive or disabled state Inverted output Negative polarity	PWM logic level low causing external power device not to conduct
PWM clock	Clock supplied to PWM and deadtime generators. Based on core clock. Rate depends on prescaler setting.
PWM cycle	PWM period determined by modulus register and PWM clock rate. Note the differences in edge- or center-aligned mode.
PWM reload cycle	A.k.a. control cycle. Determined by load frequency which is 1 to n-times the PWM cycle. PWM reload cycle triggered double-buffered registers take effect at the next PWM reload event.
Commutation cycle	For 6-step motor control only. Started by an event external to the PMF module (async_event). This may be a delayed Hall effect or back-EMF zero crossing event determining the rotor position. Commutation cycle triggered double-buffered registers take effect at the next commutation event and optionally the PWM counters are restarted.
Index x	Related to time bases. $x = A, B$ or C
Index n	Related to PWM channels. $n = 0, 1, 2, 3, 4,$ or 5
Index m	Related to fault inputs. $m = 0, 1, 2, 3, 4,$ or 5

15.1 Introduction

NOTE

Device reference manuals specify which module version is integrated on the device. Some reference manuals support families of devices, with device dependent module versions. This chapter describes the superset. The feature differences are listed in [Table 15-3](#).

Table 15-3. Comparison of PMF15B6C Module Versions

Feature	V3	V4
Write protection (WP) on REV1-0 bits	not available	available
Ability to read the PWM output value through PMFOUTB register	not available	available

The Pulse width Modulator with Fault protection (PMF) module can be configured for one, two, or three complementary pairs. For example:

- One complementary pair and four independent PWM outputs
- Two complementary pairs and two independent PWM outputs

- Three complementary pairs and zero independent PWM outputs
- Zero complementary pairs and six independent PWM outputs

All PWM outputs can be generated from the same counter, or each pair can have its own counter for three independent PWM frequencies. Complementary operation permits programmable deadtime insertion, distortion correction through current sensing by software, and separate top and bottom output polarity control. Each counter value is programmable to support a continuously variable PWM frequency. Both edge- and center-aligned synchronous pulse width-control and full range modulation from 0 percent to 100 percent, are supported. The PMF is capable of controlling most motor types: AC induction motors (ACIM), both brushless (BLDC) and brush DC motors (BDC), switched (SRM) and variable reluctance motors (VRM), and stepper motors.

15.1.1 Features

- Three complementary PWM signal pairs, or six independent PWM signals
- Edge-aligned or center-aligned mode
- Features of complementary channel operation:
 - Deadtime insertion
 - Separate top and bottom pulse width correction via current status inputs or software
 - Three variants of PWM output:
 - Asymmetric in center-aligned mode
 - Variable edge placement in edge-aligned mode
 - Double switching in center-aligned mode
- Three 15-bit counters based on core clock
- Separate top and bottom polarity control
- Half-cycle reload capability
- Integral reload rates from 1 to 16
- Programmable fault protection
- Link to timer output compare for 6-step BLDC commutation support with optional counter restart Reload overrun interrupt
- PWM compare output polarity control Software-controlled PWM outputs, complementary or independent

15.1.2 Modes of Operation

Care must be exercised when using this module in the modes listed in [Table 15-4](#). Some applications require regular software updates for proper operation. Failure to do so could result in destroying the hardware setup. Because of this, PWM outputs are placed in their inactive states in STOP mode, and optionally under WAIT and FREEZE modes. PWM outputs will be reactivated (assuming they were active to begin with) when these modes are exited.

Table 15-4. Modes When PWM Operation is Restricted

Mode	Description
STOP	PWM outputs are disabled
WAIT	PWM outputs are disabled as a function of the PMFWAI bit
FREEZE	PWM outputs are disabled as a function of the PMFFRZ bit

15.1.3 Block Diagram

Figure 15-1 provides an overview of the PMF module.

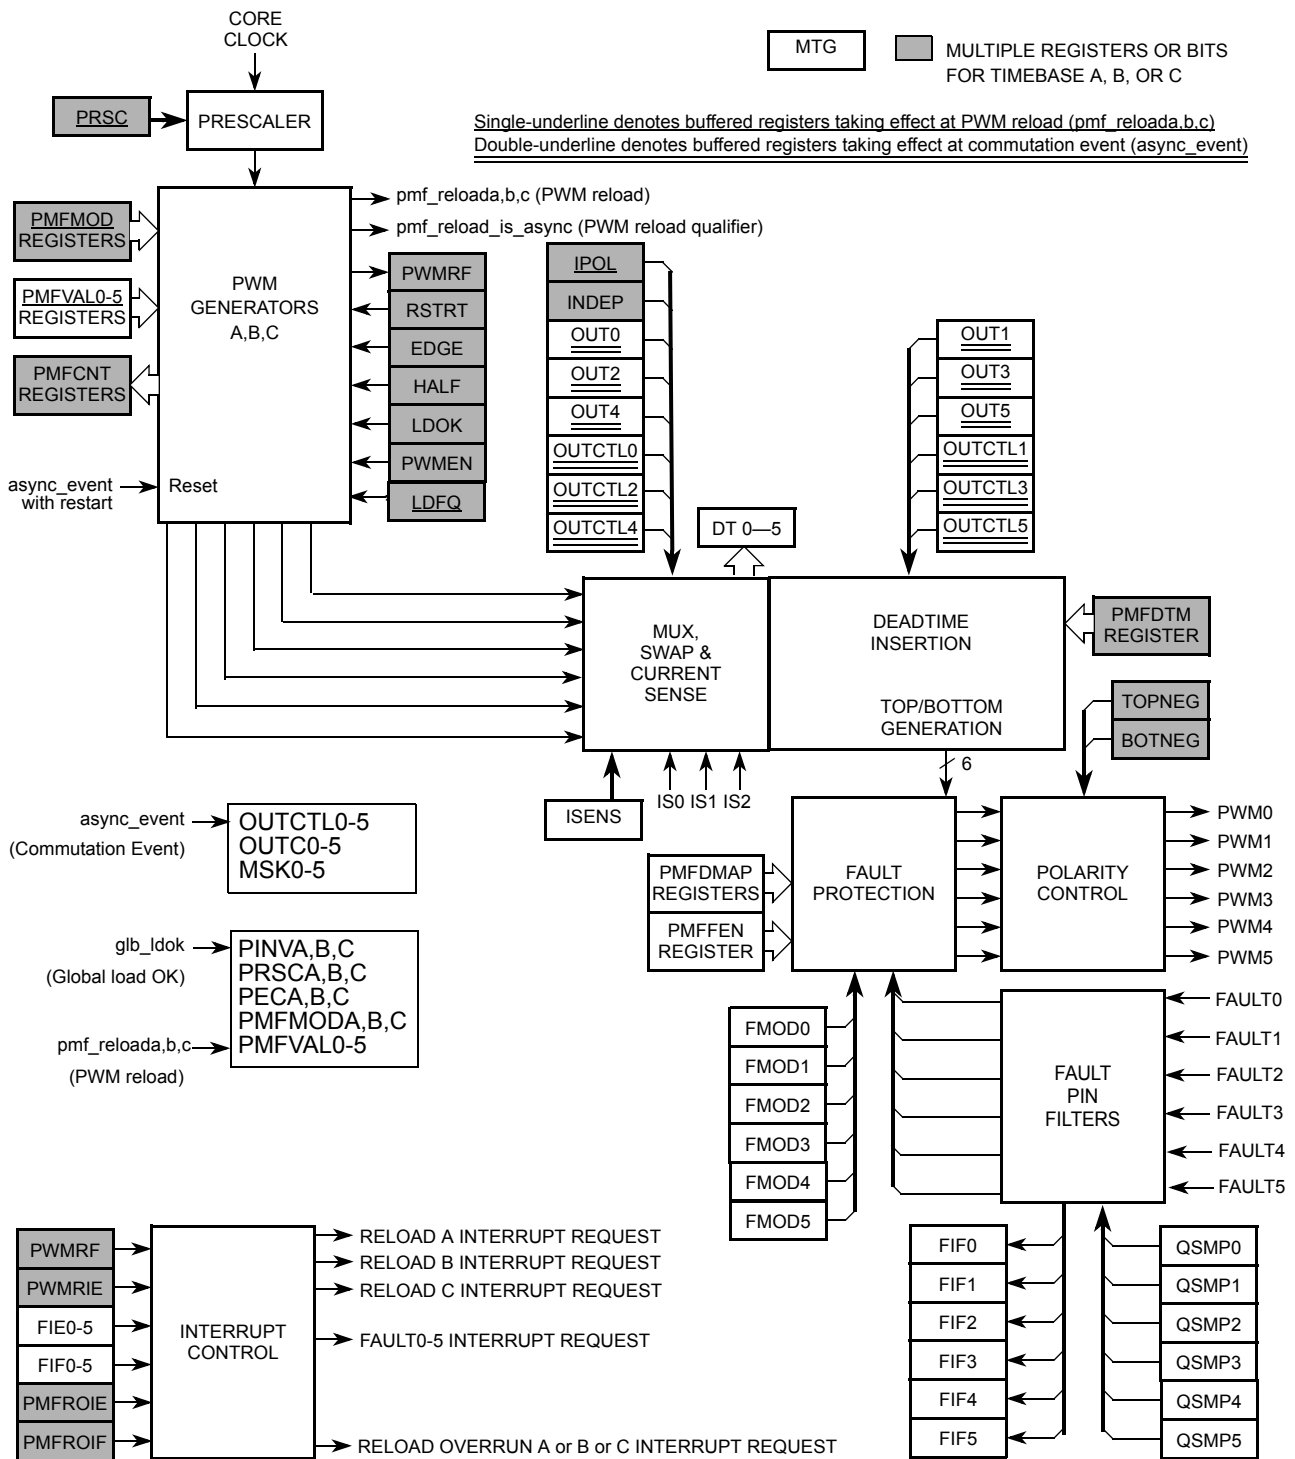

Figure 15-1. PMF Block Diagram

15.2 Signal Descriptions

If the signals are not used exclusively internally, the PMF has external pins named PWM0–5, FAULT0–5, and $\overline{IS0}$ – $\overline{IS2}$. Refer to device overview section.

15.2.1 PWM0–PWM5 Pins

PWM0–PWM5 are the output signals of the six PWM channels.

NOTE

On MCUs with an integrated gate drive unit the PWM outputs are connected internally to the GDU inputs. In these cases the PWM signals may optionally be available on pins for monitoring purposes. Refer to the device overview section for routing options and pin locations.

15.2.2 FAULT0–FAULT5 Pins

FAULT0–FAULT5 are input signals for disabling selected PWM outputs (FAULT0-3) or drive the outputs to a configurable active/inactive state (FAULT4-5).

NOTE

On MCUs with an integrated gate drive unit (GDU) either one or more FAULT inputs may be connected internally or/and available on an external pin. Refer to the device overview section for availability and pin locations.

15.2.3 $\overline{IS0}$ – $\overline{IS2}$ Pins

$\overline{IS0}$ – $\overline{IS2}$ are current status signals for top/bottom pulse width correction in complementary channel operation while deadtime is asserted.

NOTE

Refer to the device overview section for signal availability on pins.

15.2.4 Global Load OK Signal — glb_ldok

This device-internal PMF input signal is connected to the global load OK bit at integration level. For each of the three PWM generator time bases the use of the global load OK input can be enabled individually (GLDOKA,B,C).

15.2.5 Commutation Event Signal — async_event

This device-internal PMF input signal is connected to the source of the asynchronous event generator (preferably timer output compare channel) at integration level.

The commutation event input must be enabled to take effect (ENCE=1). When this bit is set the PMFOUTC, PMFOUT, and MSKx registers switch from non-buffered to async_event triggered double

buffered mode. In addition, if restart is enabled (RSTRTx=1), the commutation event generates both “PWM reload event” and “PWM reload-is-asynchronous event” simultaneously.

15.2.6 Commutation Event Edge Select Signal — `async_event_edge_sel[1:0]`

These device-internal PMF input signals select the active edge for the `async_event` input. Refer to the device overview section to determine if the selection is user configurable or tied constant at integration level.

Table 15-5. Commutation Event Edge Selection

<code>async_event_edge_sel[1:0]</code>	<code>async_event</code> active edge
00	direct input
01	rising edge
10	falling edge
11	both edges

15.2.7 PWM Reload Event Signals — `pmf_reloada,b,c`

These device-internal PMF output signals assert once per control cycle and can serve as triggers for other implemented IP modules. Signal `pmf_reloadb` and `pmf_reloadc` are related to time base B and C, respectively, while signal `pmf_reloada` is off out of reset and can be programmed for time base A, B, or C. Refer to the device overview section to determine the signal connections.

15.2.8 PWM Reload-Is-Asynchronous Signal — `pmf_reload_is_async`

This device-internal PMF output signal serves as a qualifier to the PMF reload event signal `pmf_reloada`. Whenever the `async_event` signal causes `pmf_reloada` output to assert also the `pmf_reload_is_async` output asserts for the same duration, except if asynchronous event and generated PWM reload event occur in the same cycle.

15.3 Memory Map and Registers

15.3.1 Module Memory Map

A summary of the registers associated with the PMF module is shown in [Figure 15-2](#). Detailed descriptions of the registers and bits are given in the subsections that follow.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset	Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000	PMFCFG0	R W	WP	MTG	EDGE C	EDGE B	EDGE A	INDEPC	INDEPB	INDEPA

15.3.2 Register Descriptions

15.3.2.1 PMF Configure 0 Register (PMFCFG0)

Address: Module Base + 0x0000

Access: User read/write⁽¹⁾

	7	6	5	4	3	2	1	0
R	WP	MTG	EDGEA	EDGEA	EDGEA	INDEPC	INDEPB	INDEPA
W								
Reset	0	0	0	0	0	0	0	0

Figure 15-3. PMF Configure 0 Register (PMFCFG0)

1. Read: Anytime

Write: This register cannot be modified after the WP bit is set

Table 15-6. PMFCFG0 Field Descriptions

Field	Description
7 WP	Write Protect — This bit enables write protection to be used for all write-protectable registers. While clear, WP allows write-protected registers to be written. When set, WP prevents any further writes to write-protected registers. Once set, WP can be cleared only by reset. 0 Write-protectable registers may be written 1 Write-protectable registers are write-protected
6 MTG	Multiple Timebase Generators — This bit determines the number of timebase counters used. This bit cannot be modified after the WP bit is set. If MTG is set, PWM generators B and C and registers 0x0028 – 0x0037 are available. The three generators have their own variable frequencies and are not synchronized. If MTG is cleared, PMF registers from 0x0028 – 0x0037 can not be written and read zeroes, and bits EDGEA and EDGEA are ignored. Pair A, Pair B, and Pair C PWMs are synchronized to PWM generator A and use registers from 0x0020 – 0x0027. 0 Single timebase generator 1 Multiple timebase generators
5 EDGEA	Edge-Aligned or Center-Aligned PWM for Pair C — This bit determines whether PWM4 and PWM5 channels will use edge-aligned or center-aligned waveforms. This bit has no effect if MTG bit is cleared. This bit cannot be modified after the WP bit is set. 0 PWM4 and PWM5 are center-aligned PWMs 1 PWM4 and PWM5 are edge-aligned PWMs
4 EDGEA	Edge-Aligned or Center-Aligned PWM for Pair B — This bit determines whether PWM2 and PWM3 channels will use edge-aligned or center-aligned waveforms. This bit has no effect if MTG bit is cleared. This bit cannot be modified after the WP bit is set. 0 PWM2 and PWM3 are center-aligned PWMs 1 PWM2 and PWM3 are edge-aligned PWMs
3 EDGEA	Edge-Aligned or Center-Aligned PWM for Pair A — This bit determines whether PWM0 and PWM1 channels will use edge-aligned or center-aligned waveforms. It determines waveforms for Pair B and Pair C if the MTG bit is cleared. This bit cannot be modified after the WP bit is set. 0 PWM0 and PWM1 are center-aligned PWMs 1 PWM0 and PWM1 are edge-aligned PWMs
2 INDEPC	Independent or Complementary Operation for Pair C — This bit determines if the PWM channels 4 and 5 will be independent PWMs or complementary PWMs. This bit cannot be modified after the WP bit is set. 0 PWM4 and PWM5 are complementary PWM pair 1 PWM4 and PWM5 are independent PWMs

Table 15-6. PMFCFG0 Field Descriptions (continued)

Field	Description
1 INDEPB	Independent or Complementary Operation for Pair B — This bit determines if the PWM channels 2 and 3 will be independent PWMs or complementary PWMs. This bit cannot be modified after the WP bit is set. 0 PWM2 and PWM3 are complementary PWM pair 1 PWM2 and PWM3 are independent PWMs
0 INDEPA	Independent or Complementary Operation for Pair A — This bit determines if the PWM channels 0 and 1 will be independent PWMs or complementary PWMs. This bit cannot be modified after the WP bit is set. 0 PWM0 and PWM1 are complementary PWM pair 1 PWM0 and PWM1 are independent PWMs

15.3.2.2 PMF Configure 1 Register (PMFCFG1)

Address: Module Base + 0x0001

Access: User read/write⁽¹⁾

	7	6	5	4	3	2	1	0
R	0	ENCE	BOTNEGC	TOPNEGC	BOTNEGB	TOPNEGB	BOTNEGA	TOPNEGA
W								
Reset	0	0	0	0	0	0	0	0

Figure 15-4. PMF Configure 1 Register (PMFCFG1)

1. Read: Anytime

Write: This register cannot be modified after the WP bit is set

A normal PWM output or positive polarity means that the PWM channel outputs high when the counter value is smaller than or equal to the pulse width value and outputs low otherwise. An inverted output or negative polarity means that the PWM channel outputs low when the counter value is smaller than or equal to the pulse width value and outputs high otherwise.

NOTE

The TOPNEG_x and BOTNEG_x are intended for adapting to the polarity of external predrivers on devices driving the PWM output directly to pins. If an integrated GDU is driven it must be made sure to keep the reset values of these bits in order not to violate the deadtime insertion.

Table 15-7. PMFCFG1 Field Descriptions

Field	Description
6 ENCE	Enable Commutation Event — This bit enables the commutation event input and activates buffering of registers PMFOUTC and PMFOUTB and MSK _x bits. This bit cannot be modified after the WP bit is set. If set to zero the commutation event input is ignored and writes to the above registers and bits will take effect immediately. If set to one, the commutation event input is enabled and the value written to the above registers and bits does not take effect until the next commutation event occurs. 0 Commutation event input disabled and PMFOUTC, PMFOUTB and MSK _n not buffered 1 Commutation event input enabled and PMFOUTC, PMFOUTB and MSK _n buffered
5 BOTNEGC	Pair C Bottom-Side PWM Polarity — This bit determines the polarity for Pair C bottom-side PWM (PWM5). This bit cannot be modified after the WP bit is set. 0 Positive PWM5 polarity 1 Negative PWM5 polarity

Table 15-7. PMFCFG1 Field Descriptions (continued)

Field	Description
4 TOPNEGC	Pair C Top-Side PWM Polarity — This bit determines the polarity for Pair C top-side PWM (PWM4). This bit cannot be modified after the WP bit is set. 0 Positive PWM4 polarity 1 Negative PWM4 polarity
3 BOTNEGB	Pair B Bottom-Side PWM Polarity — This bit determines the polarity for Pair B bottom-side PWM (PWM3). This bit cannot be modified after the WP bit is set. 0 Positive PWM3 polarity 1 Negative PWM3 polarity
2 TOPNEGB	Pair B Top-Side PWM Polarity — This bit determines the polarity for Pair B top-side PWM (PWM2). This bit cannot be modified after the WP bit is set. 0 Positive PWM2 polarity 1 Negative PWM2 polarity
1 BOTNEGA	Pair A Bottom-Side PWM Polarity — This bit determines the polarity for Pair A bottom-side PWM (PWM1). This bit cannot be modified after the WP bit is set. 0 Positive PWM1 polarity 1 Negative PWM1 polarity
0 TOPNEGA	Pair A Top-Side PWM Polarity — This bit determines the polarity for Pair A top-side PWM (PWM0). This bit cannot be modified after the WP bit is set. 0 Positive PWM0 polarity 1 Negative PWM0 polarity

15.3.2.3 PMF Configure 2 Register (PMFCFG2)

Address: Module Base + 0x0002

Access: User read/write⁽¹⁾

Figure 15-5. PMF Configure 2 Register (PMFCFG2)

1. Read: Anytime

Write: Anytime except REV[1:0] which cannot be modified after the WP bit is set¹.

Table 15-8. PMFCFG2 Field Descriptions

Field	Description
7-6 REV[1:0]	Select timebase counter to output reload event on pmf_reloada These bits select if timebase generator A, B or C provides the reload event on output signal pmf_reloada. This register cannot be modified after the WP bit is set. ⁽¹⁾ 00 Reload event generation disabled 01 PWM generator A generates reload event 10 PWM generator B generates reload event 11 PWM generator C generates reload event

Table 15-8. PMFCFG2 Field Descriptions (continued)

Field	Description
5–0 MSK[5:0]	Mask PWM n — Note: MSK n are buffered if ENCE is set. The value written does not take effect until the next commutation cycle begins. Reading MSK n returns the value in the buffer and not necessarily the value the output control is currently using. 0 PWM n is unmasked 1 PWM n is masked and the channel is set to a value of 0 percent duty cycle n is 0, 1, 2, 3, 4, and 5.

1. only valid for module version V4

WARNING

When using the TOPNEG/BOTNEG bits and the MSK n bits at the same time, when in complementary mode, it is possible to have both PMF channel outputs of a channel pair set to one.

15.3.2.4 PMF Configure 3 Register (PMFCFG3)

Address: Module Base + 0x0003

Access: User read/write⁽¹⁾

Figure 15-6. PMF Configure 3 Register (PMFCFG3)

1. Read: Anytime

Write: This register cannot be modified after the WP bit is set, except for bits PINVA, PINVB and PINVC

Table 15-9. PMFCFG3 Field Descriptions

Field	Description
7 PMFWAI	PMF Stops While in WAIT Mode — When set to zero, the PWM generators will continue to run while the chip is in WAIT mode. In this mode, the peripheral clock continues to run but the CPU clock does not. If the device enters WAIT mode and this bit is one, then the PWM outputs will be switched to their inactive state until WAIT mode is exited. At that point the PWM outputs will resume operation as programmed in the PWM registers. This bit cannot be modified after the WP bit is set. 0 PMF continues to run in WAIT mode 1 PMF is disabled in WAIT mode
6 PMFFRZ	PMF Stops While in FREEZE Mode — When set to zero, the PWM generators will continue to run while the chip is in FREEZE mode. If the device enters FREEZE mode and this bit is one, then the PWM outputs will be switched to their inactive state until FREEZE mode is exited. At that point the PWM outputs will resume operation as programmed in the PWM registers. This bit cannot be modified after the WP bit is set. 0 PMF continues to run in FREEZE mode 1 PMF is disabled in FREEZE mode

Table 15-9. PMFCFG3 Field Descriptions (continued)

Field	Description
4–3 VLMODE [1:0]	Value Register Load Mode — This field determines the way the value registers are being loaded. This register cannot be modified after the WP bit is set. 00 Each value register is accessed independently 01 Writing to value register zero also writes to value registers one to five 10 Writing to value register zero also writes to value registers one to three 11 Reserved (defaults to independent access)
2 PINVC	PWM Invert Complement Source Pair C — This bit controls PWM4/PWM5 pair. When set, this bit inverts the COMPSRCC signal. This bit has no effect in independent mode. Note: PINVC is buffered. The value written does not take effect until the LDOK bit or global load OK is set and the next PWM load cycle begins. Reading PINVC returns the value in the buffer and not necessarily the value in use. 0 No inversion 1 COMPSRCC inverted only in complementary mode
1 PINVB	PWM Invert Complement Source Pair B — This bit controls PWM2/PWM3 pair. When set, this bit inverts the COMPSRCB signal. This bit has no effect in independent mode. Note: PINVB is buffered. The value written does not take effect until the LDOK bit or global load OK is set and the next PWM load cycle begins. Reading PINVB returns the value in the buffer and not necessarily the value in use. 0 No inversion 1 COMPSRCB inverted only in complementary mode
0 PINVA	PWM Invert Complement Source Pair A — This bit controls PWM0/PWM1 pair. When set, this bit inverts the COMPSRCA signal. This bit has no effect on in independent mode. Note: PINVA is buffered. The value written does not take effect until the LDOKA bit or global load OK is set and the next PWM load cycle begins. Reading PINVA returns the value in the buffer and not necessarily the value in use. 0 No inversion 1 COMPSRCA inverted only in complementary mode

Figure 15-12. PMF Fault Qualifying Samples Register (PMFQSMPl)

1. Read: Anytime
Write: This register cannot be modified after the WP bit is set.

Table 15-14. PMFQSMPl Field Descriptions

Field	Description
7-0 QSMPm[1:0]	Fault m Qualifying Samples — This field indicates the number of consecutive samples taken at the FAULTm input to determine if a fault is detected. The first sample is qualified after two bus cycles from the time the fault is present and each sample after that is taken every four core clock cycles. See Table 15-15. This register cannot be modified after the WP bit is set. m is 0, 1, 2, 3, 4 and 5.

Table 15-15. Qualifying Samples

QSMPm[1:0]	Number of Samples
00	1 sample ⁽¹⁾
01	5 samples
10	10 samples
11	15 samples

1. There is an asynchronous path from fault inputs FAULT3-0, FAULT4 if DMPn4=b10, and FAULT5 if DMPn5=b10 to disable PWMs immediately but the fault is qualified in two bus cycles.

15.3.2.10 PMF Output Control Register (PMFOUTC)

Address: Module Base + 0x000C

Access: User read/write⁽¹⁾

Figure 15-13. PMF Output Control Register (PMFOUTC)

1. Read: Anytime
Write: Anytime

Table 15-16. PMFOUTC Field Descriptions

Field	Description
5–0 OUTCTL[5:0]	<p>OUTCTLn Bits — These bits enable software control of their corresponding PWM output. When OUTCTLn is set, the OUTn bit takes over the direct controls the level of the PWMn output.</p> <p>Note: OUTCTLn is buffered if ENCE is set. If ENCE is set, then the value written does not take effect until the next commutation cycle begins. Reading OUTCTLn returns the value in the buffer and not necessarily the value the output control is currently using. If ENCE is not set, then the OUTn bits take immediately effect when OUTCTLn bit is set. If the OUTCTLn bit is cleared then the OUTn control is disabled at the next PMF cycle start.</p> <p>When operating the PWM in complementary mode, these bits must be switched in pairs for proper operation. That is OUTCTL0 and OUTCTL1 must have the same value; OUTCTL2 and OUTCTL3 must have the same value; and OUTCTL4 and OUTCTL5 must have the same value. Otherwise see the behavior described on chapter Section 15.8.2, “BLDC 6-Step Commutation”.</p> <p>0 Software control disabled 1 Software control enabled n is 0, 1, 2, 3, 4 and 5.</p>

Table 15-17. PMFOUTB Field Descriptions

Field	Description
5–0 OUT[5:0]	<p>OUTn Bits — If the corresponding OUTCTLn bit is set, these bits control the PWM outputs, illustrated in Table 15-18.</p> <p>If the related OUTCTLn=1 a read returns the register contents OUTn else the current PWM output states are returned⁽¹⁾ On module version V3 the read returns always the register value.</p> <p>Note: OUTn is buffered if ENCE is set. The value written does not take effect until the next commutation cycle begins. Reading OUTn (with OUTCTLn=1) returns the value in the buffer and not necessarily the value the output control is currently using.</p> <p>n is 0, 1, 2, 3, 4 and 5.</p>

1. only valid for module version V4

Table 15-18. Software Output Control

OUT n Bit	Complementary Channel Operation	Independent Channel Operation
OUT0	1 — PWM0 is active 0 — PWM0 is inactive	1 — PWM0 is active 0 — PWM0 is inactive
OUT1	1 — PWM1 is complement of PWM0 0 — PWM1 is inactive	1 — PWM1 is active 0 — PWM1 is inactive
OUT2	1 — PWM2 is active 0 — PWM2 is inactive	1 — PWM2 is active 0 — PWM2 is inactive
OUT3	1 — PWM3 is complement of PWM2 0 — PWM3 is inactive	1 — PWM3 is active 0 — PWM3 is inactive
OUT4	1 — PWM4 is active 0 — PWM4 is inactive	1 — PWM4 is active 0 — PWM4 is inactive
OUT5	1 — PWM5 is complement of PWM4 0 — PWM5 is inactive	1 — PWM5 is active 0 — PWM5 is inactive

15.3.2.12 PMF Deadtime Sample Register (PMFDTMS)

Address: Module Base + 0x000E

Access: User read/write⁽¹⁾

Figure 15-15. PMF Deadtime Sample Register (PMFDTMS)

- 1. Read: Anytime
Write: Never

Table 15-19. PMFDTMS Field Descriptions

Field	Description
5–0 DT[5:0]	DTn Bits — The DT n bits are grouped in pairs, DT0 and DT1, DT2 and DT3, DT4 and DT5. Each pair reflects the corresponding \overline{IS} input value as sampled at the end of deadtime. n is 0, 1, 2, 3, 4 and 5.

15.3.2.13 PMF Correction Control Register (PMFCCTL)

Address: Module Base + 0x000F

Access: User read/write⁽¹⁾

Figure 15-16. PMF Correction Control Register (PMFCCTL)

1. Read: Anytime
Write: Anytime

Table 15-20. PMFCCTL Field Descriptions

Field	Description
5–4 ISENS[1:0]	<p>Current Status Sensing Method — This field selects the top/bottom correction scheme, illustrated in Table 15-21.</p> <p>Note: The user must provide current sensing circuitry causing the voltage at the corresponding input to be low for positive current and high for negative current. The top PWMs are PWM 0, 2, and 4 and the bottom PWMs are PWM 1, 3, and 5.</p> <p>Note: The ISENS bits are not buffered. Changing the current status sensing method can affect the present PWM cycle.</p>
2 IPOLC	<p>Current Polarity — This buffered bit selects the PMF Value register for PWM4 and PWM5 in top/bottom software correction in complementary mode.</p> <p>0 PMF Value 4 register in next PWM cycle 1 PMF Value 5 register in next PWM cycle</p>
1 IPOLB	<p>Current Polarity — This buffered bit selects the PMF Value register for PWM2 and PWM3 in top/bottom software correction in complementary mode.</p> <p>0 PMF Value 2 register in next PWM cycle 1 PMF Value 3 register in next PWM cycle</p>
0 IPOLA	<p>Current Polarity — This buffered bit selects the PMF Value register for PWM0 and PWM1 in top/bottom software correction in complementary mode.</p> <p>0 PMF Value 0 register in next PWM cycle 1 PMF Value 1 register in next PWM cycle</p>

Table 15-21. Correction Method Selection

ISENS	Correction Method
00	No correction ⁽¹⁾
01	Manual correction
10	Current status sample correction on inputs $\overline{IS0}$, $\overline{IS1}$, and $\overline{IS2}$ during deadtime ⁽²⁾
11	Current status sample on inputs $\overline{IS0}$, $\overline{IS1}$, and $\overline{IS2}$ ⁽³⁾ At the half cycle in center-aligned operation At the end of the cycle in edge-aligned operation

1. The current status inputs can be used as general purpose input/output ports.
2. The polarity of the related \overline{IS} input is latched when both the top and bottom PWMs are off. At the 0% and 100% duty cycle boundaries, there is no deadtime, so no new current value is sensed.
3. Current is sensed even with 0% or 100% duty cycle.

NOTE

The IPOL_x bits take effect at the beginning of the next PWM cycle, regardless of the state of the LDOK bit or global load OK. Select top/bottom software correction by writing 01 to the current select bits, ISENS[1:0], in the PWM control register. Reading the IPOL_x bits read the buffered value and not necessarily the value currently in effect.

R	0	0	PECC	PECB	PECA	ICCC	ICCB	ICCA
W								
Reset	0	0	0	0	0	0	0	0

Figure 15-20. PMF Internal Correction Control Register (PMFICCTL)

1. Read: Anytime
Write: Anytime

This register is used to control PWM pulse generation for various applications, such as a power-supply phase-shifting application.

ICCx bits apply only in center-aligned operation during complementary mode. These control bits determine whether values set in the IPOLx bits control or the whether PWM count direction controls which PWM value register is used.

NOTE

The ICCx bits are buffered. The value written does not take effect until the next PWM load cycle begins regardless of the state of the LDOK bit or global load OK. Reading ICCx returns the value in a buffer and not necessarily the value the PWM generator is currently using.

The PECx bits apply in edge-aligned and center-aligned operation during complementary mode. Setting the PECx bits overrides the ICCx settings. This allows the PWM pulses generated by both the odd and even PWM value registers to be ANDed together prior to the complementary logic and deadtime insertion.

NOTE

The PECx bits are buffered. The value written does not take effect until the related LDOK bit or global load OK is set and the next PWM load cycle begins. Reading PECn returns the value in a buffer and not necessarily the value the PWM generator is currently using.

Figure 15-21. PMF Internal Correction Control Register (PMFICCTL) Descriptions

Field	Description
5 PECC	Pulse Edge Control — This bit controls PWM4/PWM5 pair. 0 Normal operation 1 Allow one of PMFVAL4 and PMFVAL5 to activate the PWM pulse and the other to deactivate the pulse
4 PECB	Pulse Edge Control — This bit controls PWM2/PWM3 pair. 0 Normal operation 1 Allow one of PMFVAL2 and PMFVAL3 to activate the PWM pulse and the other to deactivate the pulse
3 PECA	Pulse Edge Control — This bit controls PWM0/PWM1 pair. 0 Normal operation 1 Allow one of PMFVAL0 and PMFVAL1 to activate the PWM pulse and the other to deactivate the pulse

Figure 15-21. PMF Internal Correction Control Register (PMFICCTL) Descriptions (continued)

Field	Description
2 ICCC	Internal Correction Control — This bit controls PWM4/PWM5 pair. 0 IPOLC setting determines whether to use the PMFVAL4 or PMFVAL5 register 1 Use PMFVAL4 register when the PWM counter is counting up. Use PMFVAL5 register when counting down.
1 ICCB	Internal Correction Control — This bit controls PWM2/PWM3 pair. 0 IPOLB setting determines whether to use the PMFVAL2 or PMFVAL3 register 1 Use PMFVAL2 register when the PWM counter is counting up. Use PMFVAL3 register when counting down.
0 ICCA	Internal Correction Control — This bit controls PWM0/PWM1 pair. 0 IPOLA setting determines whether to use the PMFVAL0 or PMFVAL1 register 1 Use PMFVAL0 register when the PWM counter is counting up. Use PMFVAL1 register when counting down.

15.3.2.18 PMF Compare Invert Register (PMFCINV)

Address: Module Base + 0x001F

Figure 15-23. PMF Compare Invert Register (PMFCINV) Descriptions

Field	Description
5 CINV5	PWM Compare Invert 5 — This bit controls the polarity of PWM compare output 5. Please see the output operations in Figure 15-42 and Figure 15-43 . 0 PWM output 5 is high when PMFCNTC (PMFCNTA if MTG=0) is less than PMFVAL5 1 PWM output 5 is high when PMFCNTC (PMFCNTA if MTG=0) is greater than PMFVAL5
4 CINV4	PWM Compare Invert 4 — This bit controls the polarity of PWM compare output 4. Please see the output operations in Figure 15-42 and Figure 15-43 . 0 PWM output 4 is high when PMFCNTC (PMFCNTA if MTG=0) is less than PMFVAL4 1 PWM output 4 is high when PMFCNTC (PMFCNTA if MTG=0) is greater than PMFVAL4
3 CINV3	PWM Compare Invert 3 — This bit controls the polarity of PWM compare output 3. Please see the output operations in Figure 15-42 and Figure 15-43 . 0 PWM output 3 is high when PMFCNTB (PMFCNTA if MTG=0) is less than PMFVAL3 1 PWM output 3 is high when PMFCNTB (PMFCNTA if MTG=0) is greater than PMFVAL3
2 CINV2	PWM Compare Invert 2 — This bit controls the polarity of PWM compare output 2. Please see the output operations in Figure 15-42 and Figure 15-43 . 0 PWM output 2 is high when PMFCNTB (PMFCNTA if MTG=0) is less than PMFVAL2 1 PWM output 2 is high when PMFCNTB (PMFCNTA if MTG=0) is greater than PMFVAL2

Figure 15-23. PMF Compare Invert Register (PMFCINV) Descriptions (continued)

Field	Description
1 CINV1	PWM Compare Invert 1 — This bit controls the polarity of PWM compare output 1. Please see the output operations in Figure 15-42 and Figure 15-43. 0 PWM output 1 is high when PMFCNTA is less than PMFVAL1 1 PWM output 1 is high when PMFCNTA is greater than PMFVAL1.
0 CINV0	PWM Compare Invert 0 — This bit controls the polarity of PWM compare output 0. Please see the output operations in Figure 15-42 and Figure 15-43. 0 PWM output 0 is high when PMFCNTA is less than PMFVAL0. 1 PWM output 0 is high when PMFCNTA is greater than PMFVAL0

NOTE

Changing CINV n can affect the present PWM cycle, if the related PMFVAL n is zero.

15.3.2.19 PMF Enable Control A Register (PMFENCA)

Address: Module Base + 0x0020

Access: User read/write⁽¹⁾

Figure 15-24. PMF Enable Control A Register (PMFENCA)

1. Read: Anytime

Write: Anytime except GLDOKA and RSTRTA which cannot be modified after the WP bit is set.

Table 15-25. PMFENCA Field Descriptions

Field	Description
7 PWMENA	PWM Generator A Enable — When MTG is clear, this bit when set enables the PWM generators A, B and C and PWM0–5 outputs. When PWMENA is clear, PWM generators A, B and C are disabled, and the PWM0–5 outputs are in their inactive states unless the corresponding OUTCTL bits are set. When MTG is set, this bit when set enables the PWM generator A and the PWM0 and PWM1 outputs. When PWMENA is clear, the PWM generator A is disabled and PWM0 and PWM1 outputs are in their inactive states unless the OUTCTL0 and OUTCTL1 bits are set. After setting this bit a reload event is generated at the beginning of the PWM cycle. 0 PWM generator A and PWM0-1 (2–5 if MTG = 0) outputs disabled unless the respective OUTCTL bit is set 1 PWM generator A and PWM0-1 (2–5 if MTG = 0) outputs enabled
6 GLDOKA	Global Load Okay A — When this bit is set, a PMF external global load OK defined on device level replaces the function of LDOKA. This bit cannot be modified after the WP bit is set. 0 LDOKA controls reload of double buffered registers 1 PMF external global load OK controls reload of double buffered registers
2 RSTRTA	Restart Generator A — When this bit is set, PWM generator A will be restarted at the next commutation event. This bit cannot be modified after the WP bit is set. 0 No PWM generator A restart at the next commutation event. 1 PWM generator A restarts at the next commutation event

Table 15-25. PMFENCA Field Descriptions (continued)

Field	Description
1 LDOKA	<p>Load Okay A — When MTG is clear, this bit allows loads of the PRSCA bits, the PMFMODA register, and the PMFVAL0-5 registers into a set of buffers. The buffered prescaler A divisor, PWM counter modulus A value, and all PWM pulse widths take effect at the next PWM reload.</p> <p>When MTG is set, this bit allows loads of the PRSCA bits, the PMFMODA register, and the PMFVAL0-1 registers into a set of buffers. The buffered prescaler divisor A, PWM counter modulus A value, and PWM0-1 pulse widths take effect at the next PWM reload.</p> <p>Set LDOKA by reading it when it is logic zero and then writing a logic one to it. LDOKA is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic zero to it. Reset clears LDOKA.</p> <p>0 Do not load new modulus A, prescaler A, and PWM0-1 (2-5 if MTG = 0) values 1 Load prescaler A, modulus A, and PWM0-1 (2-5 if MTG = 0) values</p> <p>Note: Do not set PWMENA bit before setting the LDOKA bit and do not clear the LDOKA bit at the same time as setting the PWMENA bit.</p>
0 PWMRIEA	<p>PWM Reload Interrupt Enable A — This bit enables the PWMRFA flag to generate CPU interrupt requests.</p> <p>0 PWMRFA CPU interrupt requests disabled 1 PWMRFA CPU interrupt requests enabled</p>

15.3.2.20 PMF Frequency Control A Register (PMFFQCA)

Address: Module Base + 0x0021

Access: User read/write⁽¹⁾

Figure 15-25. PMF Frequency Control A Register (PMFFQCA)

1. Read: Anytime
Write: Anytime

Table 15-26. PMFFQCA Field Descriptions

Field	Description
7-4 LDFQA[3:0]	<p>Load Frequency A — This field selects the PWM load frequency according to Table 15-27. See Section 15.4.12.3, “Load Frequency” for more details.</p> <p>Note: The LDFQA field takes effect when the current load cycle is complete, regardless of the state of the LDOKA bit or global load OK. Reading the LDFQA field reads the buffered value and not necessarily the value currently in effect.</p>
3 HALFA	<p>Half Cycle Reload A — This bit enables half-cycle reloads in center-aligned PWM mode. This bit has no effect on edge-aligned PWMs. It takes effect immediately. When set, reload opportunities occur also when the counter matches the modulus in addition to the start of the PWM period at count zero. See Section 15.4.12.3, “Load Frequency” for more details.</p> <p>0 Half-cycle reloads disabled 1 Half-cycle reloads enabled</p>
2-1 PRSCA[1:0]	<p>Prescaler A — This buffered field selects the PWM clock frequency illustrated in Table 15-28.</p> <p>Note: Reading the PRSCA field reads the buffered value and not necessarily the value currently in effect. The PRSCA field takes effect at the beginning of the next PWM cycle and only when the LDOKA bit or global load OK is set.</p>

Table 15-26. PMFFQCA Field Descriptions (continued)

Field	Description
0 PWMRFA	<p>PWM Reload Flag A — This flag is set at the beginning of every reload cycle regardless of the state of the LDOKA bit or global load OK. Clear PWMRFA by reading PMFFQCA with PWMRFA set and then writing a logic one to the PWMRFA bit. If another reload occurs before the clearing sequence is complete, writing logic one to PWMRFA has no effect.</p> <p>0 No new reload cycle since last PWMRFA clearing 1 New reload cycle since last PWMRFA clearing</p> <p>Note: Clearing PWMRFA satisfies pending PWMRFA CPU interrupt requests.</p>

Table 15-27. PWM Reload Frequency A

LDFQA[3:0]	PWM Reload Frequency	LDFQ[3:0]	PWM Reload Frequency
0000	Every PWM opportunity	1000	Every 9 PWM opportunities
0001	Every 2 PWM opportunities	1001	Every 10 PWM opportunities
0010	Every 3 PWM opportunities	1010	Every 11 PWM opportunities
0011	Every 4 PWM opportunities	1011	Every 12 PWM opportunities

0111	Every 8 PWM opportunities	1111	Every 16 PWM opportunities

Table 15-28. PWM Prescaler A

PRSCA[1:0]	Prescaler Value P _A	PWM Clock Frequency f _{PWM_A}
00	1	f _{core}
01	2	f _{core} /2
10	4	f _{core} /4
11	8	f _{core} /8

15.3.2.21 PMF Counter A Register (PMFCNTA)

Address: Module Base + 0x0022

Access: User read/write⁽¹⁾

Figure 15-26. PMF Counter A Register (PMFCNTA)

- 1. Read: Anytime
Write: Never

This register displays the state of the 15-bit PWM A counter.

15.3.2.22 PMF Counter Modulo A Register (PMFMODA)

Address: Module Base + 0x0024

Access: User read/write⁽¹⁾

Figure 15-27. PMF Counter Modulo A Register (PMFMODA)

1. Read: Anytime

Write: Anytime. Do not write a modulus value of zero for center-aligned operation. Do not write a modulus of zero or one in edge-aligned mode.

The 15-bit unsigned value written to this register is the PWM period in PWM clock periods.

NOTE

The PWM counter modulo register is buffered. The value written does not take effect until the LDOKA bit or global load OK is set and the next PWM load cycle begins. Reading PMFMODA returns the value in the buffer. It is not necessarily the value the PWM generator A is currently using.

15.3.2.23 PMF Deadtime A Register (PMFDTMA)

Address: Module Base + 0x0026

Access: User read/write⁽¹⁾

Figure 15-28. PMF Deadtime A Register (PMFDTMA)

1. Read: Anytime

Write: This register cannot be modified after the WP bit is set.

The 12-bit value written to this register is the number of PWM clock cycles in complementary channel operation. A reset sets the PWM deadtime register to the maximum value of 0x0FFF, selecting a deadtime of 4095 PWM clock cycles. Deadtime is affected by changes to the prescaler value. The deadtime duration is determined as follows:

$$T_{DEAD_A} = PMFDTMA / f_{PWM_A} = PMFDTMA \times P_A \times T_{core} \quad \text{Eqn. 15-1}$$

15.3.2.24 PMF Enable Control B Register (PMFENCB)

Address: Module Base + 0x0028

Access: User read/write⁽¹⁾

	7	6	5	4	3	2	1	0
R	PWMENB	GLDOKB	0	0	0	RSTRTB	LDOKB	PWMRIEB
W								
Reset	0	0	0	0	0	0	0	0

Figure 15-29. PMF Enable Control B Register (PMFENCB)

1. Read: Anytime. Returns zero if MTG is clear.

Write: Anytime if MTG is set. GLDOKB and RSTRTB cannot be modified after the WP bit is set.

Table 15-29. PMFENCB Field Descriptions

Field	Description
7 PWMENB	<p>PWM Generator B Enable — If MTG is clear, this bit reads zero and cannot be written. If MTG is set, this bit when set enables the PWM generator B and the PWM2 and PWM3 outputs. When PWMENB is clear, PWM generator B is disabled, and the PWM2 and PWM3 outputs are in their inactive states unless the corresponding OUTCTL bits are set.</p> <p>After setting this bit a reload event is generated at the beginning of the PWM cycle.</p> <p>0 PWM generator B and PWM2–3 outputs disabled unless the respective OUTCTL bit is set 1 PWM generator B and PWM2–3 outputs enabled</p>
6 GLDOKB	<p>Global Load Okay B — When this bit is set, a PMF external global load OK defined on device level replaces the function of LDOKB. This bit cannot be modified after the WP bit is set.</p> <p>0 LDOKB controls double reload of buffered registers 1 PMF external global load OK controls reload of double buffered registers</p>
2 RSTRTB	<p>Restart Generator B — When this bit is set, PWM generator B will be restarted at the next commutation event. This bit cannot be modified after the WP bit is set.</p> <p>0 No PWM generator B restart at the next commutation event 1 PWM generator B restart at the next commutation event</p>
1 LDOKB	<p>Load Okay B — If MTG is clear, this bit reads zero and cannot be written. If MTG is set, this bit loads the PRSCB bits, the PMFMODEB register and the PMFVAL2-3 registers into a set of buffers. The buffered prescaler divisor B, PWM counter modulus B value, PWM2–3 pulse widths take effect at the next PWM reload.</p> <p>Set LDOKB by reading it when it is logic zero and then writing a logic one to it. LDOKB is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic zero to it. Reset clears LDOKB.</p> <p>0 Do not load new modulus B, prescaler B, and PWM2–3 values 1 Load prescaler B, modulus B, and PWM2–3 values</p> <p>Note: Do not set PWMENB bit before setting the LDOKB bit and do not clear the LDOKB bit at the same time as setting the PWMENB bit.</p>
0 PWMRIEB	<p>PWM Reload Interrupt Enable B — If MTG is clear, this bit reads zero and cannot be written. If MTG is set, this bit enables the PWMRFB flag to generate CPU interrupt requests.</p> <p>0 PWMRFB CPU interrupt requests disabled 1 PWMRFB CPU interrupt requests enabled</p>

15.3.2.25 PMF Frequency Control B Register (PMFFQCB)

Address: Module Base + 0x0029

Access: User read/write⁽¹⁾

Figure 15-30. PMF Frequency Control B Register (PMFFQCB)

1. Read: Anytime. Returns zero if MTG is clear.
Write: Anytime if MTG is set.

Table 15-30. PMFFQCB Field Descriptions

Field	Description
7–4 LDFQB[3:0]	Load Frequency B — This field selects the PWM load frequency according to Table 15-31 . See Section 15.4.12.3, “Load Frequency” for more details. Note: The LDFQB field takes effect when the current load cycle is complete, regardless of the state of the LDOKB bit or global load OK. Reading the LDFQB field reads the buffered value and not necessarily the value currently in effect.
3 HALFB	Half Cycle Reload B — This bit enables half-cycle reloads in center-aligned PWM mode. This bit has no effect on edge-aligned PWMs. It takes effect immediately. When set, reload opportunities occur also when the counter matches the modulus in addition to the start of the PWM period at count zero. See Section 15.4.12.3, “Load Frequency” for more details. 0 Half-cycle reloads disabled 1 Half-cycle reloads enabled
2–1 PRSCB[1:0]	Precalser B — This buffered field selects the PWM clock frequency illustrated in Table 15-32 . Note: Reading the PRSCB field reads the buffered value and not necessarily the value currently in effect. The PRSCB field takes effect at the beginning of the next PWM cycle and only when the LDOKB bit or global load OK is set.
0 PWMRFB	PWM Reload Flag B — This flag is set at the beginning of every reload cycle regardless of the state of the LDOKB bit. Clear PWMRFB by reading PMFFQCB with PWMRFB set and then writing a logic one to the PWMRFB bit. If another reload occurs before the clearing sequence is complete, writing logic one to PWMRFB has no effect. 0 No new reload cycle since last PWMRFB clearing 1 New reload cycle since last PWMRFB clearing Note: Clearing PWMRFB satisfies pending PWMRFB CPU interrupt requests.

Table 15-31. PWM Reload Frequency B

LDFQB[3:0]	PWM Reload Frequency	LDFQ[3:0]	PWM Reload Frequency
0000	Every PWM opportunity	1000	Every 9 PWM opportunities

15.3.2.26 PMF Counter B Register (PMFCNTB)

Address: Module Base + 0x002A

Access: User read/write⁽¹⁾

Figure 15-31. PMF Counter B Register (PMFCNTB)

- 1. Read: Anytime. Returns zero if MTG is clear.
- Write: Never

This register displays the state of the 15-bit PWM B counter.

15.3.2.27 PMF Counter Modulo B Register (PMFMODB)

Address: Module Base + 0x002C

Access: User read/write⁽¹⁾

Figure 15-32. PMF Counter Modulo B Register (PMFMODB)

- 1. Read: Anytime. Returns zero if MTG is clear.
- Write: Anytime if MTG is set. Do not write a modulus value of zero for center-aligned operation. Do not write a modulus of zero or one in edge-aligned mode.

The 15-bit unsigned value written to this register is the PWM period in PWM clock periods.

NOTE

The PWM counter modulo register is buffered. The value written does not take effect until the LDOKB bit or global load OK is set and the next PWM load cycle begins. Reading PMFMODB returns the value in the buffer. It is not necessarily the value the PWM generator B is currently using.

15.3.2.28 PMF Deadtime B Register (PMFDTMB)

Address: Module Base + 0x002E

Access: User read/write⁽¹⁾

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	PMFDTMB											
W																
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

Figure 15-33. PMF Deadtime B Register (PMFDTMB)

1. Read: Anytime. Returns zero if MTG is clear.

Write: Anytime if MTG is set. This register cannot be modified after the WP bit is set.

The 12-bit value written to this register is the number of PWM clock cycles in complementary channel operation. A reset sets the PWM deadtime register to the maximum value of 0x0FFF, selecting a deadtime of 4095 PWM clock cycles. Deadtime is affected by changes to the prescaler value. The deadtime duration is determined as follows:

$$T_{DEAD_B} = PMFDTMB / f_{PWM_B} = PMFDTMB \times P_B \times T_{core} \quad \text{Eqn. 15-2}$$

15.3.2.29 PMF Enable Control C Register (PMFENCC)

Address: Module Base + 0x0030

Access: User read/write⁽¹⁾

	7	6	5	4	3	2	1	0
R	PWMENC	GLDOKC	0	0	0	RSTRTC	LDOKC	PWMRIEC
W								
Reset	0	0	0	0	0	0	0	0

Figure 15-34. PMF Enable Control C Register (PMFENCC)

1. Read: Anytime. Returns zero if MTG is clear.

Write: Anytime if MTG is set. GLDOKC and RSTRTC cannot be modified after the WP bit is set.

Table 15-33. PMFENCC Field Descriptions

Field	Description
7 PWMENC	PWM Generator C Enable — If MTG is clear, this bit reads zero and cannot be written. If MTG is set, this bit when set enables the PWM generator C and the PWM4 and PWM5 outputs. When PWMENC is clear, PWM generator C is disabled, and the PWM4 and PWM5 outputs are in their inactive states unless the corresponding OUTCTL bits are set. After setting this bit a reload event is generated at the beginning of the PWM cycle. 0 PWM generator C and PWM4–5 outputs disabled unless the respective OUTCTL bit is set 1 PWM generator C and PWM4–5 outputs enabled
6 GLDOKC	Global Load Okay C — When this bit is set, a PMF external global load OK defined on device level replaces the function of LDOKC. This bit cannot be modified after the WP bit is set. 0 LDOKC controls reload of double buffered registers 1 PMF external global load OK controls reload of double buffered registers
2 RSTRTC	Restart Generator C — When this bit is set, PWM generator C will be restarted at the next commutation event. This bit cannot be modified after the WP bit is set. 0 No PWM generator C restart at the next commutation event 1 PWM generator C restart at the next commutation event
1 LDOKC	Load Okay C — If MTG is clear, this bit reads zero and can not be written. If MTG is set, this bit loads the PRSCC bits, the PMFMODEC register and the PMFVAL4–5 registers into a set of buffers. The buffered prescaler divisor C, PWM counter modulus C value, PWM4–5 pulse widths take effect at the next PWM reload. Set LDOKC by reading it when it is logic zero and then writing a logic one to it. LDOKC is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic zero to it. Reset clears LDOKC. 0 Do not load new modulus C, prescaler C, and PWM4–5 values 1 Load prescaler C, modulus C, and PWM4–5 values Note: Do not set PWMENC bit before setting the LDOKC bit and do not clear the LDOKC bit at the same time as setting the PWMENC bit.
0 PWMRIEC	PWM Reload Interrupt Enable C — If MTG is clear, this bit reads zero and cannot be written. If MTG is set, this bit enables the PWMRFC flag to generate CPU interrupt requests. 0 PWMRFC CPU interrupt requests disabled 1 PWMRFC CPU interrupt requests enabled

15.3.2.30 PMF Frequency Control C Register (PMFFQCC)

Address: Module Base + 0x0031

Access: User read/write⁽¹⁾

Figure 15-35. PMF Frequency Control C Register (PMFFQCC)

1. Read: Anytime. Returns zero if MTG is clear.
Write: Anytime if MTG is set.

Table 15-34. PMFFQCC Field Descriptions

Field	Description
7–4 LDFQC[3:0]	<p>Load Frequency C — This field selects the PWM load frequency according to Table 15-35. See Section 15.4.12.3, “Load Frequency” for more details.</p> <p>Note: The LDFQC field takes effect when the current load cycle is complete, regardless of the state of the LDOKC bit or global load OK. Reading the LDFQC field reads the buffered value and not necessarily the value currently in effect.</p>
3 HALFC	<p>Half Cycle Reload C — This bit enables half-cycle reloads in center-aligned PWM mode. This bit has no effect on edge-aligned PWMs. It takes effect immediately. When set, reload opportunities occur also when the counter matches the modulus in addition to the start of the PWM period at count zero. See Section 15.4.12.3, “Load Frequency” for more details.</p> <p>0 Half-cycle reloads disabled 1 Half-cycle reloads enabled</p>
2–1 PRSCC[1:0]	<p>Prescaler C — This buffered field selects the PWM clock frequency illustrated in Table 15-36.</p> <p>Note: Reading the PRSCC field reads the buffered value and not necessarily the value currently in effect. The PRSCC field takes effect at the beginning of the next PWM cycle and only when the LDOKC bit or global load OK is set.</p>
0 PWMRFC	<p>PWM Reload Flag C — This flag is set at the beginning of every reload cycle regardless of the state of the LDOKC bit or global load OK. Clear PWMRFC by reading PMFFQCC with PWMRFC set and then writing a logic one to the PWMRFC bit. If another reload occurs before the clearing sequence is complete, writing logic one to PWMRFC has no effect.</p> <p>0 No new reload cycle since last PWMRFC clearing 1 New reload cycle since last PWMRFC clearing</p> <p>Note: Clearing PWMRFC satisfies pending PWMRFC CPU interrupt requests.</p>

Table 15-35. PWM Reload Frequency C

LDFQC[3:0]	PWM Reload Frequency	LDFQ[3:0]	PWM Reload Frequency
0000	Every PWM opportunity	1000	Every 9 PWM opportunities
0001	Every 2 PWM opportunities	1001	Every 10 PWM opportunities
0010	Every 3 PWM opportunities	1010	Every 11 PWM opportunities
0011	Every 4 PWM opportunities	1011	Every 12 PWM opportunities
0100	Every 5 PWM opportunities	1100	Every 13 PWM opportunities

0110	Every 7 PWM opportunities	1110	Every 15 PWM opportunities
0111	Every 8 PWM opportunities	1111	Every 16 PWM opportunities

Table 15-36. PWM Prescaler C

PRSCC[1:0]	Prescaler Value P_C	PWM Clock Frequency f_{PWM_C}
00	1	f_{core}
01	2	$f_{core}/2$
10	4	$f_{core}/4$
11	8	$f_{core}/8$

15.3.2.31 PMF Counter C Register (PMFCNTC)

Figure 15-36. PMF Counter C Register (PMFCNTC)

- 1. Read: Anytime. Returns zero if MTG is clear.
- Write: Never

This register displays the state of the 15-bit PWM C counter.

15.3.2.32 PMF Counter Modulo C Register (PMFMODC)

Figure 15-37. PMF Counter Modulo C Register (PMFMODC)

- 1. Read: Anytime. Returns zero if MTG is clear.
- Write: Anytime if MTG is set. Do not write a modulus value of zero for center-aligned operation. Do not write a modulus of zero or one in edge-aligned mode.

The 15-bit unsigned value written to this register is the PWM period in PWM clock periods.

NOTE

The PWM counter modulo register is buffered. The value written does not take effect until the LDOKC bit or global load OK is set and the next PWM load cycle begins. Reading PMFMODC returns the value in the buffer. It is not necessarily the value the PWM generator A is currently using.

15.3.2.33 PMF Deadtime C Register (PMFDTMC)

Figure 15-38. PMF Deadtime C Register (PMFDTMC)

- 1. Read: Anytime. Returns zero if MTG is clear.
- Write: Anytime if MTG is set. This register cannot be modified after the WP bit is set.

The 12-bit value written to this register is the number of PWM clock cycles in complementary channel operation. A reset sets the PWM deadtime register to the maximum value of 0x0FFF, selecting a deadtime of 4095 PWM clock cycles. Deadtime is affected by changes to the prescaler value. The deadtime duration is determined as follows:

$$T_{DEAD_C} = PMFDTMC / f_{PWM_C} = PMFDTMC \times P_C \times T_{core} \quad \text{Eqn. 15-3}$$

15.3.2.34 PMF Disable Mapping Registers (PMFDMP0-5)

Write: This register cannot be modified after the WP bit is set.

Table 15-38. PMFOUTF Field Descriptions

Field	Description
5–0 OUTF[5:0]	OUTF Bits — When the corresponding DMP n 4 or DMP n 5 bits are set to switch to output control on a related FAULT4 or FAULT5 event, these bits control the PWM outputs, illustrated in Table 15-39. This register cannot be modified after the WP bit is set.

Table 15-39. Software Output Control on FAULT4 or FAULT5 Event

OUTF n Bit	Complementary Channel Operation	Independent Channel Operation
OUTF0	1 — PWM0 is active 0 — PWM0 is inactive	1 — PWM0 is active 0 — PWM0 is inactive
OUTF1	1 — PWM1 is complement of PWM0 0 — PWM1 is inactive	1 — PWM1 is active 0 — PWM1 is inactive
OUTF2	1 — PWM2 is active 0 — PWM2 is inactive	1 — PWM2 is active 0 — PWM2 is inactive
OUTF3	1 — PWM3 is complement of PWM2 0 — PWM3 is inactive	1 — PWM3 is active 0 — PWM3 is inactive
OUTF4	1 — PWM4 is active 0 — PWM4 is inactive	1 — PWM4 is active 0 — PWM4 is inactive
OUTF5	1 — PWM5 is complement of PWM4 0 — PWM5 is inactive	1 — PWM5 is active 0 — PWM5 is inactive

15.4 Functional Description

15.4.1 Block Diagram

A block diagram of the PMF is shown in [Figure 15-1](#). The MTG bit allows the use of multiple PWM generators (A, B, and C) or just a single generator (A). PWM0 and PWM1 constitute Pair A, PWM2 and PWM3 constitute Pair B, and PWM4 and PWM5 constitute Pair C.

[Figure 15-41](#) depicts Pair A signal paths of PWM0 and PWM1. Pairs B and C have the same structure.

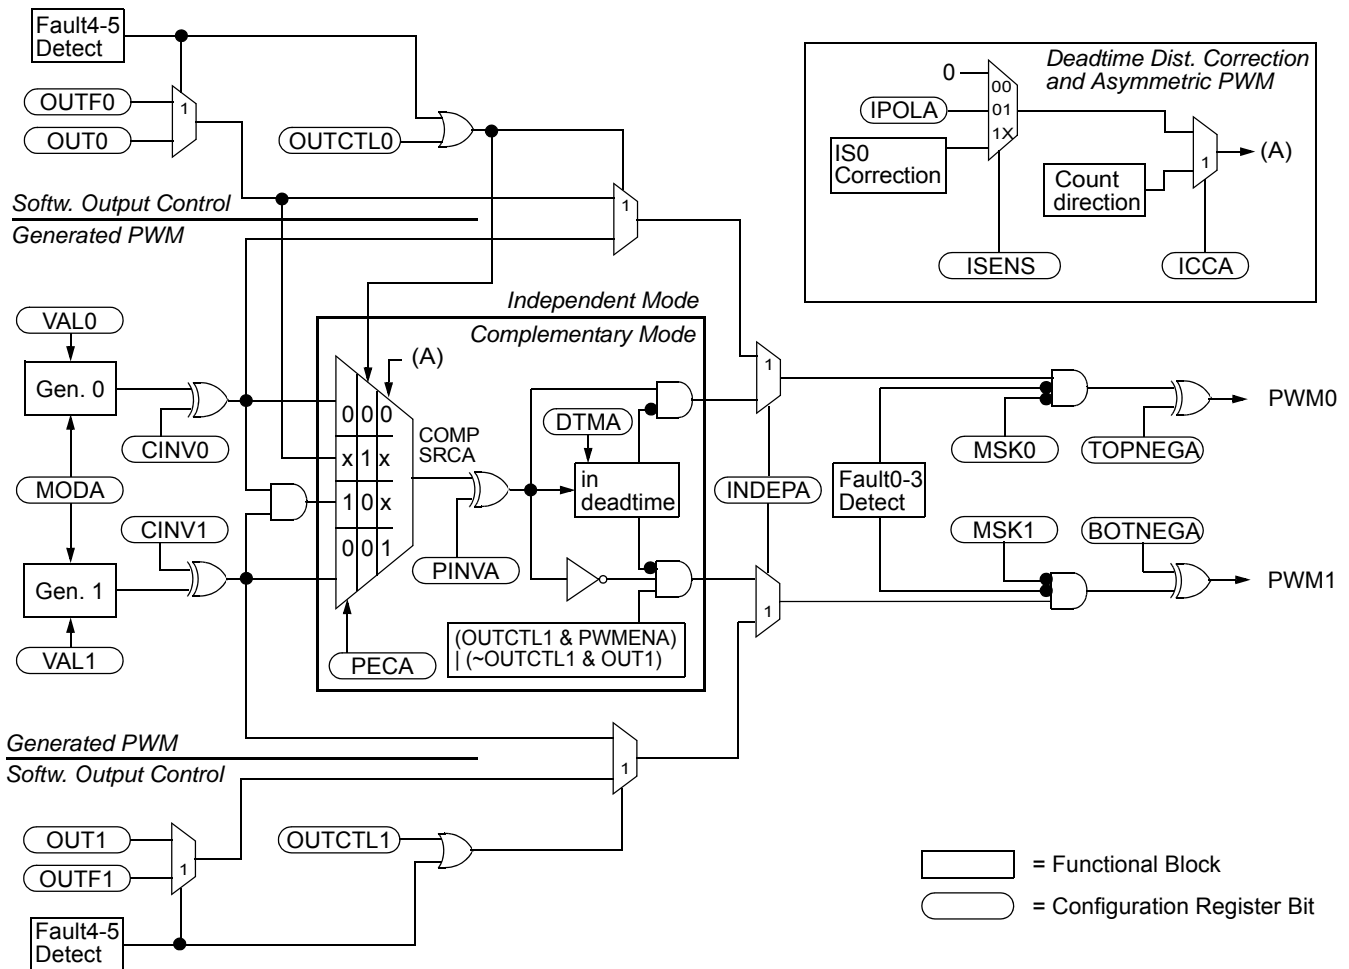

Figure 15-41. Detail of PWM0 and PWM1 Signal Paths

NOTE

It is possible to have both channels of a complementary pair to be high. For example, if the TOPNEGA (negative polarity for PWM0), BOTNEGA (negative polarity for PWM1), MSK0 and MSK1 bits are set, both the PWM complementary outputs of generator A will be high. See [Section 15.3.2.2, “PMF Configure 1 Register \(PMFCFG1\)”](#) for the description of TOPNEGA and BOTNEGA bits, and [Section 15.3.2.3, “PMF Configure 2 Register \(PMFCFG2\)”](#) for the description of the MSK0 and MSK1 bits.

15.4.2 Prescaler

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the core clock frequency by one, two, four, and eight. Each PWM generator has its own prescaler divisor. Each prescaler is buffered and will not be used by its PWM generator until the corresponding Load OK bit is set and a new PWM reload cycle begins.

15.4.3 PWM Generator

Each PWM generator contains a 15-bit up/down PWM counter producing output signals with software-selectable

- Alignment — The logic state of each pair EDGE bit determines whether the PWM pair outputs are edge-aligned or center-aligned
- Period — The value written to each pair PWM counter modulo register is used to determine the PWM pair period. The period can also be varied by using the prescaler
- With edge-aligned output, the modulus is the period of the PWM output in clock cycles
- With center-aligned output, the modulus is one-half of the PWM output period in clock cycles
- Pulse width — The number written to the PWM value register determines the pulse width duty cycle of the PWM output in clock cycles
 - With center-aligned output, the pulse width is twice the value written to the PWM value register
 - With edge-aligned output, the pulse width is the value written to the PWM value register

15.4.3.1 Alignment and Compare Output Polarity

Each edge-align bit, EDGEx, selects either center-aligned or edge-aligned PWM generator outputs.

PWM compare output polarity is selected by the CINV_n bit field in the source control (PMFCINV) register. Please see the output operations in [Figure 15-42](#) and [Figure 15-43](#).

The PWM compare output is driven to a high state when the value of PWM value (PMFVAL_n) register is greater than the value of PWM counter, and PWM compare is counting downwards if the corresponding channel CINV_n=0. Or, the PWM compare output is driven to low state if the corresponding channel CINV_n=1.

The PWM compare output is driven to low state when the value of PWM value (PMFVAL_n) register matches the value of PWM counter, and PWM counter is counting upwards if the corresponding channel CINV_n=0. Or, the PWM compare output is driven to high state if the corresponding channel CINV_n=1.

Figure 15-42. Center-Aligned PWM Output

Figure 15-43. Edge-Aligned PWM Output

15.4.3.2 Period

A PWM period is determined by the value written to the PWM counter modulo registers PMFMOD_x.

The PWM counter is an up/down counter in center-aligned mode. In this mode the PWM highest output resolution is two core clock cycles.

$$\text{PWM period} = (\text{PWM modulus}) \times (\text{PWM clock period}) \times 2$$

Eqn. 15-4

Figure 15-44. Center-Aligned PWM Period

NOTE

Because of the equals-comparator architecture of this PMF, the modulus equals zero case is considered illegal in center-aligned mode. Therefore, the modulus register does not return to zero, and a modulus value of zero will result in waveforms inconsistent with the other modulus waveforms. If a modulus of zero is loaded, the counter will continually count down from 0x7FFF. This operation will not be tested or guaranteed. Consider it illegal. However, the deadtime constraints and fault conditions will still be guaranteed.

In edge-aligned mode, the PWM counter is an up counter. The PWM output resolution is one core clock cycle.

$$\text{PWM period} = \text{PWM modulus} \times \text{PWM clock period}$$

Eqn. 15-5

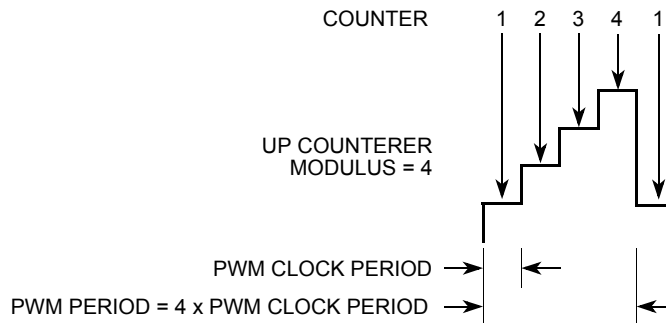

Figure 15-45. Edge-Aligned PWM Period

NOTE

In edge-aligned mode the modulus equals zero and one cases are considered illegal.

15.4.3.3 Duty Cycle

The signed 16-bit number written to the PMF value registers (PMFVAL_n) is the pulse width in PWM clock periods of the PWM generator output (or period minus the pulse width if CINV_n=1).

$$\text{Duty cycle} = \frac{\text{PMFVAL}}{\text{PMFMOD}} \times 100$$

NOTE

A PWM value less than or equal to zero deactivates the PWM output for the entire PWM period. A PWM value greater than or equal to the modulus activates the PWM output for the entire PWM period when CINV_n=0, and vice versa if CINV_n=1.

Table 15-40. PWM Value and Underflow Conditions

PMFVALn	Condition	PWM Value Used
0x0000–0x7FFF	Normal	Value in registers
0x8000–0xFFFF	Underflow	0x0000

Center-aligned operation is illustrated in [Figure 15-46](#).

$$\text{PWM pulse width} = (\text{PWM value}) \times (\text{PWM clock period}) \times 2$$

Eqn. 15-6

Figure 15-46. Center-Aligned PWM Pulse Width

Edge-aligned operation is illustrated in [Figure 15-47](#).

$$\text{PWM pulse width} = (\text{PWM value}) \times (\text{PWM clock period})$$

Eqn. 15-7

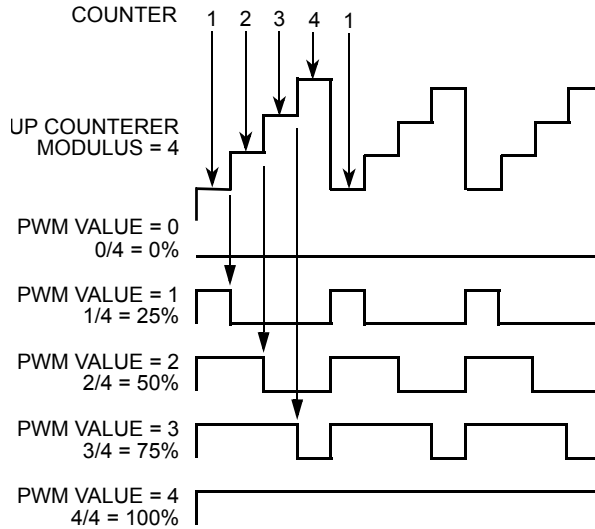

Figure 15-47. Edge-Aligned PWM Pulse Width

15.4.4 Independent or Complementary Channel Operation

Writing a logic one to an INDEP_x bit configures a pair of the PWM outputs as two independent PWM channels. Each PWM output has its own PWM value register operating independently of the other channels in independent channel operation.

Writing a logic zero to a INDEP_x bit configures the PWM output as a pair of complementary channels. The PWM outputs are paired as shown in Figure 15-48 in complementary channel operation.

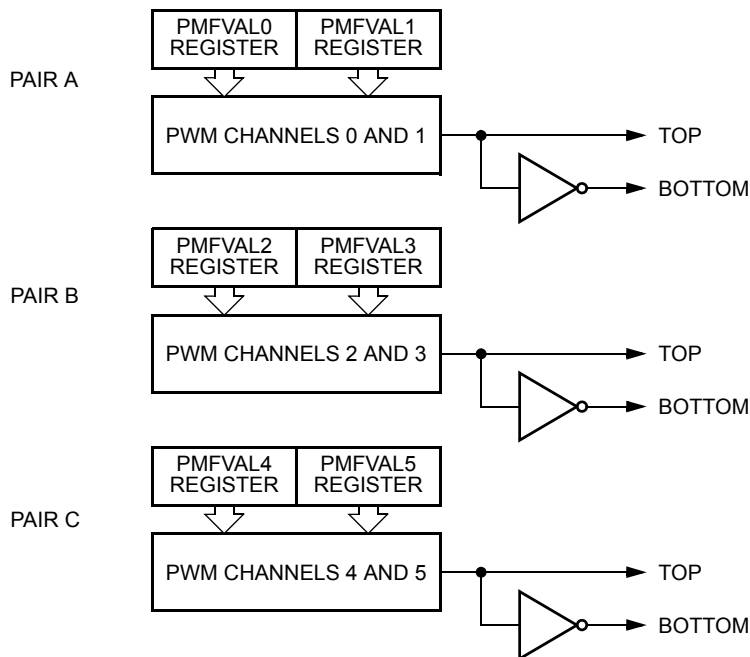

Figure 15-48. Complementary Channel Pairs

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in [Figure 15-49](#).

Figure 15-49. Typical 3-Phase AC Motor Drive

In complementary channel operation following additional features exist:

- Deadtime insertion
- Separate top and bottom pulse width correction via current status inputs or software
- Three variants of PWM output:
 - Asymmetric in center-aligned mode
 - Variable edge placement in edge-aligned mode
 - Double switching in center-aligned mode

15.4.5 Deadtime Generators

While in complementary operation, each PWM pair can be used to drive top/bottom transistors, as shown in [Figure 15-50](#). Ideally, the PWM pairs are an inversion of each other. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

NOTE

To avoid a short-circuit on the DC bus and endangering the transistor, there must be no overlap of conducting intervals between the top and bottom transistor. But the transistor's characteristics make its switching-off time longer than switching-on time. To avoid the conducting overlap of the top and bottom transistors, deadtime needs to be inserted in the switching period.

Deadtime generators automatically insert software-selectable activation delays into each pair of PWM outputs. The deadtime register (PMFDTMx) specifies the number of PWM clock cycles to use for deadtime delay. Every time the deadtime generator inputs changes state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

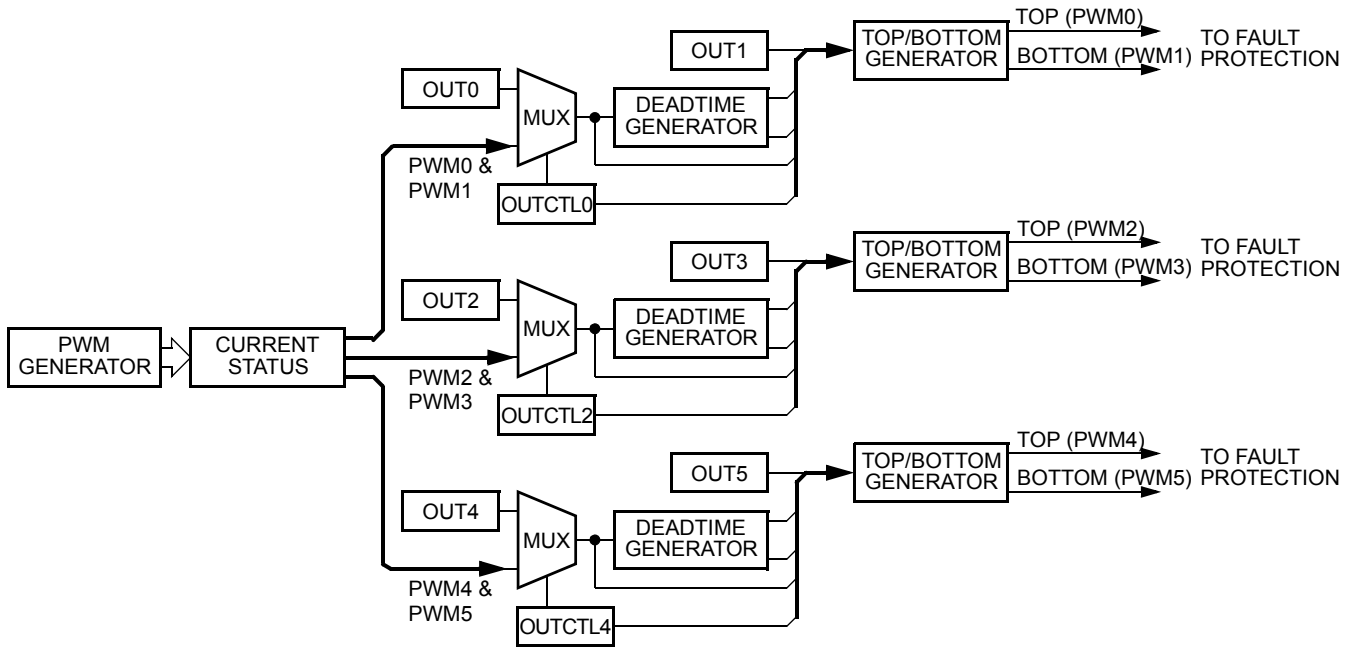

Figure 15-50. Deadtime Generators

Figure 15-51. Deadtime Insertion, Center Alignment

Figure 15-52. Deadtime at Duty Cycle Boundaries

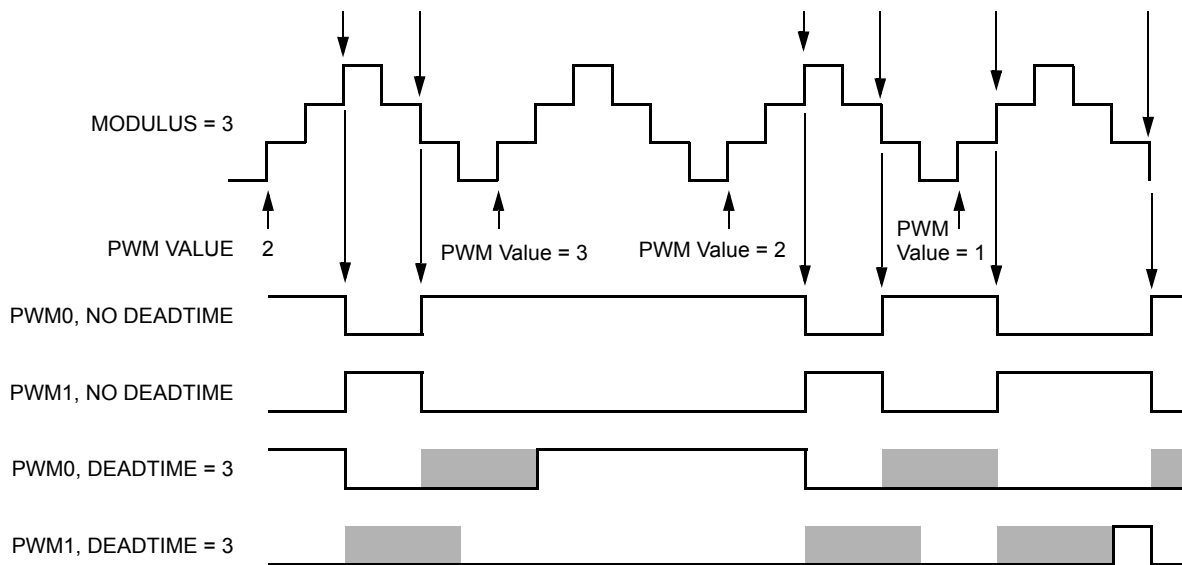

Figure 15-53. Deadtime and Small Pulse Widths

NOTE

The waveform at the output is delayed by two core clock cycles for deadtime insertion.

15.4.6 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of the load and introduce distortion in the output voltage. See [Figure 15-54](#). On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

Figure 15-54. Deadtime Distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in motor current waveform. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time, this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor current for that pair. See Figure 15-54. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in an odd-numbered/even numbered PWM register pair. Either the odd or the even PMFVAL register controls the pulse width at any given time. For a given PWM pair, whether the odd or even PMFVAL register is active depends on either:

- The state of the current status input, \overline{IS} , for that driver
- The state of the odd/even correction bit, IPOLx, for that driver if ICC bits in the PMFICCTL register are set to zeros
- The direction of PWM counter if ICC bits in the PMFICCTL register are set to ones

To correct deadtime distortion, software can decrease or increase the value in the appropriate PMFVAL register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

In the complementary channel operation, ISENS selects one of three correction methods:

- Manual correction
- Automatic current status correction during deadtime
- Automatic current status correction when the PWM counter value equals the value in the PWM counter modulus registers

Table 15-41. Correction Method Selection

ISENS	Correction Method
00	No correction ⁽¹⁾
01	Manual correction
10	Current status sample correction on inputs $\overline{IS0}$, $\overline{IS1}$, and $\overline{IS2}$ during deadtime ⁽²⁾
11	Current status sample on inputs $\overline{IS0}$, $\overline{IS1}$, and $\overline{IS2}$ ⁽³⁾ At the half cycle in center-aligned operation At the end of the cycle in edge-aligned operation

1. The current status inputs can be used as general purpose input/output ports.
2. The polarity of the \overline{IS} input is latched when both the top and bottom PWMs are off. At the 0% and 100% duty cycle boundaries, there is no deadtime, so no new current value is sensed.
3. Current is sensed even with 0% or 100% duty cycle.

NOTE

External current status sensing circuitry is required at the corresponding inputs which produces a logic zero level for positive current and logic one for negative current. PWM 0, 2, and 4 are considered the top PWMs while the bottom PWMs are PWM 1, 3, and 5.

15.4.6.1 Manual Correction

The IPOLx bits select either the odd or the even PWM value registers to use in the next PWM cycle.

Table 15-42. Top/Bottom Manual Correction

Bit	Logic state	Output Control
IPOLA	0	PMFVAL0 controls PWM0/PWM1 pair
	1	PMFVAL1 controls PWM0/PWM1 pair
IPOLB	0	PMFVAL2 controls PWM2/PWM3 pair
	1	PMFVAL3 controls PWM2/PWM3 pair
IPOLC	0	PMFVAL4 controls PWM4/PWM5 pair
	1	PMFVAL5 controls PWM4/PWM5 pair

NOTE

IPOL_x bits are buffered so only one PWM register is used per PWM cycle. If an IPOL_x bit changes during a PWM period, the new value does not take effect until the next PWM period.

IPOL_x bits take effect at the end of each PWM cycle regardless of the state of the related LDOK bit or global load OK.

Figure 15-55. Internal Correction Logic when ISENS = 01

To detect the current status, the voltage on each \overline{IS} input is sampled twice in a PWM period, at the end of each deadtime. The value is stored in the DT_n bits in the PMF Deadtime Sample register (PMFDTMS). The DT_n bits are a timing marker especially indicating when to toggle between PWM value registers. Software can then set the IPOL_x bit to toggle PMFVAL registers according to DT_n values.

Figure 15-56. Current Status Sense Scheme for Deadtime Correction

Both D flip-flops latch low, DT₀ = 0, DT₁ = 0, during deadtime periods if current is large and flowing out of the complementary circuit. See Figure 15-56. Both D flip-flops latch the high, DT₀ = 1, DT₁ = 1, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero.

Sampled results will be $DT0 = 0$ and $DT1 = 1$. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

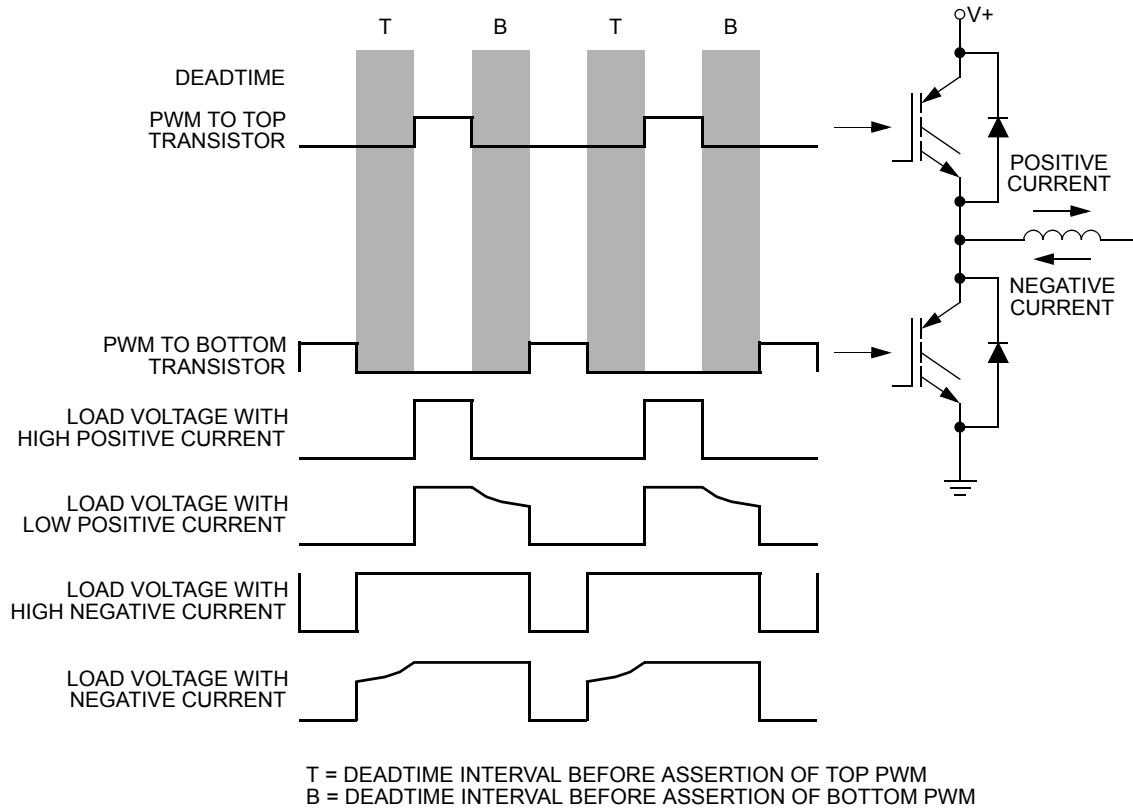

Figure 15-57. Output Voltage Waveforms

15.4.6.2 Current-Sensing Correction

A current sense input, \overline{IS} , for a PWM pair selects either the odd or the even PWM value registers to use in the next PWM cycle. The selection is based on user-provided current sense circuitry driving the related \overline{IS} input high for negative current and low for positive current.

Table 15-43. Top/Bottom Current Sense Correction

Pin	Logic State	Output Control
IS0	0	PMFVAL0 controls PWM0/PWM1 pair
	1	PMFVAL1 controls PWM0/PWM1 pair
IS1	0	PMFVAL2 controls PWM2/PWM3 pair
	1	PMFVAL3 controls PWM2/PWM3 pair
IS2	0	PMFVAL4 controls PWM4/PWM5 pair
	1	PMFVAL5 controls PWM4/PWM5 pair

Previously shown, the current direction can be determined by the output voltage during deadtime. Thus, a simple external voltage sensor can be used when current status is completed during deadtime, $ISENS = 10$. Deadtime does not exist at the 100 percent and zero percent duty cycle boundaries. Therefore, the second automatic mode must be used for correction, $ISENS = 11$, where current status is sampled at the half cycle

in center-aligned operation and at the end of cycle in edge-aligned operation. Using this mode requires external circuitry to sense current direction.

Figure 15-58. Internal Correction Logic when ISENS = 10

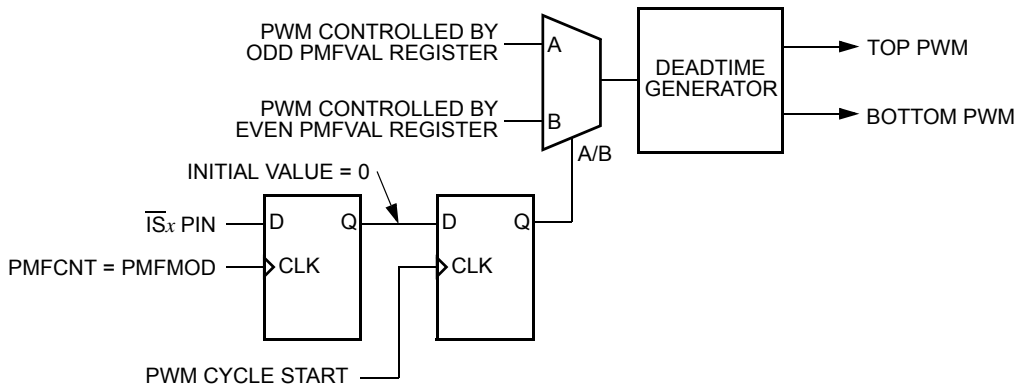

Figure 15-59. Internal Correction Logic when ISENS = 11

NOTE

Values latched on the \overline{IS}_x inputs are buffered so only one PWM register is used per PWM cycle. If a current status changes during a PWM period, the new value does not take effect until the next PWM period.

When initially enabled by setting the PWMEN bit, no current status has previously been sampled. PWM value registers one, three, and five initially control the three PWM pairs when configured for current status correction.

Figure 15-60. Correction with Positive Current

Figure 15-61. Correction with Negative Current

15.4.7 Asymmetric PWM Output

In complementary center-aligned mode, the PWM duty cycle is able to change alternatively at every half cycle. The count direction of the PWM counter selects either the odd or the even PWM value registers to use in the PWM cycle. For counting up, select even PWM value registers to use in the PWM cycle. For counting down, select odd PWM value registers to use in the PWM cycle. The related $CINV_n$ bits of the PWM pair must select the same polarity for both generators.

Table 15-44. Top/Bottom Corrections Selected by ICC_n Bits

Bit	Logic State	Output Control
ICCA	0	IPOLA Controls PWM0/PWM1 Pair
	1	PWM Count Direction Controls PWM0/PWM1 Pair
ICCB	0	IPOLB Controls PWM2/PWM3 Pair
	1	PWM Count Direction Controls PWM2/PWM3 Pair
ICCC	0	IPOLC Controls PWM4/PWM5 Pair
	1	PWM Count Direction Controls PWM4/PWM5 Pair

NOTE

If an ICC_x bit in the PMFICCTL register changes during a PWM period, the new value does not take effect until the next PWM period. ICC_x bits take effect at the end of each PWM cycle regardless of the state of the related LDOK $_x$ bit or global load OK.

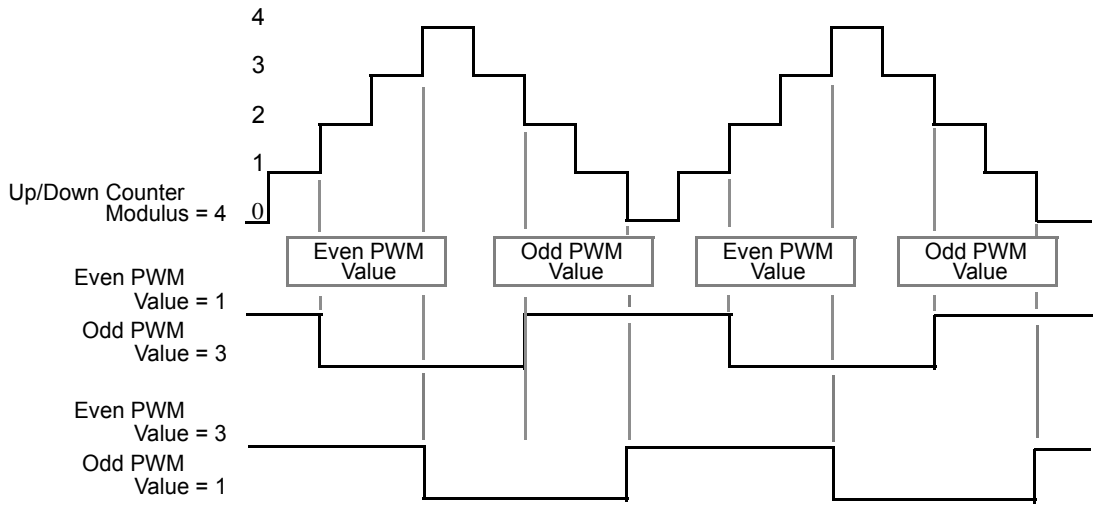

Figure 15-62. Asymmetric Waveform - Phase Shift PWM Output

15.4.8 Variable Edge Placement PWM Output

In complementary edge-aligned mode, the timing of both edges of the PWM output can be controlled using the PECx bits in the PMFICCTL register and the CINVn bits in the PMFCINV register.

The edge-aligned signal created by the even value register and the associated CINVn bit is ANDed with the signal created by the odd value register and its associated CINVn bit. The resulting signal can optionally be negated by PINVx and is then fed into the complement and deadtime logic (Figure 15-63). If the value of the inverted register exceeds the non-inverted register value, no output pulse is generated (0% or 100% duty cycle). See right half of Figure 15-64.

In contrast to asymmetric PWM output mode, the PWM phase shift can pass the PWM cycle boundary.

Figure 15-63. Logic AND Function with Signal Inversions

Figure 15-64. Variable Edge Placement Waveform - Phase Shift PWM Output (Edge-Aligned)

15.4.9 Double Switching PWM Output

By using the AND function in [Figure 15-63](#) in complementary center-aligned mode, the PWM output can be configured for double switching operation ([Figure 15-65](#), [Figure 15-66](#)). By setting the non-inverted value register greater or equal to the PWM modulus the output function can be switched to single pulse generation on PWM reload cycle basis.

Figure 15-65. Double-Switching PWM Output VAL0<VAL1 (Center-Aligned)

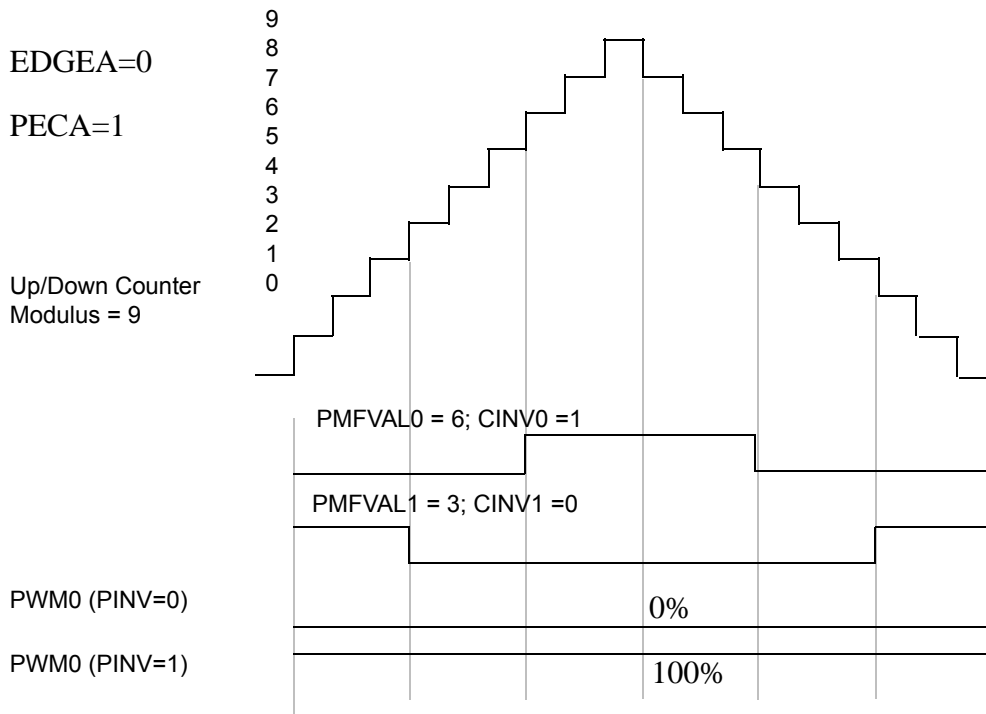

Figure 15-66. Double-Switching PWM Output VAL0>VAL1 (Center-Aligned)

15.4.10 Output Polarity

Output polarity of the PWMs is determined by two options: TOPNEG and BOTNEG. The top polarity option, TOPNEG, controls the polarity of PWM0, PWM2, and PWM4. The bottom polarity option, BOTNEG, controls the polarity of PWM1, PWM3, and PWM5.

Positive polarity means when the PWM is an active level its output is high. Conversely, *negative* polarity means when the PWM is driving an active level its output is low.

If TOPNEG is set, PWM0, PWM2, and PWM4 outputs become *active-low*. When BOTNEG is set, PWM1, PWM3, and PWM5 outputs are *active-low*. When these bits are clear, their respective PWM outputs are *active-high*. See [Figure 15-67](#).

Figure 15-67. PWM Polarity

15.4.11 Software Output Control

Setting output control enable bit, $OUTCTLn$, enables software to drive the PWM outputs instead of the PWM generator. In independent mode, with $OUTCTLn = 1$, the output bit $OUTn$, controls the $PWMn$ channel. In complementary channel operation the even $OUTCTLn$ bit is used to enable software output control for the pair. The $OUTCTLn$ bits must be switched in pairs for proper operation. The $OUTCTLn$ and $OUTn$ bits are in the PWM output control register.

NOTE

During software output control, TOPNEG and BOTNEG still control output polarity. It will take up to 3 core clock cycles to see the effect of output control on the PWM outputs.

In independent PWM operation, setting or clearing the OUT_n bit activates or deactivates the PWM_n output.

In complementary channel operation, the even-numbered OUT_n bits replace the PWM generator outputs as inputs to the deadtime generators. Complementary channel pairs still cannot drive active level simultaneously, and the deadtime generators continue to insert deadtime in both channels of that pair, whenever an even OUT_n bit toggles. Even OUT_n bits control the top PWM signals while the odd OUT_n bits control the bottom PWM signals with respect to the even OUT_n bits. Setting the odd OUT_n bit makes its corresponding PWM the complement of its even pair, while clearing the odd OUT_n bit deactivates the odd PWM.

Setting the $OUTCTL_n$ bits does not disable the PWM generators and current status sensing circuitry. They continue to run, but no longer control the outputs. When the $OUTCTL_n$ bits are cleared, the outputs of the PWM generator become the inputs to the deadtime generators at the beginning of the next PWM cycle. Software can drive the PWM outputs even when PWM enable bit ($PWMEN_x$) is set to zero.

NOTE

Avoid an unexpected deadtime insertion by clearing the OUT_n bits before setting and after clearing the $OUTCTL_n$ bits.

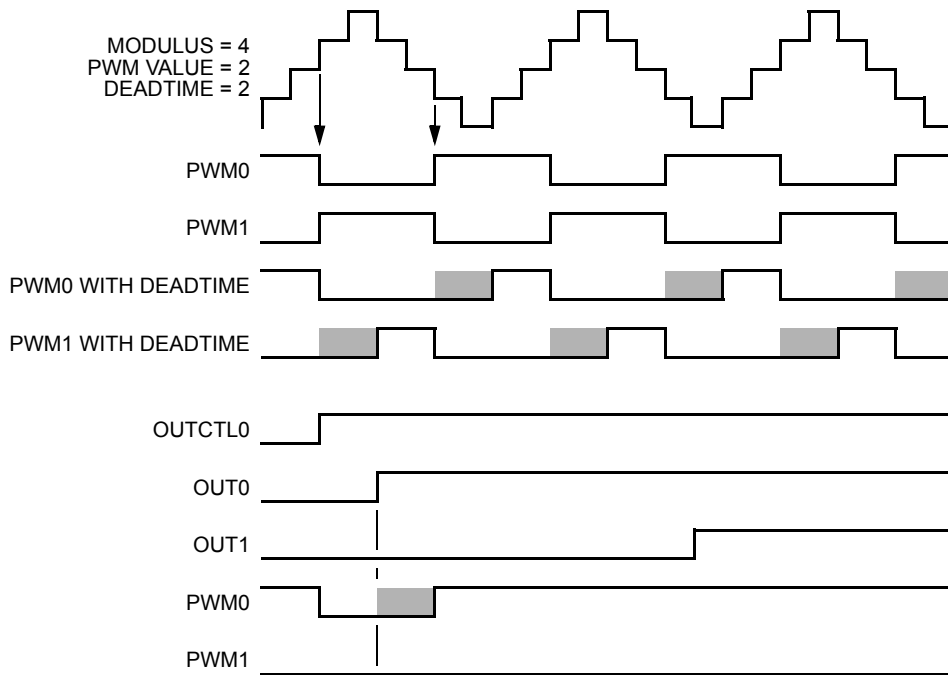

Figure 15-68. Setting OUT_0 with $OUTCTL$ Set in Complementary Mode

Figure 15-69. Clearing OUT0 with OUTCTL Set in Complementary Mode

Figure 15-70. Setting OUTCTL with OUT0 Set in Complementary Mode

15.4.12 PWM Generator Loading

15.4.12.1 Load Enable

The load okay bit, LDOK, enables loading the PWM generator with:

- A prescaler divisor—from the PRSC bits in PMFFQC register
- A PWM period—from the PWM counter modulus registers
- A PWM pulse width—from the PWM value registers

LDOK prevents reloading of these PWM parameters before software is finished calculating them. Setting LDOK allows the prescaler bits, PMFMOD and PMFVAL registers to be loaded into a set of buffers. The loaded buffers are used by the PWM generator at the beginning of the next PWM reload cycle. Set LDOK by reading it when it is a logic zero and then writing a logic one to it. After the PWM reload event, LDOK is automatically cleared.

If LDOK is set in the same cycle as the PWM reload event occurs, then the current buffers will be used and the LDOK is valid at the next PWM reload event. See [Figure 15-71](#).

If an asserted LDOK bit is attempted to be set again one cycle prior to the PWM reload event, then the buffers will be loaded and LDOK will be cleared automatically. Else if the write access to the set LDOK bit occurs in the same cycle with the reload event, the buffers will also be loaded but the LDOK remains valid also for the next PWM reload event. See [Figure 15-72](#).

Figure 15-71. Setting cleared LDOK bit at PWM reload event

Figure 15-72. Setting asserted LDOK bit at PWM reload event

15.4.12.2 Global Load Enable

If a global load enable bit GLDOKA, B, or C is set, the global load OK bit defined on device level as input to the PMF replaces the function of the related local LDOKA, B, or C bits. The global load OK signal is typically shared between multiple IP blocks with the same double buffer scheme. Software handling must be transferred to the global load OK bit at the chip level.

15.4.12.3 Load Frequency

The LDFQ3, LDFQ2, LDFQ1, and LDFQ0 bits in the PWM control register (PMFFQCx) select an integral loading frequency of 1 to 16-PWM reload opportunities. The LDFQ bits take effect at every PWM reload opportunity, regardless the state of the related load okay bit or global load OK. The *half* bit in the PMFFQC register controls half-cycle reloads for center-aligned PWMs. If the *half* bit is set, a reload opportunity occurs at the beginning of every PWM cycle and half cycle when the count equals the modulus. If the half bit is not set, a reload opportunity occurs only at the beginning of every cycle. Reload opportunities can only occur at the beginning of a PWM cycle in edge-aligned mode.

NOTE

Setting the half bit takes effect immediately. Depending on whether the counter is incrementing or decrementing at this point in time, reloads at even-numbered reload frequencies (every 2, 4, 6,... reload opportunities) will occur only when the counter matches the modulus or only when the counter equals zero, respectively (refer to example of reloading at every two opportunities in [Figure 15-74](#)).

NOTE

Loading a new modulus on a half cycle will force the count to the new modulus value minus one on the next clock cycle. Half cycle reloads are possible only in center-aligned mode. Enabling or disabling half-cycle reloads in edge-aligned mode will have no effect on the reload rate.

Figure 15-73. Full Cycle Reload Frequency Change

Figure 15-74. Half Cycle Reload Frequency Change

15.4.12.4 Reload Flag

The PWMRF reload flag is set at every reload opportunity, regardless of whether an actual reload occurs (as determined by the related LDOK bit or global load OK). If the PWM reload interrupt enable bit PWMRIE is set, the PWMRF flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When PWMRIE is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

Figure 15-75. PWMRF Reload Interrupt Request

Figure 15-76. Full-Cycle Center-Aligned PWM Value Loading

Figure 15-77. Full-Cycle Center-Aligned Modulus Loading

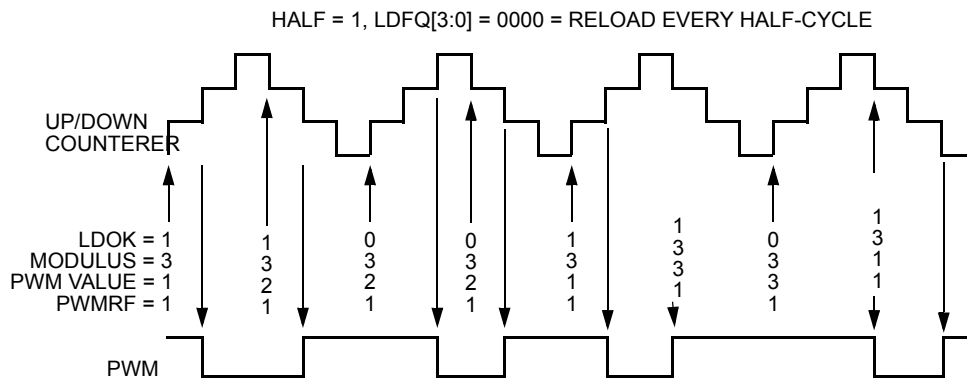

Figure 15-78. Half-Cycle Center-Aligned PWM Value Loading

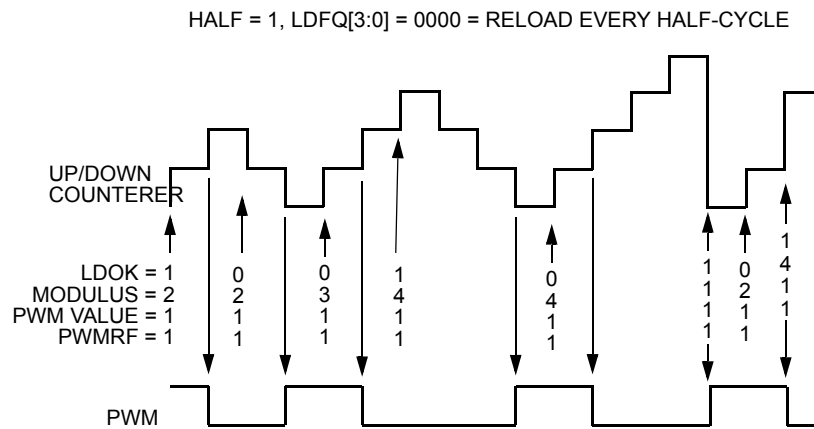

Figure 15-79. Half-Cycle Center-Aligned Modulus Loading

Figure 15-80. Edge-Aligned PWM Value Loading

Figure 15-81. Edge-Aligned Modulus Loading

15.4.12.5 Reload Overrun Flag

If a LDOK bit was not set before the PWM reload event, then the related reload overrun error flag is set (PMFROIF_x). If the PWM reload overrun interrupt enable bit PMFROIE_x is set, the PMFROIF_x flag generates a CPU interrupt request allowing software to handle the error condition.

Figure 15-82. PMFROIF Reload Overrun Interrupt Request

15.4.12.6 Synchronization Output (pmf_reload)

The PMF uses reload events to output a synchronization pulse, which can be used as an input to the timer module. A high-true pulse occurs for each PWM cycle start of the PWM, regardless of the state of the related LDOK bit or global load OK and load frequency.

15.4.13 Fault Protection

Fault protection can disable any combination of PWM outputs (for all FAULT0-5 inputs) or switch to output control register PMFOUTF on a fault event (for FAULT4-5 only). Faults are generated by an active level¹ on any of the FAULT inputs. Each FAULT input can be mapped arbitrarily to any of the PWM outputs.

In complementary mode, if a FAULT4 or FAULT5 event is programmed to switch to output control on a fault event resulting in a PWM active state on a particular output, then the transition will take place after deadtime insertion. Thus an asynchronous path to disable the PWM output is not available.

On a fault event the PWM generator continues to run.

The fault decoder affects the PWM outputs selected by the fault logic and the disable mapping register.

The fault protection is enabled even when the PWM is not enabled; therefore, a fault will be latched in and will be cleared in order to prevent an interrupt when the PWM is enabled.

15.4.13.1 Fault Input Sample Filter

Each fault input has a sample filter to test for fault conditions. After every bus cycle setting the FAULT m input at logic zero, the filter synchronously samples the input once every four bus cycles. QSMP determines the number of consecutive samples that must be logic one for a fault to be detected. When a fault is detected, the corresponding FAULT m flag, FIF m , is set. FIF m can only be cleared by writing a logic one to it.

If the FIE m , FAULT m interrupt enable bit is set, the FIF m flag generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears the FIF m flag by writing a logic one to it
- Software clears the FIE m bit by writing a logic zero to it
- A reset occurs

15.4.13.2 Automatic Fault Recovery

Setting a fault mode bit, FMODE m , configures faults from the FAULT m input for automatically reenabling the PWM outputs.

When FMODE m is set, disabled PWM outputs are enabled when the FAULT m input returns to logic zero and a new PWM half cycle begins. See [Figure 15-83](#). Clearing the FIF m flag does not affect disabled PWM outputs when FMODE m is set.

1. The active input level may be defined or programmable at SoC level. The default for internally connected resources is active-high. For availability and configurability of fault inputs on pins refer to the device overview section.

Figure 15-83. Automatic Fault Recovery

15.4.13.3 Manual Fault Recovery

Clearing a fault mode bit, $FMOD_m$, configures faults from the $FAULT_m$ input for manually reenabling the PWM outputs:

- PWM outputs disabled by the $FAULT_0$ input or the $FAULT_2$ input are enabled by clearing the corresponding FIF_m flag. The time at which the PWM outputs are enabled depends on the corresponding $QSMP_m$ bit setting. If $QSMP_m = 00$, the PWM outputs are enabled on the next IP bus cycle when the logic level detected by the filter at the fault input is logic zero. If $QSMP_m = 01, 10$ or 11 , the PWMs are enabled when the next PWM half cycle begins regardless of the state of the logic level detected by the filter at the fault. See [Figure 15-84](#) and [Figure 15-85](#).
- PWM outputs disabled by the $FAULT_1$ or $FAULT_3-5$ inputs are enabled when
 - Software clears the corresponding FIF_m flag
 - The filter detects a logic zero on the fault input at the start of the next PWM half cycle boundary. See [Figure 15-86](#).

Figure 15-84. Manual Fault Recovery (Faults 0 and 2) — $QSMP = 00$

Figure 15-85. Manual Fault Recovery (Faults 0 and 2) — QSMP = 01, 10, or 11

Figure 15-86. Manual Fault Recovery (Faults 1 and 3-5)

NOTE

PWM half-cycle boundaries occur at both the PWM cycle start and when the counter equals the modulus, so in edge-aligned operation full-cycles and half-cycles are equal.

NOTE

Fault protection also applies during software output control when the $OUTCTLn$ bits are set. Fault recovery still occurs at half PWM cycle boundaries while the PWM generator is engaged, $PWMEN$ equals one. But the $OUTn$ bits can control the PWM outputs while the PWM generator is off, $PWMEN$ equals zero. Thus, fault recovery occurs at IPbus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

15.5 Resets

All PMF registers are reset to their default values upon any system reset.

15.6 Clocks

The gated system core clock is the clock source for all PWM generators. The system clock is used as a clock source for any other logic in this module. The system bus clock is used as clock for specific control registers and flags ($LDOKx$, $PWMRFx$, $PMFOUTB$).

15.7 Interrupts

This section describes the interrupts generated by the PMF and their individual sources. Vector addresses and interrupt priorities are defined at SoC-level.

Table 15-45. PMF Interrupt Sources

Module Interrupt Sources (Interrupt Vector)	Associated Flags	Local Enable
PMF reload A	PWMRFA	PMFENCA[PWMRIEA]
PMF reload B ⁽¹⁾	PWMRFB	PMFENCB[PWMRIEB]
PMF reload CV4	PWMRFC	PMFENCC[PWMRIEC]
PMF fault	PMFFIF[FIF0] PMFFIF[FIF1] PMFFIF[FIF2] PMFFIF[FIF3]	PMFFIE[FIE0] PMFFIE[FIE1] PMFFIE[FIE2] PMFFIE[FIE3]
PMF reload overrun	PMFROIF[PMFROIFA] PMFROIF[PMFROIFB] PMFROIF[PMFROIFC]	PMFROIE[PMFROIEA] PMFROIE[PMFROIEB] PMFROIE[PMFROIEC]

1. If MTG=0: Interrupt mirrors PMF reload A interrupt

15.8 Initialization and Application Information

15.8.1 Initialization

Initialize all registers; read, then set the related LDOK bit or global load OK before setting the PWMEN bit. With LDOK set, setting PWMEN for the first time after reset immediately loads the PWM generator thereby setting the PWMRF flag. PWMRF generates a CPU interrupt request if the PWMRIE bit is set. In complementary channel operation with current-status correction selected, PWM value registers one, three, and five control the outputs for the first PWM cycle.

NOTE

Even if LDOK is not set, setting PWMEN also sets the PWMRF flag. To prevent a CPU interrupt request, clear the PWMRIE bit before setting PWMEN.

Setting PWMEN for the first time after reset without first setting LDOK loads a prescaler divisor of one, a PWM value of 0x0000, and an unknown modulus.

The PWM generator uses the last values loaded if PWMEN is cleared and then set while LDOK equals zero.

Initializing the deadtime register, after setting PWMEN or OUTCTL_n, can cause an improper deadtime insertion. However, the deadtime can never be shorter than the specified value.

Figure 15-87. PWMEN and PWM Outputs in Independent Operation

Figure 15-88. PWMEN and PWM Outputs in Complementary Operation

When the PWMEN bit is cleared:

- The PWM n outputs lose priority on associated outputs unless $OUTCTLn = 1$
- The PWM counter is cleared and does not count
- The PWM generator forces its outputs to zero
- The PWMRF flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active unless $FENm = 0$
- Software output control remains active
- Deadtime insertion continues during software output control

15.8.1.1 Register Write Protection

The following configuration registers and bits can be write protected:

PMFCFG0, PMFCFG1, PMFCFG3, PMFFEN, PMFQSMP0-1, PMFENCA[RSTRTA, GLDOKA], PMFENCB[RSTRTB, GLDOKB], PMFENCC[RSTRTC, GLDOKC], PMFDTMA, B, C, PMFDMP0-5, PMFOUTF

NOTE

Make sure to set the write protection bit WP in PMFCFG0 after configuring and prior to enabling PWM outputs and fault inputs.

15.8.2 BLDC 6-Step Commutation

15.8.2.1 Unipolar Switching Mode

Unipolar switching mode uses registers PMFOUTC and PMFOUTB to perform commutation.

Table 15-46. Effects of OUTCTL and OUT Bits on PWM Output Pair in Complementary Mode

OUTCTL (odd,even)	OUT (odd,even)	PWM (odd)	PWM (even)
00	xx	PWMgen(even)	PWMgen(even)
11	10	$\overline{\text{OUTB}}(\text{even})=1$	OUTB(even)=0
01	x0	0	OUTB(even)=0

The recommended setup is:

```
PMFCFG0 [INDEPC, INDEPB, INDEPA] = 0x0; // Complementary mode
PMFCFG1 [ENCE] = 1; // Enable commutation event
PMFOUTB = 0x2A; // Set return path pattern, high-side off, low-side on
PMFOUTC = 0x1C; // Branch A->B, "mask" C // 0°
```

The commutation sequence is:

```
PMFOUTC = 0x34; // Branch A->C, "mask" B // 60°
PMFOUTC = 0x31; // Branch B->C, "mask" A // 120°
PMFOUTC = 0x13; // Branch B->A, "mask" C // 180°
PMFOUTC = 0x07; // Branch C->A, "mask" B // 240°
PMFOUTC = 0x0D; // Branch C->B, "mask" A // 300°
PMFOUTC = 0x1C; // Branch A->B, "mask" C // 360°
```

Table 15-47. Unipolar Switching Sequence

Branch	Channel	0°	60°	120°	180°	240°	300°
A	PWM0	PWMgen		0	0	0	
	PWM1	PWMgen		0	1	0	
B	PWM2	0	0	PWMgen		0	0
	PWM3	1	0	PWMgen		0	1
C	PWM4	0	0		0	PWMgen	
	PWM5	0	1		0	PWMgen	

15.8.2.2 Bipolar Switching Mode

Bipolar switching mode uses register bits MSK5-0 and PINVA, B, C to perform commutation.

The recommended setup is:

```
PMFCFG0 [INDEPC, INDEPB, INDEPA] = 0x0; // Complementary mode
PMFCFG1 [ENCE] = 1; // Enable commutation event
PMFCFG2 [MSK5:MSK0] = 0x30; // Branch A<->B, mask C // 0°
PMFCFG3 [PINVC, PINVB, PINVA] = 0x2; // Invert B
```

The commutation sequence is:

```
PMFCFG2 [MSK5:MSK0] = 0x03; // Branch C<->B, mask A // 60°
PMFCFG3 [PINVC, PINVB, PINVA] = 0x2; // Invert B
```

PMFCFG2 [MSK5:MSK0] = 0x0c; // Branch C->A, mask B // 120°
 PMFCFG3 [PINVC, PINVB, PINVA] = 0x1; // Invert A

 PMFCFG2 [MSK5:MSK0] = 0x30; // Branch B->A, mask C // 180°
 PMFCFG3 [PINVC, PINVB, PINVA] = 0x1; // Invert A

 PMFCFG2 [MSK5:MSK0] = 0x03; // Branch B->C, mask A // 240°
 PMFCFG3 [PINVC, PINVB, PINVA] = 0x4; // Invert C

 PMFCFG2 [MSK5:MSK0] = 0x0c; // Branch A->C, mask B // 300°
 PMFCFG3 [PINVC, PINVB, PINVA] = 0x4; // Invert C

 PMFCFG2 [MSK5:MSK0] = 0x30; // Branch A->B, mask A // 360°
 PMFCFG3 [PINVC, PINVB, PINVA] = 0x2; // Invert B

Table 15-48. Bipolar Switching Sequence

Branch	Channel	0°	60°	120°	180°	240°	300°
A	PWM0	PWMgen	Masked	PWMgen		Masked	PWMgen
	PWM1	PWMgen	Masked	PWMgen		Masked	PWMgen
B	PWM2	PWMgen		Masked	PWMgen		Masked
	PWM3	PWMgen		Masked	PWMgen		Masked
C	PWM4	Masked	PWMgen		Masked	PWMgen	
	PWM5	Masked	PWMgen		Masked	PWMgen

16.1 Introduction

This block guide provides an overview of the serial communication interface (SCI) module.

The SCI allows asynchronous serial communications with peripheral devices and other CPUs.

16.1.1 Glossary

IR: InfraRed

IrDA: Infrared Design Associate

IRQ: Interrupt Request

LIN: Local Interconnect Network

LSB: Least Significant Bit

MSB: Most Significant Bit

NRZ: Non-Return-to-Zero

RZI: Return-to-Zero-Inverted

RXD: Receive Pin

SCI : Serial Communication Interface

TXD: Transmit Pin

16.1.2 Features

The SCI includes these distinctive features:

- Full-duplex or single-wire operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse widths
- 16-bit baud rate selection
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable polarity for transmitter and receiver
- Programmable transmitter output parity
- Two receiver wakeup methods:
 - Idle line wakeup
 - Address mark wakeup
- Interrupt-driven operation with eight flags:
 - Transmitter empty
 - Transmission complete
 - Receiver full
 - Idle receiver input
 - Receiver overrun
 - Noise error
 - Framing error
 - Parity error
 - Receive wakeup on active edge
 - Transmit collision detect supporting LIN
 - Break Detect supporting LIN
- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection

16.1.3 Modes of Operation

The SCI functions the same in normal, special, and emulation modes. It has two low power modes, wait and stop modes.

- Run mode
- Wait mode
- Stop mode

16.1.4 Block Diagram

Figure 16-1 is a high level block diagram of the SCI module, showing the interaction of various function blocks.

Figure 16-1. SCI Block Diagram

16.2 External Signal Description

The SCI module has a total of two external pins.

16.2.1 TXD — Transmit Pin

The TXD pin transmits SCI (standard or infrared) data. It will idle high in either mode and is high impedance anytime the transmitter is disabled.

16.2.2 RXD — Receive Pin

The RXD pin receives SCI (standard or infrared) data. An idle line is detected as a line high. This input is ignored when the receiver is disabled and should be terminated to a known voltage.

16.3 Memory Map and Register Definition

This section provides a detailed description of all the SCI registers.

16.3.1 Module Memory Map and Register Definition

The memory map for the SCI module is given below in [Figure 16-2](#). The address listed for each register is the address offset. The total address for each register is the sum of the base address for the SCI module and the address offset for each register.

16.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Writes to a reserved register locations do not have any effect and reads of these locations return a zero. Details of register bit and field function follow the register diagrams, in bit order.

Register Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 16-2. SCI Register Summary

16.3.2.1 SCI Baud Rate Registers (SCIBDH, SCIBDL)

Module Base + 0x0000

Figure 16-3. SCI Baud Rate Register (SCIBDH)

Module Base + 0x0001

Figure 16-4. SCI Baud Rate Register (SCIBDL)

Read: Anytime, if AMAP = 0.

Write: Anytime, if AMAP = 0.

NOTE

Those two registers are only visible in the memory map if AMAP = 0 (reset condition).

The SCI baud rate register is used by to determine the baud rate of the SCI, and to control the infrared modulation/demodulation submodule.

Table 16-2. SCIBDH and SCIBDL Field Descriptions

Field	Description
SBR[15:0]	<p>SCI Baud Rate Bits — The baud rate for the SCI is determined by the bits in this register. The baud rate is calculated two different ways depending on the state of the IREN bit. The formulas for calculating the baud rate are:</p> <p>When IREN = 0 then, $SCI\ baud\ rate = SCI\ bus\ clock / (SBR[15:0])$</p> <p>When IREN = 1 then, $SCI\ baud\ rate = SCI\ bus\ clock / (2 \times SBR[15:1])$</p> <p>Note: The baud rate generator is disabled after reset and not started until the TE bit or the RE bit is set for the first time. The baud rate generator is disabled when (SBR[15:4] = 0 and IREN = 0) or (SBR[15:5] = 0 and IREN = 1).</p> <p>Note: . User should write SCIBD by word access. The updated SCIBD may take effect until next RT clock start, write SCIBDH or SCIBDL separately may cause baud generator load wrong data at that time,if second write later then RT clock.</p>

16.3.2.2 SCI Control Register 1 (SCICR1)

Module Base + 0x0002

Figure 16-5. SCI Control Register 1 (SCICR1)

Read: Anytime, if AMAP = 0.

Write: Anytime, if AMAP = 0.

NOTE

This register is only visible in the memory map if AMAP = 0 (reset condition).

Table 16-3. SCICR1 Field Descriptions

Field	Description
7 LOOPS	Loop Select Bit — LOOPS enables loop operation. In loop operation, the RXD pin is disconnected from the SCI and the transmitter output is internally connected to the receiver input. Both the transmitter and the receiver must be enabled to use the loop function. 0 Normal operation enabled 1 Loop operation enabled The receiver input is determined by the RSRC bit.
6 SCISWAI	SCI Stop in Wait Mode Bit — SCISWAI disables the SCI in wait mode. 0 SCI enabled in wait mode 1 SCI disabled in wait mode
5 RSRC	Receiver Source Bit — When LOOPS = 1, the RSRC bit determines the source for the receiver shift register input. See Table 16-4 . 0 Receiver input internally connected to transmitter output 1 Receiver input connected externally to transmitter
4 M	Data Format Mode Bit — MODE determines whether data characters are eight or nine bits long. 0 One start bit, eight data bits, one stop bit 1 One start bit, nine data bits, one stop bit
3 WAKE	Wakeup Condition Bit — WAKE determines which condition wakes up the SCI: a logic 1 (address mark) in the most significant bit position of a received data character or an idle condition on the RXD pin. 0 Idle line wakeup 1 Address mark wakeup
2 ILT	Idle Line Type Bit — ILT determines when the receiver starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. 0 Idle character bit count begins after start bit 1 Idle character bit count begins after stop bit

Table 16-3. SCICR1 Field Descriptions (continued)

Field	Description
1 PE	Parity Enable Bit — PE enables the parity function. When enabled, the parity function inserts a parity bit in the most significant bit position. 0 Parity function disabled 1 Parity function enabled
0 PT	Parity Type Bit — PT determines whether the SCI generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. 0 Even parity 1 Odd parity

Table 16-4. Loop Functions

LOOPS	RSRC	Function
0	x	Normal operation
1	0	Loop mode with transmitter output internally connected to receiver input
1	1	Single-wire mode with TXD pin connected to receiver input

16.3.2.3 SCI Alternative Status Register 1 (SCIASR1)

Module Base + 0x0000

Figure 16-6. SCI Alternative Status Register 1 (SCIASR1)

Read: Anytime, if AMAP = 1

Write: Anytime, if AMAP = 1

Table 16-5. SCIASR1 Field Descriptions

Field	Description
7 RXEDGIF	Receive Input Active Edge Interrupt Flag — RXEDGIF is asserted, if an active edge (falling if RXPOL = 0, rising if RXPOL = 1) on the RXD input occurs. RXEDGIF bit is cleared by writing a “1” to it. 0 No active receive on the receive input has occurred 1 An active edge on the receive input has occurred
2 BERRV	Bit Error Value — BERRV reflects the state of the RXD input when the bit error detect circuitry is enabled and a mismatch to the expected value happened. The value is only meaningful, if BERRIF = 1. 0 A low input was sampled, when a high was expected 1 A high input reassembled, when a low was expected
1 BERRIF	Bit Error Interrupt Flag — BERRIF is asserted, when the bit error detect circuitry is enabled and if the value sampled at the RXD input does not match the transmitted value. If the BERRIE interrupt enable bit is set an interrupt will be generated. The BERRIF bit is cleared by writing a “1” to it. 0 No mismatch detected 1 A mismatch has occurred
0 BKDIF	Break Detect Interrupt Flag — BKDIF is asserted, if the break detect circuitry is enabled and a break signal is received. If the BKDIE interrupt enable bit is set an interrupt will be generated. The BKDIF bit is cleared by writing a “1” to it. 0 No break signal was received 1 A break signal was received

16.3.2.4 SCI Alternative Control Register 1 (SCIACR1)

Module Base + 0x0001

Field	Description
7 IREN	Infrared Enable Bit — This bit enables/disables the infrared modulation/demodulation submodule. 0 IR disabled 1 IR enabled
6:5 TNP[1:0]	Transmitter Narrow Pulse Bits — These bits enable whether the SCI transmits a 1/16, 3/16, 1/32 or 1/4 narrow pulse. See Table 16-8 .
2:1 BERRM[1:0]	Bit Error Mode — Those two bits determines the functionality of the bit error detect feature. See Table 16-9 .
0 BKDFE	Break Detect Feature Enable — BKDFE enables the break detect circuitry. 0 Break detect circuit disabled 1 Break detect circuit enabled

Table 16-8. IRSCI Transmit Pulse Width

TNP[1:0]	Narrow Pulse Width
11	1/4
10	1/32
01	1/16
00	3/16

Table 16-9. Bit Error Mode Coding

BERRM1	BERRM0	Function
0	0	Bit error detect circuit is disabled
0	1	Receive input sampling occurs during the 9th time tick of a transmitted bit (refer to Figure 16-19)
1	0	Receive input sampling occurs during the 13th time tick of a transmitted bit (refer to Figure 16-19)
1	1	Reserved

16.3.2.6 SCI Control Register 2 (SCICR2)

Module Base + 0x0003

Figure 16-9. SCI Control Register 2 (SCICR2)

Read: Anytime

Write: Anytime

Table 16-10. SCICR2 Field Descriptions

Field	Description
7 TIE	Transmitter Interrupt Enable Bit — TIE enables the transmit data register empty flag, TDRE, to generate interrupt requests. 0 TDRE interrupt requests disabled 1 TDRE interrupt requests enabled
6 TCIE	Transmission Complete Interrupt Enable Bit — TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0 TC interrupt requests disabled 1 TC interrupt requests enabled
5 RIE	Receiver Full Interrupt Enable Bit — RIE enables the receive data register full flag, RDRF, or the overrun flag, OR, to generate interrupt requests. 0 RDRF and OR interrupt requests disabled 1 RDRF and OR interrupt requests enabled
4 ILIE	Idle Line Interrupt Enable Bit — ILIE enables the idle line flag, IDLE, to generate interrupt requests. 0 IDLE interrupt requests disabled 1 IDLE interrupt requests enabled
3 TE	Transmitter Enable Bit — TE enables the SCI transmitter and configures the TXD pin as being controlled by the SCI. The TE bit can be used to queue an idle preamble. 0 Transmitter disabled 1 Transmitter enabled
2 RE	Receiver Enable Bit — RE enables the SCI receiver. 0 Receiver disabled 1 Receiver enabled
1 RWU	Receiver Wakeup Bit — Standby state 0 Normal operation. 1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.
0 SBK	Send Break Bit — Toggling SBK sends one break character (10 or 11 logic 0s, respectively 13 or 14 logics 0s if BRK13 is set). Toggling implies clearing the SBK bit before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10 or 11 bits, respectively 13 or 14 bits). 0 No break characters 1 Transmit break characters

16.3.2.7 SCI Status Register 1 (SCISR1)

The SCISR1 and SCISR2 registers provides inputs to the MCU for generation of SCI interrupts. Also, these registers can be polled by the MCU to check the status of these bits. The flag-clearing procedures require that the status register be read followed by a read or write to the SCI data register. It is permissible to execute other instructions between the two steps as long as it does not compromise the handling of I/O, but the order of operations is important for flag clearing.

Module Base + 0x0004

Figure 16-10. SCI Status Register 1 (SCISR1)

Read: Anytime

Write: Has no meaning or effect

Table 16-11. SCISR1 Field Descriptions

Field	Description
7 TDRE	Transmit Data Register Empty Flag — TDRE is set when the transmit shift register receives a byte from the SCI data register. When TDRE is 1, the transmit data register (SCIDRH/L) is empty and can receive a new value to transmit. Clear TDRE by reading SCI status register 1 (SCISR1), with TDRE set and then writing to SCI data register low (SCIDRL). 0 No byte transferred to transmit shift register 1 Byte transferred to transmit shift register; transmit data register empty
6 TC	Transmit Complete Flag — TC is set low when there is a transmission in progress or when a preamble or break character is loaded. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD pin becomes idle (logic 1). Clear TC by reading SCI status register 1 (SCISR1) with TC set and then writing to SCI data register low (SCIDRL). TC is cleared automatically when data, preamble, or break is queued and ready to be sent. TC is cleared in the event of a simultaneous set and clear of the TC flag (transmission not complete). 0 Transmission in progress 1 No transmission in progress
5 RDRF	Receive Data Register Full Flag — RDRF is set when the data in the receive shift register transfers to the SCI data register. Clear RDRF by reading SCI status register 1 (SCISR1) with RDRF set and then reading SCI data register low (SCIDRL). 0 Data not available in SCI data register 1 Received data available in SCI data register
4 IDLE	Idle Line Flag — IDLE is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. Once the IDLE flag is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. Clear IDLE by reading SCI status register 1 (SCISR1) with IDLE set and then reading SCI data register low (SCIDRL). 0 Receiver input is either active now or has never become active since the IDLE flag was last cleared 1 Receiver input has become idle Note: When the receiver wakeup bit (RWU) is set, an idle line condition does not set the IDLE flag.

Table 16-11. SCISR1 Field Descriptions (continued)

Field	Description
3 OR	<p>Overrun Flag — OR is set when software fails to read the SCI data register before the receive shift register receives the next frame. The OR bit is set immediately after the stop bit has been completely received for the second frame. The data in the shift register is lost, but the data already in the SCI data registers is not affected. Clear OR by reading SCI status register 1 (SCISR1) with OR set and then reading SCI data register low (SCIDRL).</p> <p>0 No overrun 1 Overrun</p> <p>Note: OR flag may read back as set when RDRF flag is clear. This may happen if the following sequence of events occurs:</p> <ol style="list-style-type: none"> 1. After the first frame is received, read status register SCISR1 (returns RDRF set and OR flag clear); 2. Receive second frame without reading the first frame in the data register (the second frame is not received and OR flag is set); 3. Read data register SCIDRL (returns first frame and clears RDRF flag in the status register); 4. Read status register SCISR1 (returns RDRF clear and OR set). <p>Event 3 may be at exactly the same time as event 2 or any time after. When this happens, a dummy SCIDRL read following event 4 will be required to clear the OR flag if further frames are to be received.</p>
2 NF	<p>Noise Flag — NF is set when the SCI detects noise on the receiver input. NF bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. Clear NF by reading SCI status register 1 (SCISR1), and then reading SCI data register low (SCIDRL).</p> <p>0 No noise 1 Noise</p>
1 FE	<p>Framing Error Flag — FE is set when a logic 0 is accepted as the stop bit. FE bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. FE inhibits further data reception until it is cleared. Clear FE by reading SCI status register 1 (SCISR1) with FE set and then reading the SCI data register low (SCIDRL).</p> <p>0 No framing error 1 Framing error</p>
0 PF	<p>Parity Error Flag — PF is set when the parity enable bit (PE) is set and the parity of the received data does not match the parity type bit (PT). PF bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. Clear PF by reading SCI status register 1 (SCISR1), and then reading SCI data register low (SCIDRL).</p> <p>0 No parity error 1 Parity error</p>

16.3.2.8 SCI Status Register 2 (SCISR2)

Module Base + 0x0005

Figure 16-11. SCI Status Register 2 (SCISR2)

Read: Anytime

Write: Anytime

Table 16-12. SCISR2 Field Descriptions

Field	Description
7 AMAP	Alternative Map — This bit controls which registers sharing the same address space are accessible. In the reset condition the SCI behaves as previous versions. Setting AMAP=1 allows the access to another set of control and status registers and hides the baud rate and SCI control Register 1. 0 The registers labelled SCIBDH (0x0000), SCIBDL (0x0001), SCICR1 (0x0002) are accessible 1 The registers labelled SCIASR1 (0x0000), SCIACR1 (0x0001), SCIACR2 (0x00002) are accessible
4 TXPOL	Transmit Polarity — This bit control the polarity of the transmitted data. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity, and a zero is represented by short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. 0 Normal polarity 1 Inverted polarity
3 RXPOL	Receive Polarity — This bit control the polarity of the received data. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity, and a zero is represented by short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. 0 Normal polarity 1 Inverted polarity
2 BRK13	Break Transmit Character Length — This bit determines whether the transmit break character is 10 or 11 bit respectively 13 or 14 bits long. The detection of a framing error is not affected by this bit. 0 Break character is 10 or 11 bit long 1 Break character is 13 or 14 bit long
1 TXDIR	Transmitter Pin Data Direction in Single-Wire Mode — This bit determines whether the TXD pin is going to be used as an input or output, in the single-wire mode of operation. This bit is only relevant in the single-wire mode of operation. 0 TXD pin to be used as an input in single-wire mode 1 TXD pin to be used as an output in single-wire mode
0 RAF	Receiver Active Flag — RAF is set when the receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character. 0 No reception in progress 1 Reception in progress

16.3.2.9 SCI Data Registers (SCIDRH, SCIDRL)

Module Base + 0x0006

Figure 16-12. SCI Data Registers (SCIDRH)

Module Base + 0x0007

Figure 16-13. SCI Data Registers (SCIDRL)

Read: Anytime; reading accesses SCI receive data register

Write: Anytime; writing accesses SCI transmit data register; writing to R8 has no effect

NOTE

The reserved bit SCIDRH[2:0] are designed for factory test purposes only, and are not intended for general user access. Writing to these bit is possible when in special mode and can alter the modules functionality.

Table 16-13. SCIDRH and SCIDRL Field Descriptions

Field	Description
SCIDRH 7 R8	Received Bit 8 — R8 is the ninth data bit received when the SCI is configured for 9-bit data format (M = 1).
SCIDRH 6 T8	Transmit Bit 8 — T8 is the ninth data bit transmitted when the SCI is configured for 9-bit data format (M = 1).
SCIDRL 7:0 R[7:0] T[7:0]	R7:R0 — Received bits seven through zero for 9-bit or 8-bit data formats T7:T0 — Transmit bits seven through zero for 9-bit or 8-bit formats

NOTE

If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten

In 8-bit data format, only SCI data register low (SCIDRL) needs to be accessed.

When transmitting in 9-bit data format and using 8-bit write instructions, write first to SCI data register high (SCIDRH), then SCIDRL.

16.4 Functional Description

This section provides a complete functional description of the SCI block, detailing the operation of the design from the end user perspective in a number of subsections.

Figure 16-14 shows the structure of the SCI module. The SCI allows full duplex, asynchronous, serial communication between the CPU and remote devices, including other CPUs. The SCI transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the SCI, writes the data to be transmitted, and processes received data.

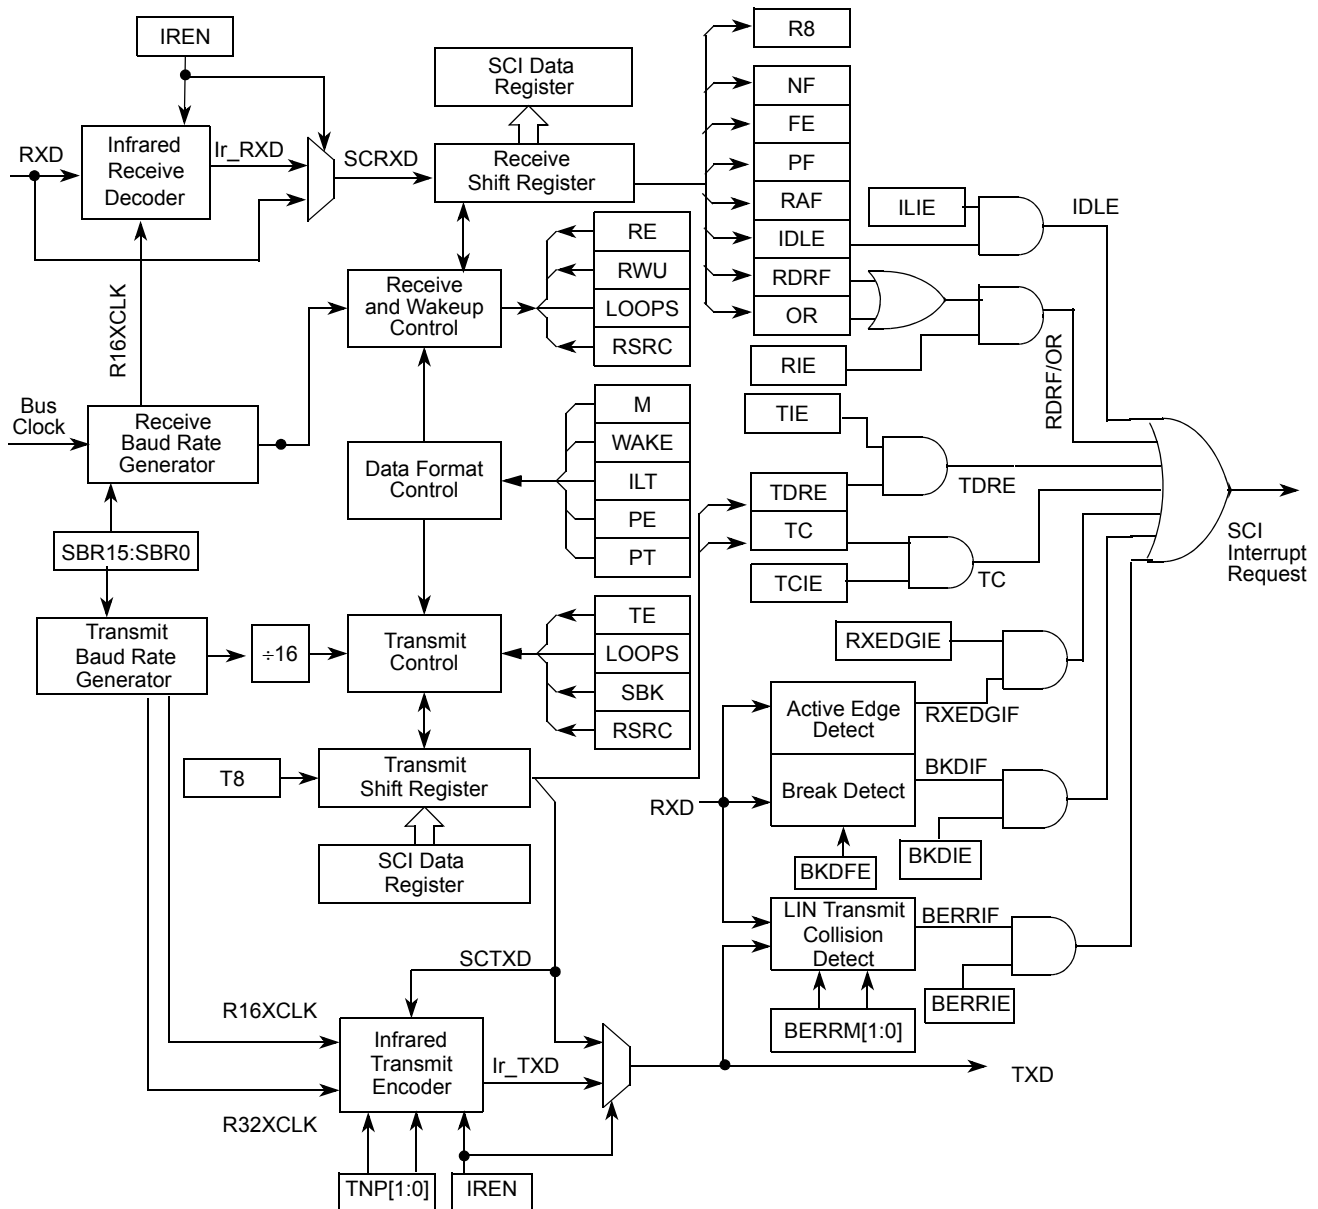

Figure 16-14. Detailed SCI Block Diagram

16.4.1 Infrared Interface Submodule

This module provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the SCI. The IrDA physical layer specification defines a half-duplex infrared communication link for exchange data. The full standard includes data rates up to 16 Mbits/s. This design covers only data rates between 2.4 Kbits/s and 115.2 Kbits/s.

The infrared submodule consists of two major blocks: the transmit encoder and the receive decoder. The SCI transmits serial bits of data which are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses should be detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder (external from the MCU). The narrow pulses are then stretched by the infrared submodule to get back to a serial bit stream to be received by the SCI. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active low pulses.

The infrared submodule receives its clock sources from the SCI. One of these two clocks are selected in the infrared submodule in order to generate either 3/16, 1/16, 1/32 or 1/4 narrow pulses during transmission. The infrared block receives two clock sources from the SCI, R16XCLK and R32XCLK, which are configured to generate the narrow pulse width during transmission. The R16XCLK and R32XCLK are internal clocks with frequencies 16 and 32 times the baud rate respectively. Both R16XCLK and R32XCLK clocks are used for transmitting data. The receive decoder uses only the R16XCLK clock.

16.4.1.1 Infrared Transmit Encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD pin. A narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent in the middle of the bit with a duration of 1/32, 1/16, 3/16 or 1/4 of a bit time. A narrow high pulse is transmitted for a zero bit when TXPOL is cleared, while a narrow low pulse is transmitted for a zero bit when TXPOL is set.

16.4.1.2 Infrared Receive Decoder

The infrared receive block converts data from the RXD pin to the receive shift register. A narrow pulse is expected for each zero received and no pulse is expected for each one received. A narrow high pulse is expected for a zero bit when RXPOL is cleared, while a narrow low pulse is expected for a zero bit when RXPOL is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

16.4.2 LIN Support

This module provides some basic support for the LIN protocol. At first this is a break detect circuitry making it easier for the LIN software to distinguish a break character from an incoming data stream. As a further addition it supports a collision detection at the bit level as well as cancelling pending transmissions.

16.4.3 Data Format

The SCI uses the standard NRZ mark/space data format. When Infrared is enabled, the SCI uses RZI data format where zeroes are represented by light pulses and ones remain low. See [Figure 16-15](#) below.

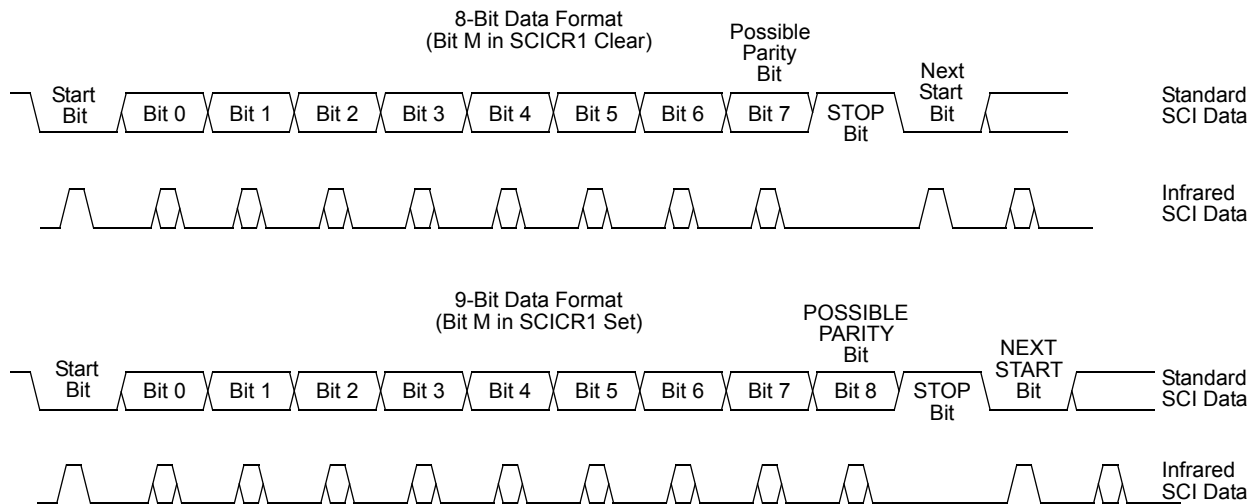

Figure 16-15. SCI Data Formats

Each data character is contained in a frame that includes a start bit, eight or nine data bits, and a stop bit. Clearing the M bit in SCI control register 1 configures the SCI for 8-bit data characters. A frame with eight data bits has a total of 10 bits. Setting the M bit configures the SCI for nine-bit data characters. A frame with nine data bits has a total of 11 bits.

Table 16-14. Example of 8-Bit Data Formats

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	8	0	0	1
1	7	0	1	1
1	7	1 ⁽¹⁾	0	1

1. The address bit identifies the frame as an address character. See [Section 16.4.6.6, "Receiver Wakeup"](#).

When the SCI is configured for 9-bit data characters, the ninth data bit is the T8 bit in SCI data register high (SCIDRH). It remains unchanged after transmission and can be used repeatedly without rewriting it. A frame with nine data bits has a total of 11 bits.

Table 16-15. Example of 9-Bit Data Formats

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	9	0	0	1
1	8	0	1	1
1	8	1 ⁽¹⁾	0	1

1. The address bit identifies the frame as an address character. See [Section 16.4.6.6, "Receiver Wakeup"](#).

16.4.4 Baud Rate Generation

A 16-bit modulus counter in the two baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 0 to 65535 written to the SBR15:SBR0 bits determines the baud rate. The value from 0 to 4095 written to the SBR15:SBR4 bits determines the baud rate clock with SBR3:SBR0 for fine adjust. The SBR bits are in the SCI baud rate registers (SCIBDH and SCIBDL) for both transmit and receive baud generator. The baud rate clock is synchronized with the bus clock and drives the receiver. The baud rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to one source of error:

- Integer division of the bus clock may not give the exact target frequency.

[Table 16-16](#) lists some examples of achieving target baud rates with a bus clock frequency of 25 MHz.

When IREN = 0 then,

$$\text{SCI baud rate} = \text{SCI bus clock} / (\text{SCIBR}[15:0])$$

Table 16-16. Baud Rates (Example: Bus Clock = 25 MHz)

Bits SBR[15:0]	Receiver ⁽¹⁾ Clock (Hz)	Transmitter ⁽²⁾ Clock (Hz)	Target Baud Rate	Error (%)
109	3669724.8	229,357.8	230,400	.452
217	1843318.0	115,207.4	115,200	.006
651	614439.3	38,402.5	38,400	.006

1. 16x faster than baud rate

2. divide 1/16 from transmit baud generator

16.4.5 Transmitter

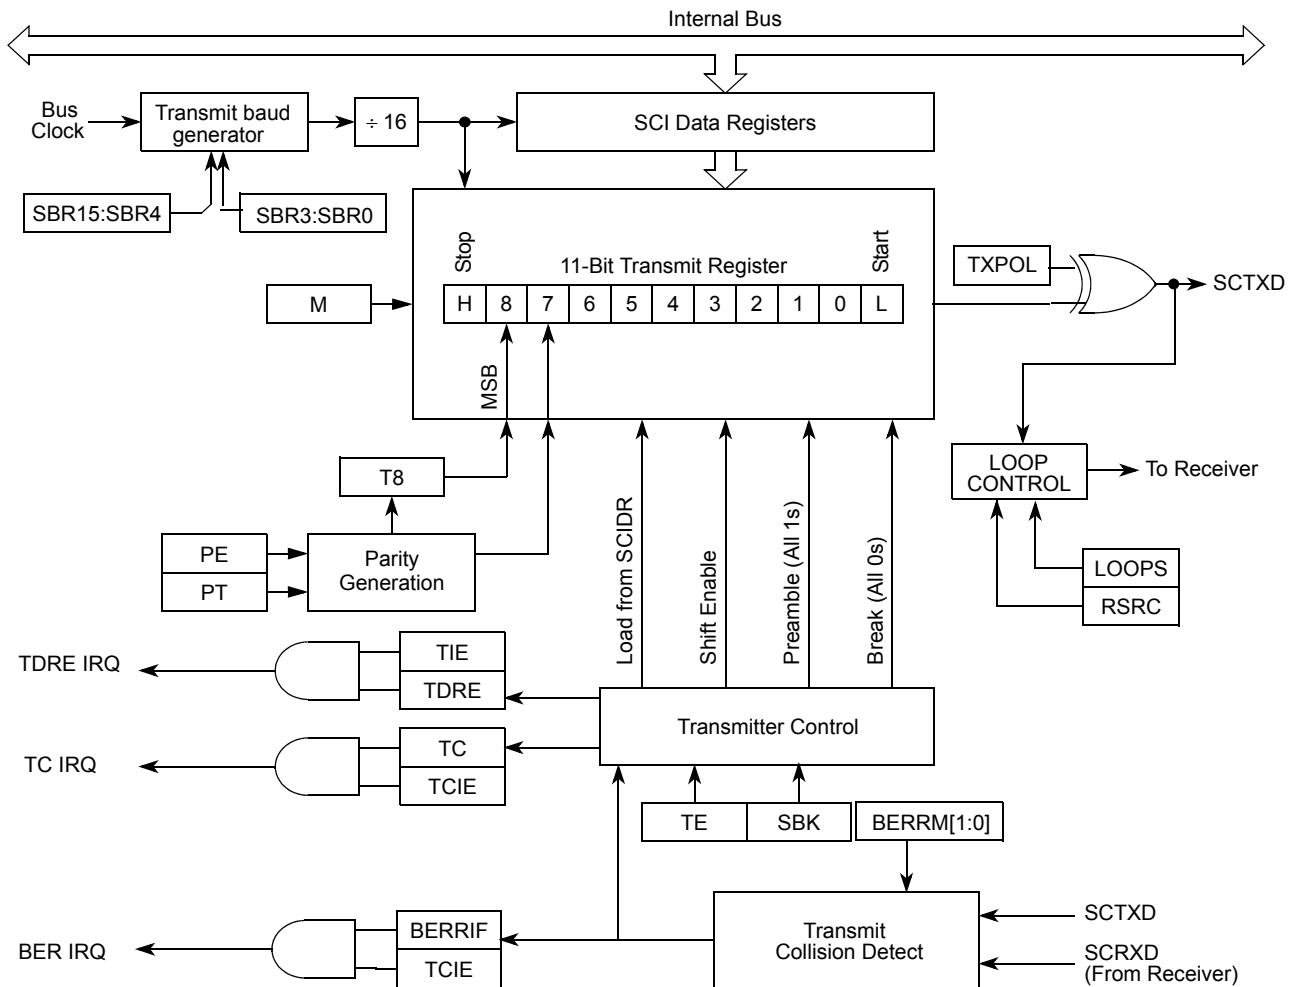

Figure 16-16. Transmitter Block Diagram

16.4.5.1 Transmitter Character Length

The SCI transmitter can accommodate either 8-bit or 9-bit data characters. The state of the M bit in SCI control register 1 (SCICR1) determines the length of data characters. When transmitting 9-bit data, bit T8 in SCI data register high (SCIDRH) is the ninth bit (bit 8).

16.4.5.2 Character Transmission

To transmit data, the MCU writes the data bits to the SCI data registers (SCIDRH/SCIDRL), which in turn are transferred to the transmitter shift register. The transmit shift register then shifts a frame out through the TXD pin, after it has prefaced them with a start bit and appended them with a stop bit. The SCI data registers (SCIDRH and SCIDRL) are the write-only buffers between the internal data bus and the transmit shift register.

The SCI also sets a flag, the transmit data register empty flag (TDRE), every time it transfers data from the buffer (SCIDRH/L) to the transmitter shift register. The transmit driver routine may respond to this flag by writing another byte to the Transmitter buffer (SCIDRH/SCIDRL), while the shift register is still shifting out the first byte.

To initiate an SCI transmission:

1. Configure the SCI:
 - a) Select a baud rate. Write this value to the SCI baud registers (SCIBDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the SCIBDH has no effect without also writing to SCIBDL.
 - b) Write to SCICR1 to configure word length, parity, and other configuration bits (LOOPS,RSRC,M,WAKE,ILT,PE,PT).
 - c) Enable the transmitter, interrupts, receive, and wake up as required, by writing to the SCICR2 register bits (TIE,TCIE,RIE,ILIE,TE,RE,RWU,SBK). A preamble or idle character will now be shifted out of the transmitter shift register.
2. Transmit Procedure for each byte:
 - a) Poll the TDRE flag by reading the SCISR1 or responding to the TDRE interrupt. Keep in mind that the TDRE bit resets to one.
 - b) If the TDRE flag is set, write the data to be transmitted to SCIDRH/L, where the ninth bit is written to the T8 bit in SCIDRH if the SCI is in 9-bit data format. A new transmission will not result until the TDRE flag has been cleared.
3. Repeat step 2 for each subsequent transmission.

NOTE

The TDRE flag is set when the shift register is loaded with the next data to be transmitted from SCIDRH/L, which happens, generally speaking, a little over half-way through the stop bit of the previous frame. Specifically, this transfer occurs 9/16ths of a bit time AFTER the start of the stop bit of the previous frame.

Writing the TE bit from 0 to a 1 automatically loads the transmit shift register with a preamble of 10 logic 1s (if M = 0) or 11 logic 1s (if M = 1). After the preamble shifts out, control logic transfers the data from the SCI data register into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

Hardware supports odd or even parity. When parity is enabled, the most significant bit (MSB) of the data character is the parity bit.

The transmit data register empty flag, TDRE, in SCI status register 1 (SCISR1) becomes set when the SCI data register transfers a byte to the transmit shift register. The TDRE flag indicates that the SCI data register can accept new data from the internal data bus. If the transmit interrupt enable bit, TIE, in SCI control register 2 (SCICR2) is also set, the TDRE flag generates a transmitter interrupt request.

When the transmit shift register is not transmitting a frame, the TXD pin goes to the idle condition, logic 1. If at any time software clears the TE bit in SCI control register 2 (SCICR2), the transmitter enable signal goes low and the transmit signal goes idle.

If software clears TE while a transmission is in progress ($TC = 0$), the frame in the transmit shift register continues to shift out. To avoid accidentally cutting off the last frame in a message, always wait for TDRE to go high after the last frame before clearing TE.

To separate messages with preambles with minimum idle line time, use this sequence between messages:

1. Write the last byte of the first message to SCIDRH/L.
2. Wait for the TDRE flag to go high, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting the TE bit.
4. Write the first byte of the second message to SCIDRH/L.

16.4.5.3 Break Characters

Writing a logic 1 to the send break bit, SBK, in SCI control register 2 (SCICR2) loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in SCI control register 1 (SCICR1). As long as SBK is at logic 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next frame.

The SCI recognizes a break character when there are 10 or 11 ($M = 0$ or $M = 1$) consecutive zero received. Depending if the break detect feature is enabled or not receiving a break character has these effects on SCI registers.

If the break detect feature is disabled ($BKDFE = 0$):

- Sets the framing error flag, FE
- Sets the receive data register full flag, RDRF
- Clears the SCI data registers (SCIDRH/L)
- May set the overrun flag, OR, noise flag, NF, parity error flag, PE, or the receiver active flag, RAF (see 3.4.4 and 3.4.5 SCI Status Register 1 and 2)

If the break detect feature is enabled ($BKDFE = 1$) there are two scenarios¹

The break is detected right from a start bit or is detected during a byte reception.

- Sets the break detect interrupt flag, BKDIF
- Does not change the data register full flag, RDRF or overrun flag OR
- Does not change the framing error flag FE, parity error flag PE.
- Does not clear the SCI data registers (SCIDRH/L)
- May set noise flag NF, or receiver active flag RAF.

1. A Break character in this context are either 10 or 11 consecutive zero received bits

Figure 16-17 shows two cases of break detect. In trace RXD_1 the break symbol starts with the start bit, while in RXD_2 the break starts in the middle of a transmission. If BRKDFE = 1, in RXD_1 case there will be no byte transferred to the receive buffer and the RDRF flag will not be modified. Also no framing error or parity error will be flagged from this transfer. In RXD_2 case, however the break signal starts later during the transmission. At the expected stop bit position the byte received so far will be transferred to the receive buffer, the receive data register full flag will be set, a framing error and if enabled and appropriate a parity error will be set. Once the break is detected the BRKDIF flag will be set.

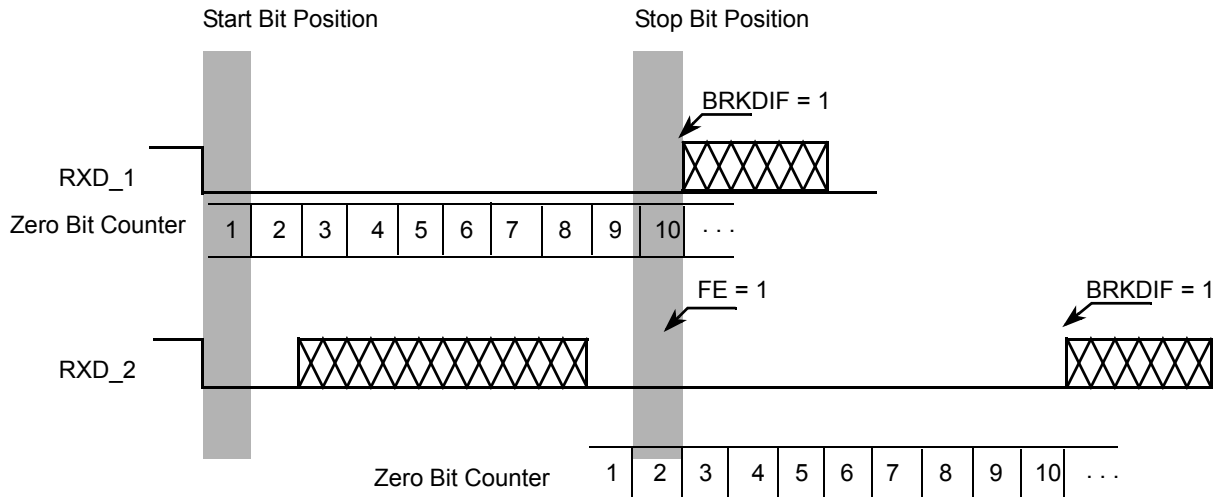

Figure 16-17. Break Detection if BRKDFE = 1 (M = 0)

16.4.5.4 Idle Characters

An idle character (or preamble) contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in SCI control register 1 (SCICR1). The preamble is a synchronizing idle character that begins the first transmission initiated after writing the TE bit from 0 to 1.

If the TE bit is cleared during a transmission, the TXD pin becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the frame currently being transmitted.

NOTE

When queuing an idle character, return the TE bit to logic 1 before the stop bit of the current frame shifts out through the TXD pin. Setting TE after the stop bit appears on TXD causes data previously written to the SCI data register to be lost. Toggle the TE bit for a queued idle character while the TDRE flag is set and immediately before writing the next byte to the SCI data register.

If the TE bit is clear and the transmission is complete, the SCI is not the master of the TXD pin

16.4.5.5 LIN Transmit Collision Detection

This module allows to check for collisions on the LIN bus.

Figure 16-18. Collision Detect Principle

If the bit error circuit is enabled ($BERRM[1:0] = 0:1$ or $= 1:0$), the error detect circuit will compare the transmitted and the received data stream at a point in time and flag any mismatch. The timing checks run when transmitter is active (not idle). As soon as a mismatch between the transmitted data and the received data is detected the following happens:

- The next bit transmitted will have a high level ($TXPOL = 0$) or low level ($TXPOL = 1$)
- The transmission is aborted and the byte in transmit buffer is discarded.
- the transmit data register empty and the transmission complete flag will be set
- The bit error interrupt flag, $BERRIF$, will be set.
- No further transmissions will take place until the $BERRIF$ is cleared.

Figure 16-19. Timing Diagram Bit Error Detection

If the bit error detect feature is disabled, the bit error interrupt flag is cleared.

NOTE

The $RXPOL$ and $TXPOL$ bit should be set the same when transmission collision detect feature is enabled, otherwise the bit error interrupt flag may be set incorrectly.

16.4.6 Receiver

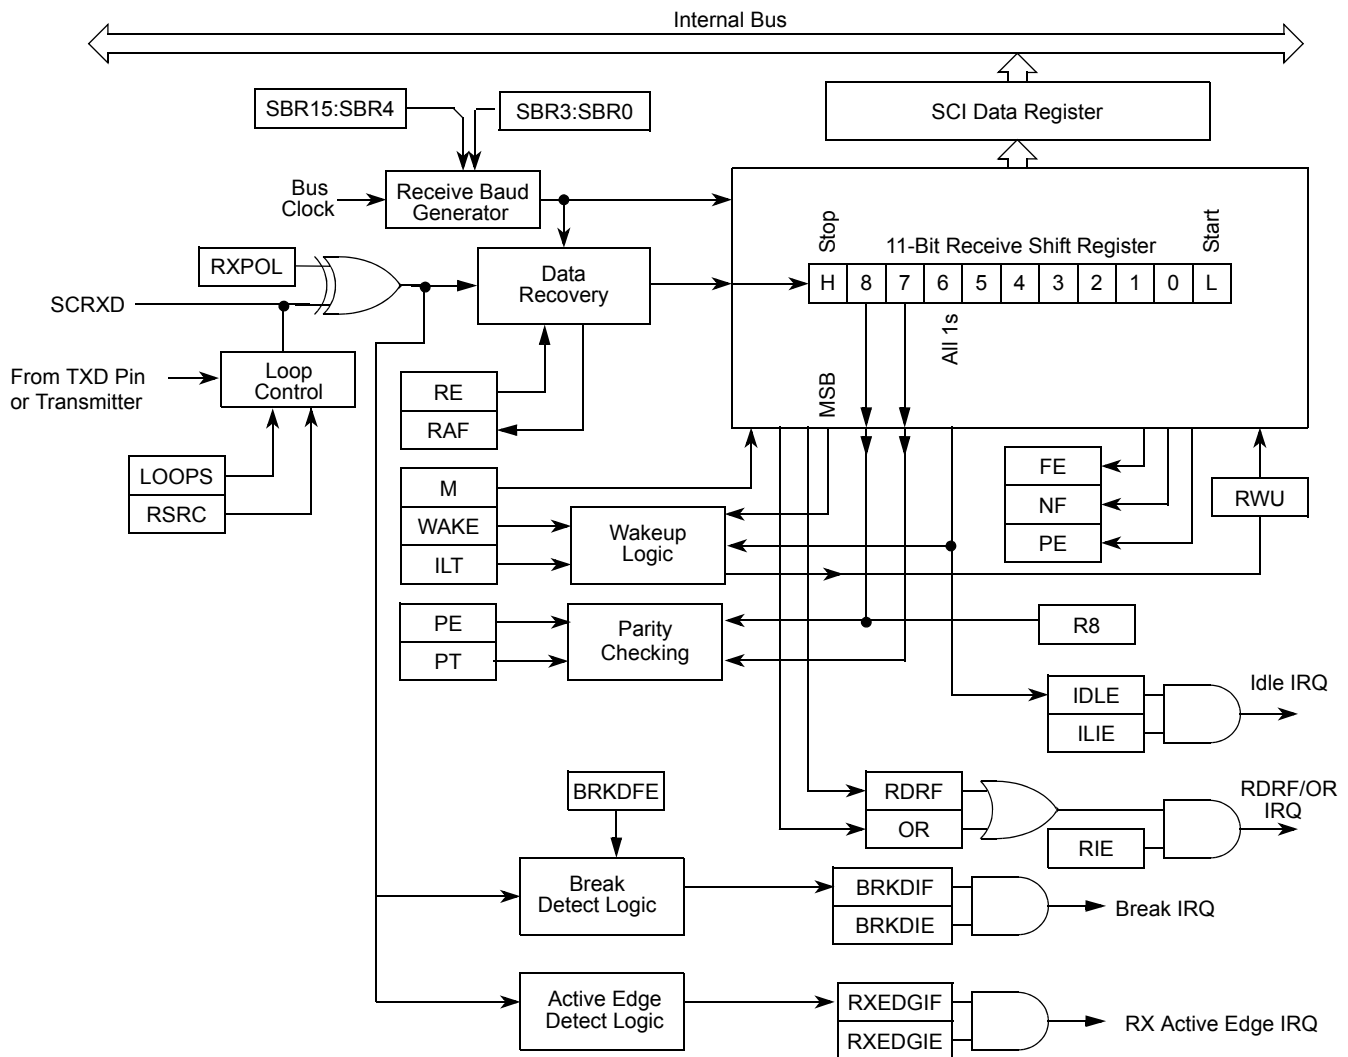

Figure 16-20. SCI Receiver Block Diagram

16.4.6.1 Receiver Character Length

The SCI receiver can accommodate either 8-bit or 9-bit data characters. The state of the M bit in SCI control register 1 (SCICR1) determines the length of data characters. When receiving 9-bit data, bit R8 in SCI data register high (SCIDRH) is the ninth bit (bit 8).

16.4.6.2 Character Reception

During an SCI reception, the receive shift register shifts a frame in from the RXD pin. The SCI data register is the read-only buffer between the internal data bus and the receive shift register.

After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the SCI data register. The receive data register full flag, RDRF, in SCI status register 1 (SCISR1) becomes set,

indicating that the received byte can be read. If the receive interrupt enable bit, RIE, in SCI control register 2 (SCICR2) is also set, the RDRF flag generates an RDRF interrupt request.

16.4.6.3 Data Sampling

The RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock (see [Figure 16-21](#)) is re-synchronized immediately at bus clock edge:

- After every start bit
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0)

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

Figure 16-21. Receiver Data Sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7. [Figure 16-17](#) summarizes the results of the start bit verification samples.

Table 16-17. Start Bit Verification

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. [Table 16-18](#) summarizes the results of the data bit samples.

Table 16-18. Data Bit Recovery

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

NOTE

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit (logic 0).

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. [Table 16-19](#) summarizes the results of the stop bit samples.

Table 16-19. Stop Bit Recovery

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

In Figure 16-22 the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.

Figure 16-22. Start Bit Search Example 1

In Figure 16-23, verification sample at RT3 is high. The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

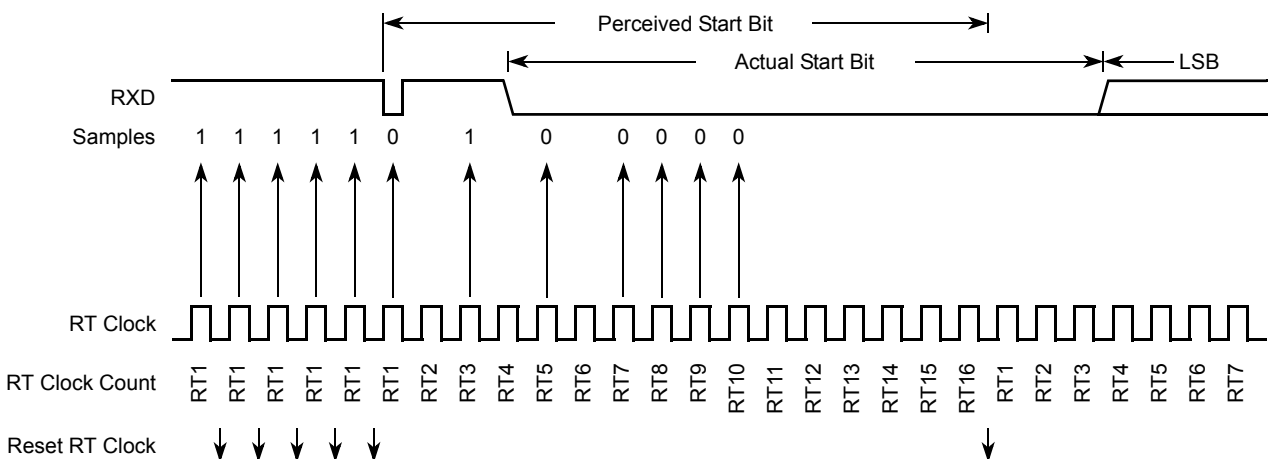

Figure 16-23. Start Bit Search Example 2

In Figure 16-24, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

Figure 16-24. Start Bit Search Example 3

Figure 16-25 shows the effect of noise early in the start bit time. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

Figure 16-25. Start Bit Search Example 4

Figure 16-26 shows a burst of noise near the beginning of the start bit that resets the RT clock. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.

Figure 16-26. Start Bit Search Example 5

In Figure 16-27, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. This sets the noise flag but does not reset the RT clock. In start bits only, the RT8, RT9, and RT10 data samples are ignored.

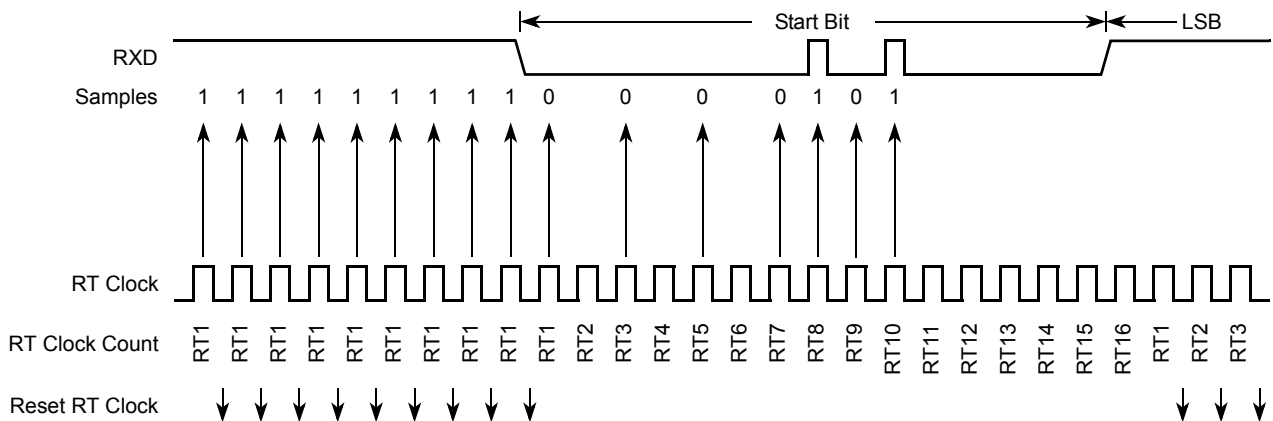

Figure 16-27. Start Bit Search Example 6

16.4.6.4 Framing Errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, FE, in SCI status register 1 (SCISR1). A break character also sets the FE flag because a break character has no stop bit. The FE flag is set at the same time that the RDRF flag is set.

16.4.6.5 Baud Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic zero.

As the receiver samples an incoming frame, it re-synchronizes the RT clock on any valid falling edge within the frame. Re synchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

16.4.6.5.1 Slow Data Tolerance

Figure 16-28 shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

Figure 16-28. Slow Data

Let's take RT_r as receiver RT clock and RT_t as transmitter RT clock.

For an 8-bit data character, it takes the receiver 9 bit times x 16 RT_r cycles + 7 RT_r cycles = 151 RT_r cycles to start data sampling of the stop bit.

With the misaligned character shown in Figure 16-28, the receiver counts 151 RT_r cycles at the point when the count of the transmitting device is 9 bit times x 16 RT_t cycles = 144 RT_t cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((151 - 144) / 151) \times 100 = 4.63\%$$

For a 9-bit data character, it takes the receiver 10 bit times x 16 RT_r cycles + 7 RT_r cycles = 167 RT_r cycles to start data sampling of the stop bit.

With the misaligned character shown in Figure 16-28, the receiver counts 167 RT_r cycles at the point when the count of the transmitting device is 10 bit times x 16 RT_t cycles = 160 RT_t cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((167 - 160) / 167) \times 100 = 4.19\%$$

16.4.6.5.2 Fast Data Tolerance

Figure 16-29 shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

Figure 16-29. Fast Data

For an 8-bit data character, it takes the receiver $9 \text{ bit times} \times 16 \text{ RTr cycles} + 9 \text{ RTr cycles} = 153 \text{ RTr cycles}$ to finish data sampling of the stop bit.

With the misaligned character shown in Figure 16-29, the receiver counts 153 RTr cycles at the point when the count of the transmitting device is $10 \text{ bit times} \times 16 \text{ RTt cycles} = 160 \text{ RTt cycles}$.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((160 - 153) / 160) \times 100 = 4.375\%$$

For a 9-bit data character, it takes the receiver $10 \text{ bit times} \times 16 \text{ RTr cycles} + 9 \text{ RTr cycles} = 169 \text{ RTr cycles}$ to finish data sampling of the stop bit.

With the misaligned character shown in Figure 16-29, the receiver counts 169 RTr cycles at the point when the count of the transmitting device is $11 \text{ bit times} \times 16 \text{ RTt cycles} = 176 \text{ RTt cycles}$.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((176 - 169) / 176) \times 100 = 3.98\%$$

NOTE

Due to asynchronous sample and internal logic, there is maximal 2 bus cycles between startbit edge and 1st RT clock, and cause to additional tolerance loss at worst case. The loss should be $2/SBR/10 \times 100\%$, it is small. For example, for highspeed baud=230400 with 25MHz bus, SBR should be 109, and the tolerance loss is $2/109/10 \times 100 = 0.18\%$, and fast data tolerance is $4.375\% - 0.18\% = 4.195\%$.

16.4.6.6 Receiver Wakeup

To enable the SCI to ignore transmissions intended only for other receivers in multiple-receiver systems, the receiver can be put into a standby state. Setting the receiver wakeup bit, RWU, in SCI control register 2 (SCICR2) puts the receiver into standby state during which receiver interrupts are disabled. The SCI will still load the receive data into the SCIDRH/L registers, but it will not set the RDRF flag.

The transmitting device can address messages to selected receivers by including addressing information in the initial frame or frames of each message.

The WAKE bit in SCI control register 1 (SCICR1) determines how the SCI is brought out of the standby state to process an incoming message. The WAKE bit enables either idle line wakeup or address mark wakeup.

16.4.6.6.1 Idle Input line Wakeup (WAKE = 0)

In this wakeup method, an idle condition on the RXD pin clears the RWU bit and wakes up the SCI. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another idle character appears on the RXD pin.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

The idle character that wakes a receiver does not set the receiver idle bit, IDLE, or the receive data register full flag, RDRF.

The idle line type bit, ILT, determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit. ILT is in SCI control register 1 (SCICR1).

16.4.6.6.2 Address Mark Wakeup (WAKE = 1)

In this wakeup method, a logic 1 in the most significant bit (MSB) position of a frame clears the RWU bit and wakes up the SCI. The logic 1 in the MSB position marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another address frame appears on the RXD pin.

The logic 1 MSB of an address frame clears the receiver's RWU bit before the stop bit is received and sets the RDRF flag.

Address mark wakeup allows messages to contain idle characters but requires that the MSB be reserved for use in address frames.

NOTE

With the WAKE bit clear, setting the RWU bit after the RXD pin has been idle can cause the receiver to wake up immediately.

16.4.7 Single-Wire Operation

Normally, the SCI uses two pins for transmitting and receiving. In single-wire operation, the RXD pin is disconnected from the SCI. The SCI uses the TXD pin for both receiving and transmitting.

Figure 16-30. Single-Wire Operation (LOOPS = 1, RSRC = 1)

Enable single-wire operation by setting the LOOPS bit and the receiver source bit, RSRC, in SCI control register 1 (SCICR1). Setting the LOOPS bit disables the path from the RXD pin to the receiver. Setting the RSRC bit connects the TXD pin to the receiver. Both the transmitter and receiver must be enabled (TE = 1 and RE = 1). The TXDIR bit (SCISR2[1]) determines whether the TXD pin is going to be used as an input (TXDIR = 0) or an output (TXDIR = 1) in this mode of operation.

NOTE

In single-wire operation data from the TXD pin is inverted if RXPOL is set.

16.4.8 Loop Operation

In loop operation the transmitter output goes to the receiver input. The RXD pin is disconnected from the SCI.

Figure 16-31. Loop Operation (LOOPS = 1, RSRC = 0)

Enable loop operation by setting the LOOPS bit and clearing the RSRC bit in SCI control register 1 (SCICR1). Setting the LOOPS bit disables the path from the RXD pin to the receiver. Clearing the RSRC bit connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (TE = 1 and RE = 1).

NOTE

In loop operation data from the transmitter is not recognized by the receiver if RXPOL and TXPOL are not the same.

16.5 Initialization/Application Information

16.5.1 Reset Initialization

See [Section 16.3.2, “Register Descriptions”](#).

16.5.2 Modes of Operation

16.5.2.1 Run Mode

Normal mode of operation.

To initialize a SCI transmission, see [Section 16.4.5.2, “Character Transmission”](#).

16.5.2.2 Wait Mode

SCI operation in wait mode depends on the state of the SCISWAI bit in the SCI control register 1 (SCICR1).

- If SCISWAI is clear, the SCI operates normally when the CPU is in wait mode.
- If SCISWAI is set, SCI clock generation ceases and the SCI module enters a power-conservation state when the CPU is in wait mode. Setting SCISWAI does not affect the state of the receiver enable bit, RE, or the transmitter enable bit, TE.

If SCISWAI is set, any transmission or reception in progress stops at wait mode entry. The transmission or reception resumes when either an internal or external interrupt brings the CPU out of wait mode. Exiting wait mode by reset aborts any transmission or reception in progress and resets the SCI.

16.5.2.3 Stop Mode

The SCI is inactive during stop mode for reduced power consumption. The STOP instruction does not affect the SCI register states, but the SCI bus clock will be disabled. The SCI operation resumes from where it left off after an external interrupt brings the CPU out of stop mode. Exiting stop mode by reset aborts any transmission or reception in progress and resets the SCI.

The receive input active edge detect circuit is still active in stop mode. An active edge on the receive input can be used to bring the CPU out of stop mode.

16.5.3 Interrupt Operation

This section describes the interrupt originated by the SCI block. The MCU must service the interrupt requests. [Table 16-20](#) lists the eight interrupt sources of the SCI.

Table 16-20. SCI Interrupt Sources

Interrupt	Source	Local Enable	Description
TDRE	SCISR1[7]	TIE	Active high level. Indicates that a byte was transferred from SCIDRH/L to the transmit shift register.
TC	SCISR1[6]	TCIE	Active high level. Indicates that a transmit is complete.
RDRF	SCISR1[5]	RIE	Active high level. The RDRF interrupt indicates that received data is available in the SCI data register.
OR	SCISR1[3]		Active high level. This interrupt indicates that an overrun condition has occurred.
IDLE	SCISR1[4]	ILIE	Active high level. Indicates that receiver input has become idle.

Table 16-20. SCI Interrupt Sources

RXEDGIF	SCIASR1[7]	RXEDGIE	Active high level. Indicates that an active edge (falling for RXPOL = 0, rising for RXPOL = 1) was detected.
BERRIF	SCIASR1[1]	BERRIE	Active high level. Indicates that a mismatch between transmitted and received data in a single wire application has happened.
BKDIF	SCIASR1[0]	BRKDIE	Active high level. Indicates that a break character has been received.

16.5.3.1 Description of Interrupt Operation

The SCI only originates interrupt requests. The following is a description of how the SCI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt number are chip dependent. The SCI only has a single interrupt line (SCI Interrupt Signal, active high operation) and all the following interrupts, when generated, are ORed together and issued through that port.

16.5.3.1.1 TDRE Description

The TDRE interrupt is set high by the SCI when the transmit shift register receives a byte from the SCI data register. A TDRE interrupt indicates that the transmit data register (SCIDRH/L) is empty and that a new byte can be written to the SCIDRH/L for transmission. Clear TDRE by reading SCI status register 1 with TDRE set and then writing to SCI data register low (SCIDRL).

16.5.3.1.2 TC Description

The TC interrupt is set by the SCI when a transmission has been completed. Transmission is completed when all bits including the stop bit (if transmitted) have been shifted out and no data is queued to be transmitted. No stop bit is transmitted when sending a break character and the TC flag is set (providing there is no more data queued for transmission) when the break character has been shifted out. A TC interrupt indicates that there is no transmission in progress. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD pin becomes idle (logic 1). Clear TC by reading SCI status register 1 (SCISR1) with TC set and then writing to SCI data register low (SCIDRL). TC is cleared automatically when data, preamble, or break is queued and ready to be sent.

16.5.3.1.3 RDRF Description

The RDRF interrupt is set when the data in the receive shift register transfers to the SCI data register. A RDRF interrupt indicates that the received data has been transferred to the SCI data register and that the byte can now be read by the MCU. The RDRF interrupt is cleared by reading the SCI status register one (SCISR1) and then reading SCI data register low (SCIDRL).

16.5.3.1.4 OR Description

The OR interrupt is set when software fails to read the SCI data register before the receive shift register receives the next frame. The newly acquired data in the shift register will be lost in this case, but the data already in the SCI data registers is not affected. The OR interrupt is cleared by reading the SCI status register one (SCISR1) and then reading SCI data register low (SCIDRL).

16.5.3.1.5 IDLE Description

The IDLE interrupt is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. Once the IDLE is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. Clear IDLE by reading SCI status register 1 (SCISR1) with IDLE set and then reading SCI data register low (SCIDRL).

16.5.3.1.6 RXEDGIF Description

The RXEDGIF interrupt is set when an active edge (falling if RXPOL = 0, rising if RXPOL = 1) on the RXD pin is detected. Clear RXEDGIF by writing a “1” to the SCIASR1 SCI alternative status register 1.

16.5.3.1.7 BERRIF Description

The BERRIF interrupt is set when a mismatch between the transmitted and the received data in a single wire application like LIN was detected. Clear BERRIF by writing a “1” to the SCIASR1 SCI alternative status register 1. This flag is also cleared if the bit error detect feature is disabled.

16.5.3.1.8 BKDIF Description

The BKDIF interrupt is set when a break signal was received. Clear BKDIF by writing a “1” to the SCIASR1 SCI alternative status register 1. This flag is also cleared if break detect feature is disabled.

16.5.4 Recovery from Wait Mode

The SCI interrupt request can be used to bring the CPU out of wait mode.

16.5.5 Recovery from Stop Mode

An active edge on the receive input can be used to bring the CPU out of stop mode.

Chapter 17

Serial Peripheral Interface (S12SPIV5)

Table 17-1. Revision History

Revision Number	Revision Date	Sections Affected	Description of Changes
V05.00	24 Mar 2005	17.3.2/17-677	- Added 16-bit transfer width feature.

17.1 Introduction

The SPI module allows a duplex, synchronous, serial communication between the MCU and peripheral devices. Software can poll the SPI status flags or the SPI operation can be interrupt driven.

17.1.1 Glossary of Terms

SPI	Serial Peripheral Interface
SS	Slave Select
SCK	Serial Clock
MOSI	Master Output, Slave Input
MISO	Master Input, Slave Output
MOMI	Master Output, Master Input
SISO	Slave Input, Slave Output

17.1.2 Features

The SPI includes these distinctive features:

- Master mode and slave mode
- Selectable 8 or 16-bit transfer width
- Bidirectional mode
- Slave select output
- Mode fault error flag with CPU interrupt capability
- Double-buffered data register
- Serial clock with programmable polarity and phase
- Control of SPI operation during wait mode

17.1.3 Modes of Operation

The SPI functions in three modes: run, wait, and stop.

- Run mode
This is the basic mode of operation.
- Wait mode
SPI operation in wait mode is a configurable low power mode, controlled by the SPISWAI bit located in the SPICR2 register. In wait mode, if the SPISWAI bit is clear, the SPI operates like in run mode. If the SPISWAI bit is set, the SPI goes into a power conservative state, with the SPI clock generation turned off. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU goes into run mode. If the SPI is configured as a slave, reception and transmission of data continues, so that the slave stays synchronized to the master.
- Stop mode
The SPI is inactive in stop mode for reduced power consumption. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU goes into run mode. If the SPI is configured as a slave, reception and transmission of data continues, so that the slave stays synchronized to the master.

For a detailed description of operating modes, please refer to [Section 17.4.7, “Low Power Mode Options”](#).

17.1.4 Block Diagram

[Figure 17-1](#) gives an overview on the SPI architecture. The main parts of the SPI are status, control and data registers, shifter logic, baud rate generator, master/slave control logic, and port control logic.

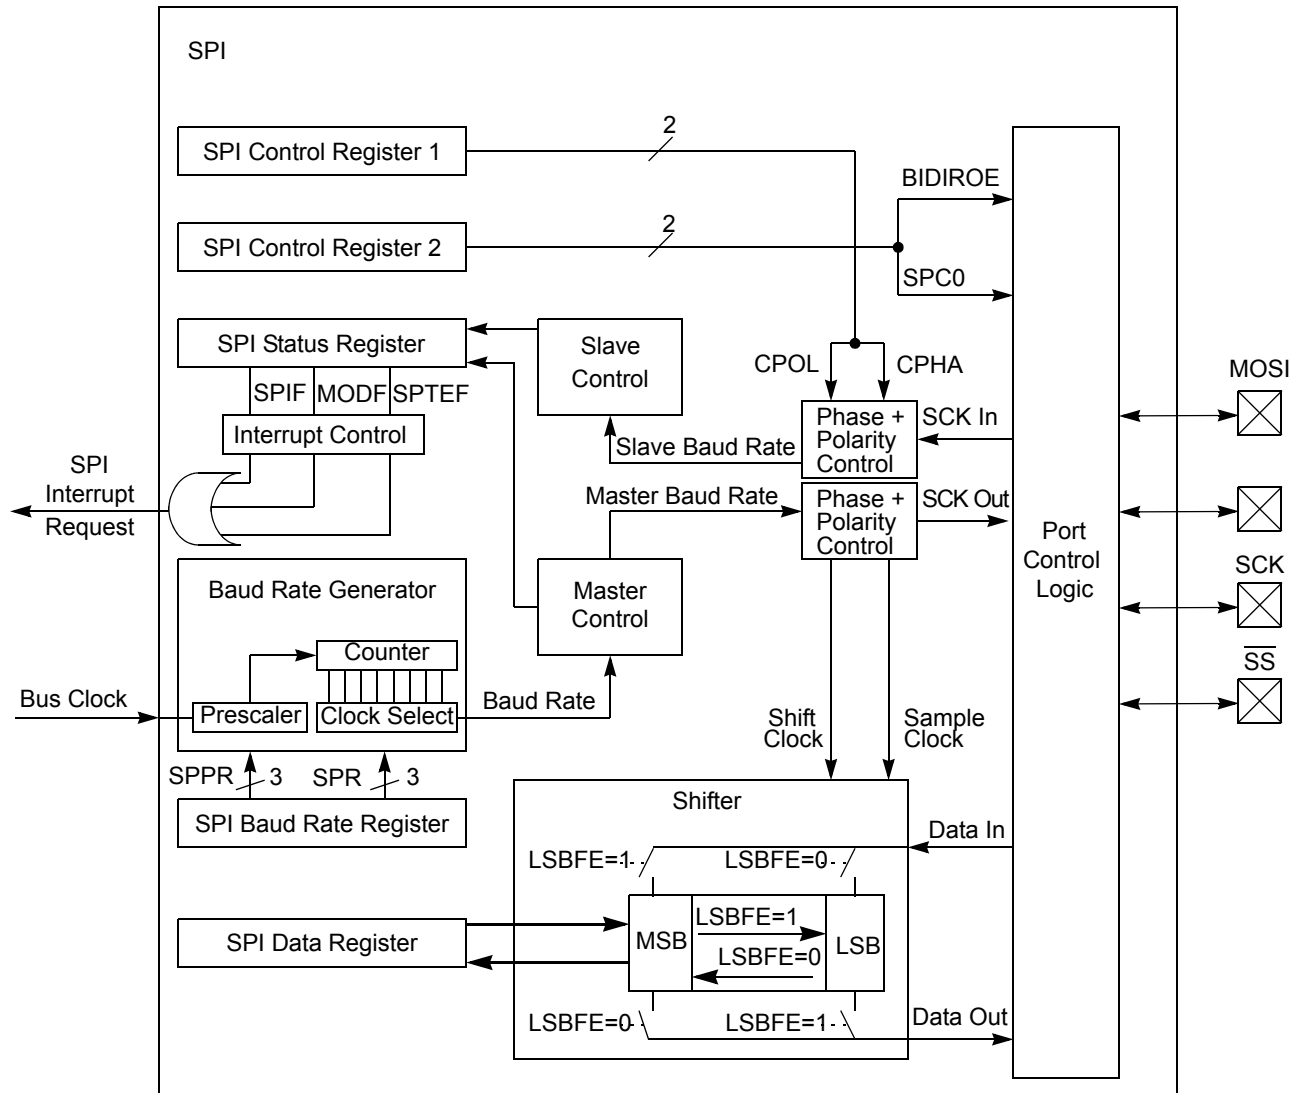

Figure 17-1. SPI Block Diagram

17.2 External Signal Description

This section lists the name and description of all ports including inputs and outputs that do, or may, connect off chip. The SPI module has a total of four external pins.

17.2.1 MOSI — Master Out/Slave In Pin

This pin is used to transmit data out of the SPI module when it is configured as a master and receive data when it is configured as slave.

17.2.2 MISO — Master In/Slave Out Pin

This pin is used to transmit data out of the SPI module when it is configured as a slave and receive data when it is configured as master.

17.2.3 \overline{SS} — Slave Select Pin

This pin is used to output the select signal from the SPI module to another peripheral with which a data transfer is to take place when it is configured as a master and it is used as an input to receive the slave select signal when the SPI is configured as slave.

17.2.4 SCK — Serial Clock Pin

In master mode, this is the synchronous output clock. In slave mode, this is the synchronous input clock.

17.3 Memory Map and Register Definition

This section provides a detailed description of address space and registers used by the SPI.

17.3.1 Module Memory Map

The memory map for the SPI is given in [Figure 17-2](#). The address listed for each register is the sum of a base address and an address offset. The base address is defined at the SoC level and the address offset is defined at the module level. Reads from the reserved bits return zeros and writes to the reserved bits have no effect.

Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 SPICR1	R W	SPIE	SPE	SPTIE	MSTR	CPOL	CPHA	SSOE	LSBFE
0x0001 SPICR2	R W	0	XFRW	0	MODFEN	BIDIROE	0	SPISWAI	SPC0
0x0002 SPIBR	R W	0	SPPR2	SPPR1	SPPR0	0	SPR2	SPR1	SPR0

Figure 17-2. SPI Register Summary

Figure 17-2. SPI Register Summary

17.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

17.3.2.1 SPI Control Register 1 (SPICR1)

Module Base +0x0000

Figure 17-3. SPI Control Register 1 (SPICR1)

Read: Anytime

Write: Anytime

Table 17-2. SPICR1 Field Descriptions

Field	Description
7 SPIE	SPI Interrupt Enable Bit — This bit enables SPI interrupt requests, if SPIF or MODF status flag is set. 0 SPI interrupts disabled. 1 SPI interrupts enabled.
6 SPE	SPI System Enable Bit — This bit enables the SPI system and dedicates the SPI port pins to SPI system functions. If SPE is cleared, SPI is disabled and forced into idle state, status bits in SPISR register are reset. 0 SPI disabled (lower power consumption). 1 SPI enabled, port pins are dedicated to SPI functions.
5 SPTIE	SPI Transmit Interrupt Enable — This bit enables SPI interrupt requests, if SPTEF flag is set. 0 SPTEF interrupt disabled. 1 SPTEF interrupt enabled.
4 MSTR	SPI Master/Slave Mode Select Bit — This bit selects whether the SPI operates in master or slave mode. Switching the SPI from master to slave or vice versa forces the SPI system into idle state. 0 SPI is in slave mode. 1 SPI is in master mode.

Table 17-2. SPICR1 Field Descriptions (continued)

Field	Description
3 CPOL	SPI Clock Polarity Bit — This bit selects an inverted or non-inverted SPI clock. To transmit data between SPI modules, the SPI modules must have identical CPOL values. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 Active-high clocks selected. In idle state SCK is low. 1 Active-low clocks selected. In idle state SCK is high.
2 CPHA	SPI Clock Phase Bit — This bit is used to select the SPI clock format. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 Sampling of data occurs at odd edges (1,3,5,...) of the SCK clock. 1 Sampling of data occurs at even edges (2,4,6,...) of the SCK clock.
1 SSOE	Slave Select Output Enable — The \overline{SS} output feature is enabled only in master mode, if MODFEN is set, by asserting the SSOE as shown in Table 17-3. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state.
0 LSBFE	LSB-First Enable — This bit does not affect the position of the MSB and LSB in the data register. Reads and writes of the data register always have the MSB in the highest bit position. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 Data is transferred most significant bit first. 1 Data is transferred least significant bit first.

Table 17-3. \overline{SS} Input / Output Selection

MODFEN	SSOE	Master Mode	Slave Mode
0	0	SS not used by SPI	SS input
0	1	\overline{SS} not used by SPI	SS input
1	0	SS input with MODF feature	SS input
1	1	SS is slave select output	SS input

17.3.2.2 SPI Control Register 2 (SPICR2)

Module Base +0x0001

Figure 17-4. SPI Control Register 2 (SPICR2)

Read: Anytime

Write: Anytime; writes to the reserved bits have no effect

Table 17-4. SPICR2 Field Descriptions

Field	Description
6 XFRW	Transfer Width — This bit is used for selecting the data transfer width. If 8-bit transfer width is selected, SPIDRL becomes the dedicated data register and SPIDRH is unused. If 16-bit transfer width is selected, SPIDRH and SPIDRL form a 16-bit data register. Please refer to Section 17.3.2.4, “SPI Status Register (SPISR) for information about transmit/receive data handling and the interrupt flag clearing mechanism. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 8-bit Transfer Width (n = 8) ⁽¹⁾ 1 16-bit Transfer Width (n = 16) ¹
4 MODFEN	Mode Fault Enable Bit — This bit allows the MODF failure to be detected. If the SPI is in master mode and MODFEN is cleared, then the \overline{SS} port pin is not used by the SPI. In slave mode, the \overline{SS} is available only as an input regardless of the value of MODFEN. For an overview on the impact of the MODFEN bit on the \overline{SS} port pin configuration, refer to Table 17-3. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 \overline{SS} port pin is not used by the SPI. 1 \overline{SS} port pin with MODF feature.
3 BIDIROE	Output Enable in the Bidirectional Mode of Operation — This bit controls the MOSI and MISO output buffer of the SPI, when in bidirectional mode of operation (SPC0 is set). In master mode, this bit controls the output buffer of the MOSI port, in slave mode it controls the output buffer of the MISO port. In master mode, with SPC0 set, a change of this bit will abort a transmission in progress and force the SPI into idle state. 0 Output buffer disabled. 1 Output buffer enabled.
1 SPISWAI	SPI Stop in Wait Mode Bit — This bit is used for power conservation while in wait mode. 0 SPI clock operates normally in wait mode. 1 Stop SPI clock generation when in wait mode.
0 SPC0	Serial Pin Control Bit 0 — This bit enables bidirectional pin configurations as shown in Table 17-5. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state.

1. n is used later in this document as a placeholder for the selected transfer width.

Table 17-5. Bidirectional Pin Configurations

Pin Mode	SPC0	BIDIROE	MISO	MOSI
Master Mode of Operation				
Normal	0	X	Master In	Master Out
Bidirectional	1	0	MISO not used by SPI	Master In
		1		Master I/O
Slave Mode of Operation				
Normal	0	X	Slave Out	Slave In
Bidirectional	1	0	Slave In	MOSI not used by SPI
		1	Slave I/O	

17.3.2.3 SPI Baud Rate Register (SPIBR)

Module Base +0x0002

Figure 17-5. SPI Baud Rate Register (SPIBR)

Read: Anytime

Write: Anytime; writes to the reserved bits have no effect

Table 17-6. SPIBR Field Descriptions

Field	Description
6–4 SPPR[2:0]	SPI Baud Rate Preselection Bits — These bits specify the SPI baud rates as shown in Table 17-7. In master mode, a change of these bits will abort a transmission in progress and force the SPI system into idle state.
2–0 SPR[2:0]	SPI Baud Rate Selection Bits — These bits specify the SPI baud rates as shown in Table 17-7. In master mode, a change of these bits will abort a transmission in progress and force the SPI system into idle state.

The baud rate divisor equation is as follows:

$$\text{BaudRateDivisor} = (\text{SPPR} + 1) \cdot 2^{(\text{SPR} + 1)} \tag{Eqn. 17-1}$$

The baud rate can be calculated with the following equation:

$$\text{Baud Rate} = \text{BusClock} / \text{BaudRateDivisor} \tag{Eqn. 17-2}$$

NOTE

For maximum allowed baud rates, please refer to the SPI Electrical Specification in the Electricals chapter of this data sheet.

17.3.2.4 SPI Status Register (SPISR)

Module Base +0x0003

Figure 17-6. SPI Status Register (SPISR)

Read: Anytime

Write: Has no effect

Table 17-8. SPISR Field Descriptions

Field	Description
7 SPIF	SPIF Interrupt Flag — This bit is set after received data has been transferred into the SPI data register. For information about clearing SPIF Flag, please refer to Table 17-9 . 0 Transfer not yet complete. 1 New data copied to SPIDR.
5 SPTEF	SPI Transmit Empty Interrupt Flag — If set, this bit indicates that the transmit data register is empty. For information about clearing this bit and placing data into the transmit data register, please refer to Table 17-10 . 0 SPI data register not empty. 1 SPI data register empty.
4 MODF	Mode Fault Flag — This bit is set if the \overline{SS} input becomes low while the SPI is configured as a master and mode fault detection is enabled, MODFEN bit of SPICR2 register is set. Refer to MODFEN bit description in Section 17.3.2.2, “SPI Control Register 2 (SPICR2)” . The flag is cleared automatically by a read of the SPI status register (with MODF set) followed by a write to the SPI control register 1. 0 Mode fault has not occurred. 1 Mode fault has occurred.

Table 17-9. SPIF Interrupt Flag Clearing Sequence

XFRW Bit	SPIF Interrupt Flag Clearing Sequence		
0	Read SPISR with SPIF == 1	then	Read SPIDRL
1	Read SPISR with SPIF == 1	then	Byte Read SPIDRL ⁽¹⁾
			or
			Byte Read SPIDRH ⁽²⁾ Byte Read SPIDRL
			or
			Word Read (SPIDRH:SPIDRL)

1. Data in SPIDRH is lost in this case.

2. SPIDRH can be read repeatedly without any effect on SPIF. SPIF Flag is cleared only by the read of SPIDRL after reading SPISR with SPIF == 1.

Table 17-10. SPTEF Interrupt Flag Clearing Sequence

XFRW Bit	SPTEF Interrupt Flag Clearing Sequence		
0	Read SPISR with SPTEF == 1	then	Write to SPIDRL ⁽¹⁾
1	Read SPISR with SPTEF == 1	then	Byte Write to SPIDRL ¹⁽²⁾
			or
			Byte Write to SPIDRH ¹⁽³⁾ Byte Write to SPIDRL ¹
			or
			Word Write to (SPIDRH:SPIDRL) ¹

1. Any write to SPIDRH or SPIDRL with SPTEF == 0 is effectively ignored.

2. Data in SPIDRH is undefined in this case.

3. SPIDRH can be written repeatedly without any effect on SPTEF. SPTEF Flag is cleared only by writing to SPIDRL after reading SPISR with SPTEF == 1.

Figure 17-8. SPI Data Register Low (SPIDL)

Read: Anytime; read data only valid when SPIF is set

Write: Anytime

The SPI data register is both the input and output register for SPI data. A write to this register allows data to be queued and transmitted. For an SPI configured as a master, queued data is transmitted immediately after the previous transmission has completed. The SPI transmitter empty flag SPTEF in the SPISR register indicates when the SPI data register is ready to accept new data. Received data in the SPIDR is valid when SPIF is set.

If SPIF is cleared and data has been received, the received data is transferred from the receive shift register to the SPIDR and SPIF is set.

If SPIF is set and not serviced, and a second data value has been received, the second received data is kept as valid data in the receive shift register until the start of another transmission. The data in the SPIDR does not change.

If SPIF is set and valid data is in the receive shift register, and SPIF is serviced before the start of a third transmission, the data in the receive shift register is transferred into the SPIDR and SPIF remains set (see [Figure 17-9](#)).

If SPIF is set and valid data is in the receive shift register, and SPIF is serviced after the start of a third transmission, the data in the receive shift register has become invalid and is not transferred into the SPIDR (see [Figure 17-10](#)).

Figure 17-9. Reception with SPIF serviced in Time

Figure 17-10. Reception with SPIF serviced too late

17.4 Functional Description

The SPI module allows a duplex, synchronous, serial communication between the MCU and peripheral devices. Software can poll the SPI status flags or SPI operation can be interrupt driven.

The SPI system is enabled by setting the SPI enable (SPE) bit in SPI control register 1. While SPE is set, the four associated SPI port pins are dedicated to the SPI function as:

- Slave select (\overline{SS})
- Serial clock (SCK)
- Master out/slave in (MOSI)
- Master in/slave out (MISO)

The main element of the SPI system is the SPI data register. The n -bit¹ data register in the master and the n -bit¹ data register in the slave are linked by the MOSI and MISO pins to form a distributed $2n$ -bit¹ register. When a data transfer operation is performed, this $2n$ -bit¹ register is serially shifted n ¹ bit positions by the S-clock from the master, so data is exchanged between the master and the slave. Data written to the master SPI data register becomes the output data for the slave, and data read from the master SPI data register after a transfer operation is the input data from the slave.

A read of SPISR with SPTEF = 1 followed by a write to SPIDR puts data into the transmit data register. When a transfer is complete and SPIF is cleared, received data is moved into the receive data register. This data register acts as the SPI receive data register for reads and as the SPI transmit data register for writes. A common SPI data register address is shared for reading data from the read data buffer and for writing data to the transmit data register.

The clock phase control bit (CPHA) and a clock polarity control bit (CPOL) in the SPI control register 1 (SPICR1) select one of four possible clock formats to be used by the SPI system. The CPOL bit simply selects a non-inverted or inverted clock. The CPHA bit is used to accommodate two fundamentally different protocols by sampling data on odd numbered SCK edges or on even numbered SCK edges (see [Section 17.4.3, “Transmission Formats”](#)).

The SPI can be configured to operate as a master or as a slave. When the MSTR bit in SPI control register 1 is set, master mode is selected, when the MSTR bit is clear, slave mode is selected.

NOTE

A change of CPOL or MSTR bit while there is a received byte pending in the receive shift register will destroy the received byte and must be avoided.

17.4.1 Master Mode

The SPI operates in master mode when the MSTR bit is set. Only a master SPI module can initiate transmissions. A transmission begins by writing to the master SPI data register. If the shift register is empty, data immediately transfers to the shift register. Data begins shifting out on the MOSI pin under the control of the serial clock.

- Serial clock

The SPR2, SPR1, and SPR0 baud rate selection bits, in conjunction with the SPPR2, SPPR1, and SPPR0 baud rate preselection bits in the SPI baud rate register, control the baud rate generator and determine the speed of the transmission. The SCK pin is the SPI clock output. Through the SCK pin, the baud rate generator of the master controls the shift register of the slave peripheral.

- MOSI, MISO pin

In master mode, the function of the serial data output pin (MOSI) and the serial data input pin (MISO) is determined by the SPC0 and BIDIROE control bits.

- \overline{SS} pin

If MODFEN and SSOE are set, the \overline{SS} pin is configured as slave select output. The \overline{SS} output becomes low during each transmission and is high when the SPI is in idle state.

If MODFEN is set and SSOE is cleared, the \overline{SS} pin is configured as input for detecting mode fault error. If the \overline{SS} input becomes low this indicates a mode fault error where another master tries to

1. n depends on the selected transfer width, please refer to [Section 17.3.2.2, “SPI Control Register 2 \(SPICR2\)”](#)

drive the MOSI and SCK lines. In this case, the SPI immediately switches to slave mode, by clearing the MSTR bit and also disables the slave output buffer MISO (or SISO in bidirectional mode). So the result is that all outputs are disabled and SCK, MOSI, and MISO are inputs. If a transmission is in progress when the mode fault occurs, the transmission is aborted and the SPI is forced into idle state.

This mode fault error also sets the mode fault (MODF) flag in the SPI status register (SPISR). If the SPI interrupt enable bit (SPIE) is set when the MODF flag becomes set, then an SPI interrupt sequence is also requested.

When a write to the SPI data register in the master occurs, there is a half SCK-cycle delay. After the delay, SCK is started within the master. The rest of the transfer operation differs slightly, depending on the clock format specified by the SPI clock phase bit, CPHA, in SPI control register 1 (see [Section 17.4.3, “Transmission Formats”](#)).

NOTE

A change of the bits CPOL, CPHA, SSOE, LSBFE, XFRW, MODFEN, SPC0, or BIDIROE with SPC0 set, SPPR2-SPPR0 and SPR2-SPR0 in master mode will abort a transmission in progress and force the SPI into idle state. The remote slave cannot detect this, therefore the master must ensure that the remote slave is returned to idle state.

17.4.2 Slave Mode

The SPI operates in slave mode when the MSTR bit in SPI control register 1 is clear.

- Serial clock
In slave mode, SCK is the SPI clock input from the master.
- MISO, MOSI pin
In slave mode, the function of the serial data output pin (MISO) and serial data input pin (MOSI) is determined by the SPC0 bit and BIDIROE bit in SPI control register 2.
- \overline{SS} pin
The \overline{SS} pin is the slave select input. Before a data transmission occurs, the \overline{SS} pin of the slave SPI must be low. \overline{SS} must remain low until the transmission is complete. If \overline{SS} goes high, the SPI is forced into idle state.

The \overline{SS} input also controls the serial data output pin, if \overline{SS} is high (not selected), the serial data output pin is high impedance, and, if \overline{SS} is low, the first bit in the SPI data register is driven out of the serial data output pin. Also, if the slave is not selected (\overline{SS} is high), then the SCK input is ignored and no internal shifting of the SPI shift register occurs.

Although the SPI is capable of duplex operation, some SPI peripherals are capable of only receiving SPI data in a slave mode. For these simpler devices, there is no serial data out pin.

NOTE

When peripherals with duplex capability are used, take care not to simultaneously enable two receivers whose serial outputs drive the same system slave's serial data output line.

As long as no more than one slave device drives the system slave's serial data output line, it is possible for several slaves to receive the same transmission from a master, although the master would not receive return information from all of the receiving slaves.

If the CPHA bit in SPI control register 1 is clear, odd numbered edges on the SCK input cause the data at the serial data input pin to be latched. Even numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

If the CPHA bit is set, even numbered edges on the SCK input cause the data at the serial data input pin to be latched. Odd numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

When CPHA is $\overline{\text{set}}$, the first edge is used to get the first data bit onto the serial data output pin. When CPHA is clear and the $\overline{\text{SS}}$ input is low (slave selected), the first bit of the SPI data is driven out of the serial data output pin. After the n^{th} ¹ shift, the transfer is considered complete and the received data is transferred into the SPI data register. To indicate transfer is complete, the SPIF flag in the SPI status register is set.

NOTE

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0, or BIDIROE with SPC0 set in slave mode will corrupt a transmission in progress and must be avoided.

17.4.3 Transmission Formats

During an SPI transmission, data is transmitted (shifted out serially) and received (shifted in serially) simultaneously. The serial clock (SCK) synchronizes shifting and sampling of the information on the two serial data lines. A slave select line allows selection of an individual slave SPI device; slave devices that are not selected do not interfere with SPI bus activities. Optionally, on a master SPI device, the slave select line can be used to indicate multiple-master bus contention.

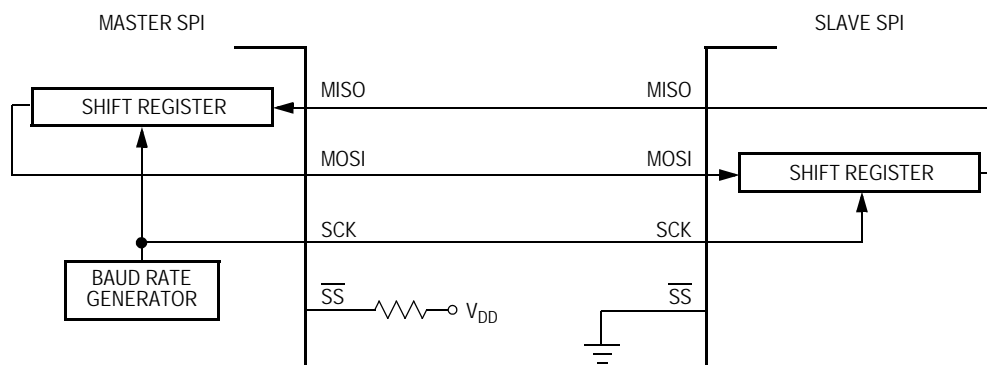

Figure 17-11. Master/Slave Transfer Block Diagram

17.4.3.1 Clock Phase and Polarity Controls

Using two bits in the SPI control register 1, software selects one of four combinations of serial clock phase and polarity.

1. n depends on the selected transfer width, please refer to [Section 17.3.2.2, "SPI Control Register 2 \(SPICR2\)"](#)

The CPOL clock polarity control bit specifies an active high or low clock and has no significant effect on the transmission format.

The CPHA clock phase control bit selects one of two fundamentally different transmission formats.

Clock phase and polarity should be identical for the master SPI device and the communicating slave device. In some cases, the phase and polarity are changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

17.4.3.2 CPHA = 0 Transfer Format

The first edge on the SCK line is used to clock the first data bit of the slave into the master and the first data bit of the master into the slave. In some peripherals, the first bit of the slave's data is available at the slave's data out pin as soon as the slave is selected. In this format, the first SCK edge is issued a half cycle after \overline{SS} has become low.

A half SCK cycle later, the second edge appears on the SCK line. When this second edge occurs, the value previously latched from the serial data input pin is shifted into the LSB or MSB of the shift register, depending on LSBFE bit.

After this second edge, the next bit of the SPI master data is transmitted out of the serial data output pin of the master to the serial input pin on the slave. This process continues for a total of 16 edges on the SCK line, with data being latched on odd numbered edges and shifted on even numbered edges.

Data reception is double buffered. Data is shifted serially into the SPI shift register during the transfer and is transferred to the parallel SPI data register after the last bit is shifted in.

After $2n^1$ (last) SCK edges:

- Data that was previously in the master SPI data register should now be in the slave data register and the data that was in the slave data register should be in the master.
- The SPIF flag in the SPI status register is set, indicating that the transfer is complete.

Figure 17-12 is a timing diagram of an SPI transfer where CPHA = 0. SCK waveforms are shown for CPOL = 0 and CPOL = 1. The diagram may be interpreted as a master or slave timing diagram because the SCK, MISO, and MOSI pins are connected directly between the master and the slave. The MISO signal is the output from the slave and the MOSI signal is the output from the master. The \overline{SS} pin of the master must be either high or reconfigured as a general-purpose output not affecting the SPI.

1. n depends on the selected transfer width, please refer to [Section 17.3.2.2, "SPI Control Register 2 \(SPICR2\)"](#)

Figure 17-12. SPI Clock Format 0 (CPHA = 0), with 8-bit Transfer Width selected (XFRW = 0)

Figure 17-13. SPI Clock Format 0 (CPHA = 0), with 16-Bit Transfer Width selected (XFRW = 1)

In slave mode, if the \overline{SS} line is not deasserted between the successive transmissions then the content of the SPI data register is not transmitted; instead the last received data is transmitted. If the \overline{SS} line is deasserted for at least minimum idle time (half SCK cycle) between successive transmissions, then the content of the SPI data register is transmitted.

In master mode, with slave select output enabled the \overline{SS} line is always deasserted and reasserted between successive transfers for at least minimum idle time.

17.4.3.3 CPHA = 1 Transfer Format

Some peripherals require the first SCK edge before the first data bit becomes available at the data out pin, the second edge clocks data into the system. In this format, the first SCK edge is issued by setting the CPHA bit at the beginning of the n^1 -cycle transfer operation.

The first edge of SCK occurs immediately after the half SCK clock cycle synchronization delay. This first edge commands the slave to transfer its first data bit to the serial data input pin of the master.

A half SCK cycle later, the second edge appears on the SCK pin. This is the latching edge for both the master and slave.

1. n depends on the selected transfer width, please refer to [Section 17.3.2.2, "SPI Control Register 2 \(SPICR2\)](#)

When the third edge occurs, the value previously latched from the serial data input pin is shifted into the LSB or MSB of the SPI shift register, depending on LSBFE bit. After this edge, the next bit of the master data is coupled out of the serial data output pin of the master to the serial input pin on the slave.

This process continues for a total of n^1 edges on the SCK line with data being latched on even numbered edges and shifting taking place on odd numbered edges.

Data reception is double buffered, data is serially shifted into the SPI shift register during the transfer and is transferred to the parallel SPI data register after the last bit is shifted in.

After $2n^1$ SCK edges:

- Data that was previously in the SPI data register of the master is now in the data register of the slave, and data that was in the data register of the slave is in the master.
- The SPIF flag bit in SPISR is set indicating that the transfer is complete.

Figure 17-14 shows two clocking variations for $CPHA = 1$. The diagram may be interpreted as a master or slave timing diagram because the SCK, MISO, and MOSI pins are connected directly between the master and the slave. The MISO signal is the output from the slave, and the MOSI signal is the output from the master. The \overline{SS} line is the slave select input to the slave. The \overline{SS} pin of the master must be either high or reconfigured as a general-purpose output not affecting the SPI.

Figure 17-14. SPI Clock Format 1 (CPHA = 1), with 8-Bit Transfer Width selected (XFRW = 0)

MSB first (LSBFE = 0)	MSB	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	LSB	Minimum 1/2 SCK for t_T , t_I , t_L
LSB first (LSBFE = 1)	LSB	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7	Bit 8	Bit 9	Bit 10	Bit 11	Bit 12	Bit 13	Bit 14	MSB	

t_L = Minimum leading time before the first SCK edge, not required for back-to-back transfers
 t_T = Minimum trailing time after the last SCK edge
 t_I = Minimum idling time between transfers (minimum \overline{SS} high time), not required for back-to-back transfers

Figure 17-15. SPI Clock Format 1 (CPHA = 1), with 16-Bit Transfer Width selected (XFRW = 1)

The \overline{SS} line can remain active low between successive transfers (can be tied low at all times). This format is sometimes preferred in systems having a single fixed master and a single slave that drive the MISO data line.

- Back-to-back transfers in master mode

In master mode, if a transmission has completed and new data is available in the SPI data register, this data is sent out immediately without a trailing and minimum idle time.

The SPI interrupt request flag (SPIF) is common to both the master and slave modes. SPIF gets set one half SCK cycle after the last SCK edge.

17.4.4 SPI Baud Rate Generation

Baud rate generation consists of a series of divider stages. Six bits in the SPI baud rate register (SPPR2, SPPR1, SPPR0, SPR2, SPR1, and SPR0) determine the divisor to the SPI module clock which results in the SPI baud rate.

The SPI clock rate is determined by the product of the value in the baud rate preselection bits (SPPR2–SPPR0) and the value in the baud rate selection bits (SPR2–SPR0). The module clock divisor equation is shown in [Equation 17-3](#).

$$\text{BaudRateDivisor} = (\text{SPPR} + 1) \cdot 2^{(\text{SPR} + 1)} \quad \text{Eqn. 17-3}$$

When all bits are clear (the default condition), the SPI module clock is divided by 2. When the selection bits (SPR2–SPR0) are 001 and the preselection bits (SPPR2–SPPR0) are 000, the module clock divisor becomes 4. When the selection bits are 010, the module clock divisor becomes 8, etc.

When the preselection bits are 001, the divisor determined by the selection bits is multiplied by 2. When the preselection bits are 010, the divisor is multiplied by 3, etc. See [Table 17-7](#) for baud rate calculations for all bit conditions, based on a 25 MHz bus clock. The two sets of selects allows the clock to be divided by a non-power of two to achieve other baud rates such as divide by 6, divide by 10, etc.

The baud rate generator is activated only when the SPI is in master mode and a serial transfer is taking place. In the other cases, the divider is disabled to decrease I_{DD} current.

NOTE

For maximum allowed baud rates, please refer to the SPI Electrical Specification in the Electricals chapter of this data sheet.

17.4.5 Special Features

17.4.5.1 \overline{SS} Output

The \overline{SS} output feature automatically drives the \overline{SS} pin low during transmission to select external devices and drives it high during idle to deselect external devices. When \overline{SS} output is selected, the \overline{SS} output pin is connected to the \overline{SS} input pin of the external device.

The \overline{SS} output is available only in master mode during normal SPI operation by asserting SSOE and MODFEN bit as shown in [Table 17-3](#).

The mode fault feature is disabled while \overline{SS} output is enabled.

NOTE

Care must be taken when using the \overline{SS} output feature in a multimaster system because the mode fault feature is not available for detecting system errors between masters.

17.4.5.2 Bidirectional Mode (MOMI or SISO)

The bidirectional mode is selected when the SPC0 bit is set in SPI control register 2 (see [Table 17-11](#)). In this mode, the SPI uses only one serial data pin for the interface with external device(s). The MSTR bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the master mode, and the MISO pin becomes serial data I/O (SISO) pin for the slave mode. The MISO pin in master mode and MOSI pin in slave mode are not used by the SPI.

Table 17-11. Normal Mode and Bidirectional Mode

When SPE = 1	Master Mode MSTR = 1	Slave Mode MSTR = 0
Normal Mode SPC0 = 0		
Bidirectional Mode SPC0 = 1		

The direction of each serial I/O pin depends on the BIDIROE bit. If the pin is configured as an output, serial data from the shift register is driven out on the pin. The same pin is also the serial input to the shift register.

- The SCK is output for the master mode and input for the slave mode.
- The \overline{SS} is the input or output for the master mode, and it is always the input for the slave mode.
- The bidirectional mode does not affect SCK and \overline{SS} functions.

NOTE

In bidirectional master mode, with mode fault enabled, both data pins MISO and MOSI can be occupied by the SPI, though MOSI is normally used for transmissions in bidirectional mode and MISO is not used by the SPI. If a mode fault occurs, the SPI is automatically switched to slave mode. In this case MISO becomes occupied by the SPI and MOSI is not used. This must be considered, if the MISO pin is used for another purpose.

17.4.6 Error Conditions

The SPI has one error condition:

- Mode fault error

17.4.6.1 Mode Fault Error

If the \overline{SS} input becomes low while the SPI is configured as a master, it indicates a system error where more than one master may be trying to drive the MOSI and SCK lines simultaneously. This condition is not permitted in normal operation, the MODF bit in the SPI status register is set automatically, provided the MODFEN bit is set.

In the special case where the SPI is in master mode and MODFEN bit is cleared, the \overline{SS} pin is not used by the SPI. In this special case, the mode fault error function is inhibited and MODF remains cleared. In case

the SPI system is configured as a slave, the \overline{SS} pin is a dedicated input pin. Mode fault error doesn't occur in slave mode.

If a mode fault error occurs, the SPI is switched to slave mode, with the exception that the slave output buffer is disabled. So SCK, MISO, and MOSI pins are forced to be high impedance inputs to avoid any possibility of conflict with another output driver. A transmission in progress is aborted and the SPI is forced into idle state.

If the mode fault error occurs in the bidirectional mode for a SPI system configured in master mode, output enable of the MOMI (MOSI in bidirectional mode) is cleared if it was set. No mode fault error occurs in the bidirectional mode for SPI system configured in slave mode.

The mode fault flag is cleared automatically by a read of the SPI status register (with MODF set) followed by a write to SPI control register 1. If the mode fault flag is cleared, the SPI becomes a normal master or slave again.

NOTE

If a mode fault error occurs and a received data byte is pending in the receive shift register, this data byte will be lost.

17.4.7 Low Power Mode Options

17.4.7.1 SPI in Run Mode

In run mode with the SPI system enable (SPE) bit in the SPI control register clear, the SPI system is in a low-power, disabled state. SPI registers remain accessible, but clocks to the core of this module are disabled.

17.4.7.2 SPI in Wait Mode

SPI operation in wait mode depends upon the state of the SPISWAI bit in SPI control register 2.

- If SPISWAI is clear, the SPI operates normally when the CPU is in wait mode
- If SPISWAI is set, SPI clock generation ceases and the SPI module enters a power conservation state when the CPU is in wait mode.
 - If SPISWAI is set and the SPI is configured for master, any transmission and reception in progress stops at wait mode entry. The transmission and reception resumes when the SPI exits wait mode.
 - If SPISWAI is set and the SPI is configured as a slave, any transmission and reception in progress continues if the SCK continues to be driven from the master. This keeps the slave synchronized to the master and the SCK.

If the master transmits several bytes while the slave is in wait mode, the slave will continue to send out bytes consistent with the operation mode at the start of wait mode (i.e., if the slave is currently sending its SPIDR to the master, it will continue to send the same byte. Else if the slave is currently sending the last received byte from the master, it will continue to send each previous master byte).

NOTE

Care must be taken when expecting data from a master while the slave is in wait or stop mode. Even though the shift register will continue to operate, the rest of the SPI is shut down (i.e., a SPIF interrupt will **not** be generated until exiting stop or wait mode). Also, the byte from the shift register will not be copied into the SPIDR register until after the slave SPI has exited wait or stop mode. In slave mode, a received byte pending in the receive shift register will be lost when entering wait or stop mode. An SPIF flag and SPIDR copy is generated only if wait mode is entered or exited during a transmission. If the slave enters wait mode in idle mode and exits wait mode in idle mode, neither a SPIF nor a SPIDR copy will occur.

17.4.7.3 SPI in Stop Mode

Stop mode is dependent on the system. The SPI enters stop mode when the module clock is disabled (held high or low). If the SPI is in master mode and exchanging data when the CPU enters stop mode, the transmission is frozen until the CPU exits stop mode. After stop, data to and from the external SPI is exchanged correctly. In slave mode, the SPI will stay synchronized with the master.

The stop mode is not dependent on the SPISWAI bit.

17.4.7.4 Reset

The reset values of registers and signals are described in [Section 17.3, “Memory Map and Register Definition”](#), which details the registers and their bit fields.

- If a data transmission occurs in slave mode after reset without a write to SPIDR, it will transmit garbage, or the data last received from the master before the reset.
- Reading from the SPIDR after reset will always read zeros.

17.4.7.5 Interrupts

The SPI only originates interrupt requests when SPI is enabled (SPE bit in SPICR1 set). The following is a description of how the SPI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt priority are chip dependent.

The interrupt flags MODF, SPIF, and SPTEF are logically ORed to generate an interrupt request.

17.4.7.5.1 MODF

MODF occurs when the master detects an error on the \overline{SS} pin. The master SPI must be configured for the MODF feature (see [Table 17-3](#)). After MODF is set, the current transfer is aborted and the following bit is changed:

- MSTR = 0, The master bit in SPICR1 resets.

The MODF interrupt is reflected in the status register MODF flag. Clearing the flag will also clear the interrupt. This interrupt will stay active while the MODF flag is set. MODF has an automatic clearing process which is described in [Section 17.3.2.4, “SPI Status Register \(SPISR\)”](#).

17.4.7.5.2 SPIF

SPIF occurs when new data has been received and copied to the SPI data register. After SPIF is set, it does not clear until it is serviced. SPIF has an automatic clearing process, which is described in [Section 17.3.2.4, “SPI Status Register \(SPISR\)”](#).

17.4.7.5.3 SPTEF

SPTEF occurs when the SPI data register is ready to accept new data. After SPTEF is set, it does not clear until it is serviced. SPTEF has an automatic clearing process, which is described in [Section 17.3.2.4, “SPI Status Register \(SPISR\)”](#).

Chapter 18

Gate Drive Unit (GDU)

Table 18-1. Revision History Table

Version Number	Revision Date	Description of Changes
V6 Initial Draft	25-January-2015	Initial Draft based on GDUV4/V5 with following changes for SR Motor support: <ul style="list-style-type: none"> • additional drain connections LD[2:0] for SR motor drive • GDUCTR1 register with control bits for SR motor drive • Removed EPRES control bit functionality for V5 and V6 • Changed GSUF startup flag functionality for V6
V6	28-January-2016	<ul style="list-style-type: none"> • Removed EPRES Functionality • Common specification for GSUF with reference to device overview • Common specification for GDUCTR1 with reference to device overview
V6.1	4-February-2016	<ul style="list-style-type: none"> • Corrected Table 1-2 TDEL availability and low-side driver on or off out of reset dependent on NVM option for GDU V4
V6.2	17-May-2016	<ul style="list-style-type: none"> • Removed desaturation comparator level and desaturation comparator filter time constant (relocated in electrical spec.)
V6.2	17-May-2016	<ul style="list-style-type: none"> • Removed desaturation comparator level and desaturation

18.1 Differences GDUV4 vs GDUV5 vs GDUV6

1. Refer to device overview for mask set / GDU version info.

The GDU module is a Field Effect Transistor (FET) pre-driver designed for three phase motor control applications.

18.1.1 Features

The GDU module includes these distinctive features:

- 11V voltage regulator for FET pre-drivers
- Boost converter option for low supply voltage condition
- 3-phase bridge FET pre-drivers
- Bootstrap circuit for high-side FET pre-drivers with external bootstrap capacitor
- Charge pump for static high-side driver operation
- Phase voltage measurement with internal ADC
- Two low-side current measurement amplifiers for DC phase current measurement
- Phase comparators for BEMF zero crossing detection in sensorless BLDC applications
- Voltage measurement on HD pin (DC-Link voltage) with internal ADC
- Desaturation comparator for high-side drivers and low-side drivers protection
- Undervoltage detection on FET pre-driver supply pin VLS
- Two overcurrent comparators with programmable voltage threshold
- Overvoltage detection on 3-phase bridge supply HD pin

18.1.2 Modes of Operation

The GDU module behaves as follows in the system power modes:

1. Run mode

All features are available.

2. Wait mode

All features are available.

3. Stop mode

The GDU is disabled in stop mode. The high-side drivers, low-side drivers, charge pump, voltage regulator, boost circuit, and current sense amplifier are switched off. The GDU will weakly pull the gates of the MOSFET to their source potential. On entering stop mode the GDUE register bits are cleared. GFDE=0, GCPE=0, GBOE=0, GCSE1=0 and GCSE0=0.

NOTE

The device does not support putting the MOSFET in specific state during stop mode as GDU charge pump clock is not running. This means device can not be put in stop mode if FETs needs to be in specific state to protect the system from external energy supply (e.g. externally driven motor-generator).

18.1.3 Block Diagram

Figure shows a block diagram of the GDU module.

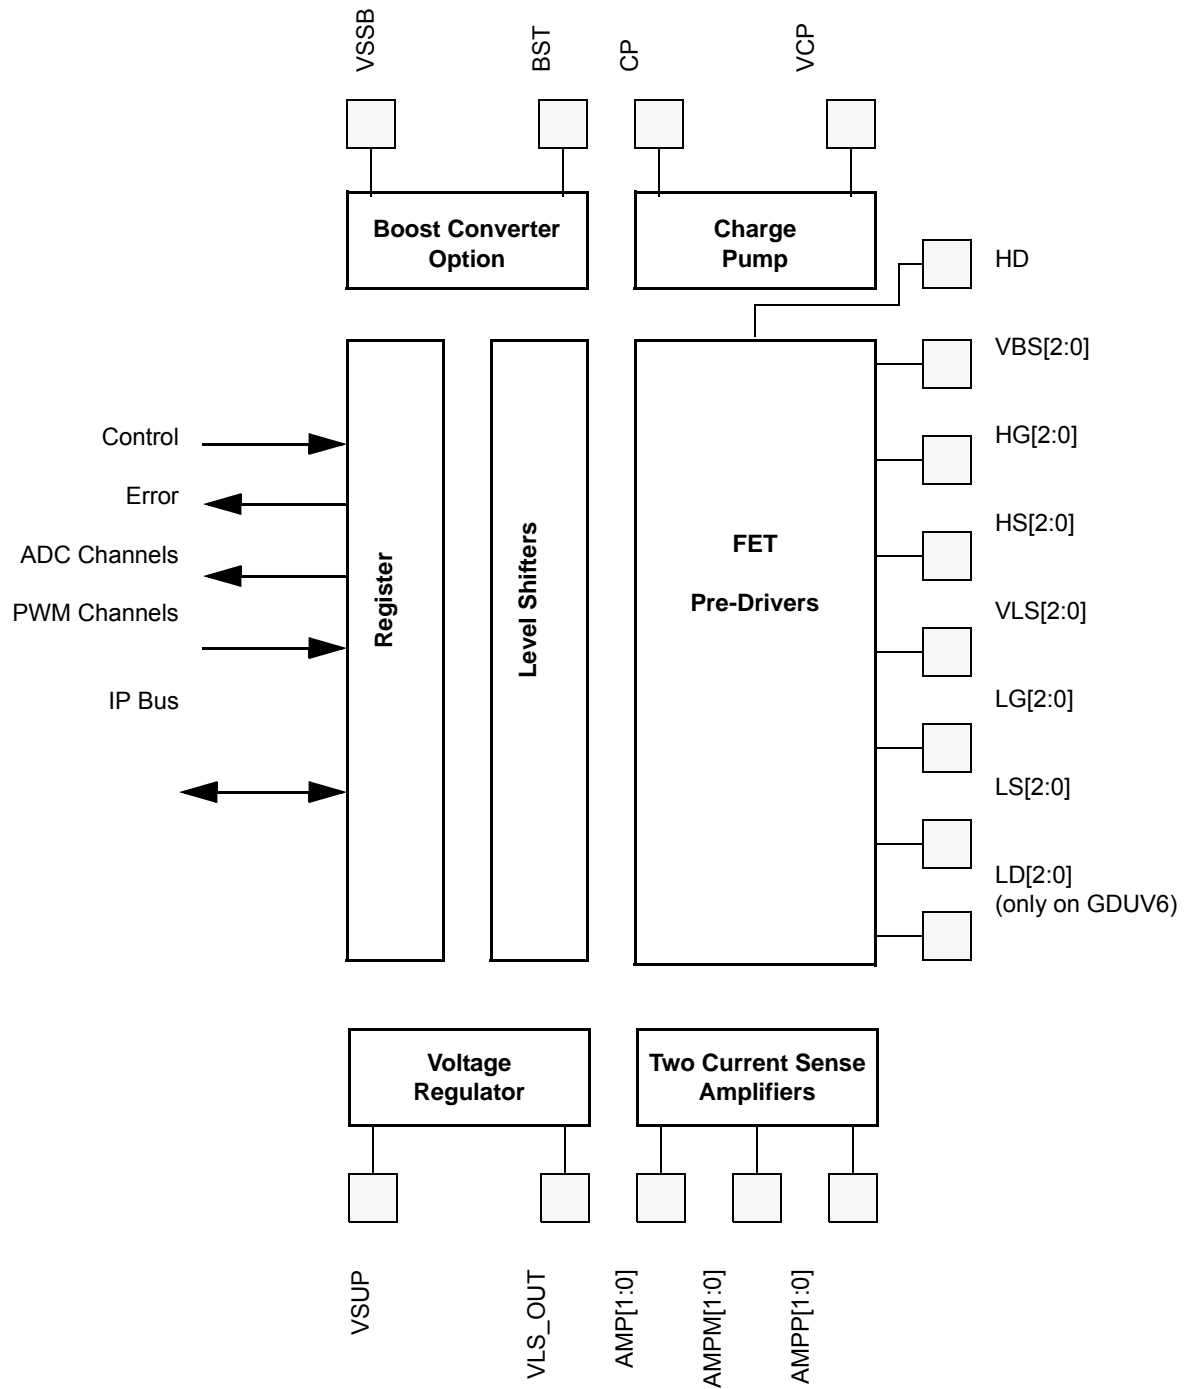

Figure 18-1. GDU Block Diagram

18.2 External Signal Description

18.2.1 HD — High-Side Drain Connection

This pin is the power supply for the 3-phase bridge (DC-link voltage).

NOTE

The HD pin should be connected as near as possible to the drain connections of the high-side MOSFETs.

18.2.2 VBS[2:0] — Bootstrap Capacitor Connection Pins

The pins are the bootstrap capacitor connections for phases HS[2:0]. The capacitor is connected between HS[2:0] and this pin. The bootstrap capacitor provides the gate voltage and current to drive the gate of the external power FET.

18.2.3 HG[2:0] — High-Side Gate Pins

The pins are the gate drives for the high-side power FETs. The drivers provide a high current with low impedance to turn on and off the high-side power FETs.

18.2.4 HS[2:0] — High-Side Source Pins

The pins are the source connection for the high-side power FETs and the drain connection for the low-side power FETs. The low voltage end of the bootstrap capacitor is also connected to this pin.

18.2.5 VLS[2:0] — Voltage Supply for Low-Side Pre-Drivers

The pins are the voltage supply pins for the three low-side FET pre-drivers. These pins should be connected to the voltage regulator output pin VLS_OUT. The output voltage on VLS_OUT pin is typically $V_{VLS}=11V$.

NOTE

It is recommended to add a 110nF-220nF X7R ceramic capacitor close to each VLS pin.

18.2.6 LG[2:0] — Low-Side Gate Pins

The pins are the gate drives for the low-side power FETs. The drivers provide a high current with low impedance to turn on and off the the low-side power FETs.

18.2.7 LD[2:0] — Low-Side Gate Pins (only on GDUV6)

These pins are the drain connections for the low-side power FETs.

18.2.7.1 LS[2:0] — Low-Side Source Pins

The pins are the low-side source connections for the low-side power FETs. The pins are the power ground pins used to return the gate currents from the low-side power FETs.

18.2.7.2 AMPP[1:0] — Current Sense Amplifier Non-Inverting Input Pins

These pins are the non-inverting inputs to the current sense amplifiers.

18.2.7.3 AMPM[1:0] — Current Sense Amplifier Inverting Input Pins

These pins are the inverting inputs to the current sense amplifiers.

18.2.7.4 AMP[1:0] — Current Sense Amplifier Output Pins

These pins are the outputs of the current sense amplifiers. At the MCU level these pins are shared with ADC channels. For ADC channel assignment, see MCU pinout section.

18.2.7.5 CP — Charge Pump Output Pin

This pin is the switching node of the charge pump circuit. The supply voltage for charge pump driver is the output of the voltage regulator V_{VLS} . The output voltage of this pin switches typically between 0V and 11V.

18.2.7.6 VCP — Charge Pump Input for High-Side Driver Supply

This pin is the charge pump input for the high-side FET pre-driver supply $VBS[2:0]$.

18.2.7.7 BST — Boost Converter Pin

This pin provides the basic switching elements required to implement a boost converter for low battery voltage conditions. This requires external diodes, capacitors and a coil.

18.2.7.8 VSSB — Boost Ground Pin

This pin is a separate power ground pin for the on chip boost converter switching device.

18.2.7.9 VSUP — Battery Voltage Supply Input Pin

This pin should be connected to the battery voltage. It is the input voltage to the integrated voltage regulator. The output of the voltage regulator is pin VLS_OUT .

18.2.7.10 VLS_OUT — Voltage Regulator Output Pin

This pin is the output of the integrated voltage regulator. The output voltage is typically $V_{VLS}=11V$. The input voltage to the voltage regulator is the VSUP pin.

NOTE

A 4.7uF or 10uF capacitor should be connected to this pin for stability of the the voltage regulator output.

18.3 Memory Map and Register Definition

This section provides the detailed information of all registers for the GDU module.

18.3.1 Register Summary

Figure 18-2 shows the summary of all implemented registers inside the GDU module.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 GDUE	R W	GWP	0	0	GCSE1	GBOE	GCSE0	GCPE	GFDE

Figure 18-2. GDU Register Summary

1. Not available on GDUV4
2. On GDUV4 only GOCT0[3:0] available
3. On GDUV4 only GOCT1[3:0] available
4. GDUCTR1 register availability is defined at device level.

18.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order. Unused bits read back zero.

18.3.2.1 GDU Module Enable Register (GDUE)

Figure 18-3. GDU Module Enable Register (GDUE)

1. Read: Anytime

Write: Anytime, write protected bits only if GWP=0. On entry in stop mode bits GCSE0, GCSE1, GBOE, GCPE & GFDE are cleared. After exit from stop mode write protected bits GBOE, GCPE & GFDE can be written once when GWP=1.

Table 18-3. GDUE Register Field Description

Field	Description
7 GWP	<p>GDUE Write Protect— This bit enables write protection to be used for the write protectable bits. While clear, GWP allows write protectable bits to be written. When set GWP prevents any further writes to write protectable bits. Once set , GWP is cleared by reset.</p> <p>0 Write-protectable bits may be written 1 Write-protectable bits cannot be written</p>
4 GCSE1	<p>GDUE Current Sense Amplifier 1 Enable— This bit enables the current sense amplifier. See Section 18.4.8, “Current Sense Amplifier and Overcurrent Comparator</p> <p>0 Current sense amplifier 1 is disabled 1 Current sense amplifier 1 is enabled</p>
3 GBOE	<p>GDUE Boost Converter Enable — This bit enables the boost option. This bit cannot be modified after GWP bit is set. See Section 18.4.10, “Boost Converter</p> <p>0 Boost option is disabled 1 Boost option is enabled</p>
2 GCSE0	<p>GDUE Current Sense Amplifier 0 Enable— This bit enables the current sense amplifier. See Section 18.4.8, “Current Sense Amplifier and Overcurrent Comparator</p> <p>0 Current sense amplifier 0 is disabled 1 Current sense amplifier 0 is enabled</p>

Table 18-3. GDUE Register Field Description

Field	Description
1 GCPE	<p>GDUE Charge Pump Enable — This bit enables the charge pump. This bit cannot be modified after GWP bit is set. See Section 18.4.4, “Charge Pump</p> <p>0 Charge pump is disabled 1 Charge pump is enabled</p>
0 GFDE	<p>GDUE FET Pre-Driver Enable — This bit enables the low-side and high-side FET pre-drivers. It must also be set in order to use the boost converter and the current sense amplifiers. This bit cannot be modified after GWP bit is set. See Section 18.4.2, “Low-Side FET Pre-Drivers and Section 18.4.3, “High-Side FET Pre-Driver.</p> <p>0 Low-side and high-side drivers are disabled 1 Low-side and high-side drivers are enabled</p> <p style="text-align: center;">NOTE</p> <p style="text-align: center;">It is not allowed to set and clear GFDE bit periodically in order to switch on and off the FET pre-drivers. In order to switch on and off the FET pre-drivers the PMF module has to be used to mask and un-mask the PWM channels.</p>

18.3.2.2 GDU Control Register (GDUCTR)

Figure 18-4. GDU Control Register (GDUCTR)

1. Read: Anytime
Write: Only if GWP=0

Table 18-4. GDUCTR Register Field Descriptions

Field	Description
7 GHHDLVL	<p>GDU High HD Level Select — Selects the voltage threshold of the overvoltage detection on HD pin. This bit cannot be modified after GWP bit is set.</p> <p>0 Voltage thresholds of the overvoltage detection on HD pin configured for V_{HVHDLA} and $V_{HVHDL D}$</p> <p>1 Voltage thresholds of the overvoltage detection on HD pin configured for V_{HVHDHA} and V_{HVHDHD}</p>
6 GVLSLVL (Not featured on GDUV4)	<p>GDU VLS Level Select — Selects the voltage threshold of the undervoltage detection on VLS pin. This bit cannot be modified after GWP bit is set.</p> <p>0 Voltage thresholds of the undervoltage detection on VLS pin configured for V_{LVLSLA} and V_{LVLSLD}</p> <p>1 Voltage thresholds of the undervoltage detection on VLS pin configured for V_{LVLSHA} and V_{LVLSHD}</p>
5-2 GBKTIM2[3:0]	<p>GDU Blanking Time — These bits adjust the blanking time t_{BLANK} of the desaturation error comparators. The resulting blanking time t_{BLANK} can be calculated from the equation below. For GBKTIM2[3:0]=$\\$F$ no desaturation errors are captured and the drivers are unprotected and the charge pump will not connect to the high-side drivers. These bits cannot be modified after GWP bit is set.</p> $t_{BLANK} = [((GBKTIM2 + 1) \cdot 2^{GBKTIM1 + 1}) + 2] \cdot T_{BUS}$
1-0 GBKTIM1[1:0]	<p>GDU Blanking Time — These bits adjust the blanking time t_{BLANK} of the desaturation error comparators. The resulting blanking time t_{BLANK} can be calculated from the equation in the field description above. These bits cannot be modified after GWP bit is set.</p>

NOTE

The register bits GBKTIM1 and GBKTIM2 must be set to the required values before the PWM channel is activated. Once the PWM channel is activated, the value of GBKTIM1 & GBKTIM2 must not change. If a different blanking time is required, the PWM channel has to be turned off before new values to GBKTIM1 & GBKTIM2 are written.

18.3.2.3 GDU Interrupt Enable Register (GDUIE)

Figure 18-5. GDU Interrupt Enable Register (GDUIE)

1. Read: Anytime
Write: Anytime

Table 18-5. GDUIE Register Field Descriptions

Field	Description
4-3 GOCIE[1:0]	GDU Overcurrent Interrupt Enable — Enables overcurrent interrupt. 0 No interrupt will be requested if any of the flags GOCIF[1:0] in the GDUF register is set 1 Interrupt will be requested if any of the flags GOCIF[1:0] in the GDUF register is set
2 GDSEIE	GDU Desaturation Error Interrupt Enable — Enables desaturation error interrupt on low-side or high-side drivers 0 No interrupt will be requested if any of the flags in the GDUDSE register is set 1 Interrupt will be requested if any of the flags in the GDUDSE register is set
1 GHH DIE	GDU High HD Interrupt Enable — Enables the high HD interrupt. 0 No interrupt will be requested whenever GHH DIF flag is set 1 Interrupt will be requested whenever GHH DIF flag is set
0 GLVLSIE	GDU Low VLS Interrupt Enable — Enables the interrupt which indicates low VLS supply 0 No interrupt will be requested whenever GLVLSIF flag is set 1 Interrupt will be requested whenever GLVLSIF flag is set

18.3.2.4 GDU Desaturation Error Flag Register (GDUDSE)

Figure 18-6. GDU Desaturation Error Flag Register (GDUDSE)

1. Read: Anytime
Write: Anytime, write 1 to clear

Table 18-6. GDUDSE Register Field Descriptions

Field	Description
6-4 GDHSIF[2:0]	GDU High-Side Driver Desaturation Interrupt Flags — The flag is set by hardware to “1” when a desaturation error on associated high-side driver pin HS[2:0] occurs. If the GDSEIE bit is set an interrupt is requested. Writing a logic “1” to the bit field clears the flag. 0 No desaturation error on high-side driver 1 Desaturation error on high-side driver
2-0 GDLSIF[2:0]	GDU Low-Side Driver Desaturation Interrupt Flag — The flag is set to “1” when a desaturation error on associated low-side driver pin LS[2:0] occurs. If the GDSEIE bit is set an interrupt is requested. Writing a logic “1” to the bit field clears the flag. 0 No desaturation error on low-side driver 1 Desaturation error on low-side driver

18.3.2.5 GDU Status Register (GDUSTAT)

Figure 18-7. GDU Status Register (GDUSTAT)

1. Read: Anytime
Write: Never

Table 18-7. GDUSTAT Register Field Descriptions

Field	Description
7-5 GPHS[2:0]	GDU Phase Status — The status bits are set to 1 when the voltage on associated pin HS[2:0] is greater than $V_{HD}/2$. The flags are cleared when the voltage on associated pin HS[2:0] is less than $V_{HD}/2$. See Section 18.4.6, “Phase Comparators” 0 Voltage on pin HSx is $V_{HSx} < V_{HD}/2$ 1 Voltage on pin HSx is $V_{HSx} > V_{HD}/2$
4-3 GOCS[1:0]	GDU Overcurrent Status — The status bits are set to 1 when the voltage on the overcurrent comparator input is above the threshold voltage V_{OCT} . The flag is cleared when the voltage on the overcurrent comparator input is less than V_{OCT} . Section 18.4.8, “Current Sense Amplifier and Overcurrent Comparator” 0 Voltage on overcurrent comparator input is less than V_{OCT} 1 Voltage on overcurrent comparator is greater than V_{OCT}
1 GHHDS	GDU High HD Supply Status — The status bit is set to 1 when the voltage on HD pin is above the threshold voltage V_{HVHDLA} or V_{HVHDHA} depending on the value of the GHHDLVL bit. The flag is cleared when the voltage on HD pin is less than V_{HVHDLA} or V_{HVHDHA} depending on the value of the GHHDLVL bit. 0 Voltage on pin HD is less than V_{HVHDLA} or V_{HVHDHA} 1 Voltage on pin HD is greater than V_{HVHDLA} or V_{HVHDHA}
0 GLVLSS	GDU Low VLS Status — The status bit is set to 1 when the voltage on VLS_OUT pin is below the threshold voltage V_{LVLSSA} . The flag is cleared when the voltage on VLS_OUT pin is greater than V_{LVLSSD} . 0 Voltage on pin VLS_OUT is greater than V_{LVLSSD} 1 Voltage on pin VLS_OUT is less than V_{LVLSSA}

18.3.2.6 GDU Slew Rate Control Register (GDUSRC)

Figure 18-8. GDU Slew Rate Control Register (GDUSRC)

1. Read: Anytime
Write: Only if GWP=0

Table 18-8. GDU Slew Rate Control Register Field Descriptions

Field	Description
6:4 GSRCHS[2:0]	GDU Slew Rate Control Bits High-Side FET Pre-Drivers — These bits control the slew rate on the HG[2:0] pins (see FET Pre-Driver Details) .These bits cannot be modified after GWP bit is set. 000 : slowest . . 111 : fastest
3:0 GSRCLS[2:0]	GDU Slew Rate Control Bits Low-Side FET Pre-Drivers — These bits control the slew rate on the LG[2:0] pins (see FET Pre-Driver Details). These bits cannot be modified after GWP bit is set. 000 : slowest . . 111 : fastest

18.3.2.7 GDU Flag Register (GDUF)

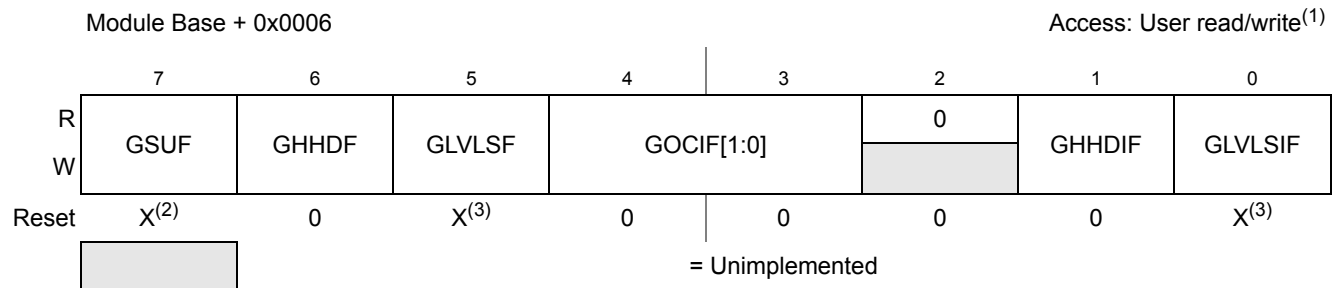

Figure 18-9. GDU Flag Register (GDUF)

1. Read: Anytime
Write: Anytime, write 1 to clear flag
2. Loaded out of reset depending on mask set implementation as specified in the device overview
3. Out of power on reset the flags may be set.

Table 18-9. GDUF Register Field Descriptions

Field	Description
7 GSUF	<p>GDU Start-up Flag — The start-up flag is cleared by reset and loaded depending on the device mask set implementation, as specified in the device overview, after reset de-asserts. Writing a logic “1” to the bit field clears the flag. If the flag is set all high-side FET pre-drivers are turned off and all low-side FET pre-drivers are turned on. If the flag is cleared and there is no error condition present all high-side and low-side FET pre-drivers are driven by the pwm channels.</p> <p>0 High-side and low-side FET pre-drivers are driven by pwm channels 1 High-side FET pre-drivers turned off and low-side FET pre-drivers are turned on</p>
6 GHHDF	<p>GDU High V_{HD} Supply Flag — The flag controls the state of the FET pre-drivers. If the flag is set and GOCA1=0 the high-side pre-drivers are turned off and the low-side pre-drivers are turned on. If GOCA1=1 all high-side and low-side FET pre-drivers are turned off. If the flag is cleared and no other error condition is present the high-side and low-side pre-drivers are driven by the PWM channels. The flag is set by hardware if a high voltage condition on HD pin occurs. The flag is set if the voltage on pin HD is greater than the threshold voltage V_{HVHDLA} or V_{HVHDHA}. Writing a logic “1” to the bit field clears the flag.</p> <p>0 Voltage on pin HD is less than V_{HVHDLA} or V_{HVHDHA} 1 Voltage on pin HD is greater than V_{HVHDLA} or V_{HVHDHA}</p>
5 GLVLSF	<p>GDU Low VLS Supply Flag — The flag controls the state of the FET pre-drivers. If the flag is set all high-side and low-side pre-drivers are turned off. If the flag is cleared and no other error condition is present the high-side and low-side pre-drivers are driven by the PWM channels. The flag is set by hardware if a low voltage condition on VLS_OUT pin occurs. Writing a logic “1” to the bit field clears the flag.</p> <p>0 VLS_OUT pin voltage is above V_{LVLSD} 1 VLS_OUT pin voltage is below V_{LVLSHA}, or V_{LVLSLA} all high-side and low-side FET pre-drivers are turned off</p>
4-3 GOCIF[1:0]	<p>GDU Overcurrent Interrupt Flag — The interrupt flags are set by hardware if an overcurrent condition occurs. The flags are set if the voltage on the overcurrent comparator input is greater than the threshold voltage V_{OCT}. If the GOCIE bit is set an interrupt is requested. Writing a logic “1” to the bit field clears the flag. If the GOCAX bit is cleared all high-side FET pre-drivers are turned off and fault[4] is asserted. If GOCAX is set all high-side and low-side FET pre-drivers are turned off and fault[2:0] are asserted.</p> <p>0 Voltage on overcurrent comparator input is less than V_{OCT} 1 Voltage on overcurrent comparator is greater than V_{OCT}</p>

Table 18-9. GDUF Register Field Descriptions

Field	Description
1 GHHDF	GDU High V_{HD} Supply Interrupt Flag— The interrupt flag is set by hardware if GHHDF is set or if GHHDS is cleared. If the GHHDF bit is set an interrupt is requested. Writing a logic “1” to the bit field clears the flag.
0 GLVLSIF	GDU Low VLS Supply Interrupt Flag— The interrupt flag is set by hardware if GLVLSF is set or GLVLSS is cleared. If the GLVLSIE bit is set an interrupt is requested. Writing a logic “1” to the bit field clears the flag.

NOTE

The purpose of the GSUF flag is to allow dissipation of the energy in the motor coils through the low side FETs in case of short reset pulses whilst the motor is spinning.

18.3.2.8 GDU Clock Control Register 1 (GDUCLK1)

Figure 18-10. GDU Clock Control Register 1 (GDUCLK1)

1. Read: Anytime
Write: Anytime if GWP=0

Table 18-10. GDUCLK1 Register Field Descriptions

Field	Description
6-2 GBOCD[4:0]	GDU Boost Option Clock Divider — These bits select the clock divider factor which is used to divide down the bus clock frequency f_{BUS} for the boost converter clock f_{BOOST} . These bits cannot be modified after GWP bit is set. See Table 18-11 for divider factors. See also Section 18.4.10, “Boost Converter
1-0 GBODC[1:0]	GDU Boost Option Clock Duty Cycle— These bits select the duty cycle of the boost option clock f_{boost} . For GBOCD[4]= 0 the duty cycle of the boost option clock is always 50%. These bits cannot be modified after GWP bit is set. 00 Duty Cycle = 50% 01 Duty Cycle = 25% 10 Duty Cycle = 50% 11 Duty Cycle = 75%

NOTE

The GBODC & GBOCD register bits must be set to the required value before GBOE bit is set. If a different boost clock frequency and duty cycle is required GBOE has to be cleared before new values to GBODC & GBOCD are written.

Table 18-11. Boost Option Clock Divider Factors $k = f_{\text{BUS}} / f_{\text{BOOST}}$

GBOCD[4:0]	f_{BOOST}
00000	$f_{\text{BUS}} / 4$
00001	$f_{\text{BUS}} / 4$
00010	$f_{\text{BUS}} / 4$
00011	$f_{\text{BUS}} / 4$
00100	$f_{\text{BUS}} / 4$
00101	$f_{\text{BUS}} / 4$
00110	$f_{\text{BUS}} / 6$
00111	$f_{\text{BUS}} / 6$
01000	$f_{\text{BUS}} / 8$
01001	$f_{\text{BUS}} / 8$
01010	$f_{\text{BUS}} / 10$
01011	$f_{\text{BUS}} / 10$
01100	$f_{\text{BUS}} / 12$
01101	$f_{\text{BUS}} / 12$
01110	$f_{\text{BUS}} / 14$
01111	$f_{\text{BUS}} / 14$
10000	$f_{\text{BUS}} / 16$
10001	$f_{\text{BUS}} / 24$
10010	$f_{\text{BUS}} / 32$
10011	$f_{\text{BUS}} / 48$
10100	$f_{\text{BUS}} / 64$
10101	$f_{\text{BUS}} / 96$
10110	$f_{\text{BUS}} / 100$
10111	$f_{\text{BUS}} / 128$
11000	$f_{\text{BUS}} / 192$
11001	$f_{\text{BUS}} / 200$
11010	$f_{\text{BUS}} / 256$

Table 18-11. Boost Option Clock Divider Factors $k = f_{\text{BUS}} / f_{\text{BOOST}}$

GBOCD[4:0]	f_{BOOST}
11011	$f_{\text{BUS}} / 384$
11100	$f_{\text{BUS}} / 400$
11101	$f_{\text{BUS}} / 512$
11110	$f_{\text{BUS}} / 768$
11111	$f_{\text{BUS}} / 800$

18.3.2.9 GDU Boost Current Limit Register (GDUBCL)

Figure 18-11. GDU Boost Current Limit Register (GDUBCL)

1. Read: Anytime
Write: Anytime if GWP=0

Table 18-12. GDU Boost Current Limit Register Field Descriptions

Field	Description
GBCL[3:0]	GDU Boost Current Limit Register— These bits are used to adjust the boost coil current limit $I_{COIL0,16}$ on the BST pin. These bits cannot be modified after GWP bit is set. See GDU electrical parameters.

18.3.2.10 GDU Phase Mux Register (GDUPHMUX)

Figure 18-12. GDU Phase Mux Register (GDUPHMUX)

1. Read: Anytime
Write: Anytime

Table 18-13. GDU Phase Mux Register Field Descriptions

Field	Description
[1:0] GPHMUX	<p>GDU Phase Multiplexer — These buffered bits are used to select the voltage which is routed to internal ADC channel. The value written to the GDUPHMUX register does not take effect until the LDOK bit is set and the next PWM reload cycle begins. Reading GDUPHMUX register reads the value in the buffer. It is not necessary the value which is currently used.</p> <p>00 Pin HD selected, V_{HD} / 12 connected to ADC channel 01 Pin HS0 selected, V_{HS0} / 6 connected to ADC channel 10 Pin HS1 selected, V_{HS1} / 6 connected to ADC channel 11 Pin HS2 selected, V_{HS2} / 6 connected to ADC channel</p>

18.3.2.11 GDU Current Sense Offset Register (GDUCSO)

Figure 18-13. GDU Current Sense Offset (GDUCSO)

1. Read: Anytime
Write: Anytime

Table 18-14. GDUCSO Register Field Descriptions

Field	Description (See also Section 18.4.8, “Current Sense Amplifier and Overcurrent Comparator)
6:4 GCSO1[2:0]	GDU Current Sense Amplifier 1 Offset — These bits adjust the offset of the current sense amplifier 000 No offset 001 Offset is +3mV (GDUV5 and V6). Offset is +5mV (GDUV4). 010 Offset is +6mV (GDUV5 and V6). Offset is +10mV (GDUV4) 011 Offset is +9mV (GDUV5 and V6). Offset is +15mV (GDUV4) 100 No offset 101 Offset is -9mV (GDUV5 and V6). Offset is -15mV (GDUV4) 110 Offset is -6mV (GDUV5 and V6). Offset is -10mV (GDUV4). 111 Offset is -3mV (GDUV5 and V6). Offset is -5mV (GDUV4).
2:0 GCSO0[2:0]	GDU Current Sense Amplifier 0 Offset — These bits adjust the offset of the current sense amplifier. 000 No offset 001 Offset is +3mV (GDUV5 and V6). Offset is +5mV (GDUV4). 010 Offset is +6mV (GDUV5 and V6). Offset is +10mV (GDUV4) 011 Offset is +9mV (GDUV5 and V6). Offset is +15mV (GDUV4) 100 No offset 101 Offset is -9mV (GDUV5 and V6). Offset is -15mV (GDUV4) 110 Offset is -6mV (GDUV5 and V6). Offset is -10mV (GDUV4). 111 Offset is -3mV (GDUV5 and V6). Offset is -5mV (GDUV4).

18.3.2.12 GDU Desaturation Level Register (GDUDSLVL)

Figure 18-14. GDU Desaturation Level Register (GDUDSLVL)

1. Read: Anytime
Write: Only if GWP=0

Table 18-15. GDU Desaturation Level Register Field Descriptions

Field	Description
7 GDSFHS (Not featured on GDUV4)	GDU Desaturation Filter Characteristic for High-Side Drivers — This bit adjusts the desaturation filter characteristic of the three high-side FET pre-drivers. These bits cannot be modified after GWP bit is set. See Section 18.4.5, “Desaturation Error.”
6:4 GDSLHS	GDU Desaturation Level for High-Side Drivers — These bits adjust the desaturation levels of the three high-side FET pre-drivers. These bits cannot be modified after GWP bit is set. See Section 18.4.5, “Desaturation Error” 000 $V_{desathS} = V_{HD} - 0.35V$ (typical value) 001 to 110 see device electrical specification 111 $V_{desathS} = V_{HD} - 1.40V$ (typical value)
3 GDSFLS (Not featured on GDUV4)	GDU Desaturation Filter Characteristic for Low-Side Drivers — This bit adjusts the desaturation filter characteristic of the three low-side FET pre-drivers. These bits cannot be modified after GWP bit is set. See Section 18.4.5, “Desaturation Error.”
2:0 GDSLLS	GDU Desaturation Level for Low-Side Drivers — These bits adjust the desaturation level of the three low-side FET pre-drivers. These bits cannot be modified after GWP bit is set. See Section 18.4.5, “Desaturation Error” 000 $V_{desatlS} = 0.35V$ (typical value) 001 to 110 see device electrical specification 111 $V_{desatlS} = 1.40V$ (typical value)

18.3.2.13 GDU Phase Log Register (GDUPHL)

Figure 18-15. GDU Phase Log Register (GDUPHL)

1. Read: Anytime
Write: never

Table 18-16. GDU Phase Log Register Field Descriptions

Field	Description
2:0 GPHL	GDU Phase Log Bits— If a desaturation error occurs the phase status bits GPHS[2:0] in register GDUSTAT are copied to this register. The GDUPHL register is cleared only on reset. See Section 18.4.5, “Desaturation Error

18.3.2.14 GDU Clock Control Register 2 (GDUCLK2)

Figure 18-16. GDU Clock Control Register 2 (GDUCLK2)

1. Read: Anytime
Write: Only if GWP=0

Table 18-17. GDUCLK2 Register Field Descriptions

Field	Description
3-0 GCPCD[3:0]	GDU Charge Pump Clock Divider — These bits select the clock divider factor which is used to divide down the bus clock frequency f_{BUS} for the charge pump clock f_{CP} . See Table 18-18 for divider factors. These bits cannot be modified after GWP bit is set. See also Section 18.4.4, “Charge Pump

NOTE

The GCPCD bits must be set to the required value before GCPE bit is set. If a different charge pump clock frequency is required GCPE has to be cleared before new values to GCPCD bits are written.

Table 18-18. Charge Pump Clock Divider Factors $k = f_{\text{BUS}} / f_{\text{CP}}$

GPCPD[3:0]	f_{CP}
0000	$f_{\text{BUS}} / 16$
0001	$f_{\text{BUS}} / 24$
0010	$f_{\text{BUS}} / 32$
0011	$f_{\text{BUS}} / 48$
0100	$f_{\text{BUS}} / 64$
0101	$f_{\text{BUS}} / 96$
0110	$f_{\text{BUS}} / 100$
0111	$f_{\text{BUS}} / 128$
1000	$f_{\text{BUS}} / 192$
1001	$f_{\text{BUS}} / 200$
1010	$f_{\text{BUS}} / 256$
1011	$f_{\text{BUS}} / 384$
1100	$f_{\text{BUS}} / 400$
1101	$f_{\text{BUS}} / 512$
1110	$f_{\text{BUS}} / 768$
1111	$f_{\text{BUS}} / 800$

18.3.2.15 GDU Overcurrent Register 0 (GDUOC0)

Figure 18-17. GDU Overcurrent Register 0 (GDUOC0)

1. Read: Anytime
Write: Only if GWP=0

Table 18-19. GDUOC0 Register Field Descriptions

Field	Description
7 GOCA0	GDU Overcurrent Action — This bit cannot be modified after GWP bit is set. This bit controls the action in case of an overcurrent event. See Table 18-24 and Table 18-23
6 GOCE0	GDU Overcurrent Comparator Enable — This bit cannot be modified after GWP bit is set. 0 Overcurrent Comparator is disabled 1 Overcurrent Comparator is enabled
GDUV4 (includes GOCT0 bits 3:0)	
3:0 GOCT0[3:0]	GDU Overcurrent Comparator Threshold — These bits cannot be modified after GWP bit is set. The overcurrent comparator threshold voltage is the output of a 6-bit digital-to-analog converter. The upper two bits of the digital inputs are tied to one. The other bits of the digital inputs are driven by GOCT0. The overcurrent comparator threshold voltage can be calculated from equation below. $V_{oct0} = (48 + GOCT0) \cdot \frac{V_{DDA}}{64}$
GDUV5 and V6 (includes GOCT0 bits 4:0)	
4:0 GOCT0[4:0]	GDU Overcurrent Comparator Threshold — These bits cannot be modified after GWP bit is set. The overcurrent comparator threshold voltage is the output of a 6-bit digital-to-analog converter. The upper bit of the digital inputs is tied to one. The other bits of the digital inputs are driven by GOCT0. The overcurrent comparator threshold voltage can be calculated from equation below. $V_{oct0} = (32 + GOCT0) \cdot \frac{V_{DDA}}{64}$

18.3.2.16 GDU Overcurrent Register 1 (GDUOC1)

Figure 18-18. GDU Overcurrent Register 1 (GDUOC1)

1. Read: Anytime
Write: Only if GWP=0

Table 18-20. GDUOC1 Register Field Descriptions

Field	Description
7 GOCA1	GDU Overcurrent Action — This bit cannot be modified after GWP bit is set. This bit controls the action in case of an overcurrent event or overvoltage event. See Table 18-24 and Table 18-23
6 GOCE1	GDU Overcurrent Enable — This bit cannot be modified after GWP bit is set. 0 Overcurrent Comparator 1 is disabled 1 Overcurrent Comparator 1 is enabled
GDUV4 (includes GOCT1 bits 3:0)	
3:0 GOCT1[3:0]	GDU Overcurrent Comparator Threshold — These bits cannot be modified after GWP bit is set. The overcurrent comparator threshold voltage is the output of a 6-bit digital-to-analog converter. The upper two bits of the digital inputs are tied to one. The other bits of the digital inputs are driven by GOCT1. The overcurrent comparator threshold voltage can be calculated from equation below. $V_{oct1} = (48 + GOCT1) \cdot \frac{V_{DDA}}{64}$
GDUV5 and V6 (includes GOCT1 bits 4:0)	
4:0 GOCT1[4:0]	GDU Overcurrent Comparator Threshold — These bits cannot be modified after GWP bit is set. The overcurrent comparator threshold voltage is the output of a 6-bit digital-to-analog converter. The upper bit of the digital inputs is tied to one. The other bits of the digital inputs are driven by GOCT1. The overcurrent comparator threshold voltage can be calculated from equation below. $V_{oct1} = (32 + GOCT1) \cdot \frac{V_{DDA}}{64}$

18.3.2.17 GDU Control Register 1 (GDUCTR1)

Figure 18-19. GDU Control Register 1 (GDUCTR1)

1. Read: Anytime
Write: Only if GWP=0

Table 18-21. GDUCTR1 Register Field Descriptions

Field	Description
7 GSRMOD1	GDU Switched Reluctance Motor Mode 1 — This bit cannot be modified after GWP bit is set. This bit controls the routing of the LDx pins to the low-side desaturation comparators for switched reluctance motor. See Figure 18-23 0 HSx routed to low-side desaturation comparator 1 LDx routed to low-side desaturation comparator
6 GSRMOD0	GDU Switched Reluctance Motor Mode 0 — This bit cannot be modified after GWP bit is set. 0 BLDC mode. Don't allow HGx and LGx high at the same time. 1 SR mode. Allow HGx and LGx high at the same time.
0 TDEL	t_{delon} / t_{deloff} Control — This bit controls the parameters t _{delon} and t _{deloff} . It cannot be modified after GWP bit is set. This bit must be set to meet the min and max values for t _{delon} and t _{deloff} specified in the electrical specification. If this bit is cleared the values for t _{delon} and t _{deloff} are out of spec.

NOTE

GDU Control Register 1 GDUCTR1 availability is defined at device level.

18.4 Functional Description

18.4.1 General

The PMF module provides the values to be driven onto the outputs of the low-side and high-side FET pre-drivers. If the FET pre-drivers are enabled, the PMF channels drive their corresponding high-side or low-side FET pre-drivers according [Table 18-22](#).

Table 18-22. PMF Channel Assignment

PMF Channel	PMF Channel Assignment
0	High-Side Gate and Source Pins HG[0], HS[0]
1	Low-Side Gate and Source Pins LG[0], LS[0]
2	High-Side Gate and Source Pins HG[1], HS[1]
3	Low-Side Gate and Source Pins LG[1], LS[1]
4	High-Side Gate and Source Pins HG[2], HS[2]
5	Low-Side Gate and Source Pins LG[2], LS[2]

18.4.2 Low-Side FET Pre-Drivers

The three low-side FET pre-drivers turn on and off the external low-side power FETs. The energy required to charge the gate capacitance of the power FET C_G is drawn from the output of the voltage regulator VLS. See [Figure 18-20](#). The register bits GSRCLS[2:0] in the GDUSRC Register (see [Figure 18-8](#)) control the slew rate of the low-side FET pre-drivers in order to control fast voltage changes dv/dt (see also [Section 18.5.1, “FET Pre-Driver Details](#)).

18.4.3 High-Side FET Pre-Driver

The three high-side FET pre-drivers turn on and off the external high-side power FETs. The required charge for the gate capacitance of the external power FET is delivered by the bootstrap capacitor. After the supply voltage is applied to the microcontroller or after exit from stop mode, the low-side FET pre-drivers should be activated for a short time in order to charge the bootstrap capacitor C_{BS} . Care must be taken after a long period of inactivity of the low-side FET pre-drivers to verify that the bootstrap capacitor C_{BS} is not discharged.

The register bits GSRCHS[2:0] in the GDUSRC Register (see [Figure 18-8](#)) control the slew rate of the high-side FET pre-driver in order to control fast voltage changes dv/dt (see also [Section 18.5.1, “FET Pre-Driver Details](#)).

NOTE

The minimum PWM pulse on & off time must be t_{minpulse} .

NOTE

If the GFDE bit is cleared the high-side gate and source pins and the low-side gate and source pins are shorted with an internal resistor. The voltage differences are $V_{HGx} - V_{HSx} \sim 0V$ and $V_{LGx} - V_{LSx} \sim 0V$ so that the external FETs are turned off.

NOTE

The PWM channel outputs for high-side and low-side drivers are delayed by two core clock cycles.

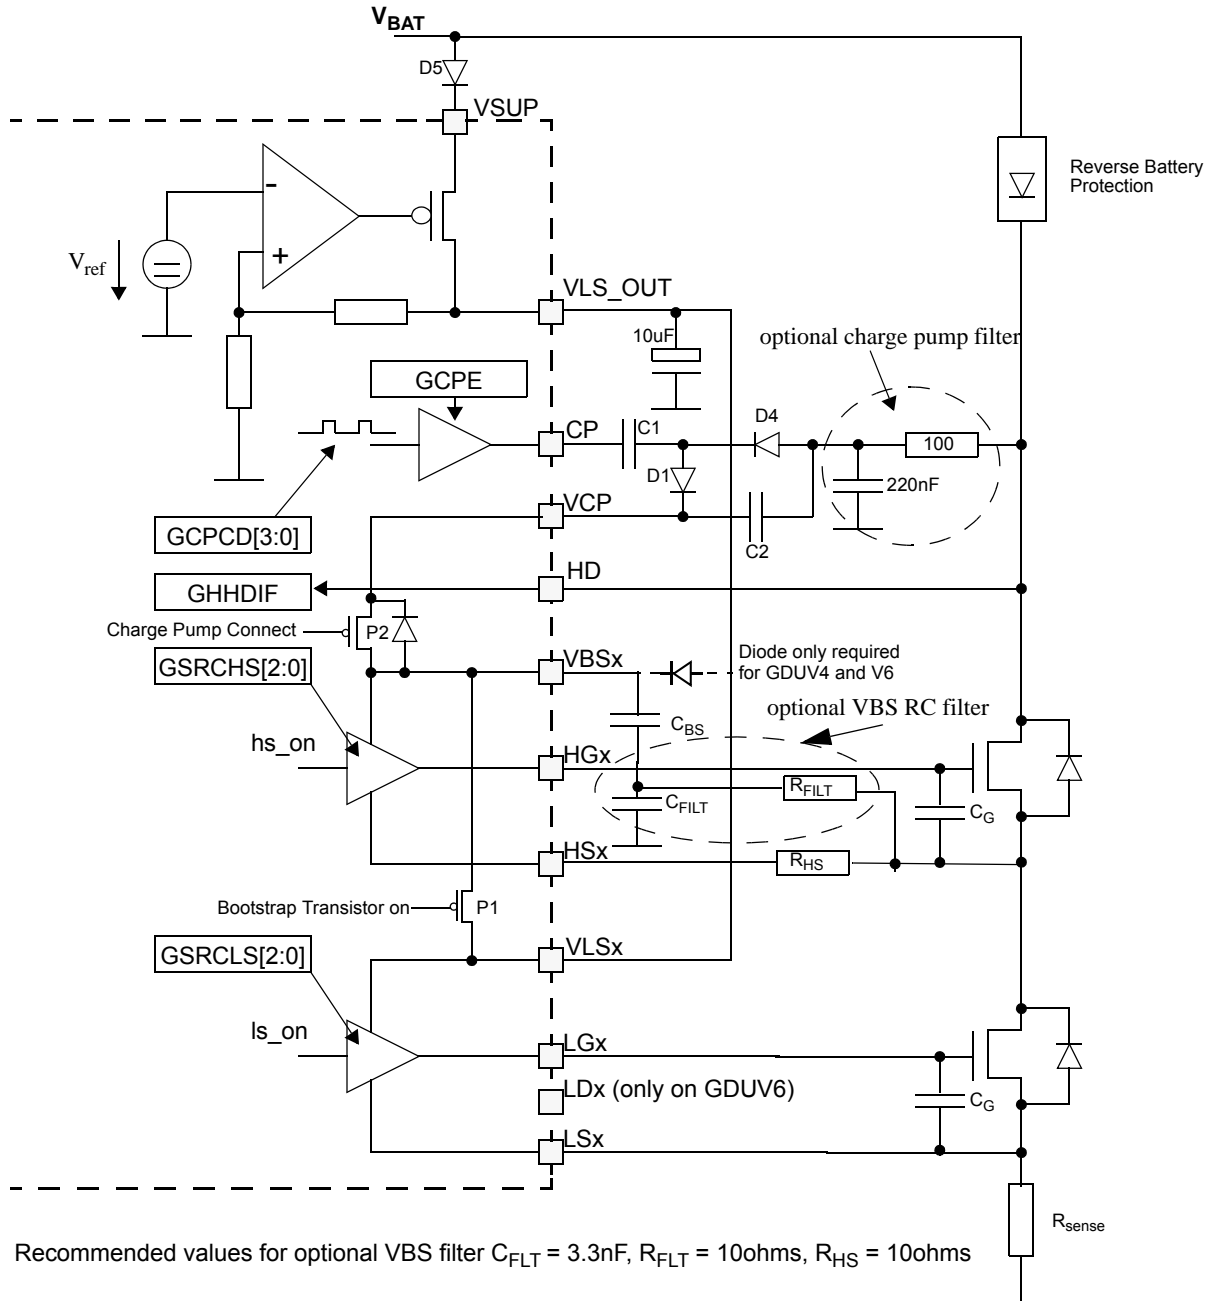

Figure 18-20. FET Pre-Driver Circuit and Voltage Regulator

NOTE

Optional charge pump input RC filter can be used to avoid over pumping effect when voltage spikes are present on the high-side drains.

NOTE

Optional RC filter to VBS pin should be used to avoid overshoot above maximum voltage on VBS pin. The RC filter needs to be carefully designed in order not to influence the charging time of the bootstrap capacitor C_{BS} .

NOTE

GDUV4 and V6 does not include Bootstrap Transistor P1. It is only available on GDUV5. An external bootstrap diode is required for GDUV4 and V6.

On GDUV5 the bootstrap transistor P1 is turned on when the corresponding low-side driver is turned on and no high voltage condition on HD pin and no desaturation error is flagged.

18.4.4 Charge Pump

The GDU module integrates the necessary hardware to build a charge pump with external components. The charge pump is used to maintain the high-side driver gate source voltage V_{GS} when PWM is running at 100% duty cycle. The external components needed are capacitors and diodes. The supply voltage of the charge pump driver on pin CP is V_{VLS} . The output voltage on pin CP typically switches between 0 and 11V. The charge pump clock frequency depends on the setting of GCPCD bits.

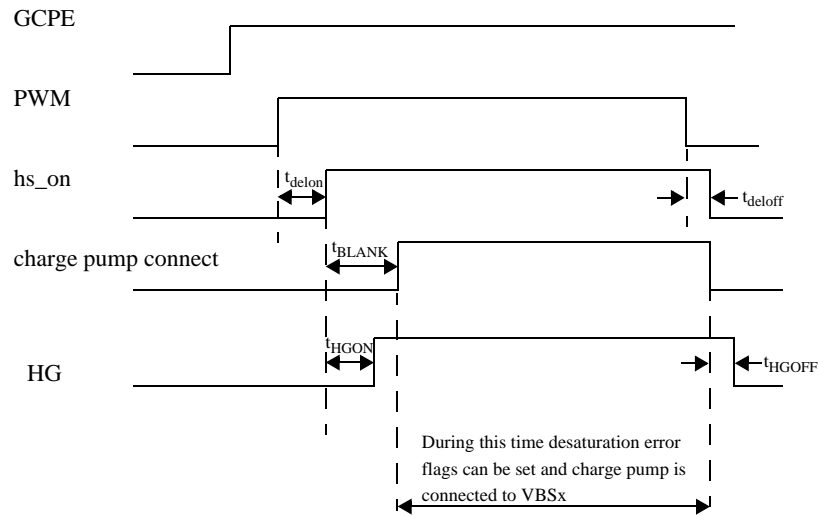

The transistor P2 shown in [Figure 18-20](#) connects VCP pin to VBSx pin. [Figure 18-21](#) shows the timing diagram when transistor P2 connects VCP to VBSx.

Figure 18-21. Timing Diagram Charge Pump Connect

t_{delon} / t_{deloff} : GDU propagation delay

t_{HGON} / t_{HGOFF} : HS driver turn on/off time

t_{BLANK} : Blanking Time (see GDUCTR register)

18.4.5 Desaturation Error

A desaturation error is generated if the output signal at HSx does not properly reflect the drive condition of the low-side and high-side FET pre-drivers. The GDU integrates three desaturation comparators for the low-side FET pre-drivers and three desaturation comparators for the high-side FET pre-drivers.

If the low-side power FET T2 (see Figure 18-23) is turned on and the drain source voltage V_{DS2} of T2 is greater than $V_{desatls}$ after the blanking time t_{BLANK} a desaturation error will be flagged. In this case the associated desaturation error flag GDLSIF[2:0] will be set (see Figure 18-6) and the low-side power FET T2 will be turned off. The level of the voltage $V_{desatls}$ can be adjusted in the range of 0.35V to 1.40V (see Figure 18-14).

If the high-side power FET T1 (see Figure 18-23) is turned on and the drain source voltage V_{DS1} is greater than V_{desath} after the blanking time t_{BLANK} a desaturation error will be flagged. In this case the associated desaturation error flag GDHSIF[2:0] will be set (see Figure 18-6) and the high-side power FET T1 will be turned off. The level of the voltage V_{desath} can be adjusted in the range of 0.35 to 1.40V (see Figure 18-14).

NOTE

The filter on the output of desaturation comparators described below is only available on GDUV5 and V6.

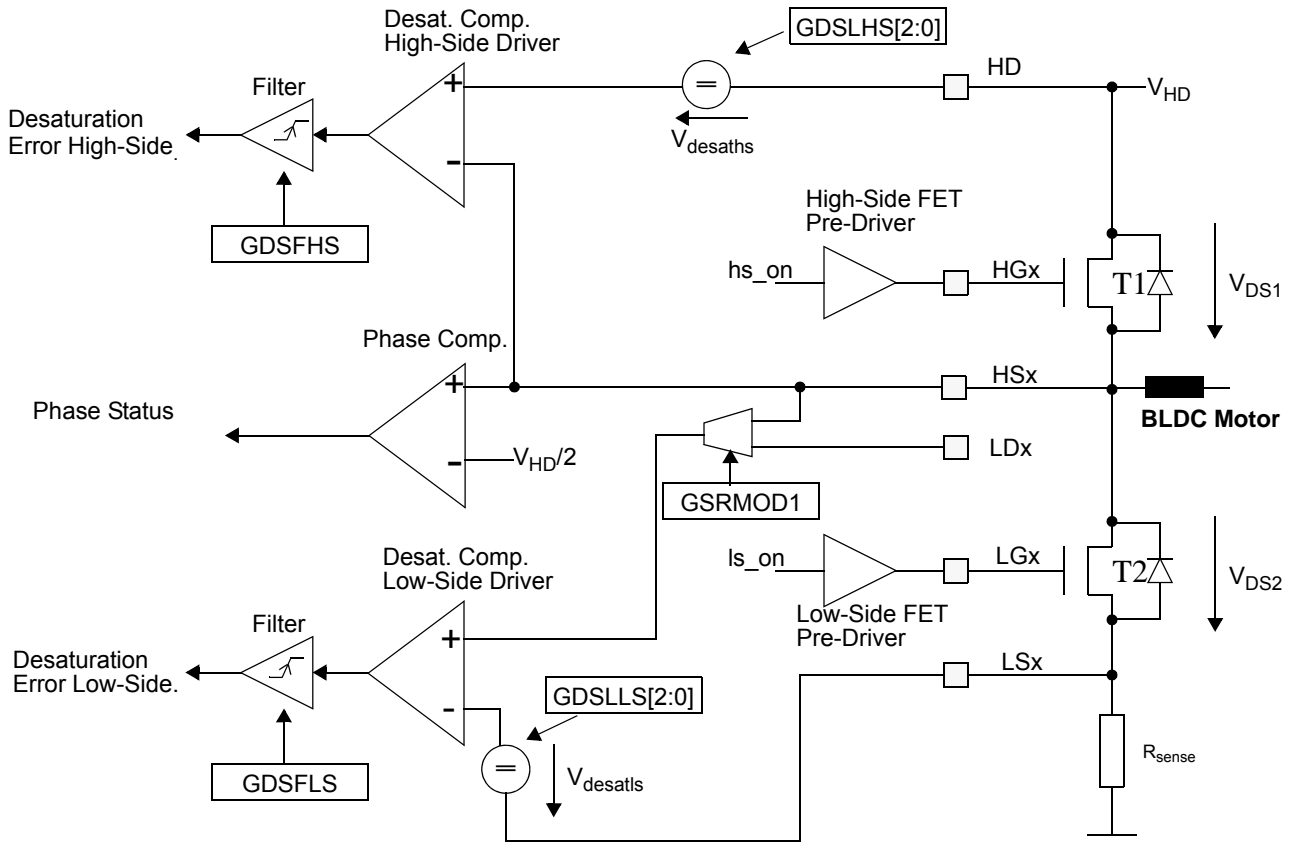

The desaturation comparator outputs of the low-side and high-side drivers are filtered. The filter characteristic is controlled by the GDSFHS and GDSFLS bits as shown in Figure 18-22. A slow filter time constant can be selected by setting the corresponding GDSFHS or GDSFLS bit. If the bit is clear, then a fast time constant is selected. The time constant values, derived from simulation, are included in the device electrical specification, for both fast and slow filter time constants.

Figure 18-22. Filter Characteristic of Desaturation Comparator Output

The low-side and high-side desaturation interrupt flags GDHSIF and GDLSIF are cleared by writing a one to the associated flag. After the flag is cleared the associated low-side or high-side FET pre-driver is enabled again and is driven by the source selected in the PMF module.

Figure 18-23. Desaturation Comparators and Phase Comparators in BLDC Mode (LDx not connected)¹

1. LDx pins and the routing option of HSx or LDx to the desaturation comparator of the low-side driver controlled by GSRMOD1 is only available on GDUV6.

Figure 18-24. Desaturation Comparators and Phase Comparators in SR mode (LDx connected)¹

18.4.6 Phase Comparators

The GDU module includes three phase comparators. The phase comparators compare the voltage on the HS[2:0] pins with one half voltage on HD pin. If V_{HSx} is greater than $0.5 V_{HD}$ the associated phase status bit GPHS[2:0] is set. (see Figure 18-7) If the V_{HSx} is less than $0.5 V_{HD}$ the associated phase status bit GPHS[2:0] is cleared. If a desaturation error is detected the state of the phase status bit GPHS[2:0] are copied to the GDUPHL register. The phase flags get unlocked when the associated desaturation interrupt flag is cleared.

1. LDx pins and the routing option of HSx or LDx to the desaturation comparator of the low-side driver controlled by GSRMOD1 is only available on GDUV6.

18.4.7 Fault Protection Features

The GDU includes a number of fault protection features against overvoltage, overcurrent, undervoltage and power bridge faults like phase shorted to ground or supply. These fault protection features allow selection of the appropriate low side and high side driver state in case of a fault condition, shown in [Table 18-24](#). In addition five fault outputs are provided to signal detected faults to other modules of the MCU. For connectivity of the fault outputs see the device specific information. [Table 18-23](#) shows the logic equations for the five fault outputs.

Table 18-23. Fault Outputs Logic Equations⁽¹⁾

Fault Output	Logic Equation
Fault[0]	$(GDLSIF[0] GDHSIF[0]) (GOCIF[0] \& GOCA0) (GOCIF[1] \& GOCA1)$

NOTE

Since all MOSFET transistors are turned off, VBSX can reach phase voltage plus bootstrap voltage which may exceed allowable levels during high supply voltage conditions. If such operating condition exist the application must make sure that VBSX levels are clamped below maximum ratings for example by using clamping diodes.

Figure 18-25. Short to Supply Detection

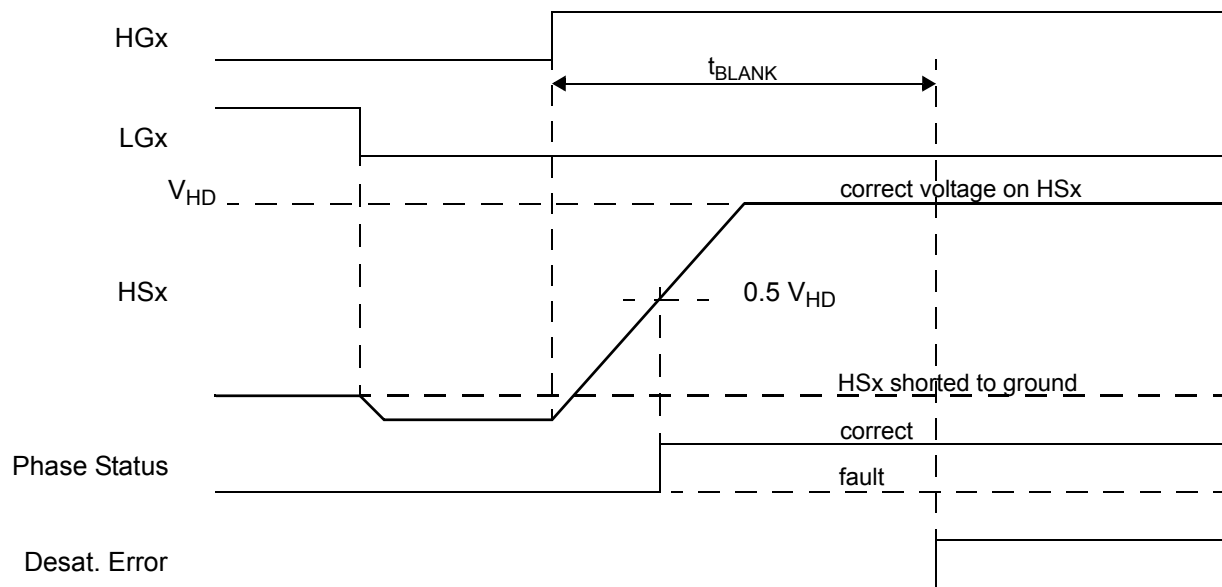

Figure 18-26. Short to Ground Detection

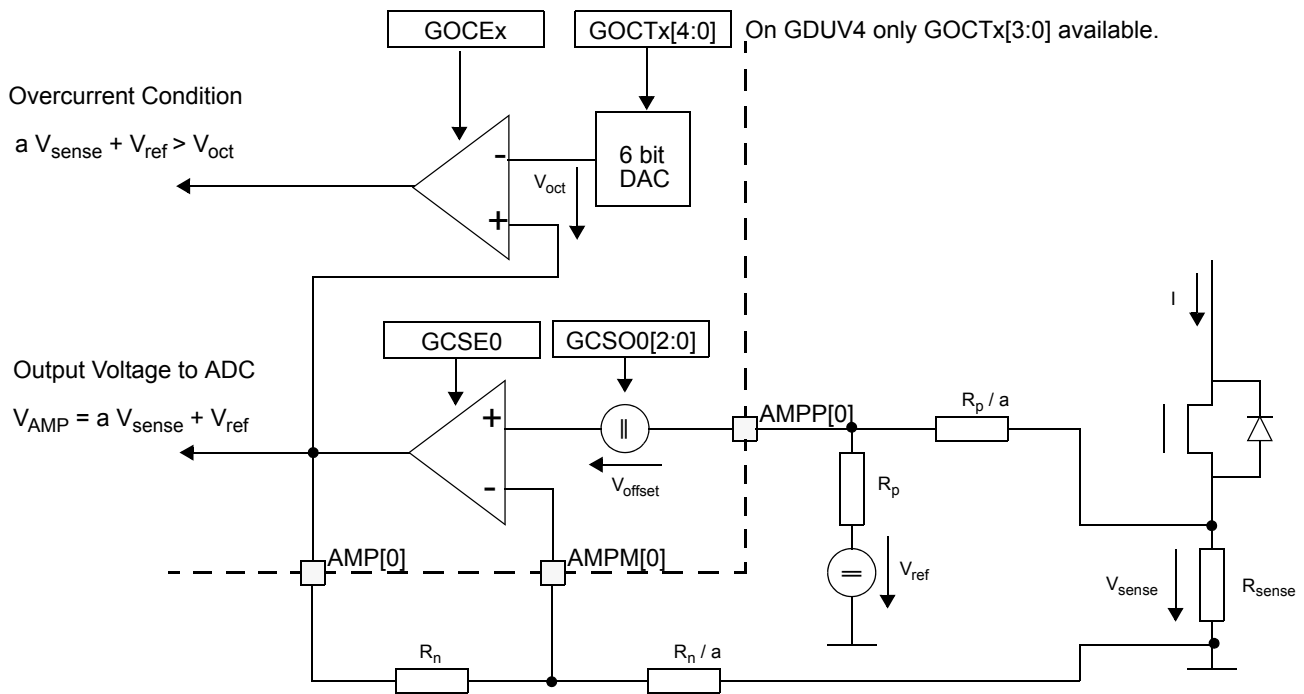

18.4.8 Current Sense Amplifier and Overcurrent Comparator

The current sense amplifier is usually connected as a differential amplifier (see [Figure 18-27](#)). It senses the current flowing through the external power FET as a voltage across the current sense resistor R_{sense} . In order to measure both positive and negative currents, an external reference has to be used. The output of the current sense amplifier can be connected to an ADC channel. For more details on ADC channel assignment, refer to Device Overview Internal Signal Mapping Section. The input offset voltage of the current sense amplifier can be adjusted with the GCSO[2:0] bits in the GDUCSO register. (see [Figure 18-13](#)) The output of the current sense amplifier is connected to the plus input of the overcurrent comparator. The minus input is driven by the output voltage of a 6 Bit DA converter. The digital input of the DA converter is {11,GOCTx[3:0]}. In order to use the overcurrent comparator GOCEx and GCSxE have to be set.

NOTE

If both overcurrent comparators are used both action bits GOCA0 and GOCA1 must have the same value. For example GOCA0=0 and GOCA1=1 is not allowed. Only GOCA0=GOCA1=1 or GOCA0=GOCA1=0 is allowed.

Figure 18-27. Current Sense Amplifier Connected as Differential Amplifier

18.4.9 GDU DC Link Voltage Monitor

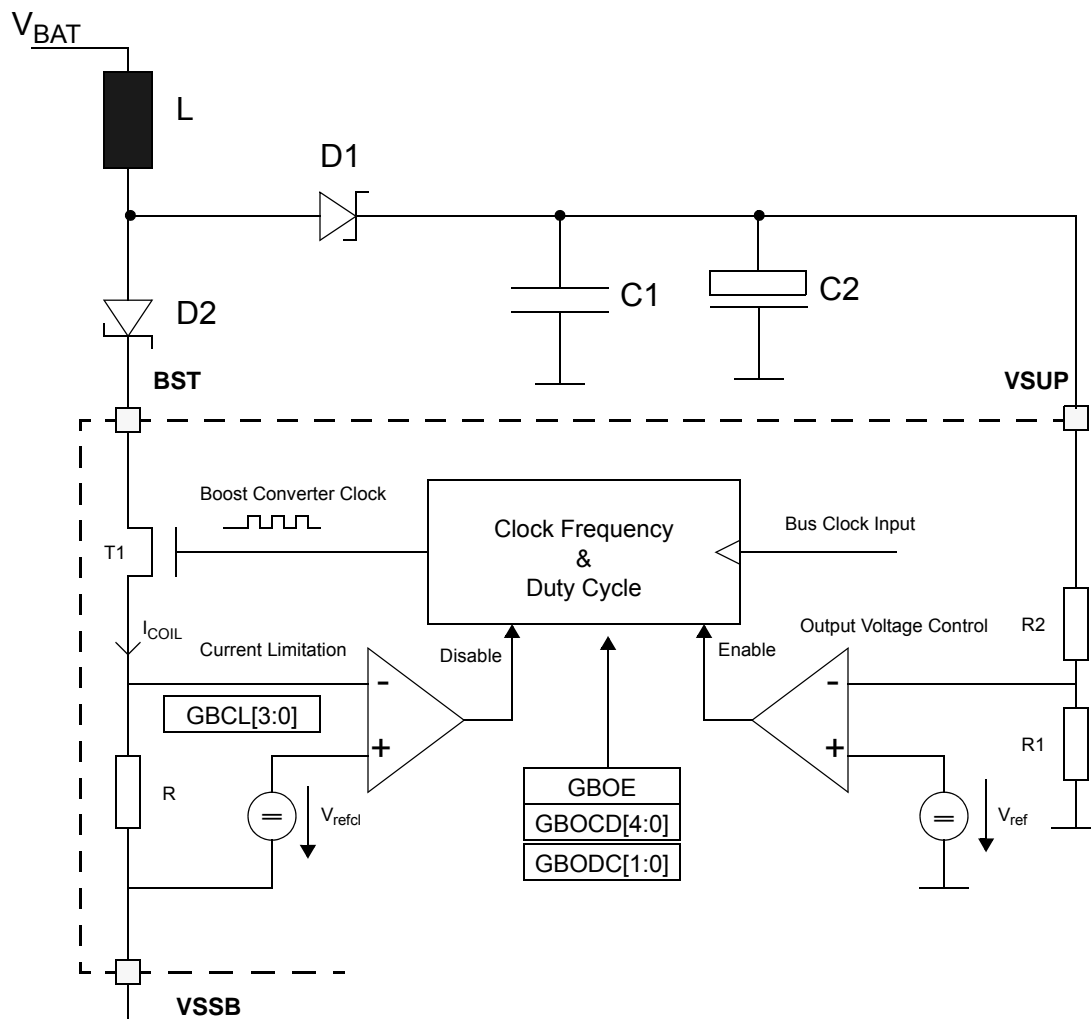

In addition to the feature described in [Section 18.3.2.10](#), “GDU Phase Mux Register (GDUPHMUX) the voltage on pin HD divide by 5 is routed to an ADC channel. See device specific information for ADC channel number. This feature is only available if GFDE is set.

18.4.10 Boost Converter

The GDU module integrates the necessary hardware to build a boost converter with external components in case of low voltage condition. The external components needed are two Schottky diodes, one coil, and capacitors. See Figure 18-28. The boost converter clock which is driving the transistor T1 (see Figure 18-28) is derived from the bus clock. This clock can be divided down as described in Table 18-10. The boost converter also includes a circuit to limit the current through coil. This current limit can be adjusted with the bits GBCL[3:0] in the GDUBCL register. See GDU electrical parameters.

The output voltage of the boost converter on VSUP pin is divided down and compared with a reference voltage V_{ref} . As long as the divided voltage V_{VSUP} is below V_{ref} the boost converter clock is enabled assuming that GBOE (GDU Boost Option Enable) is set.

Figure 18-28. Boost Converter Option with external Components¹

1. Diode D2 shown is optional if coil is connected behind reverse battery protection.

18.4.11 Interrupts

This section describes the interrupts generated in the GDU module. The interrupts are only available in CPU run mode. Entering and exiting stop mode has no effect on the interrupt flags. The GDU module has two interrupt vectors which are listed in [Table 18-25](#). The low-side and high-side desaturation error flags are combined into one interrupt line and the over and under voltage detection are combined into another interrupt line. (see device specific section interrupt vector table)

Table 18-25. GDU Module Interrupt Sources

#	GDU Module Interrupt Source	Module Internal Interrupt Source	Local Enable
0	GDU desaturation error interrupt	GDU low-side and high-side desaturation error flags GDHSF[2:0] and GDLSF[2:0]	GDSEIE = 1
1	GDU over/under voltage detection and overcurrent detection interrupt	GDU low voltage condition on pin VLS (GLVLSIF)	GLVLSIE = 1
		GDU high voltage condition on pin HD (GHHDIF)	GHHDIE = 1
		GDU Overcurrent Condition (GOCIF[1:0])	GOCIE[1:0]=11

18.5 Application Information

18.5.1 FET Pre-Driver Details

The basic concept of the high-side driver is shown in Figure 18-29. If the FET pre-driver is switched on the transistor T2 is driving the output HG. For on resistance R_{gduon} of transistor T2 refer to GDU electricals. The output current is limited to I_{OUT} which is derived from the reference current I_{REF} . The current source is controlled by the slew rate control bits GSRCHS[2:0]. If the FET pre-driver is switched off transistors T3 and T4 are switched on. For on resistance $R_{gduoffn}$ and $R_{gduoffp}$ of transistors T3 and T4 refer to GDU electricals.

The reference current I_{REF} is controlled by the slew rate control bits GSRCHS[2:0] :

- $I_{REF} = 10\mu A + GSRCHS \ 10\mu A, [10\mu A, 20\mu A \dots 80\mu A]$

Assuming an ideal op-amp the voltage across R_1 is equal voltage across R_2 and I_{OUT2} is given by:

- $V_1 = V_2 = I_{REF} R_1 = I_{OUT2} R_2$
- $I_{OUT2} = I_{REF} (R_1/R_2)$

With the ratio of the transistor sizes of T_1 and T_2 $k=450$, and the ratio of the resistors $R_1/R_2=36$, and neglect the current through R_{HSpul} the output current I_{OUT} is:

- $I_{OUT1} = k I_{OUT2}$
- $I_{OUT} = I_{OUT1} + I_{OUT2} = I_{REF} (R_1/R_2) (1+k)$
- $I_{OUT} \sim I_{REF} (R_1/R_2) k$

Figure 18-29. FET Pre-Driver Concept for High-Side Driver

NOTE

FET pre-driver concept shown in [Figure 18-29](#) for the high-side driver applies also to low-side driver. The reference current for the low-side driver is controlled by GSRCLS[2:0].

18.5.2 GDU Intrinsic Dead Time

The basic point of dead time is to prevent cross conduction of the high-side and low-side power MOSFETs.

The GDU adds an amount of dead time to the PWM signals driving the high-side and low-side power MOSFETs. A PWM signal applied to the input of the GDU does not appear instantly on the output. There is propagation delay (t_{delon} , t_{deloff}) through the FET pre-drivers and it takes time to turn on and off the gates of the power MOSFETs (t_{HGON} , t_{HGOFF}) (see [Figure 18-30](#)). The propagation delay and the turn on and off time change over temperature. There are differences between propagation delay paths to the high-side MOSFETs and low-side MOSFETs. Worst case must be considered. The turn on time t_{HGON} depends also on the setting of the slew rate control bits GSRCLS[2:0] and GSRCHS[2:0].

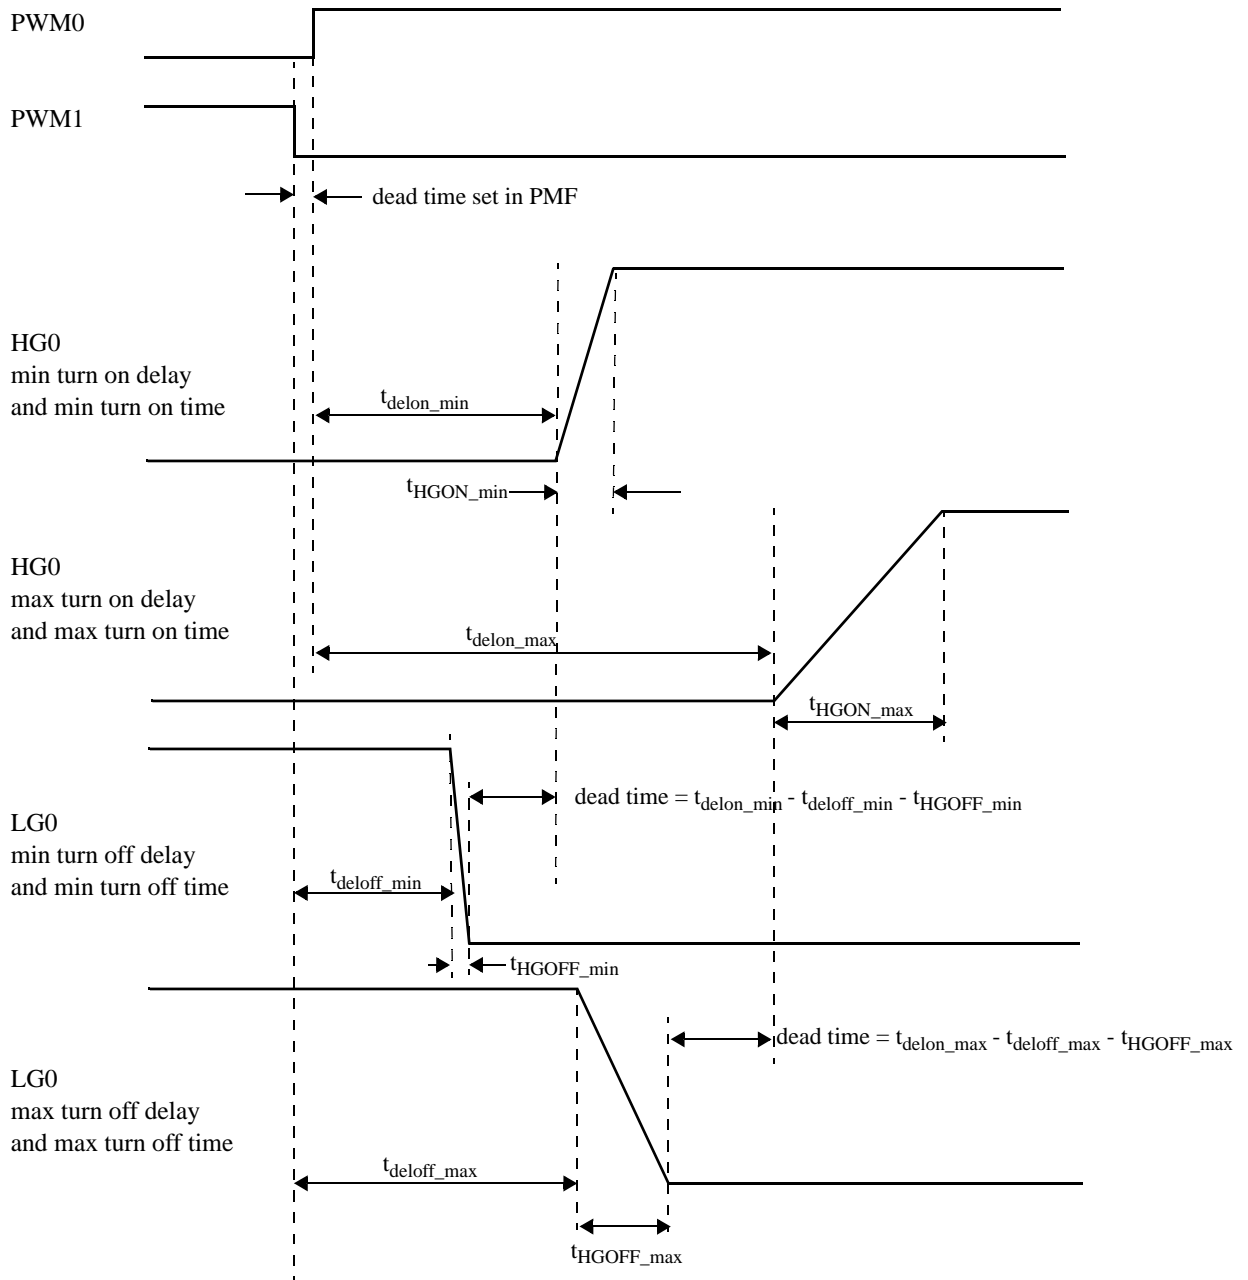

Figure 18-30. Driver on/off Delay and on/off Time¹

[Figure 18-31](#) shows examples of intrinsic dead times. For example assuming minimum values for t_{HGON} and t_{delon} for the high side gate HG0 and minimum values for t_{HGOFF} and t_{deloff} for low-side gate LG0 no additional dead time setting in the PMF module is required and the PWM channels can change at the same time without cross conduction of the power MOSFETs.

1. Note that t_{HGON} and t_{HGOFF} is the turn on and turn off time for high-side and low-side gate

Figure 18-31. Examples of Intrinsic Dead Time

18.5.3 Calculation of Bootstrap Capacitor

The size of the bootstrap capacitor C_{BS} depends on the total gate charge Q_G needed to turn on the power FET used in the application. If the bootstrap capacitor is too small there can be a large voltage drop due to charge sharing between bootstrap capacitor C_{BS} and the total gate capacitance of the power FET C_G . The resulting voltage on the gate of the power FET can be calculated as follow:

Eqn. 18-1

$$V_G = \frac{Q_{BS}}{C_{BS} + C_G} = \frac{V_{BS}}{1 + \frac{C_G}{C_{BS}}}$$

For example if $C_{BS} = 20 C_G$ then the resulting gate voltage is $V_G = 0.95 V_{BS}$.

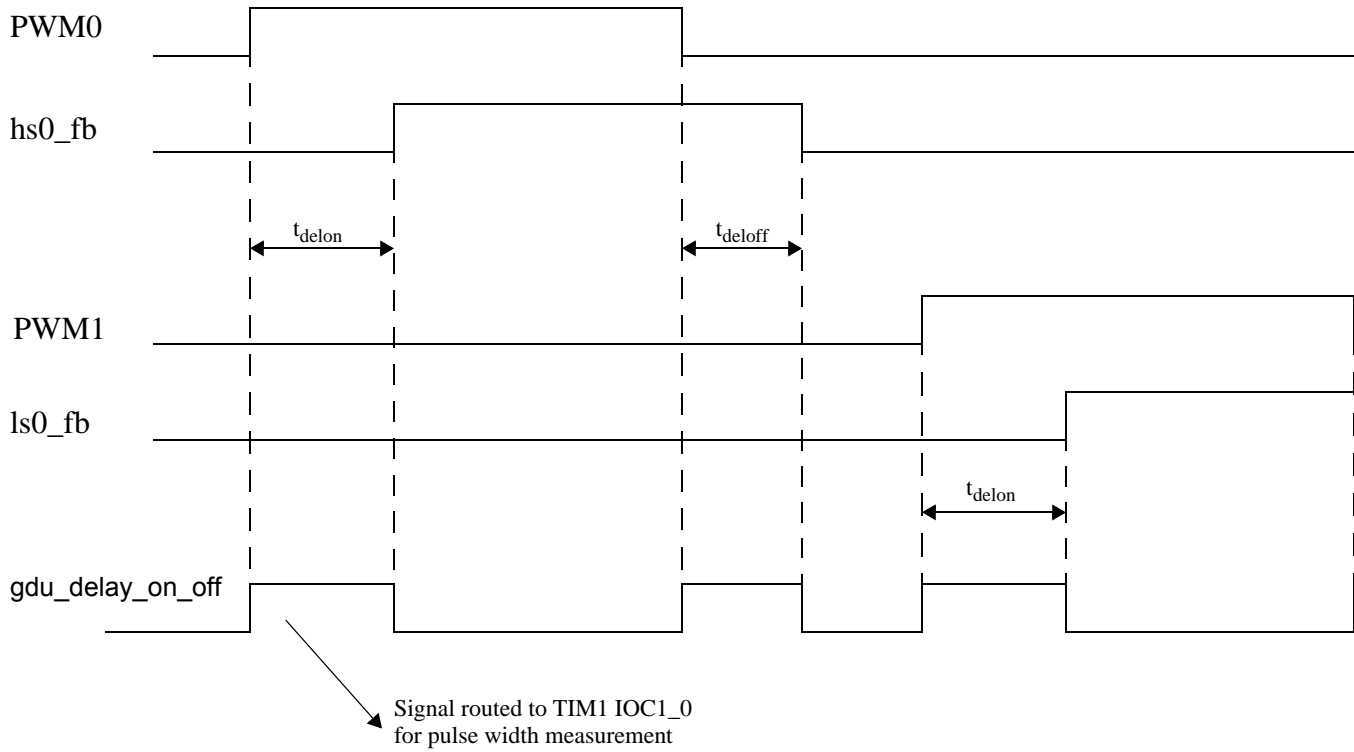

18.5.4 On Chip GDU t_{delon} and t_{deloff} Measurement

The S12ZVM256 provides the capability to measure the GDU t_{delon} and t_{deloff} delays of the high-side and low-side drivers with the on chip timer. The timing diagram [Figure 18-32](#) shows the basic concept. The high-side and low-side drivers provide the feedback signals `hs0_fb` and `ls0_fb` which indicate that the drivers are turned on or off. The feedback signals and the related pwm signals are used to generate the `gdu_del_on_off` output signal. (see [Figure 18-32](#)) This signal can be routed to TIM1 input capture channel `IOC1_0` for pulse width measurement.

Following below are the steps to do the delay measurement:

- 1. Route `gdu_del_on_off` signal to TIM1 `IOC1_0` in PIM routing register `MODRR2.T1ICORR`
- 2. Setup TIM1 `IOC1_0` for pulse width measurement
- 3. Use software control of PWM output feature `PMFOUTC` and `PMFOUTB` to assert `PWM0`
- 4. Store measured pulse width (t_{delon} of high-side driver 0) in RAM
- 5. Use software control of PWM output feature `PMFOUTC` and `PMFOUTB` to deassert `PWM0`
- 6. Store measured pulse width (t_{deloff} of high-side driver 0) in RAM
- repeat 3 to 6 for all PWM channels

Figure 18-32. Measurement of GDU t_{delon} and t_{deloff}

Chapter 19

LIN/HV Physical Layer (S12LINPHYV3)

Table 19-1. Revision History Table

Rev. No. (Item No.)	Date (Submitted By)	Sections Affected	Substantial Change(s)
V02.09	27 Jun 2013	Feature list	- Added the SAE J2602-2 LIN compliance.
V02.10	21 Aug 2013	Overcurrent and TxD-dominant timeout interrupt descriptions	- Specified the time after which the interrupt flags are set again after having been cleared while the error condition is still present.
V02.11	19 Sep 2013	All	- Removed preliminary note. - Fixed grammar and spelling throughout the document.
V02.12	20 Sep 2013	Standby Mode	- Clarified Standby mode behavior.
V02.13	8 Oct 2013	All	- More grammar, spelling, and formatting fixes throughout the document.
V03.01	08 May 2014	All	- Added HV PHY feature.

19.1 Introduction

This chapter provides information for both the LIN physical interface and the HV interface. Devices may include either a LINPHY or HVPHY module. The device overview section specifies the LINPHY/HVPHY to device mapping.

The LIN (Local Interconnect Network) bus pin provides a physical layer for single-wire communication in automotive applications. The LIN Physical Layer is designed to meet the LIN Physical Layer 2.2 specification from LIN consortium.

The HV physical interface provides a physical layer for single-wire communication. It can be used, among other examples, for PWM applications since it can be connected to an internal timer.

NOTE

All references to LIN (e.g. names of bits, registers, signals, pins, interrupts, etc.) apply to the HV physical interface as well. The same names have been kept to highlight and facilitate the hardware and software compatibility between both versions. Nevertheless, cases where particular LIN features do not apply to the HV physical interface version are specifically mentioned.

19.1.1 Features

The LIN Physical Layer module includes the following distinctive features:

- Compliant with LIN Physical Layer 2.2 specification.
- Compliant with the SAE J2602-2 LIN standard.
- Standby mode with glitch-filtered wake-up.
- Slew rate selection optimized for the baud rates: 10.4 kbit/s, 20 kbit/s and Fast Mode (up to 250 kbit/s).
- Switchable 34 k Ω /330 k Ω pullup resistors (in shutdown mode, 330 k Ω only)
- Current limitation for LIN Bus pin falling edge.
- Overcurrent protection.
- LIN TxD-dominant timeout feature monitoring the LPTxD signal.
- Automatic transmitter shutdown in case of an overcurrent or TxD-dominant timeout.
- Fulfills the OEM “Hardware Requirements for LIN (CAN and FlexRay) Interfaces in Automotive Applications” v1.3.

The HV Physical Layer module includes the following distinctive features:

- Compliant with the ISO9141 (K-line) standard.
- Standby mode with glitch-filtered wake-up.
- Slew rate selection optimized for: 5.2 kHz, 10 kHz and Fast Mode (up to 125 kHz).
- Switchable 34 k Ω /330 k Ω pullup resistors (in shutdown mode, 330 k Ω only).
- Current limitation for LIN Bus pin falling edge.
- Overcurrent protection.

The LIN/HV transmitter is a low-side MOSFET with current limitation and overcurrent transmitter shutdown. A selectable internal pullup resistor with a serial diode structure is integrated, so no external pullup components are required for the application in a slave node. To be used as a master node, an external resistor of 1 k Ω must be placed in parallel between VLINSUP and the LIN Bus pin, with a diode between VLINSUP and the resistor. The fall time from recessive to dominant and the rise time from dominant to recessive is selectable and controlled to guarantee communication quality and reduce EMC emissions. The symmetry between both slopes is guaranteed.

19.1.2 Modes of Operation

The LIN/HV Physical Layer can operate in the following four modes:

1. Shutdown Mode

The LIN/HV Physical Layer is fully disabled. No wake-up functionality is available. The internal pullup resistor is replaced by a high ohmic one (330 k Ω) to maintain the LIN Bus pin in the recessive state. All registers are accessible.

2. Normal Mode

The full functionality is available. Both receiver and transmitter are enabled.

3. Receive Only Mode

The transmitter is disabled and the receiver is running in full performance mode.

4. Standby Mode

The transmitter of the LIN/HV Physical Layer is disabled. If the wake-up feature is enabled, the internal pullup resistor can be selected (330 k Ω or 34 k Ω). The receiver enters a low power mode and optionally it can pass wake-up events to the Serial Communication Interface (SCI). If the wake-up feature is enabled and if the LIN Bus pin is driven with a dominant level longer than t_{WUFR} followed by a rising edge, the LIN/HV Physical Layer sends a wake-up pulse to the SCI, which requests a wake-up interrupt. (This feature is only available if the LIN/HV Physical Layer is routed to the SCI).

19.1.3 Block Diagram

Figure 19-1 shows the block diagram of the LIN/HV Physical Layer. The module consists of a receiver with wake-up control, a transmitter with slope and timeout control, a current sensor with overcurrent protection as well as a registers control block.

*The VLINSUP supply mapping is described in device level documentation

Figure 19-1. LIN/HV Physical Layer Block Diagram

NOTE

The external 220 pF capacitance between LIN and LGND is strongly recommended for correct operation.

19.2 External Signal Description

This section lists and describes the signals that connect off chip as well as internal supply nodes and special signals.

19.2.1 LIN — LIN Bus Pin

This pad is connected to the single-wire LIN data bus.

19.2.2 LGND — LIN Ground Pin

This pin is the device LIN ground connection. It is used to sink currents related to the LIN Bus pin. A decoupling capacitor external to the device (typically 220 pF, X7R ceramic) between LIN and LGND can further improve the quality of this ground and filter noise.

19.2.3 VLINSUP — Positive Power Supply

External power supply to the chip. The VLINSUP supply mapping is described in device level documentation.

19.2.4 LPTxD — LIN Transmit Pin

This pin can be routed to the SCI, LPDR1 register bit, an external pin, or other options. Please refer to the PIM chapter of the device specification for the available routing options.

In the HV Phy version, LPTxD can be used to send diagnostic feedback.

This input is only used in normal mode; in other modes the value of this pin is ignored.

19.2.5 LPRxD — LIN Receive Pin

This pin can be routed to the SCI, an external pin, or other options like a timer. Please refer to the PIM chapter of the device specification for the available routing options.

In the HV Phy version, LPRxD can be used to receive control information since it can be connected to an internal timer channel.

In standby mode this output is disabled, and sends only a short pulse in case the wake-up functionality is enabled and a valid wake-up pulse was received in the LIN Bus.

19.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the LIN/HV Physical Layer.

19.3.1 Module Memory Map

A summary of the registers associated with the LIN/HV Physical Layer module is shown in [Table 19-2](#). Detailed descriptions of the registers and bits are given in the subsections that follow.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 LPDR	R	0	0	0	0	0	0	LPDR1	LPDR0
	W								
0x0001 LPCR	R	0	0	0	0	LPE	RXONLY	LPWUE	LPPUE
	W								
0x0002 Reserved	R	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
	W								
0x0003 LPSLRM	R	LPDTPDIS	0	0	0	0	0	LPSLR1	LPSLR0
	W								
0x0004 Reserved	R	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
	W								
0x0005 LPSR	R	LPDT	0	0	0	0	0	0	0
	W								
0x0006 LPIE	R	LPDTIE	LPOCIE	0	0	0	0	0	0
	W								
0x0007 LPIF	R	LPDTIF	LPOCIF	0	0	0	0	0	0
	W								

Figure 19-2. Register Summary

19.3.2 Register Descriptions

This section describes all the registers of the LIN/HV Physical Layer and their individual bits.

19.3.2.1 Port LP Data Register (LPDR)

Module Base + Address 0x0000

Access: User read/write⁽¹⁾

Figure 19-3. Port LP Data Register (LPDR)

1. Read: Anytime

Write: Anytime

Table 19-2. LPDR Field Description

Field	Description
1 LPDR1	Port LP Data Bit 1 — The LPTxD input of the LIN/HV Physical Layer (see Figure 19-1) can be directly controlled by this register bit. The routing of the LPTxD input is done in the Port Inetrgation Module (PIM). Please refer to the device PIM description for more info. In the HV Phy version, this bit can be use to send diagnostic feedback.
0 LPDR0	Port LP Data Bit 0 — Read-only bit. The LIN Physical Layer LPRxD output state can be read at any time.

19.3.2.2 LIN Control Register (LPCR)

Module Base + Address 0x0001

Access: User read/write⁽¹⁾

Figure 19-4. LIN Control Register (LPCR)

1. Read: Anytime

Write: Anytime,

Table 19-3. LPCR Field Description

Field	Description
3 LPE	LIN Enable Bit — If set, this bit enables the LIN Physical Layer. 0 The LIN Physical Layer is in shutdown mode. None of the LIN Physical Layer functions are available, except that the bus line is held in its recessive state by a high ohmic (330kΩ) resistor. All registers are normally accessible. 1 The LIN Physical Layer is not in shutdown mode.
2 RXONLY	Receive Only Mode bit — This bit controls RXONLY mode. 0 The LIN Physical Layer is not in receive only mode. 1 The LIN Physical Layer is in receive only mode.
1 LPWUE	LIN Wake-Up Enable — This bit controls the wake-up feature in standby mode. 0 In standby mode the wake-up feature is disabled. 1 In standby mode the wake-up feature is enabled.
0 LPPUE	LIN Pullup Resistor Enable — Selects pullup resistor. 0 The pullup resistor is high ohmic (330 kΩ). 1 The 34 kΩ pullup is switched on (except if LPE=0 or when in standby mode with LPWUE=0).

19.3.2.3 Reserved Register

Module Base + Address 0x0002

Access: User read/write⁽¹⁾

Figure 19-5. LIN Test register

1. Read: Anytime

Write: Only in special mode

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in special mode can alter the module's functionality.

Table 19-4. Reserved Register Field Description

Field	Description
7-0 Reserved	These reserved bits are used for test purposes. Writing to these bits can alter the module functionality.

19.3.2.4 LIN Slew Rate Mode Register (LPSLRM)

Module Base + Address 0x0003

Access: User read/write⁽¹⁾

Figure 19-6. LIN Slew Rate Mode Register (LPSLRM)

1. Read: Anytime

Write: Only in shutdown mode (LPE=0)

Table 19-5. LPSLRM Field Description

Field	Description
7 LPDTPDIS	TxD-dominant timeout disable Bit — This bit disables the TxD-dominant timeout feature. Disabling this feature is only recommended for using the LIN Physical Layer for other applications than LIN protocol. It is only writable in shutdown mode (LPE=0). 0 TxD-dominant timeout feature is enabled. 1 TxD-dominant timeout feature is disabled.
1-0 LPSLR[1:0]	Slew-Rate Bits — Please see section 19.4.2 for details on how the slew rate control works. These bits are only writable in shutdown mode (LPE=0). 00 Normal Slew Rate (optimized for 20 kbit/s). 01 Slow Slew Rate (optimized for 10.4 kbit/s). 10 Fast Mode Slew Rate (up to 250 kbit/s). This mode is not compliant with the LIN Protocol (LIN electrical characteristics like duty cycles, reference levels, etc. are not fulfilled). It is only meant to be used for fast data transmission. Please refer to section 19.4.2.2 for more details on fast mode. Please note that an external pullup resistor stronger than 1 kΩ might be necessary for the range 100 kbit/s to 250 kbit/s. 11 Reserved .

19.3.2.5 Reserved Register

Module Base + Address 0x0004

Access: User read/write⁽¹⁾

Figure 19-7. Reserved Register

1. Read: Anytime

Write: Only in special mode

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in special mode can alter the module’s functionality.

Table 19-6. Reserved Register Field Description

Field	Description
7-0 Reserved	These reserved bits are used for test purposes. Writing to these bits can alter the module functionality.

19.3.2.6 LIN Status Register (LPSR)

Module Base + Address 0x0005

Access: User read/write⁽¹⁾

Figure 19-8. LIN Status Register (LPSR)

1. Read: Anytime

Write: Never, writes to this register have no effect

Table 19-7. LPSR Field Description

Field	Description
7 LPDT	LIN Transmitter TxD-dominant timeout Status Bit — This read-only bit signals that the LPTxD pin is still dominant after a TxD-dominant timeout. As long as the LPTxD is dominant after the timeout the LIN transmitter is shut down and the LPTDIF is set again after attempting to clear it. 0 If there was a TxD-dominant timeout, LPTxD has ceased to be dominant after the timeout. 1 LPTxD is still dominant after a TxD-dominant timeout.

19.3.2.7 LIN Interrupt Enable Register (LPIE)

Module Base + Address 0x0006

Access: User read/write⁽¹⁾

Figure 19-9. LIN Interrupt Enable Register (LPIE)

1. Read: Anytime

Write: Anytime

Table 19-8. LPIE Field Description

Field	Description
7 LPDTIE	LIN transmitter TxD-dominant timeout Interrupt Enable — 0 Interrupt request is disabled. 1 Interrupt is requested if LPDTIF bit is set.
6 LPOCIE	LIN transmitter Overcurrent Interrupt Enable — 0 Interrupt request is disabled. 1 Interrupt is requested if LPOCIF bit is set.

19.3.2.8 LIN Interrupt Flags Register (LPIF)

Module Base + Address 0x0007

Access: User read/write⁽¹⁾

Figure 19-10. LIN Interrupt Flags Register (LPIF)

1. Read: Anytime

Write: Writing '1' clears the flags, writing a '0' has no effect

Table 19-9. LPIF Field Description

Field	Description
7 LPDTIF	<p>LIN Transmitter TxD-dominant timeout Interrupt Flag — LPDTIF is set to 1 when LPTxD is still dominant (0) after t_{TDLIM} of the falling edge of LPTxD. For protection, the transmitter is disabled. This flag can only be cleared by writing a 1. Writing a 0 has no effect. Please make sure that LPDTIF=1 before trying to clear it. Clearing LPDTIF is not allowed if LPDTIF=0 already. If the LPTxD is still dominant after clearing the flag, the transmitter stays disabled and this flag is set again (see 19.4.4.2 TxD-dominant timeout Interrupt).</p> <p>If interrupt requests are enabled (LPDTIE= 1), LPDTIF causes an interrupt request.</p> <p>0 No TxD-dominant timeout has occurred. 1 A TxD-dominant timeout has occurred.</p>
6 LPOCIF	<p>LIN Transmitter Overcurrent Interrupt Flag — LPOCIF is set to 1 when an overcurrent event happens. For protection, the transmitter is disabled. This flag can only be cleared by writing a 1. Writing a 0 has no effect. Please make sure that LPOCIF=1 before trying to clear it. Clearing LPOCIF is not allowed if LPOCIF=0 already. If the overcurrent is still present or LPTxD is dominant after clearing the flag, the transmitter stays disabled and this flag is set again (see 19.4.4.1 Overcurrent Interrupt).</p> <p>If interrupt requests are enabled (LPOCIE= 1), LPOCIF causes an interrupt request.</p> <p>0 No overcurrent event has occurred. 1 Overcurrent event has occurred.</p>

19.4 Functional Description

19.4.1 General

The LIN/HV Physical Layer module implements the physical layer of the LIN/HV interface. In the LIN version, this physical layer can be driven by the SCI (Serial Communication Interface) module or directly through the LPDR register. In the HV Phy version, the input can be routed to an internal timer to measure the frequency and duty cycle of the PWM input signal. If required, the output can directly be controlled by the LPDR register, e.g. to send diagnostic feedback.

19.4.2 Slew Rate and LIN Mode Selection

The slew rate can be selected for Electromagnetic Compatibility (EMC) optimized operation at 10.4 kbit/s and 20 kbit/s as well as at fast baud rate (up to 250 kbit/s) for test and programming. The slew rate can be chosen with the bits LPSLR[1:0] in the LIN Slew Rate Mode Register (LPSLRM). The default slew rate corresponds to 20 kbit/s.

In the HV Phy version, the TxD-dominant timeout must be disabled (LPDTDIS=1) in order e.g. to transmit a PWM pulse.

Changing the slew rate (LPSLRM Register) during transmission is not allowed in order to avoid unwanted effects. To change the register, the LIN/HV Physical Layer must first be disabled (LPE=0). Once it is updated, the LIN/HV Physical Layer can be enabled again.

NOTE

For 20 kbit/s and Fast Mode communication speeds, the corresponding slew rate **MUST** be set; otherwise, the communication is not guaranteed (violation of the specified LIN duty cycles). For 10.4 kbit/s, the 20 kbit/s slew rate **can** be set but the EMC performance is worse. The up to 250 kbit/s slew rate must be chosen **ONLY** for fast mode, not for any of the 10.4 kbit/s or 20 kbit/s LIN compliant communication speeds.

19.4.2.1 10.4 kbit/s and 20 kbit/s

When the slew rate is chosen for 10.4 kbit/s or 20 kbit/s communication, a control loop is activated within the module to make the rise and fall times of the LIN bus independent from VLINSUP and the load on the bus.

19.4.2.2 Fast Mode (not LIN compliant)

Choosing this slew rate allows baud rates up to 250 kbit/s by having much steeper edges (please refer to electricals). As for the 10.4 kbit/s and 20 kbit/s modes, the slope control loop is also engaged. This mode is used for fast communication only, and the LIN electricals are not supported (for example, the LIN duty cycles).

A stronger external pullup resistor might be necessary to sustain communication speeds up to 250 kbit/s. The signal on the LIN pin and the LPRxD signal might not be symmetrical for high baud rates with high loads on the bus.

Please note that if the bit time is smaller than the parameter t_{OCLIM} (please refer to electricals), then no overcurrent is reported nor does an overcurrent shutdown occur. However, the current limitation is always engaged in case of a failure.

19.4.3 Modes

Figure 19-11 shows the possible mode transitions depending on control bits, stop mode, and error conditions.

19.4.3.1 Shutdown Mode

The LIN/HV Physical Layer is fully disabled. No wake-up functionality is available. The internal pullup resistor is high ohmic only (330 k Ω) to maintain the LIN pin in the recessive state. LPTxD is not monitored in this mode for a TxD-dominant timeout. All the registers are accessible.

Setting LPE causes the module to leave the shutdown mode and to enter the normal mode or receive only mode (if RXONLY bit is set).

Clearing LPE causes the module to leave the normal or receive only modes and go back to shutdown mode.

19.4.3.2 Normal Mode

The full functionality is available. Both receiver and transmitter are enabled. The internal pullup resistor can be chosen to be high ohmic (330 k Ω) if LPPUE = 0, or LIN compliant (34 k Ω) if LPPUE = 1.

If RXONLY is set, the module leaves normal mode to enter receive only mode.

If the MCU enters stop mode, the LIN/HV Physical Layer enters standby mode.

19.4.3.3 Receive Only Mode

Entering this mode disables the transmitter and immediately stops any on-going transmission. LPTxD is not monitored in this mode for a TxD-dominant timeout.

The receiver is running in full performance mode in all cases.

To return to normal mode, the RXONLY bit must be cleared.

If the device enters stop mode, the module leaves receive only mode to enter standby mode.

19.4.3.4 Standby Mode with Wake-Up Feature

The transmitter of the LIN/HV Physical Layer is disabled and the receiver enters a low power mode.

NOTE

Before entering standby mode, please ensure that no transmission is ongoing.

If LPWUE is not set, no wake up feature is available and the standby mode has the same electrical properties as the shutdown mode. This allows a low-power consumption of the device in stop mode if the wake-up feature is not needed.

If LPWUE is set, the receiver is able to pass wake-up events to the SCI (Serial Communication Interface). If the LIN/HV Physical Layer receives a dominant level longer than t_{WUFR} followed by a rising edge, it sends a pulse to the SCI which can generate a wake-up interrupt.

Once the device exits stop mode, the LIN/HV Physical Layer returns to normal or receive only mode depending on the status of the RXONLY bit.

NOTE

Since the wake-up interrupt is requested by the SCI, the wake-up feature is not available if LPRxD is not connected to the SCI.

The internal pullup resistor is selectable only if LPWUE = 1 (wake-up enabled). If LPWUE = 0, the internal pullup resistor is not selectable and remains at 330 k Ω regardless of the state of the LPPUE bit.

If LPWUE = 1, selecting the 330 k Ω pullup resistor (LPPUE = 0) reduces the current consumption in standby mode.

NOTE

The use of the LIN wake-up feature in combination with other non-LIN device wake-up features (like a periodic time interrupt) must be handled with care.

If the device leaves stop mode while the LIN bus is dominant, the LIN/HV Physical Layer returns to normal or receive only mode and the LPRxD signal is re-routed to the RxD pin of the SCI and triggers the edge detection interrupt (if the interrupt's priority of the hardware that awakes the MCU is less than the priority of the SCI interrupt, then the SCI interrupt will execute first). It is up to the software to decide what to do in this case because the LIN/HV Physical Layer may not determine whether it was a valid wake-up pulse.

Figure 19-11. LIN/HV Physical Layer Mode Transitions

19.4.4 Interrupts

The interrupt vector requested by the LIN/HV Physical Layer is listed in [Table 19-10](#). Vector address and interrupt priority is defined at the MCU level.

The module internal interrupt sources are combined into a single interrupt request at the device level.

Table 19-10. Interrupt Vectors

Module Interrupt Source	Module Internal Interrupt Source	Local Enable
LIN Interrupt (LPI)	LIN Txd-Dominant Timeout Interrupt (LPDTIF)	LPDTIE = 1
	LIN Overcurrent Interrupt (LPOCIF)	LPOCIE = 1

19.4.4.1 Overcurrent Interrupt

The transmitter is protected against overcurrent. In case of an overcurrent condition occurring within a time frame called t_{OCLIM} starting from LPTxD falling edge, the current through the transmitter is limited (the transmitter is not shut down). The masking of an overcurrent event within the time frame t_{OCLIM} is meant to avoid “false” overcurrent conditions that can happen during the discharging of the LIN bus. If an overcurrent event occurs out of this time frame, the transmitter is disabled and the LPOCIF flag is set.

In order to re-enable the transmitter again, the following prerequisites must be met:

- 1) Overcurrent condition is over
- 2) LPTxD is recessive or the LIN/HV Physical Layer is in shutdown or receive only mode for a minimum of a transmit bit time.

To re-enable the transmitter then, the LPOCIF flag must be cleared (by writing a 1).

NOTE

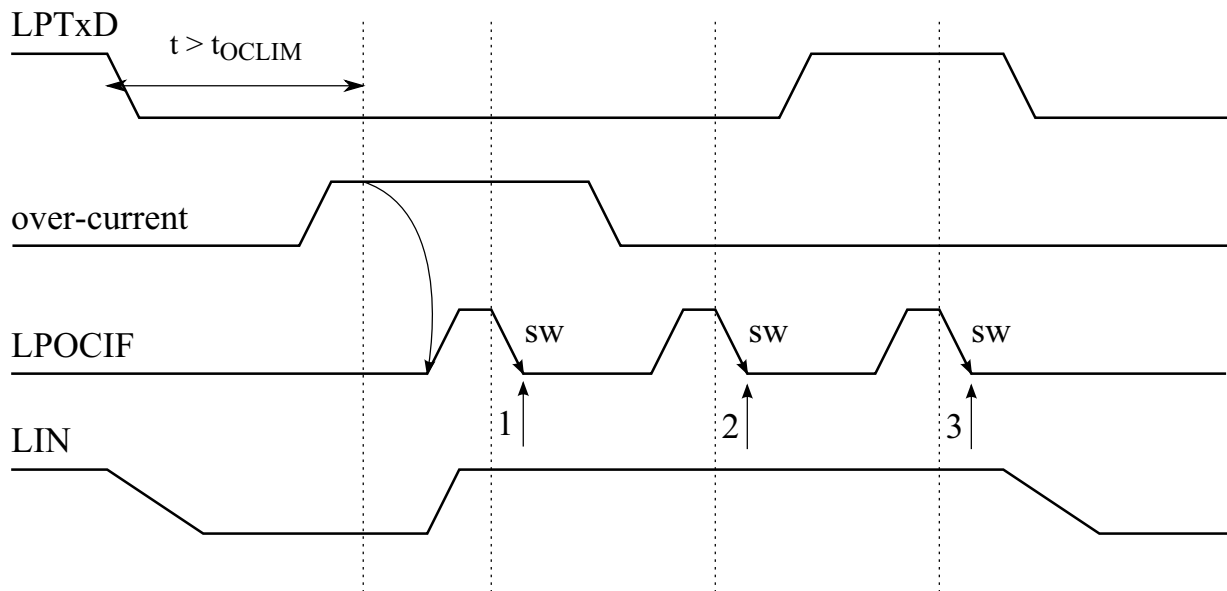

Please make sure that LPOCIF=1 before trying to clear it. It is not allowed to try to clear LPOCIF if LPOCIF=0 already.

After clearing LPOCIF, if the overcurrent condition is still present or the LPTxD pin is dominant while being in normal mode, the transmitter remains disabled and the LPOCIF flag is set again after a time to indicate that the attempt to re-enable has failed. This time is equal to:

- minimum 1 IRC period (1 us) + 2 bus periods
- maximum 2 IRC periods (2 us) + 3 bus periods

If the bit LPOCIE is set in the LPIE register, an interrupt is requested.

[Figure 19-12](#) shows the different scenarios for overcurrent interrupt handling.

- 1: Flag cleared, transmitter re-enable not successful because over-current is still present
- 2: Flag cleared, transmitter re-enable not successful because LPTxD is dominant
- 3: Flag cleared, transmitter re-enable successful

Figure 19-12. Overcurrent interrupt handling

19.4.4.2 TxD-dominant timeout Interrupt

NOTE

In order to perform PWM communication, the TxD-dominant timeout feature must be disabled.

To protect the LIN bus from a network lock-up, the LIN Physical Layer implements a TxD-dominant timeout mechanism. When the LPTxD signal has been dominant for more than t_{DTLIM} the transmitter is disabled and the LPDT status flag and the LPDTIF interrupt flag are set.

In order to re-enable the transmitter again, the following prerequisites must be met:

- 1) TxD-dominant condition is over (LPDT=0)
- 2) LPTxD is recessive or the LIN Physical Layer is in shutdown or receive only mode for a minimum of a transmit bit time

To re-enable the transmitter then, the LPDTIF flag must be cleared (by writing a 1).

NOTE

Please make sure that LPDTIF=1 before trying to clear it. It is not allowed to try to clear LPDTIF if LPDTIF=0 already.

After clearing LPDTIF, if the TxD-dominant timeout condition is still present or the LPTxD pin is dominant while being in normal mode, the transmitter remains disabled and the LPDTIF flag is set after a time again to indicate that the attempt to re-enable has failed. This time is equal to:

- minimum 1 IRC period (1 us) + 2 bus periods
- maximum 2 IRC periods (2 us) + 3 bus periods

If the bit LPDTIE is set in the LPIE register, an interrupt is requested.

Figure 19-13 shows the different scenarios of TxD-dominant timeout interrupt handling.

- 1: Flag cleared, transmitter re-enable not successful because TxD-dominant timeout condition is still present
- 2: Flag cleared, transmitter re-enable not successful because LPTxD is dominant
- 3: Flag cleared, transmitter re-enable successful

Figure 19-13. TxD-dominant timeout interrupt handling

19.5 Application Information

19.5.1 Module Initialization

The following steps should be used to configure the module before starting the transmission:

- In the LIN version, set the slew rate in the LPSLRM register to the desired transmission baud rate.
- In the HV Phy version, de-activate the dominant timeout feature in the LPSLRM register if needed.
- In most cases, the internal pullup should be enabled in the LPCR register.
- Perform the correct routing settings in the PIM module:
 - In the LIN version, select the SCI as source, i.e. connect the TxD pin of the SCI to LPTxD, and the RxD pin of the SCI to LPRxD.
 - In the HV Phy version, connect LPRxD to the internal timer (control information) and if required, connect the LPDR1 bit of the LPDR register to LPTxD (diagnostic feedback). If the wake-up feature is required, the RxD pin of the SCI must also be connected to LPRxD.
- Select the transmit mode (Receive only mode or Normal mode) in the LPCR register.
- If the RxD pin of the SCI is connected to LPRxD, activate the wake-up feature in the LPCR register if needed for the application (SCI active edge interrupt must also be enabled).
- Enable the LIN/HV Physical Layer in the LPCR register.
- Wait for a minimum of a transmit bit.
- Begin transmission if needed.

NOTE

It is not allowed to try to clear LPOCIF or LPDTIF if they are already cleared. Before trying to clear an error flag, always make sure that it is already set.

19.5.2 Interrupt handling in Interrupt Service Routine (ISR)

Both interrupts (TxD-dominant timeout and overcurrent) represent a failure in transmission. To avoid more disturbances on the transmission line, the transmitter is de-activated in both cases. The interrupt subroutine must take care of clearing the error condition and starting the routine that re-enables the transmission. For that purpose, the following steps are recommended:

1. First, the cause of the interrupt must be cleared:
 - The overcurrent will be gone after the transmitter has been disabled.
 - The TxD-dominant timeout condition will be gone once the selected source for LPTxD has turned recessive.
2. Clear the corresponding enable bit (LPDTIE or LPOCIE) to avoid entering the ISR again until the flags are cleared.
3. Notify the application of the error condition (LIN Error handler) and leave the ISR.

In the LIN Error handler, the following sequence is recommended:

1. Disable the LIN/HV Physical Layer (LPCR) while re-configuring the transmission.

- If the receiver must remain enabled, set the LIN/HV Physical Layer into receive only mode instead.
- 2. Do all required configurations (SCI, etc.) to re-enable the transmission.
- 3. Wait for a transmit bit (this is needed to successfully re-enable the transmitter).
- 4. Clear the error flag.
- 5. Enable the interrupts again (LPDTIE and LPOCIE).
- 6. Enable the LIN/HV Physical Layer or leave the receive only mode (LPCR register).
- 7. Wait for a minimum of a transmit bit before beginning transmission again.

If there is a problem re-enabling the transmitter, then the error flag will be set again during step 3 and the ISR will be called again.

Chapter 20

Flash Module (S12ZFTMRZ)

Table 20-1. Revision History

Revision Number	Revision Date	Sections Affected	Description of Changes
V02.03	12 Apr 2012	20.3	Corrected many typo. Changed caution note
V02.04	17 May 2012	20.3.2.6	- Removed flag DFDIE
V02.05	11 Jul 2012		- Added explanation about when MGSTAT[1:0] bits are cleared, Section 20.3.2.7 - Added note about possibility of reading P-Flash and EEPROM simultaneously, Section 20.4.6
V02.06	18 Mar 2013		- Standardized nomenclature in references to memory sizes
V02.07	24 May 2013		- Revised references to NVM Resource Area to improve readability
V02.8	12 Jun 2013		- Changed MLOADU Section 20.4.7.12 and MLOADF Section 20.4.7.13 FCCOB1 to FCCOB2
V02.9	15 Oct 2014		Created memory-size independent version of this module description

20.1 Introduction

The P-Flash (Program Flash) and EEPROM memory sizes are specified at device level (Reference Manual device overview chapter). The description in the following sections is valid for all P-Flash and EEPROM memory sizes.

The Flash memory is ideal for single-supply applications allowing for field reprogramming without requiring external high voltage sources for program or erase operations. The Flash module includes a memory controller that executes commands to modify Flash memory contents. The user interface to the memory controller consists of the indexed Flash Common Command Object (FCCOB) register which is written to with the command, global address, data, and any required command parameters. The memory controller must complete the execution of a command before the FCCOB register can be written to with a new command.

CAUTION

A Flash word or phrase must be in the erased state before being programmed. Cumulative programming of bits within a Flash word or phrase is not allowed.

The Flash memory may be read as bytes and aligned words. Read access time is one bus cycle for bytes and aligned words. For misaligned words access, the CPU has to perform twice the byte read access command. For Flash memory, an erased bit reads 1 and a programmed bit reads 0.

It is possible to read from P-Flash memory while some commands are executing on EEPROM memory. It is not possible to read from EEPROM memory while a command is executing on P-Flash memory **from the same block**. Simultaneous P-Flash and EEPROM operations are discussed in [Section 20.4.6](#).

Both P-Flash and EEPROM memories are implemented with Error Correction Codes (ECC) that can resolve single bit faults and detect double bit faults. For P-Flash memory, the ECC implementation requires that programming be done on an aligned 8 byte basis (a Flash phrase). Since P-Flash memory is always read by half-phrase, only one single bit fault in an aligned 4 byte half-phrase containing the byte or word accessed will be corrected.

20.1.1 Glossary

Command Write Sequence — An MCU instruction sequence to execute built-in algorithms (including program and erase) on the Flash memory.

EEPROM Memory — The EEPROM memory constitutes the nonvolatile memory store for data.

EEPROM Sector — The EEPROM sector is the smallest portion of the EEPROM memory that can be erased. The EEPROM sector consists of 4 bytes.

NVM Command Mode — An NVM mode using the CPU to setup the FCCOB register to pass parameters required for Flash command execution.

Phrase — An aligned group of four 16-bit words within the P-Flash memory. Each phrase includes two sets of aligned double words with each set including 7 ECC bits for single bit fault correction and double bit fault detection within each double word.

P-Flash Memory — The P-Flash memory constitutes the main nonvolatile memory store for applications.

P-Flash Sector — The P-Flash sector is the smallest portion of the P-Flash memory that can be erased. Each P-Flash sector contains 512 bytes.

Program IFR — Nonvolatile information register located in the P-Flash block that contains the Version ID, and the Program Once field.

20.1.2 Features

20.1.2.1 P-Flash Features

- Derivatives featuring up to and including 128 KB of P-Flash include one P-Flash block
- Derivatives featuring more than 128 KB of P-Flash include two Flash blocks

- In each case the P-Flash sector size is 512 bytes
- Single bit fault correction and double bit fault detection within a 32-bit double word during read operations
- Automated program and erase algorithm with verify and generation of ECC parity bits
- Fast sector erase and phrase program operation
- Ability to read the P-Flash memory while programming a word in the EEPROM memory
- Flexible protection scheme to prevent accidental program or erase of P-Flash memory

20.1.2.2 EEPROM Features

- The EEPROM memory is composed of one Flash block divided into sectors of 4 bytes
- Single bit fault correction and double bit fault detection within a word during read operations
- Automated program and erase algorithm with verify and generation of ECC parity bits
- Fast sector erase and word program operation
- Protection scheme to prevent accidental program or erase of EEPROM memory
- Ability to program up to four words in a burst sequence

20.1.2.3 Other Flash Module Features

- No external high-voltage power supply required for Flash memory program and erase operations
- Interrupt generation on Flash command completion and Flash error detection
- Security mechanism to prevent unauthorized access to the Flash memory

20.1.3 Block Diagram

The block diagrams of the Flash modules are shown in the following figures.

Figure 20-1. FTMRZ Block Diagram (Single P-Flash Block plus EEPROM block)

Table 20-2. FTMRZ Block Diagram (Two P-Flash blocks plus EEPROM block)

20.2 External Signal Description

The Flash module contains no signals that connect off-chip.

20.3 Memory Map and Registers

This section describes the memory map and registers for the Flash module. Read data from unimplemented memory space in the Flash module is undefined. Write access to unimplemented or reserved memory space in the Flash module will be ignored by the Flash module.

CAUTION

Writing to the Flash registers while a Flash command is executing (that is indicated when the value of flag CCIF reads as '0') is not allowed. If such action is attempted, the result of the write operation will be unpredictable.

Writing to the Flash registers is allowed when the Flash is not busy executing commands (CCIF = 1) and during initialization right after reset, despite the value of flag CCIF in that case (refer to [Section 20.6](#) for a complete description of the reset sequence).

Table 20-3. FTMRZ Memory Map

Global Address (in Bytes)	Description
0x0_0000 – 0x0_0FFF	Register Space
0x10_0000 – 0x1F_4000	EEPROM memory range. Allocation is device dependent.
0x1F_4000 – 0x1F_FFFF	NVM Resource Area ⁽¹⁾ (see Figure 20-3)
0x80_0000 – 0xFD_FFFF	P-Flash memory range (Hardblock 0S). Allocation is device dependent.
0xFE_0000 – 0xFF_FFFF	P-Flash memory range (Hardblock 0N). Allocation is device dependent.

1. See NVM Resource area description in [Section 20.4.4](#)

20.3.1 Module Memory Map

The P-Flash memory is located between global addresses 0x80_0000 and 0xFF_FFFF. The P-Flash is high aligned from 0xFF_FFFF. Thus, for example, a 128 KB P-Flash extends from 0xFF_FFFF to 0xFE_0000.

The flash configuration field is mapped to the same addresses independent of the P-Flash memory size, as shown in [Figure 20-2](#).

The FPROT register, described in [Section 20.3.2.9](#), can be set to protect regions in the Flash memory from accidental program or erase. Three separate memory regions, one growing upward from global address 0xFF_8000 in the Flash memory (called the lower region), one growing downward from global address 0xFF_FFFF in the Flash memory (called the higher region), and the remaining addresses in the Flash memory, can be activated for protection. The Flash memory addresses covered by these protectable regions are shown in the P-Flash memory map. The higher address region is mainly targeted to hold the boot loader code since it covers the vector space. Default protection settings as well as security information

that allows the MCU to restrict access to the Flash module are stored in the Flash configuration field as described in [Table 20-4](#).

Table 20-4. Flash Configuration Field

Global Address	Size (Bytes)	Description
0xFF_FE00-0xFF_FE07	8	Backdoor Comparison Key Refer to Section 20.4.7.11 , “Verify Backdoor Access Key Command,” and Section 20.5.1 , “Unsecuring the MCU using Backdoor Key Access”
0xFF_FE08-0xFF_FE09 ¹	2	Protection Override Comparison Key. Refer to Section 20.4.7.17 , “Protection Override Command”
0xFF_FE0A-0xFF_FE0B ⁽¹⁾	2	Reserved
0xFF_FE0C ¹	1	P-Flash Protection byte. Refer to Section 20.3.2.9 , “P-Flash Protection Register (FPROT)”
0xFF_FE0D ¹	1	EEPROM Protection byte. Refer to Section 20.3.2.10 , “EEPROM Protection Register (DFPROT)”
0xFF_FE0E ¹	1	Flash Nonvolatile byte Refer to Section 20.3.2.11 , “Flash Option Register (FOPT)”
0xFF_FE0F ¹	1	Flash Security byte Refer to Section 20.3.2.2 , “Flash Security Register (FSEC)”

1. 0xFF_FE08-0xFF_FE0F form a Flash phrase and must be programmed in a single command write sequence. Each byte in the 0xFF_FE0A - 0xFF_FE0B reserved field should be programmed to 0xFF.

Figure 20-2. P-Flash Memory Map With Protection Alignment

Table 20-5. Program IFR Fields

Global Address	Size (Bytes)	Field Description
0x1F_C000 – 0x1F_C007	8	Reserved
0x1F_C008 – 0x1F_C0B5	174	Reserved
0x1F_C0B6 – 0x1F_C0B7	2	Version ID ⁽¹⁾
0x1F_C0B8 – 0x1F_C0BF	8	Reserved
0x1F_C0C0 – 0x1F_C0FF	64	Program Once Field Refer to Section 20.4.7.6 , “Program Once Command”

1. Used to track firmware patch versions, see [Section 20.4.2](#)

Table 20-6. Memory Controller Resource Fields (NVM Resource Area⁽¹⁾)

Global Address	Size (Bytes)	Description
0x1F_4000 – 0x1F_41FF	512	Reserved
0x1F_4200 – 0x1F_7FFF	15,872	Reserved
0x1F_8000 – 0x1F_97FF	6,144	Reserved
0x1F_9800 – 0x1F_BFFF	10,240	Reserved
0x1F_C000 – 0x1F_C0FF	256	P-Flash IFR (see Table 20-5)
0x1F_C100 – 0x1F_C1FF	256	Reserved.
0x1F_C200 – 0x1F_FFFF	15,872	Reserved.

1. See [Section 20.4.4](#) for NVM Resources Area description.

Figure 20-3. Memory Controller Resource Memory Map (NVM Resources Area)

20.3.2 Register Descriptions

The Flash module contains a set of 24 control and status registers located between Flash module base + 0x0000 and 0x0017.

In the case of the writable registers, the write accesses are forbidden during Flash command execution (for more detail, see Caution note in Section 20.3).

A summary of the Flash module registers is given in Figure 20-4 with detailed descriptions in the following subsections.

Address & Name		7	6	5	4	3	2	1	0

Figure 20-4. FTMZR128K512 Register Summary (continued)

1. Number of implemented DPS bits depends on EEPROM memory size.

20.3.2.1 Flash Clock Divider Register (FCLKDIV)

The FCLKDIV register is used to control timed events in program and erase algorithms.

Offset Module Base + 0x0000

Figure 20-5. Flash Clock Divider Register (FCLKDIV)

All bits in the FCLKDIV register are readable, bit 7 is not writable, bit 6 is write-once-hi and controls the writability of the FDIV field in normal mode. In special mode, bits 6-0 are writable any number of times but bit 7 remains unwritable.

CAUTION

The FCLKDIV register should never be written while a Flash command is executing (CCIF=0).

Table 20-7. FCLKDIV Field Descriptions

Field	Description
7 FDIVLD	Clock Divider Loaded 0 FCLKDIV register has not been written since the last reset 1 FCLKDIV register has been written since the last reset
6 FDIVLCK	Clock Divider Locked 0 FDIV field is open for writing 1 FDIV value is locked and cannot be changed. Once the lock bit is set high, only reset can clear this bit and restore writability to the FDIV field in normal mode.
5–0 FDIV[5:0]	Clock Divider Bits — FDIV[5:0] must be set to effectively divide BUSCLK down to 1 MHz to control timed events during Flash program and erase algorithms. Table 20-8 shows recommended values for FDIV[5:0] based on the BUSCLK frequency. Please refer to Section 20.4.5, “Flash Command Operations,” for more information.

Table 20-8. FDIV values for various BUSCLK Frequencies

BUSCLK Frequency (MHz)		FDIV[5:0]	BUSCLK Frequency (MHz)		FDIV[5:0]
MIN ⁽¹⁾	MAX ⁽²⁾		MIN ¹	MAX ²	
1.0	1.6	0x00	26.6	27.6	0x1A
1.6	2.6	0x01	27.6	28.6	0x1B

23.6	24.6	0x17	49.6	50.6	0x31
24.6	25.6	0x18			
25.6	26.6	0x19			

1. BUSCLK is Greater Than this value.
2. BUSCLK is Less Than or Equal to this value.

20.3.2.2 Flash Security Register (FSEC)

The FSEC register holds all bits associated with the security of the MCU and Flash module.

Offset Module Base + 0x0001

Figure 20-6. Flash Security Register (FSEC)

1. Loaded from Flash configuration field, during reset sequence.

All bits in the FSEC register are readable but not writable.

During the reset sequence, the FSEC register is loaded with the contents of the Flash security byte in the Flash configuration field at global address 0xFF_FE0F located in P-Flash memory (see Table 20-4) as indicated by reset condition F in Figure 20-6. If a double bit fault is detected while reading the P-Flash phrase containing the Flash security byte during the reset sequence, all bits in the FSEC register will be set to leave the Flash module in a secured state with backdoor key access disabled.

Table 20-9. FSEC Field Descriptions

Field	Description
7–6 KEYEN[1:0]	Backdoor Key Security Enable Bits — The KEYEN[1:0] bits define the enabling of backdoor key access to the Flash module as shown in Table 20-10 .
5–2 RNV[5:2]	Reserved Nonvolatile Bits — The RNV bits should remain in the erased state for future enhancements.
1–0 SEC[1:0]	Flash Security Bits — The SEC[1:0] bits define the security state of the MCU as shown in Table 20-11 . If the Flash module is unsecured using backdoor key access, the SEC bits are forced to 10.

Table 20-10. Flash KEYEN States

KEYEN[1:0]	Status of Backdoor Key Access
00	DISABLED
01	DISABLED ⁽¹⁾
10	ENABLED
11	DISABLED

1. Preferred KEYEN state to disable backdoor key access.

Table 20-11. Flash Security States

SEC[1:0]	Status of Security
00	SECURED
01	SECURED ⁽¹⁾
10	UNSECURED
11	SECURED

1. Preferred SEC state to set MCU to secured state.

The security function in the Flash module is described in [Section 20.5](#).

20.3.2.3 Flash CCOB Index Register (FCCOBIX)

The FCCOBIX register is used to indicate the amount of parameters loaded into the FCCOB registers for Flash memory operations.

Offset Module Base + 0x0002

Figure 20-7. FCCOB Index Register (FCCOBIX)

CCOBIX bits are readable and writable while remaining bits read 0 and are not writable.

Table 20-12. FCCOBIX Field Descriptions

Field	Description
2–0 CCOBIX[1:0]	Common Command Register Index — The CCOBIX bits are used to indicate how many words of the FCCOB register array are being read or written to. See Section 20.3.2.13, “Flash Common Command Object Registers (FCCOB)” , for more details.

20.3.2.4 Flash Protection Status Register (FPSTAT)

This Flash register holds the status of the Protection Override feature.

Offset Module Base + 0x0003

	7	6	5	4	3	2	1	0
R	FPOVRD	0	0	0	0	0	0	WSTATAACK
W								
Reset	0	0	0	0	0	0	0	1

 = Unimplemented or Reserved

Figure 20-8. Flash Protection Status Register (FPSTAT)

All bits in the FPSTAT register are readable but are not writable.

Table 20-13. FPSTAT Field Descriptions

Field	Description
7 FPOVRD	Flash Protection Override Status — The FPOVRD bit indicates if the Protection Override feature is currently enabled. See Section 20.4.7.17, “Protection Override Command” for more details. 0 Protection is not overridden 1 Protection is overridden, contents of registers FPROT and/or DFPROT (and effective protection limits determined by their current contents) were determined during execution of command Protection Override
0 WSTATAACK	Wait-State Switch Acknowledge — The WSTATAACK bit indicates that the wait-state configuration is effectively set according to the value configured on bits FCNFG[WSTAT] (see Section 20.3.2.5, “Flash Configuration Register (FCNFG)”). WSTATAACK bit is cleared when a change in FCNFG[WSTAT] is requested by writing to those bits, and is set when the Flash has effectively switched to the new wait-state configuration. The application must check the status of WSTATAACK bit to make sure it reads as 1 before changing the frequency setup (see Section 20.4.3, “Flash Block Read Access”). 0 Wait-State switch is pending, Flash reads are still happening according to the previous value of FCNFG[WSTAT] 1 Wait-State switch is complete, Flash reads are already working according to the value set on FCNFG[WSTAT]

20.3.2.5 Flash Configuration Register (FCNFG)

The FCNFG register enables the Flash command complete interrupt, control generation of wait-states and forces ECC faults on Flash array read access from the CPU.

Offset Module Base + 0x0004

Figure 20-9. Flash Configuration Register (FCNFG)

CCIE, IGNSF, WSTAT, FDFD, and FSFD bits are readable and writable, ERSAREQ bit is read only, and remaining bits read 0 and are not writable.

Table 20-14. FCNFG Field Descriptions

Field	Description
7 CCIE	<p>Command Complete Interrupt Enable — The CCIE bit controls interrupt generation when a Flash command has completed.</p> <p>0 Command complete interrupt disabled</p> <p>1 An interrupt will be requested whenever the CCIF flag in the FSTAT register is set (see Section 20.3.2.7)</p>
5 ERSAREQ	<p>Erase All Request — Requests the Memory Controller to execute the Erase All Blocks command and release security. ERSAREQ is not directly writable but is under indirect user control. Refer to the Reference Manual for assertion of the <i>soc_erase_all_req</i> input to the FTMRZ module.</p> <p>0 No request or request complete</p> <p>1 Request to:</p> <ol style="list-style-type: none"> run the Erase All Blocks command verify the erased state program the security byte in the Flash Configuration Field to the unsecure state release MCU security by setting the SEC field of the FSEC register to the unsecure state as defined in Table 20-9 of Section 20.3.2.2. <p>The ERSAREQ bit sets to 1 when <i>soc_erase_all_req</i> is asserted, CCIF=1 and the Memory Controller starts executing the sequence. ERSAREQ will be reset to 0 by the Memory Controller when the operation is completed (see Section 20.4.7.7.1).</p>
4 IGNSF	<p>Ignore Single Bit Fault — The IGNSF controls single bit fault reporting in the FERSTAT register (see Section 20.3.2.8).</p> <p>0 All single bit faults detected during array reads are reported</p> <p>1 Single bit faults detected during array reads are not reported and the single bit fault interrupt will not be generated</p>
3–2 WSTAT[1:0]	<p>Wait State control bits — The WSTAT[1:0] bits define how many wait-states are inserted on each read access to the Flash as shown on Table 20-15. Right after reset the maximum amount of wait-states is set, to be later re-configured by the application if needed. Depending on the system operating frequency being used the number of wait-states can be reduced or disabled, please refer to the Data Sheet for details. For additional information regarding the procedure to change this configuration please see Section 20.4.3. The WSTAT[1:0] bits should not be updated while the Flash is executing a command (CCIF=0); if that happens the value of this field will not change and no action will take place.</p>

Table 20-14. FCNFG Field Descriptions (continued)

Field	Description
1 FDFD	Force Double Bit Fault Detect — The FDFD bit allows the user to simulate a double bit fault during Flash array read operations. The FDFD bit is cleared by writing a 0 to FDFD. 0 Flash array read operations will set the DFDF flag in the FERSTAT register only if a double bit fault is detected 1 Any Flash array read operation will force the DFDF flag in the FERSTAT register to be set (see Section 20.3.2.7)
0 FSFD	Force Single Bit Fault Detect — The FSFD bit allows the user to simulate a single bit fault during Flash array read operations and check the associated interrupt routine. The FSFD bit is cleared by writing a 0 to FSFD. 0 Flash array read operations will set the SFDIF flag in the FERSTAT register only if a single bit fault is detected 1 Flash array read operation will force the SFDIF flag in the FERSTAT register to be set (see Section 20.3.2.7) and an interrupt will be generated as long as the SFDIE interrupt enable in the FERCNFG register is set (see Section 20.3.2.6)

Table 20-15. Flash Wait-States control

WSTAT[1:0]	Wait-State configuration
00	ENABLED, maximum number of cycles ⁽¹⁾
01	reserved ⁽²⁾
10	reserved ²
11	DISABLED

1. Reset condition. For a target of 100MHz core frequency / 50MHz bus frequency the maximum number required is 1 cycle.

2. Value will read as 01 or 10, as written. In the current implementation the Flash will behave the same as 00 (wait-states enabled, maximum number of cycles).

20.3.2.6 Flash Error Configuration Register (FERCNFG)

The FERCNFG register enables the Flash error interrupts for the FERSTAT flags.

Offset Module Base + 0x0005

Figure 20-10. Flash Error Configuration Register (FERCNFG)

All assigned bits in the FERCNFG register are readable and writable.

Table 20-16. FERCNFG Field Descriptions

Field	Description
0 SFDIE	Single Bit Fault Detect Interrupt Enable — The SFDIE bit controls interrupt generation when a single bit fault is detected during a Flash block read operation. 0 SFDIF interrupt disabled whenever the SFDIF flag is set (see Section 20.3.2.8) 1 An interrupt will be requested whenever the SFDIF flag is set (see Section 20.3.2.8)

20.3.2.7 Flash Status Register (FSTAT)

The FSTAT register reports the operational status of the Flash module.

Offset Module Base + 0x0006

Figure 20-11. Flash Status Register (FSTAT)

1. Reset value can deviate from the value shown if a double bit fault is detected during the reset sequence (see [Section 20.6](#)).

CCIF, ACCERR, and FPVIOL bits are readable and writable, MGBUSY and MGSTAT bits are readable but not writable, while remaining bits read 0 and are not writable.

Table 20-17. FSTAT Field Descriptions

Field	Description
7 CCIF	Command Complete Interrupt Flag — The CCIF flag indicates that a Flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command and CCIF will stay low until command completion or command violation. 0 Flash command in progress 1 Flash command has completed
5 ACCERR	Flash Access Error Flag — The ACCERR bit indicates an illegal access has occurred to the Flash memory caused by either a violation of the command write sequence (see Section 20.4.5.2) or issuing an illegal Flash command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to ACCERR. Writing a 0 to the ACCERR bit has no effect on ACCERR. 0 No access error detected 1 Access error detected
4 FPVIOL	Flash Protection Violation Flag — The FPVIOL bit indicates an attempt was made to program or erase an address in a protected area of P-Flash or EEPROM memory during a command write sequence. The FPVIOL bit is cleared by writing a 1 to FPVIOL. Writing a 0 to the FPVIOL bit has no effect on FPVIOL. While FPVIOL is set, it is not possible to launch a command or start a command write sequence. 0 No protection violation detected 1 Protection violation detected
3 MGBUSY	Memory Controller Busy Flag — The MGBUSY flag reflects the active state of the Memory Controller. 0 Memory Controller is idle 1 Memory Controller is busy executing a Flash command (CCIF = 0)

Table 20-17. FSTAT Field Descriptions (continued)

Field	Description
2 RSVD	Reserved Bit — This bit is reserved and always reads 0.
1–0 MGSTAT[1:0]	Memory Controller Command Completion Status Flag — One or more MGSTAT flag bits are set if an error is detected during execution of a Flash command or during the Flash reset sequence. The MGSTAT bits are cleared automatically at the start of the execution of a Flash command. See Section 20.4.7, “Flash Command Description,” and Section 20.6, “Initialization” for details.

20.3.2.8 Flash Error Status Register (FERSTAT)

The FERSTAT register reflects the error status of internal Flash operations.

Offset Module Base + 0x0007

Figure 20-12. Flash Error Status Register (FERSTAT)

All flags in the FERSTAT register are readable and only writable to clear the flag.

Table 20-18. FERSTAT Field Descriptions

Field	Description
1 DFDF	Double Bit Fault Detect Flag — The setting of the DFDF flag indicates that a double bit fault was detected in the stored parity and data bits during a Flash array read operation or that a Flash array read operation returning invalid data was attempted on a Flash block that was under a Flash command operation. ⁽¹⁾ The DFDF flag is cleared by writing a 1 to DFDF. Writing a 0 to DFDF has no effect on DFDF. ⁽²⁾ 0 No double bit fault detected 1 Double bit fault detected or a Flash array read operation returning invalid data was attempted while command running. See Section 20.4.3, “Flash Block Read Access” for details
0 SFDIF	Single Bit Fault Detect Interrupt Flag — With the IGNSF bit in the FCNFG register clear, the SFDIF flag indicates that a single bit fault was detected in the stored parity and data bits during a Flash array read operation or that a Flash array read operation returning invalid data was attempted on a Flash block that was under a Flash command operation. The SFDIF flag is cleared by writing a 1 to SFDIF. Writing a 0 to SFDIF has no effect on SFDIF. 0 No single bit fault detected 1 Single bit fault detected and corrected or a Flash array read operation returning invalid data was attempted while command running

1. In case of ECC errors the corresponding flag must be cleared for the proper setting of any further error, i.e. any new error will only be indicated properly when DFDF and/or SFDIF are clear at the time the error condition is detected.
2. There is a one cycle delay in storing the ECC DFDF and SFDIF fault flags in this register. At least one NOP is required after a flash memory read before checking FERSTAT for the occurrence of ECC errors.

20.3.2.9 P-Flash Protection Register (FPROT)

The FPROT register defines which P-Flash sectors are protected against program and erase operations.

Offset Module Base + 0x0008

Figure 20-13. Flash Protection Register (FPROT)

1. Loaded from Flash configuration field, during reset sequence.

The (unreserved) bits of the FPROT register are writable Normal Single Chip Mode with the restriction that the size of the protected region can only be increased see [Section 20.3.2.9.1, “P-Flash Protection Restrictions,”](#) and [Table 20-23](#)). All (unreserved) bits of the FPROT register are writable without restriction in Special Single Chip Mode.

During the reset sequence, the FPROT register is loaded with the contents of the P-Flash protection byte in the Flash configuration field at global address 0xFF_FE0C located in P-Flash memory (see [Table 20-4](#)) as indicated by reset condition ‘F’ in [Figure 20-13](#). To change the P-Flash protection that will be loaded during the reset sequence, the upper sector of the P-Flash memory must be unprotected, then the P-Flash protection byte must be reprogrammed. If a double bit fault is detected while reading the P-Flash phrase containing the P-Flash protection byte during the reset sequence, the FPOpen bit will be cleared and remaining bits in the FPROT register will be set to leave the P-Flash memory fully protected.

Trying to alter data in any protected area in the P-Flash memory will result in a protection violation error and the FPVIOL bit will be set in the FSTAT register. The block erase of a P-Flash block is not possible if any of the P-Flash sectors contained in the same P-Flash block are protected.

Table 20-19. FPROT Field Descriptions

Field	Description
7 FPOpen	Flash Protection Operation Enable — The FPOpen bit determines the protection function for program or erase operations as shown in Table 20-20 for the P-Flash block. 0 When FPOpen is clear, the FPHDIS and FPLDIS bits define unprotected address ranges as specified by the corresponding FPHS and FPLS bits 1 When FPOpen is set, the FPHDIS and FPLDIS bits enable protection for the address range specified by the corresponding FPHS and FPLS bits
6 RNV[6]	Reserved Nonvolatile Bit — The RNV bit should remain in the erased state for future enhancements.
5 FPHDIS	Flash Protection Higher Address Range Disable — The FPHDIS bit determines whether there is a protected/unprotected area in a specific region of the P-Flash memory ending with global address 0xFF_FFFF. 0 Protection/Unprotection enabled 1 Protection/Unprotection disabled
4–3 FPHS[1:0]	Flash Protection Higher Address Size — The FPHS bits determine the size of the protected/unprotected area in P-Flash memory as shown in Table 20-21 . The FPHS bits can only be written to while the FPHDIS bit is set.

Table 20-19. FPROT Field Descriptions (continued)

Field	Description
2 FPLDIS	Flash Protection Lower Address Range Disable — The FPLDIS bit determines whether there is a protected/unprotected area in a specific region of the P-Flash memory beginning with global address 0xFF_8000. 0 Protection/Unprotection enabled 1 Protection/Unprotection disabled
1–0 FPLS[1:0]	Flash Protection Lower Address Size — The FPLS bits determine the size of the protected/unprotected area in P-Flash memory as shown in Table 20-22 . The FPLS bits can only be written to while the FPLDIS bit is set.

Table 20-20. P-Flash Protection Function

FPOPEN	FPHDIS	FPLDIS	Function ⁽¹⁾
1	1	1	No P-Flash Protection
1	1	0	Protected Low Range
1	0	1	Protected High Range
1	0	0	Protected High and Low Ranges
0	1	1	Full P-Flash Memory Protected
0	1	0	Unprotected Low Range
0	0	1	Unprotected High Range
0	0	0	Unprotected High and Low Ranges

1. For range sizes, refer to [Table 20-21](#) and [Table 20-22](#).

Table 20-21. P-Flash Protection Higher Address Range

FPHS[1:0]	Global Address Range	Protected Size
00	0xFF_F800–0xFF_FFFF	2 KB
01	0xFF_F000–0xFF_FFFF	4 KB
10	0xFF_E000–0xFF_FFFF	8 KB
11	0xFF_C000–0xFF_FFFF	16 KB

Table 20-22. P-Flash Protection Lower Address Range

FPLS[1:0]	Global Address Range	Protected Size
00	0xFF_8000–0xFF_83FF	1 KB
01	0xFF_8000–0xFF_87FF	2 KB
10	0xFF_8000–0xFF_8FFF	4 KB
11	0xFF_8000–0xFF_9FFF	8 KB

All possible P-Flash protection scenarios are shown in [Figure 20-14](#). Although the protection scheme is loaded from the Flash memory at global address 0xFF_FE0C during the reset sequence, it can be changed by the user. The P-Flash protection scheme can be used by applications requiring reprogramming in normal single chip mode while providing as much protection as possible if reprogramming is not required.

Figure 20-14. P-Flash Protection Scenarios

20.3.2.9.1 P-Flash Protection Restrictions

In Normal Single Chip mode the general guideline is that P-Flash protection can only be added and not removed. Table 20-23 specifies all valid transitions between P-Flash protection scenarios. Any attempt to write an invalid scenario to the FPROT register will be ignored. The contents of the FPROT register reflect the active protection scenario. See the FPHS and FPLS bit descriptions for additional restrictions.

Table 20-23. P-Flash Protection Scenario Transitions

From Protection Scenario	To Protection Scenario ⁽¹⁾							
	0	1	2	3	4	5	6	7
0	X	X	X	X				
1		X		X				
2			X	X				
3				X				
4				X	X			
5			X	X	X	X		
6		X		X	X		X	
7	X	X	X	X	X	X	X	X

1. Allowed transitions marked with X, see Figure 20-14 for a definition of the scenarios.

20.3.2.10 EEPROM Protection Register (DFPROT)

The DFPROT register defines which EEPROM sectors are protected against program and erase operations.

Offset Module Base + 0x0009

Figure 20-15. EEPROM Protection Register (DFPROT)

1. The number of implemented DPS bits depends on the EEPROM memory size, as explained below.
2. Loaded from Flash configuration field, during reset sequence.

The (unreserved) bits of the DFPROT register are writable in Normal Single Chip mode with the restriction that protection can be added but not removed. Writes in Normal Single Chip mode must increase the DPS value and the DPOPEN bit can only be written from 1 (protection disabled) to 0

(protection enabled). If the DPOPEN bit is set, the state of the DPS bits is irrelevant. All DPOPEN/DPS bit registers are writable without restriction in Special Single Chip Mode.

During the reset sequence, fields DPOPEN and DPS of the DFPROT register are loaded with the contents of the EEPROM protection byte in the Flash configuration field at global address 0xFF_FE0D located in P-Flash memory (see Table 20-4) as indicated by reset condition F in Table 20-25. To change the EEPROM protection that will be loaded during the reset sequence, the P-Flash sector containing the EEPROM protection byte must be unprotected, then the EEPROM protection byte must be programmed. If a double bit fault is detected while reading the P-Flash phrase containing the EEPROM protection byte during the reset sequence, the DPOPEN bit will be cleared and DPS bits will be set to leave the EEPROM memory fully protected.

Trying to alter data in any protected area in the EEPROM memory will result in a protection violation error and the FPVIOL bit will be set in the FSTAT register. Block erase of the EEPROM memory is not possible if any of the EEPROM sectors are protected.

Table 20-24. DFPROT Field Descriptions

Field	Description
7 DPOPEN	EEPROM Protection Control 0 Enables EEPROM memory protection from program and erase with protected address range defined by DPS bits 1 Disables EEPROM memory protection from program and erase
6–0 DPS[6:0]	EEPROM Protection Size — The DPS bits determine the size of the protected area in the EEPROM memory as shown in Table 20-25 .

Table 20-25. EEPROM Protection Address Range

DPS[6:0]	Global Address Range	Protected Size
0000000	0x10_0000 – 0x10_001F	32 bytes
0000001	0x10_0000 – 0x10_003F	64 bytes
0000010	0x10_0000 – 0x10_005F	96 bytes
0000011	0x10_0000 – 0x10_007F	128 bytes
0000100	0x10_0000 – 0x10_009F	160 bytes
The Protection Size goes on enlarging in step of 32 bytes, for each DPS value increment .		
0001111	0x10_0000 – 0x10_01FF	512 bytes
0011111	0x10_0000 – 0x10_03FF	1K byte
0111111	0x10_0000 – 0x10_07FF	2K bytes
1111111	0x10_0000 – 0x10_0FFF	4K bytes

The number of DPS bits depends on the size of the implemented EEPROM. The whole implemented EEPROM range can always be protected. Each DPS value increment increases the size of the protected range by 32-bytes. Thus to protect a 1 KB range DPS[4:0] must be set (protected range of 32 x 32 bytes).

20.3.2.11 Flash Option Register (FOPT)

The FOPT register is the Flash option register.

Offset Module Base + 0x000A

Figure 20-16. Flash Option Register (FOPT)

1. Loaded from Flash configuration field, during reset sequence.

All bits in the FOPT register are readable but can only be written in special mode.

During the reset sequence, the FOPT register is loaded from the Flash nonvolatile byte in the Flash configuration field at global address 0xFF_FE0E located in P-Flash memory (see Table 20-4) as indicated by reset condition F in Figure 20-16. If a double bit fault is detected while reading the P-Flash phrase containing the Flash nonvolatile byte during the reset sequence, all bits in the FOPT register will be set.

Table 20-26. FOPT Field Descriptions

Field	Description
7–0 NV[7:0]	Nonvolatile Bits — The NV[7:0] bits are available as nonvolatile bits. Refer to the device overview for proper use of the NV bits.

20.3.2.12 Flash Reserved1 Register (FRSV1)

This Flash register is reserved for factory testing.

Offset Module Base + 0x000B

Figure 20-17. Flash Reserved1 Register (FRSV1)

All bits in the FRSV1 register read 0 and are not writable.

20.3.2.13 Flash Common Command Object Registers (FCCOB)

The FCCOB is an array of six words. Byte wide reads and writes are allowed to the FCCOB registers.

Offset Module Base + 0x000C

Figure 20-18. Flash Common Command Object 0 High Register (FCCOB0HI)

Offset Module Base + 0x000D

Figure 20-19. Flash Common Command Object 0 Low Register (FCCOB0LO)

Figure 20-28. Flash Common Command Object 5 High Register (FCCOB5HI)

Offset Module Base + 0x0017

Figure 20-29. Flash Common Command Object 5 Low Register (FCCOB5LO)

20.3.2.13.1 FCCOB - NVM Command Mode

NVM command mode uses the FCCOB registers to provide a command code and its relevant parameters to the Memory Controller. The user first sets up all required FCCOB fields and then initiates the command's execution by writing a 1 to the CCIF bit in the FSTAT register (a 1 written by the user clears the CCIF command completion flag to 0). When the user clears the CCIF bit in the FSTAT register all FCCOB parameter fields are locked and cannot be changed by the user until the command completes (as evidenced by the Memory Controller returning CCIF to 1). Some commands return information to the FCCOB register array.

The generic format for the FCCOB parameter fields in NVM command mode is shown in [Table 20-27](#). The return values are available for reading after the CCIF flag in the FSTAT register has been returned to 1 by the Memory Controller. The value written to the FCCOBIX field must reflect the amount of CCOB words loaded for command execution.

[Table 20-27](#) shows the generic Flash command format. The high byte of the first word in the CCOB array contains the command code, followed by the parameters for this specific Flash command. For details on the FCCOB settings required by each command, see the Flash command descriptions in [Section 20.4.7](#).

Table 20-27. FCCOB - NVM Command Mode (Typical Usage)

CCOBIX[2:0]	Register	Byte	FCCOB Parameter Fields (NVM Command Mode)
000	FCCOB0	HI	FCMD[7:0] defining Flash command
		LO	Global address [23:16]
001	FCCOB1	HI	Global address [15:8]
		LO	Global address [7:0]
010	FCCOB2	HI	Data 0 [15:8]
		LO	Data 0 [7:0]

Table 20-27. FCCOB - NVM Command Mode (Typical Usage)

CCOBIX[2:0]	Register	Byte	FCCOB Parameter Fields (NVM Command Mode)
011	FCCOB3	HI	Data 1 [15:8]
		LO	Data 1 [7:0]
100	FCCOB4	HI	Data 2 [15:8]
		LO	Data 2 [7:0]
101	FCCOB5	HI	Data 3 [15:8]
		LO	Data 3 [7:0]

20.4 Functional Description

20.4.1 Modes of Operation

The module provides the modes of operation normal and special. The operating mode is determined by module-level inputs and affects the FCLKDIV, FCNFG, and DFPROT registers (see [Table 20-29](#)).

20.4.2 IFR Version ID Word

The version ID word is stored in the IFR at address 0x1F_C0B6. The contents of the word are defined in [Table 20-28](#).

Table 20-28. IFR Version ID Fields

[15:4]	[3:0]
Reserved	VERNUM

- VERNUM: Version number. The first version is number 0b_0001 with both 0b_0000 and 0b_1111 meaning 'none'.

20.4.3 Flash Block Read Access

If data read from the Flash block results in a double-bit fault ECC error (meaning that data is detected to be in error and cannot be corrected), the read data will be tagged as invalid during that access (please look

into the Reference Manual for details). Forcing the DFDF status bit by setting FDFD (see [Section 20.3.2.5](#)) has effect only on the DFDF status bit value and does not result in an invalid access.

To guarantee the proper read timing from the Flash array, the Flash will control (i.e. pause) the S12Z core accesses, considering that the MCU can be configured to fetch data at a faster frequency than the Flash block can support. Right after reset the Flash will be configured to run with the maximum amount of wait-states enabled; if the user application is setup to run at a slower frequency the control bits FCNFG[WSTAT] (see [Section 20.3.2.5](#)) can be configured by the user to disable the generation of wait-states, so it does not impose a performance penalty to the system if the read timing of the S12Z core is setup to be within the margins of the Flash block. For a definition of the frequency values where wait-states can be disabled please refer to the device electrical parameters.

The following sequence must be followed when the transition from a higher frequency to a lower frequency is going to happen:

- Flash resets with wait-states enabled;
- system frequency must be configured to the lower target;
- user writes to FNCNF[WSTAT] to disable wait-states;
- user reads the value of FPSTAT[WSTATACK], the new wait-state configuration will be effective when it reads as 1;
- user must re-write FCLKDIV to set a new value based on the lower frequency.

The following sequence must be followed on the contrary direction, going from a lower frequency to a higher frequency:

- user writes to FCNFG[WSTAT] to enable wait-states;
- user reads the value of FPSTAT[WSTATACK], the new wait-state configuration will be effective when it reads as 1;
- user must re-write FCLKDIV to set a new value based on the higher frequency;
- system frequency must be set to the upper target.

CAUTION

If the application is going to require the frequency setup to change, the value to be loaded on register FCLKDIV will have to be updated according to the new frequency value. In this scenario the application must take care to avoid locking the value of the FCLKDIV register: bit FDIVLCK must not be set if the value to be loaded on FDIV is going to be re-written, otherwise a reset is going to be required. Please refer to [Section 20.3.2.1](#), “Flash Clock Divider Register (FCLKDIV)” and [Section 20.4.5.1](#), “Writing the FCLKDIV Register”.

20.4.4 Internal NVM resource

IFR is an internal NVM resource readable by CPU. The IFR fields are shown in [Table 20-5](#).

The NVM Resource Area global address map is shown in [Table 20-6](#).

20.4.5 Flash Command Operations

Flash command operations are used to modify Flash memory contents.

The next sections describe:

- How to write the FCLKDIV register that is used to generate a time base (FCLK) derived from BUSCLK for Flash program and erase command operations
- The command write sequence used to set Flash command parameters and launch execution
- Valid Flash commands available for execution, according to MCU functional mode and MCU security state.

20.4.5.1 Writing the FCLKDIV Register

Prior to issuing any Flash program or erase command after a reset, the user is required to write the FCLKDIV register to divide BUSCLK down to a target FCLK of 1 MHz. [Table 20-8](#) shows recommended values for the FDIV field based on BUSCLK frequency.

NOTE

Programming or erasing the Flash memory cannot be performed if the bus clock runs at less than 0.8 MHz. Setting FDIV too high can destroy the Flash memory due to overstress. Setting FDIV too low can result in incomplete programming or erasure of the Flash memory cells.

When the FCLKDIV register is written, the FDIVLD bit is set automatically. If the FDIVLD bit is 0, the FCLKDIV register has not been written since the last reset. If the FCLKDIV register has not been written, any Flash program or erase command loaded during a command write sequence will not execute and the ACCERR bit in the FSTAT register will set.

20.4.5.2 Command Write Sequence

The Memory Controller will launch all valid Flash commands entered using a command write sequence.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be clear (see [Section 20.3.2.7](#)) and the CCIF flag should be tested to determine the status of the current command write sequence. If CCIF is 0, the previous command write sequence is still active, a new command write sequence cannot be started, and all writes to the FCCOB register are ignored.

20.4.5.2.1 Define FCCOB Contents

The FCCOB parameter fields must be loaded with all required parameters for the Flash command being executed. The CCOBIX bits in the FCCOBIX register must reflect the amount of words loaded into the FCCOB registers (see [Section 20.3.2.3](#)).

The contents of the FCCOB parameter fields are transferred to the Memory Controller when the user clears the CCIF command completion flag in the FSTAT register (writing 1 clears the CCIF to 0). The CCIF flag will remain clear until the Flash command has completed. Upon completion, the Memory Controller will return CCIF to 1 and the FCCOB register will be used to communicate any results. The flow for a generic command write sequence is shown in [Figure 20-30](#).

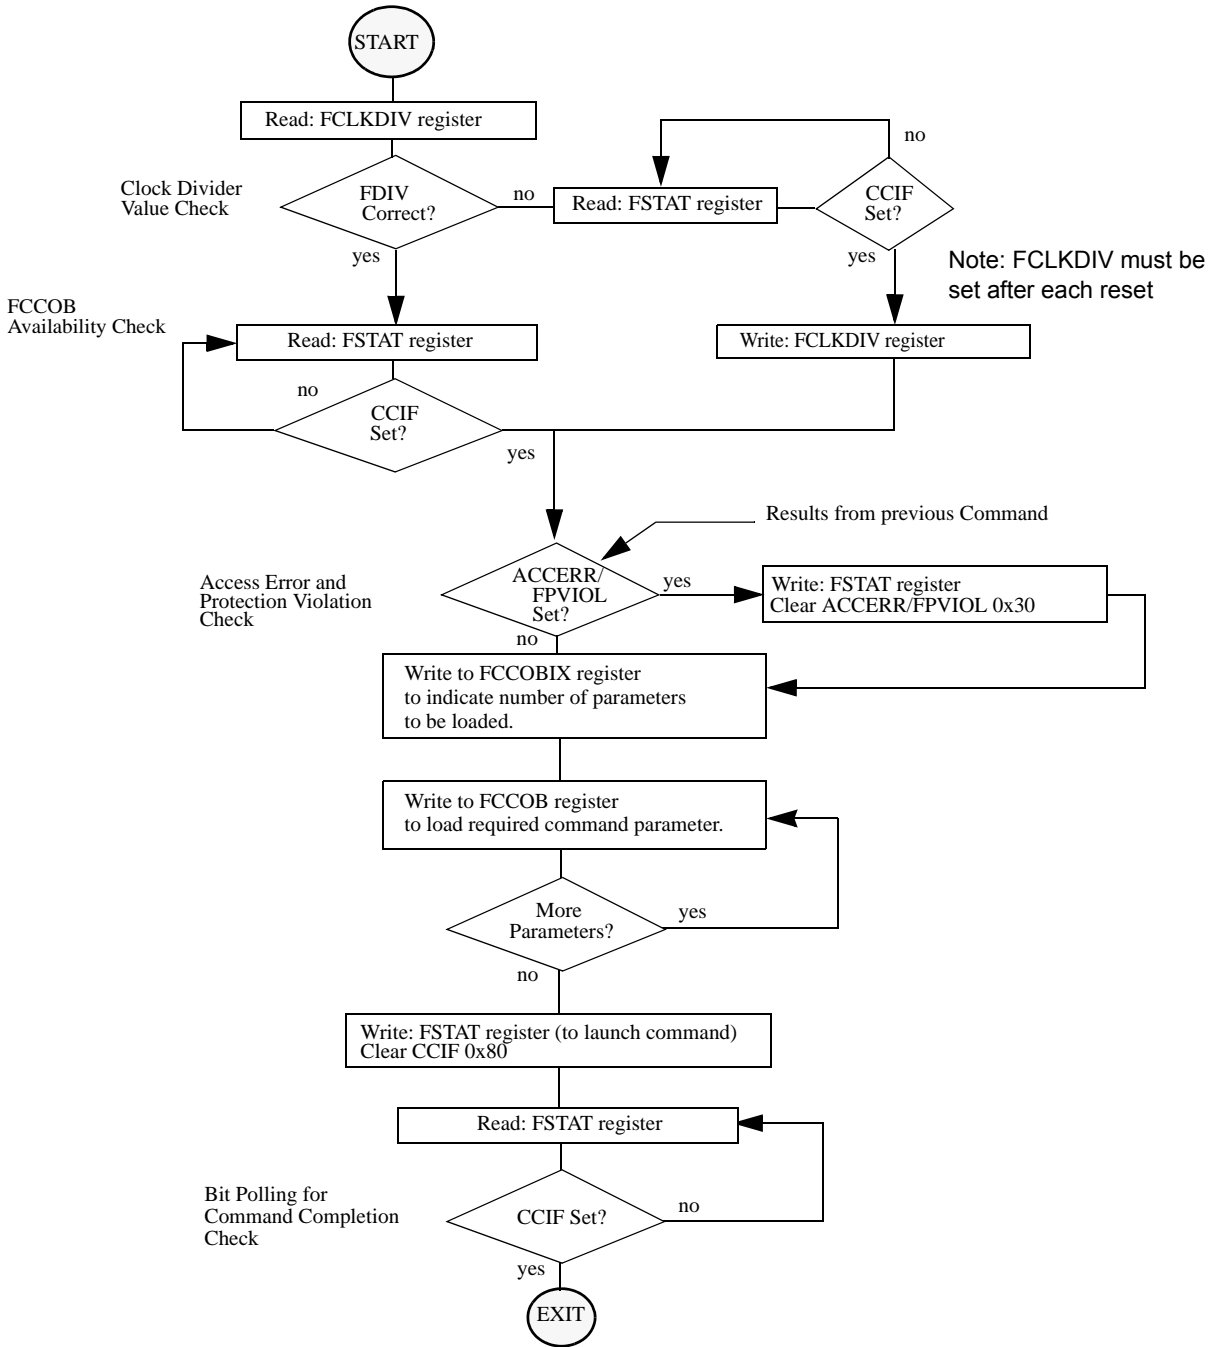

Figure 20-30. Generic Flash Command Write Sequence Flowchart

20.4.5.3 Valid Flash Module Commands

Table 20-29 present the valid Flash commands, as enabled by the combination of the functional MCU mode (Normal SingleChip NS, Special Singlechip SS) with the MCU security state (Unsecured, Secured).

Table 20-29. Flash Commands by Mode and Security State

FCMD	Command	Unsecured		Secured	
		NS (1)	SS ⁽²⁾	NS (3)	SS ⁽⁴⁾
0x01	Erase Verify All Blocks	*	*	*	*
0x02	Erase Verify Block	*	*	*	*
0x03	Erase Verify P-Flash Section	*	*	*	
0x04	Read Once	*	*	*	
0x06	Program P-Flash	*	*	*	
0x07	Program Once	*	*	*	
0x08	Erase All Blocks		*		*
0x09	Erase Flash Block	*	*	*	
0x0A	Erase P-Flash Sector	*	*	*	
0x0B	Unsecure Flash		*		*
0x0C	Verify Backdoor Access Key	*		*	
0x0D	Set User Margin Level	*	*	*	
0x0E	Set Field Margin Level		*		
0x10	Erase Verify EEPROM Section	*	*	*	
0x11	Program EEPROM	*	*	*	
0x12	Erase EEPROM Sector	*	*	*	
0x13	Protection Override	*	*	*	*

1. Unsecured Normal Single Chip mode

2. Unsecured Special Single Chip mode.

3. Secured Normal Single Chip mode.

4. Secured Special Single Chip mode.

20.4.5.4 P-Flash Commands

Table 20-30 summarizes the valid P-Flash commands along with the effects of the commands on the P-Flash block and other resources within the Flash module.

Table 20-30. P-Flash Commands

FCMD	Command	Function on P-Flash Memory
0x01	Erase Verify All Blocks	Verify that all P-Flash (and EEPROM) blocks are erased.
0x02	Erase Verify Block	Verify that a P-Flash block is erased.
0x03	Erase Verify P-Flash Section	Verify that a given number of words starting at the address provided are erased.
0x04	Read Once	Read a dedicated 64 byte field in the nonvolatile information register in P-Flash block that was previously programmed using the Program Once command.
0x06	Program P-Flash	Program a phrase in a P-Flash block.
0x07	Program Once	Program a dedicated 64 byte field in the nonvolatile information register in P-Flash block that is allowed to be programmed only once.
0x08	Erase All Blocks	Erase all P-Flash (and EEPROM) blocks. An erase of all Flash blocks is only possible when the FPLDIS, FPHDIS, and FPOPEN bits in the FPROT register and the DPOPEN bit in the DFPROT register are set prior to launching the command.
0x09	Erase Flash Block	Erase a P-Flash (or EEPROM) block. An erase of the full P-Flash block is only possible when FPLDIS, FPHDIS and FPOPEN bits in the FPROT register are set prior to launching the command.
0x0A	Erase P-Flash Sector	Erase all bytes in a P-Flash sector.
0x0B	Unsecure Flash	Supports a method of releasing MCU security by erasing all P-Flash (and EEPROM) blocks and verifying that all P-Flash (and EEPROM) blocks are erased.
0x0C	Verify Backdoor Access Key	Supports a method of releasing MCU security by verifying a set of security keys.
0x0D	Set User Margin Level	Specifies a user margin read level for all P-Flash blocks.
0x0E	Set Field Margin Level	Specifies a field margin read level for all P-Flash blocks (special modes only).
0x13	Protection Override	Supports a mode to temporarily override Protection configuration (for P-Flash and/or EEPROM) by verifying a key.

20.4.5.5 EEPROM Commands

Table 20-31 summarizes the valid EEPROM commands along with the effects of the commands on the EEPROM block.

Table 20-31. EEPROM Commands

FCMD	Command	Function on EEPROM Memory
0x01	Erase Verify All Blocks	Verify that all EEPROM (and P-Flash) blocks are erased.
0x02	Erase Verify Block	Verify that the EEPROM block is erased.
0x08	Erase All Blocks	Erase all EEPROM (and P-Flash) blocks. An erase of all Flash blocks is only possible when the FPLDIS, FPHDIS, and FPOPEN bits in the FPROT register and the DPOPEN bit in the DFPROT register are set prior to launching the command.
0x09	Erase Flash Block	Erase a EEPROM (or P-Flash) block. An erase of the full EEPROM block is only possible when DPOPEN bit in the DFPROT register is set prior to launching the command.
0x0B	Unsecure Flash	Supports a method of releasing MCU security by erasing all EEPROM (and P-Flash) blocks and verifying that all EEPROM (and P-Flash) blocks are erased.
0x0D	Set User Margin Level	Specifies a user margin read level for the EEPROM block.
0x0E	Set Field Margin Level	Specifies a field margin read level for the EEPROM block (special modes only).
0x10	Erase Verify EEPROM Section	Verify that a given number of words starting at the address provided are erased.
0x11	Program EEPROM	Program up to four words in the EEPROM block.
0x12	Erase EEPROM Sector	Erase all bytes in a sector of the EEPROM block.
0x13	Protection Override	Supports a mode to temporarily override Protection configuration (for P-Flash and/or EEPROM) by verifying a key.

20.4.6 Allowed Simultaneous P-Flash and EEPROM Operations

Only the operations marked 'OK' in [Table 20-32](#) are permitted to be run simultaneously on **combined** Program Flash and EEPROM blocks. Some operations cannot be executed simultaneously because certain hardware resources are shared by the two memories. The priority has been placed on permitting Program Flash reads while program and erase operations execute on the EEPROM, providing read (P-Flash) while write (EEPROM) functionality. Any attempt to access P-Flash and EEPROM simultaneously when it is not allowed will result in an illegal access that will trigger a machine exception in the CPU (see device information for details). Please note that during the execution of each command there is a period, before the operation in the Flash array actually starts, where reading is allowed and valid data is returned. Even if the simultaneous operation is marked as not allowed the Flash will report an illegal access only in the cycle the read collision actually happens, maximizing the time the array is available for reading.

If more than one hardblock exists on a device, then read operations on one hardblock are permitted whilst program or erase operations are executed on the other hardblock.

Table 20-32. Allowed P-Flash and EEPROM Simultaneous Operations on a single hardblock

Program Flash	EEPROM				
	Read	Margin Read ²	Program	Sector Erase	Mass Erase ²
Read	OK ⁽¹⁾	OK	OK	OK	
Margin Read ⁽²⁾					
Program					
Sector Erase					
Mass Erase ⁽³⁾					OK

1. Strictly speaking, only one read of either the P-Flash or EEPROM can occur at any given instant, but the memory controller will transparently arbitrate P-Flash and EEPROM accesses giving uninterrupted read access whenever possible.
2. A 'Margin Read' is any read after executing the margin setting commands 'Set User Margin Level' or 'Set Field Margin Level' with anything but the 'normal' level specified. See the Note on margin settings in [Section 20.4.7.12](#) and [Section 20.4.7.13](#).
3. The 'Mass Erase' operations are commands 'Erase All Blocks' and 'Erase Flash Block'

20.4.7 Flash Command Description

This section provides details of all available Flash commands launched by a command write sequence. The ACCERR bit in the FSTAT register will be set during the command write sequence if any of the following illegal steps are performed, causing the command not to be processed by the Memory Controller:

- Starting any command write sequence that programs or erases Flash memory before initializing the FCLKDIV register
- Writing an invalid command as part of the command write sequence
- For additional possible errors, refer to the error handling table provided for each command

If a Flash block is read during execution of an algorithm (CCIF = 0) on that same block, the read operation may return invalid data resulting in an illegal access (as described on [Section 20.4.6](#)).

If the ACCERR or FPVIOL bits are set in the FSTAT register, the user must clear these bits before starting any command write sequence (see [Section 20.3.2.7](#)).

CAUTION

A Flash word or phrase must be in the erased state before being programmed. Cumulative programming of bits within a Flash word or phrase is not allowed.

20.4.7.1 Erase Verify All Blocks Command

The Erase Verify All Blocks command will verify that all P-Flash and EEPROM blocks have been erased.

Table 20-33. Erase Verify All Blocks Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x01	Not required

Upon clearing CCIF to launch the Erase Verify All Blocks command, the Memory Controller will verify that the entire Flash memory space is erased. The CCIF flag will set after the Erase Verify All Blocks operation has completed. If all blocks are not erased, it means blank check failed, both MGSTAT bits will be set.

Table 20-34. Erase Verify All Blocks Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 000 at command launch
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the read or if blank check failed .
	MGSTAT0	Set if any non-correctable errors have been encountered during the read or if blank check failed.

20.4.7.2 Erase Verify Block Command

The Erase Verify Block command allows the user to verify that an entire P-Flash or EEPROM block has been erased.

Table 20-35. Erase Verify Block Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x02	Global address [23:16] to identify Flash block
FCCOB1	Global address [15:0] to identify Flash block	

Upon clearing CCIF to launch the Erase Verify Block command, the Memory Controller will verify that the selected P-Flash or EEPROM block is erased. The CCIF flag will set after the Erase Verify Block operation has completed. If the block is not erased, it means blank check failed, both MGSTAT bits will be set.

Table 20-36. Erase Verify Block Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if an invalid global address [23:0] is supplied see Table 20-3)
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the read or if blank check failed.
	MGSTAT0	Set if any non-correctable errors have been encountered during the read or if blank check failed.

20.4.7.3 Erase Verify P-Flash Section Command

The Erase Verify P-Flash Section command will verify that a section of code in the P-Flash memory is erased. The Erase Verify P-Flash Section command defines the starting point of the code to be verified and the number of phrases.

Table 20-37. Erase Verify P-Flash Section Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x03	Global address [23:16] of a P-Flash block
FCCOB1	Global address [15:0] of the first phrase to be verified	
FCCOB2	Number of phrases to be verified	

Upon clearing CCIF to launch the Erase Verify P-Flash Section command, the Memory Controller will verify the selected section of Flash memory is erased. The CCIF flag will set after the Erase Verify P-Flash Section operation has completed. If the section is not erased, it means blank check failed, both MGSTAT bits will be set.

Table 20-38. Erase Verify P-Flash Section Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 010 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied see Table 20-3)
		Set if a misaligned phrase address is supplied (global address [2:0] != 000)
		Set if the requested section crosses a the P-Flash address boundary
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the read or if blank check failed.
	MGSTAT0	Set if any non-correctable errors have been encountered during the read or if blank check failed.

20.4.7.4 Read Once Command

The Read Once command provides read access to a reserved 64 byte field (8 phrases) located in the nonvolatile information register of P-Flash. The Read Once field is programmed using the Program Once command described in [Section 20.4.7.6](#). The Read Once command must not be executed from the Flash block containing the Program Once reserved field to avoid code runaway.

Table 20-39. Read Once Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x04	Not Required
FCCOB1	Read Once phrase index (0x0000 - 0x0007)	
FCCOB2	Read Once word 0 value	
FCCOB3	Read Once word 1 value	
FCCOB4	Read Once word 2 value	
FCCOB5	Read Once word 3 value	

Upon clearing CCIF to launch the Read Once command, a Read Once phrase is fetched and stored in the FCCOB indexed register. The CCIF flag will set after the Read Once operation has completed. Valid phrase index values for the Read Once command range from 0x0000 to 0x0007. During execution of the Read Once command, any attempt to read addresses within P-Flash block will return invalid data.

Table 20-40. Read Once Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid phrase index is supplied
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the read
	MGSTAT0	Set if any non-correctable errors have been encountered during the read

20.4.7.5 Program P-Flash Command

The Program P-Flash operation will program a previously erased phrase in the P-Flash memory using an embedded algorithm.

CAUTION

A P-Flash phrase must be in the erased state before being programmed. Cumulative programming of bits within a Flash phrase is not allowed.

Table 20-41. Program P-Flash Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x06	Global address [23:16] to identify P-Flash block
FCCOB1	Global address [15:0] of phrase location to be programmed ⁽¹⁾	
FCCOB2	Word 0 program value	
FCCOB3	Word 1 program value	
FCCOB4	Word 2 program value	
FCCOB5	Word 3 program value	

1. Global address [2:0] must be 000

Upon clearing CCIF to launch the Program P-Flash command, the Memory Controller will program the data words to the supplied global address and will then proceed to verify the data words read back as expected. The CCIF flag will set after the Program P-Flash operation has completed.

Table 20-42. Program P-Flash Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 101 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied see Table 20-3)
		Set if a misaligned phrase address is supplied (global address [2:0] != 000)
	FPVIOL	Set if the global address [17:0] points to a protected area
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation

20.4.7.6 Program Once Command

The Program Once command restricts programming to a reserved 64 byte field (8 phrases) in the nonvolatile information register located in P-Flash. The Program Once reserved field can be read using the Read Once command as described in [Section 20.4.7.4](#). The Program Once command must only be issued once since the nonvolatile information register in P-Flash cannot be erased. The Program Once command must not be executed from the Flash block containing the Program Once reserved field to avoid code runaway.

Table 20-43. Program Once Command FCCOB Requirements

CCOBIX[2:0]	FCCOB Parameters	
FCCOB0	0x07	Not Required
FCCOB1	Program Once phrase index (0x0000 - 0x0007)	
FCCOB2	Program Once word 0 value	

Table 20-43. Program Once Command FCCOB Requirements

CCOBIX[2:0]	FCCOB Parameters
FCCOB3	Program Once word 1 value
FCCOB4	Program Once word 2 value
FCCOB5	Program Once word 3 value

Upon clearing CCIF to launch the Program Once command, the Memory Controller first verifies that the selected phrase is erased. If erased, then the selected phrase will be programmed and then verified with read back. The CCIF flag will remain clear, setting only after the Program Once operation has completed.

The reserved nonvolatile information register accessed by the Program Once command cannot be erased and any attempt to program one of these phrases a second time will not be allowed. Valid phrase index values for the Program Once command range from 0x0000 to 0x0007. During execution of the Program Once command, any attempt to read addresses within P-Flash will return invalid data.

Table 20-44. Program Once Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 101 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid phrase index is supplied
		Set if the requested phrase has already been programmed ⁽¹⁾
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the verify operation
MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation	

1. If a Program Once phrase is initially programmed to 0xFFFF_FFFF_FFFF_FFFF, the Program Once command will be allowed to execute again on that same phrase.

20.4.7.7 Erase All Blocks Command

The Erase All Blocks operation will erase the entire P-Flash and EEPROM memory space.

Table 20-45. Erase All Blocks Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x08	Not required

Upon clearing CCIF to launch the Erase All Blocks command, the Memory Controller will erase the entire Flash memory space and verify that it is erased. If the Memory Controller verifies that the entire Flash memory space was properly erased, security will be released. During the execution of this command (CCIF=0) the user must not write to any Flash module register. The CCIF flag will set after the Erase All Blocks operation has completed.

Table 20-46. Erase All Blocks Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 000 at command launch
		Set if command not available in current mode (see Table 20-29)
	FPVIOL	Set if any area of the P-Flash or EEPROM memory is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation

20.4.7.7.1 Erase All Pin

The functionality of the Erase All Blocks command is also available in an uncommanded fashion from the *soc_erase_all_req* input pin on the Flash module. Refer to the Reference Manual for information on control of *soc_erase_all_req*.

The erase-all function requires the clock divider register FCLKDIV (see [Section 20.3.2.1](#)) to be loaded before invoking this function using *soc_erase_all_req* input pin. The FCLKDIV configuration for this feature is described at device level. If FCLKDIV is not properly set the erase-all operation will not execute and the ACCERR flag in FSTAT register will set. After the execution of the erase-all function the FCLKDIV register will be reset and the value of register FCLKDIV must be loaded before launching any other command afterwards.

Before invoking the erase-all function using the *soc_erase_all_req* pin, the ACCERR and FPVIOL flags in the FSTAT register must be clear. When invoked from *soc_erase_all_req* the erase-all function will erase all P-Flash memory and EEPROM memory space regardless of the protection settings. If the post-erase verify passes, the routine will then release security by setting the SEC field of the FSEC register to the unsecure state (see [Section 20.3.2.2](#)). The security byte in the Flash Configuration Field will be programmed to the unsecure state (see [Table 20-9](#)). The status of the erase-all request is reflected in the ERSAREQ bit in the FCNFG register (see [Section 20.3.2.5](#)). The ERSAREQ bit in FCNFG will be cleared once the operation has completed and the normal FSTAT error reporting will be available as described in [Table 20-47](#).

At the end of the erase-all sequence Protection will remain configured as it was before executing the erase-all function. If the application requires programming P-Flash and/or EEPROM after the erase-all function completes, the existing protection limits must be taken into account. If protection needs to be disabled the user may need to reset the system right after completing the erase-all function.

Table 20-47. Erase All Pin Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if command not available in current mode (see Table 20-29)
	MGSTAT1	Set if any errors have been encountered during the erase verify operation, or during the program verify operation
	MGSTAT0	Set if any non-correctable errors have been encountered during the erase verify operation, or during the program verify operation

20.4.7.8 Erase Flash Block Command

The Erase Flash Block operation will erase all addresses in a P-Flash or EEPROM block.

Table 20-48. Erase Flash Block Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x09	Global address [23:16] to identify Flash block
FCCOB1	Global address [15:0] in Flash block to be erased	

Upon clearing CCIF to launch the Erase Flash Block command, the Memory Controller will erase the selected Flash block and verify that it is erased. The CCIF flag will set after the Erase Flash Block operation has completed.

Table 20-49. Erase Flash Block Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied
		Set if the supplied P-Flash address is not phrase-aligned or if the EEPROM address is not word-aligned
	FPVIOL	Set if an area of the selected Flash block is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation

20.4.7.9 Erase P-Flash Sector Command

The Erase P-Flash Sector operation will erase all addresses in a P-Flash sector.

Table 20-50. Erase P-Flash Sector Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x0A	Global address [23:16] to identify P-Flash block to be erased
FCCOB1	Global address [15:0] anywhere within the sector to be erased. Refer to Section 20.1.2.1 for the P-Flash sector size.	

Upon clearing CCIF to launch the Erase P-Flash Sector command, the Memory Controller will erase the selected Flash sector and then verify that it is erased. The CCIF flag will be set after the Erase P-Flash Sector operation has completed.

Table 20-51. Erase P-Flash Sector Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied see Table 20-3)
		Set if a misaligned phrase address is supplied (global address [2:0] != 000)
	FPVIOL	Set if the selected P-Flash sector is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation	

20.4.7.10 Unsecure Flash Command

The Unsecure Flash command will erase the entire P-Flash and EEPROM memory space and, if the erase is successful, will release security.

Table 20-52. Unsecure Flash Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x0B	Not required

Upon clearing CCIF to launch the Unsecure Flash command, the Memory Controller will erase the entire P-Flash and EEPROM memory space and verify that it is erased. If the Memory Controller verifies that the entire Flash memory space was properly erased, security will be released. If the erase verify is not successful, the Unsecure Flash operation sets MGSTAT1 and terminates without changing the security state. During the execution of this command (CCIF=0) the user must not write to any Flash module register. The CCIF flag is set after the Unsecure Flash operation has completed.

Table 20-53. Unsecure Flash Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 000 at command launch
		Set if command not available in current mode (see Table 20-29)
	FPVIOL	Set if any area of the P-Flash or EEPROM memory is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation

20.4.7.11 Verify Backdoor Access Key Command

The Verify Backdoor Access Key command will only execute if it is enabled by the KEYEN bits in the FSEC register (see [Table 20-10](#)). The Verify Backdoor Access Key command releases security if user-supplied keys match those stored in the Flash security bytes of the Flash configuration field (see [Table 20-](#)

4). The Verify Backdoor Access Key command must not be executed from the Flash block containing the backdoor comparison key to avoid code runaway.

Table 20-54. Verify Backdoor Access Key Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x0C	Not required
FCCOB1	Key 0	
FCCOB2	Key 1	
FCCOB3	Key 2	
FCCOB4	Key 3	

Upon clearing CCIF to launch the Verify Backdoor Access Key command, the Memory Controller will check the FSEC KEYEN bits to verify that this command is enabled. If not enabled, the Memory Controller sets the ACCERR bit in the FSTAT register and terminates. If the command is enabled, the Memory Controller compares the key provided in FCCOB to the backdoor comparison key in the Flash configuration field with Key 0 compared to 0xFF_FE00, etc. If the backdoor keys match, security will be released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are aborted (set ACCERR) until a reset occurs. The CCIF flag is set after the Verify Backdoor Access Key operation has completed.

Table 20-55. Verify Backdoor Access Key Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 100 at command launch
		Set if an incorrect backdoor key is supplied
		Set if backdoor key access has not been enabled (KEYEN[1:0] != 10, see Section 20.3.2.2)
		Set if the backdoor key has mismatched since the last reset
	FPVIOL	None
	MGSTAT1	None
	MGSTAT0	None

20.4.7.12 Set User Margin Level Command

The Set User Margin Level command causes the Memory Controller to set the margin level for future read operations of the P-Flash or EEPROM block.

Table 20-56. Set User Margin Level Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x0D	Global address [23:16] to identify Flash block
FCCOB1	Global address [15:0] to identify Flash block	

Table 20-56. Set User Margin Level Command FCCOB Requirements

Register	FCCOB Parameters
FCCOB2	Margin level setting.

Upon clearing CCIF to launch the Set User Margin Level command, the Memory Controller will set the user margin level for the targeted block and then set the CCIF flag.

NOTE

When the EEPROM block is targeted, the EEPROM user margin levels are applied only to the EEPROM reads. However, when the P-Flash block is targeted, the P-Flash user margin levels are applied to both P-Flash and EEPROM reads. It is not possible to apply user margin levels to the P-Flash block only.

Valid margin level settings for the Set User Margin Level command are defined in [Table 20-57](#).

Table 20-57. Valid Set User Margin Level Settings

FCCOB2	Level Description
0x0000	Return to Normal Level
0x0001	User Margin-1 Level ⁽¹⁾
0x0002	User Margin-0 Level ⁽²⁾

1. Read margin to the erased state
2. Read margin to the programmed state

Table 20-58. Set User Margin Level Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 010 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied see Table 20-3)
		Set if an invalid margin level setting is supplied
	FPVIOL	None
	MGSTAT1	None
	MGSTAT0	None

NOTE

User margin levels can be used to check that Flash memory contents have adequate margin for normal level read operations. If unexpected results are encountered when checking Flash memory contents at user margin levels, a potential loss of information has been detected.

20.4.7.13 Set Field Margin Level Command

The Set Field Margin Level command, valid in special modes only, causes the Memory Controller to set the margin level specified for future read operations of the P-Flash or EEPROM block.

Table 20-59. Set Field Margin Level Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x0E	Global address [23:16] to identify Flash block
FCCOB1	Global address [15:0] to identify Flash block	
FCCOB2	Margin level setting.	

Upon clearing CCIF to launch the Set Field Margin Level command, the Memory Controller will set the field margin level for the targeted block and then set the CCIF flag.

NOTE

When the EEPROM block is targeted, the EEPROM field margin levels are applied only to the EEPROM reads. However, when the P-Flash block is targeted, the P-Flash field margin levels are applied to both P-Flash and EEPROM reads. It is not possible to apply field margin levels to the P-Flash block only.

Valid margin level settings for the Set Field Margin Level command are defined in [Table 20-60](#).

Table 20-60. Valid Set Field Margin Level Settings

FCCOB2	Level Description
0x0000	Return to Normal Level
0x0001	User Margin-1 Level ⁽¹⁾
0x0002	User Margin-0 Level ⁽²⁾
0x0003	Field Margin-1 Level ¹
0x0004	Field Margin-0 Level ²

1. Read margin to the erased state
2. Read margin to the programmed state

Table 20-61. Set Field Margin Level Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 010 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied see Table 20-3)
		Set if an invalid margin level setting is supplied
	FPVIOL	None
	MGSTAT1	None
	MGSTAT0	None

CAUTION

Field margin levels must only be used during verify of the initial factory programming.

NOTE

Field margin levels can be used to check that Flash memory contents have adequate margin for data retention at the normal level setting. If unexpected results are encountered when checking Flash memory contents at field margin levels, the Flash memory contents should be erased and reprogrammed.

20.4.7.14 Erase Verify EEPROM Section Command

The Erase Verify EEPROM Section command will verify that a section of code in the EEPROM is erased. The Erase Verify EEPROM Section command defines the starting point of the data to be verified and the number of words.

Table 20-62. Erase Verify EEPROM Section Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x10	Global address [23:16] to identify the EEPROM block
FCCOB1	Global address [15:0] of the first word to be verified	
FCCOB2	Number of words to be verified	

Upon clearing CCIF to launch the Erase Verify EEPROM Section command, the Memory Controller will verify the selected section of EEPROM memory is erased. The CCIF flag will set after the Erase Verify EEPROM Section operation has completed. If the section is not erased, it means blank check failed, both MGSTAT bits will be set.

Table 20-63. Erase Verify EEPROM Section Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 010 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied
		Set if a misaligned word address is supplied (global address [0] != 0)
		Set if the requested section breaches the end of the EEPROM block
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the read or if blank check failed.
MGSTAT0	Set if any non-correctable errors have been encountered during the read or if blank check failed.	

20.4.7.15 Program EEPROM Command

The Program EEPROM operation programs one to four previously erased words in the EEPROM block. The Program EEPROM operation will confirm that the targeted location(s) were successfully programmed upon completion.

CAUTION

A Flash word must be in the erased state before being programmed. Cumulative programming of bits within a Flash word is not allowed.

Table 20-64. Program EEPROM Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x11	Global address [23:16] to identify the EEPROM block
FCCOB1	Global address [15:0] of word to be programmed	
FCCOB2	Word 0 program value	
FCCOB3	Word 1 program value, if desired	
FCCOB4	Word 2 program value, if desired	
FCCOB5	Word 3 program value, if desired	

Upon clearing CCIF to launch the Program EEPROM command, the user-supplied words will be transferred to the Memory Controller and be programmed if the area is unprotected. The CCOBIX index value at Program EEPROM command launch determines how many words will be programmed in the EEPROM block. The CCIF flag is set when the operation has completed.

Table 20-65. Program EEPROM Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] < 010 at command launch
		Set if CCOBIX[2:0] > 101 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied
		Set if a misaligned word address is supplied (global address [0] != 0)
		Set if the requested group of words breaches the end of the EEPROM block
	FPVIOL	Set if the selected area of the EEPROM memory is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation	

20.4.7.16 Erase EEPROM Sector Command

The Erase EEPROM Sector operation will erase all addresses in a sector of the EEPROM block.

Table 20-66. Erase EEPROM Sector Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x12	Global address [23:16] to identify EEPROM block
FCCOB1	Global address [15:0] anywhere within the sector to be erased. See Section 20.1.2.2 for EEPROM sector size.	

Upon clearing CCIF to launch the Erase EEPROM Sector command, the Memory Controller will erase the selected Flash sector and verify that it is erased. The CCIF flag will set after the Erase EEPROM Sector operation has completed.

Table 20-67. Erase EEPROM Sector Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if command not available in current mode (see Table 20-29)
		Set if an invalid global address [23:0] is supplied see Table 20-3
		Set if a misaligned word address is supplied (global address [0] != 0)
	FPVIOL	Set if the selected area of the EEPROM memory is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any non-correctable errors have been encountered during the verify operation

20.4.7.17 Protection Override Command

The Protection Override command allows the user to temporarily override the protection limits, either decreasing, increasing or disabling protection limits, on P-Flash and/or EEPROM, if the comparison key provided as a parameter loaded on FCCOB matches the value of the key previously programmed on the Flash Configuration Field (see [Table 20-4](#)). The value of the Protection Override Comparison Key must not be 16'hFFFF, that is considered invalid and if used as argument will cause the Protection Override feature to be disabled. Any valid key value that does not match the value programmed in the Flash Configuration Field will cause the Protection Override feature to be disabled. Current status of the Protection Override feature can be observed on FPSTAT FPOVRD bit (see [Section 20.3.2.4](#), “Flash Protection Status Register (FPSTAT)”).

Table 20-68. Protection Override Command FCCOB Requirements

Register	FCCOB Parameters	
FCCOB0	0x13	Protection Update Selection [1:0] See Table 20-69
FCCOB1	Comparison Key	
FCCOB2	reserved	New FPROT value
FCCOB3	reserved	New DFPROT value

Table 20-69. Protection Override selection description

Protection Update Selection code [1:0]	Protection register selection
bit 0	Update P-Flash protection 0 - keep unchanged (do not update) 1 - update P-Flash protection with new FPROT value loaded on FCCOB
bit 1	Update EEPROM protection 0 - keep unchanged (do not update) 1 - update EEPROM protection with new DFPROT value loaded on FCCOB

If the comparison key successfully matches the key programmed in the Flash Configuration Field the Protection Override command will preserve the current values of registers FPROT and DFPROT stored in an internal area and will override these registers as selected by the Protection Update Selection field with the value(s) loaded on FCCOB parameters. The new values loaded into FPROT and/or DFPROT can reconfigure protection without any restriction (by increasing, decreasing or disabling protection limits). If the command executes successfully the FPSTAT FPOVRD bit will set.

If the comparison key does not match the key programmed in the Flash Configuration Field, or if the key loaded on FCCOB is 16'hFFFF, the value of registers FPROT and DFPROT will be restored to their original contents before executing the Protection Override command and the FPSTAT FPOVRD bit will be cleared. If the contents of the Protection Override Comparison Key in the Flash Configuration Field is left in the erased state (i.e. 16'hFFFF) the Protection Override feature is permanently disabled. If the command execution is flagged as an error (ACCERR being set for incorrect command launch) the values of FPROT and DFPROT will not be modified.

The Protection Override command can be called multiple times and every time it is launched it will preserve the current values of registers FPROT and DFPROT in a single-entry buffer to be restored later; when the Protection Override command is launched to restore FPROT and DFPROT these registers will assume the values they had before executing the Protection Override command on the last time. If contents of FPROT and/or DFPROT registers were modified by direct register writes while protection is overridden these modifications will be lost. Running Protection Override command to restore the contents of registers FPROT and DFPROT will not force them to the reset values.

Table 20-70. Protection Override Command Error Handling

Register	Error Bit	Error Condition
FSTAT	ACCERR	Set if CCOBIX[2:0] != (001, 010 or 011) at command launch.
		Set if command not available in current mode (see Table 20-29).
		Set if protection is supposed to be restored (if key does not match or is invalid) and Protection Override command was not run previously (bit FPSTAT FPOVRD is 0), so there are no previous valid values of FPROT and DFPROT to be re-loaded.
		Set if Protection Update Selection[1:0] = 00 (in case of CCOBIX[2:0] = 010 or 011)
		Set if Protection Update Selection[1:0] = 00, CCOBIX[2:0] = 001 and a valid comparison key is loaded as a command parameter.
	FPVIOL	None
	MGSTAT1	None
MGSTAT0	None	

20.4.8 Interrupts

The Flash module can generate an interrupt when a Flash command operation has completed or when a Flash command operation has detected an ECC fault.

Table 20-71. Flash Interrupt Sources

Interrupt Source	Interrupt Flag	Local Enable	Global (CCR) Mask
Flash Command Complete	CCIF (FSTAT register)	CCIE (FCNFG register)	I Bit
ECC Single Bit Fault on Flash Read	SFDIF (FERSTAT register)	SFDIE (FERCNFG register)	I Bit

NOTE

Vector addresses and their relative interrupt priority are determined at the MCU level.

20.4.8.1 Description of Flash Interrupt Operation

The Flash module uses the CCIF flag in combination with the CCIE interrupt enable bit to generate the Flash command interrupt request. The Flash module uses the SFDIF flag in combination with the SFDIE interrupt enable bits to generate the Flash error interrupt request. For a detailed description of the register bits involved, refer to [Section 20.3.2.5, “Flash Configuration Register \(FCNFG\)”](#), [Section 20.3.2.6, “Flash Error Configuration Register \(FERCNFG\)”](#), [Section 20.3.2.7, “Flash Status Register \(FSTAT\)”](#), and [Section 20.3.2.8, “Flash Error Status Register \(FERSTAT\)”](#).

The logic used for generating the Flash module interrupts is shown in [Figure 20-31](#).

Figure 20-31. Flash Module Interrupts Implementation

20.4.9 Wait Mode

The Flash module is not affected if the MCU enters wait mode. The Flash module can recover the MCU from wait via the CCIF interrupt (see [Section 20.4.8, “Interrupts”](#)).

20.4.10 Stop Mode

If a Flash command is active ($CCIF = 0$) when the MCU requests stop mode, the current Flash operation will be completed before the MCU is allowed to enter stop mode.

20.5 Security

The Flash module provides security information to the MCU. The Flash security state is defined by the SEC bits of the FSEC register (see [Table 20-11](#)). During reset, the Flash module initializes the FSEC register using data read from the security byte of the Flash configuration field at global address $0xFF_FE0F$. The security state out of reset can be permanently changed by programming the security byte assuming that the MCU is starting from a mode where the necessary P-Flash erase and program commands are available and that the upper region of the P-Flash is unprotected. If the Flash security byte is successfully programmed, its new value will take effect after the next MCU reset.

The following subsections describe these security-related subjects:

- Unsecuring the MCU using Backdoor Key Access
- Unsecuring the MCU in Special Single Chip Mode using BDM
- Mode and Security Effects on Flash Command Availability

20.5.1 Unsecuring the MCU using Backdoor Key Access

The MCU may be unsecured by using the backdoor key access feature which requires knowledge of the contents of the backdoor keys (four 16-bit words programmed at addresses 0xFF_FE00-0xFF_FE07). If the KEYEN[1:0] bits are in the enabled state (see [Section 20.3.2.2](#)), the Verify Backdoor Access Key command (see [Section 20.4.7.11](#)) allows the user to present four prospective keys for comparison to the keys stored in the Flash memory via the Memory Controller. If the keys presented in the Verify Backdoor Access Key command match the backdoor keys stored in the Flash memory, the SEC bits in the FSEC register (see [Table 20-11](#)) will be changed to unsecure the MCU. Key values of 0x0000 and 0xFFFF are not permitted as backdoor keys. While the Verify Backdoor Access Key command is active, P-Flash memory and EEPROM memory will not be available for read access and will return invalid data.

The user code stored in the P-Flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN[1:0] bits are in the enabled state (see [Section 20.3.2.2](#)), the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Section 20.4.7.11](#)
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the SEC[1:0] bits in the FSEC register are forced to the unsecure state of 10

The Verify Backdoor Access Key command is monitored by the Memory Controller and an illegal key will prohibit future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command. The security as defined in the Flash security byte (0xFF_FE0F) is not changed by using the Verify Backdoor Access Key command sequence. The backdoor keys stored in addresses 0xFF_FE00-0xFF_FE07 are unaffected by the Verify Backdoor Access Key command sequence. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the Flash protection register, FPROT.

After the backdoor keys have been correctly matched, the MCU will be unsecured. After the MCU is unsecured, the sector containing the Flash security byte can be erased and the Flash security byte can be reprogrammed to the unsecure state, if desired. In the unsecure state, the user has full control of the contents of the backdoor keys by programming addresses 0xFF_FE00-0xFF_FE07 in the Flash configuration field.

20.5.2 Unsecuring the MCU in Special Single Chip Mode using BDM

A secured MCU can be unsecured in special single chip mode using an automated procedure described in [Section 20.4.7.7.1](#), “Erase All Pin”.

20.5.3 Mode and Security Effects on Flash Command Availability

The availability of Flash module commands depends on the MCU operating mode and security state as shown in [Table 20-29](#).

20.6 Initialization

On each system reset the flash module executes an initialization sequence which establishes initial values for the Flash Block Configuration Parameters, the FPROT and DFPROT protection registers, and the FOPT and FSEC registers. The initialization routine reverts to built-in default values that leave the module in a fully protected and secured state if errors are encountered during execution of the reset sequence. If a double bit fault is detected during the reset sequence, both MGSTAT bits in the FSTAT register will be set.

CCIF is cleared throughout the initialization sequence. The Flash module holds off all CPU access for a portion of the initialization sequence. Flash reads are allowed once the hold is removed. Completion of the initialization sequence is marked by setting CCIF high which enables user commands.

If a reset occurs while any Flash command is in progress, that command will be immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed.

Chapter 21

CAN Physical Layer (S12CANPHYV3)

Table 21-1. Revision History Table

Revision Number	Revision Date	Sections Affected	Description of Changes
V02.00	05 Nov 2012		<ul style="list-style-type: none">• Added CPTXD-dominant timeout feature
V03.00	15 Apr 2013		<ul style="list-style-type: none">• Made transmit driver (CANH & CANL) independent of CPCHVL condition• Changed CPCLVL condition to disable CANL only• Added mode to cover separation of CANH and CANL drivers• Added configurable wake-up filter

NOTE

The information given in this section are preliminary and should be used as a guide only. Values in this section cannot be guaranteed and are subject to change without notice.

21.1 Introduction

The CAN Physical Layer provides a physical layer for high speed CAN area network communication in automotive applications. It serves as an integrated interface to the CAN bus lines for the internally connected MSCAN controller through the pins CANH, CANL and SPLIT.

The CAN Physical Layer is designed to meet the CAN Physical Layer ISO 11898-2 and ISO 11898-5 standards.

21.1.1 Features

The CAN Physical Layer module includes these distinctive features:

- High speed CAN interface for baud rates of up to 1 Mbit/s
- ISO 11898-2 and ISO 11898-5 compliant for 12 V battery systems
- SPLIT pin driver for bus recessive level stabilization
- Low power mode with remote CAN wake-up handled by MSCAN module
- Configurable wake-up pulse filtering
- Over-current shutdown for CANH and CANL
- Voltage monitoring on CANH and CANL
- CPTXD-dominant timeout feature monitoring the CPTXD signal
- Fulfills the OEM “Hardware Requirements for (LIN,) CAN (and FlexRay) Interfaces in Automotive Applications” v1.3

21.1.2 Modes of Operation

There are five modes the CAN Physical Layer can take (refer to 21.5.2 for details):

1. Shutdown mode
In shutdown mode the CAN Physical Layer is fully de-biased including the wake-up receiver.
 2. Normal mode
In normal mode the transceiver is fully biased and functional. The SPLIT pin drives 2.5 V if enabled.
 3. Pseudo-normal mode
Same as normal mode with CANL driver disabled.
 4. Listen-only mode
Same as normal mode with transmitter de-biased.
 5. Standby mode with configurable wake-up feature
In standby mode the transceiver is fully de-biased. The wake-up receiver is enabled out of reset.
- CPU Run Mode
The CAN Physical Layer is able to operate normally in modes 1 to 4.
 - CPU Wait Mode
The CAN Physical Layer operation is the same as in CPU run mode.
 - CPU Stop Mode
The CAN Physical Layer enters standby mode when the device voltage regulator switches to reduced performance mode (“RPM”) after a CPU stop mode request.
If enabled, the wake-up pulse filtering mechanism is activated immediately at CPU stop mode entry.

21.1.3 Block Diagram

Figure 21-1 shows a block diagram of the CAN Physical Layer. The module consists of a precision receiver, a low-power wake-up receiver, an output driver and diagnostics.

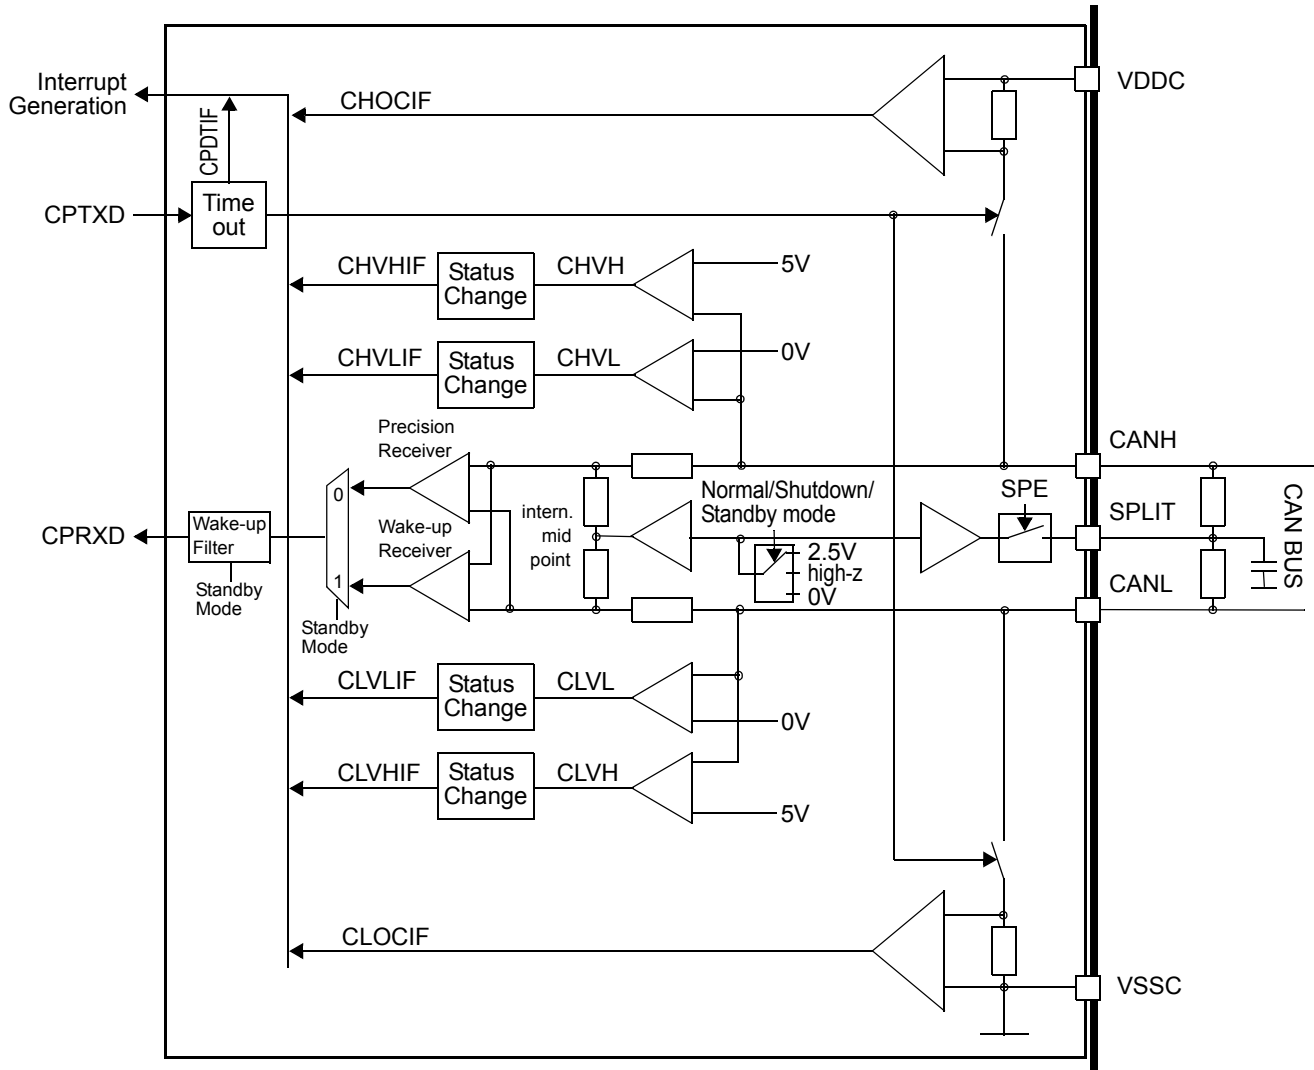

Figure 21-1. CAN Physical Layer Block Diagram

21.2 External Signal Description

Table 21-2 shows the external pins associated with the CAN Physical Layer.

Table 21-2. CAN Physical Layer Signal Properties

Name	Function
CANH	CAN Bus High Pin
SPLIT	2.5 V Termination Pin
CANL	CAN Bus Low Pin
VDDC	Supply Pin for CAN Physical Layer
VSSC	Ground Pin for CAN Physical Layer

21.2.1 CANH — CAN Bus High Pin

The CANH signal either connects directly to CAN bus high line or through an optional external common mode choke.

21.2.2 CANL — CAN Bus Low Pin

The CANL signal either connects directly to CAN bus low line or through an optional external common mode choke.

21.2.3 SPLIT — CAN Bus Termination Pin

The SPLIT pin can drive a 2.5 V bias for bus termination purpose (CAN bus middle point). Usage of this pin is optional and depends on bus termination strategy for a given bus network.

21.2.4 VDDC — Supply Pin for CAN Physical Layer

The VDDC pin is used to supply the CAN Physical Layer with 5 V from an external source.

21.2.5 VSSC — Ground Pin for CAN Physical Layer

The VSSC pin is the return path for the 5 V supply (VDDC).

21.3 Internal Signal Description

21.3.1 CPTXD — TXD Input to CAN Physical Layer

CPTXD is the input signal to the CAN Physical Layer. A logic 1 on this input is considered CAN recessive and a logic 0 as dominant level.

Per default, CPTXD is connected device-internally to the TXCAN transmitter output of the MSCAN module. For optional routing options consult the device level documentation.

21.3.2 CPRXD — RXD Output of CAN Physical Layer

CPRXD is the output signal of the CAN Physical Layer. A logic 1 on this output represents CAN recessive and a logic 0 a dominant level.

In stand-by mode the wake-up receiver is routed to this output. A dominant pulse filter can optionally be enabled to increase robustness against false wake-up pulses. In any other mode this signal defaults to the precision receiver without a pulse filter.

Per default, CPRXD is connected device-internally to the RXCAN receiver input of the MSCAN module. For optional routing options consult the device level documentation.

21.4 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the CAN Physical Layer.

21.4.1 Module Memory Map

A summary of the registers associated with the CAN Physical Layer sub-block is shown in [Table 21-3](#). Detailed descriptions of the registers and bits are given in the following sections.

NOTE

Register Address = Module Base Address + Address Offset, where the Module Base Address is defined at the MCU level and the Address Offset is defined at the module level.

Address Offset	Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000	CPDR	R	CPDR7	0	0	0	0	0	CPDR1	CPDR0

Table 21-3. CAN Physical Layer Register Summary

21.4.2 Register Descriptions

This section describes all CAN Physical Layer registers and their individual bits.

21.4.2.1 Port CP Data Register (CPDR)

Module Base + 0x0000

Access: User read/write⁽¹⁾

Figure 21-2. Port CP Data Register (CPDR)

- 1. Read: Anytime
- Write: Anytime

Table 21-4. CPDR Register Field Descriptions

Field	Description
7 CPDR7	Port CP Data Bit 7 Read-only bit. The synchronized CAN Physical Layer wake-up receiver output can be read at any time.
1 CPDR1	Port CP Data Bit 1 The CAN Physical Layer CPTXD input can be directly controlled through this register bit if routed here (see device-level specification). In this case the register bit value is driven to the pin. 0 CPTXD is driven low (dominant) 1 CPTXD is driven high (recessive)
0 CPDR0	Port CP Data Bit 0 Read-only bit. The synchronized CAN Physical Layer CPRXD output state can be read at any time.

21.4.2.2 CAN Physical Layer Control Register (CPCR)

Module Base + 0x0001

Access: User read/write⁽¹⁾

Figure 21-3. CAN Physical Layer Control Register (CPCR)

1. Read: Anytime

Write: Anytime except CPE which is set once

Table 21-5. CPCR Register Field Descriptions

Field	Description
7 CPE	CAN Physical Layer Enable Set once. If set to 1, the CAN Physical Layer exits shutdown mode and enters normal mode. 0 CAN Physical Layer is disabled (shutdown mode) 1 CAN Physical Layer is enabled
6 SPE	Split Enable If set to 1, the CAN Physical Layer SPLIT pin drives a 2.5 V bias in normal and listen-only mode. 0 SPLIT pin is high-impedance 1 SPLIT pin drives a 2.5 V bias
5-4 WUPE1-0	Wake-Up Receiver Enable and Filter Select If WUPE[1:0]≠0, the CAN Physical Layer wake-up receiver is enabled when not in shutdown mode. To save additional power, these bits should be set to 00, if the CAN bus is not used to wake up the device. For robustness against false wake-up an optional pulse filter can be enabled. 00 Wake-up receiver is disabled 10 Wake-up receiver is enabled, no filtering 01 Wake-up receiver is enabled, first wake-up event is masked 11 Wake-up receiver is enabled, first two wake-up events are masked
2-0 SLR2-0	Slew Rate The slew rate controls recessive to dominant and dominant to recessive transitions. This affects the delay time from CPTXD to the bus and from the bus to CPRXD. The loop time is thus affected by the slew rate selection. Six slew rates are available: 000 CAN Physical Layer slew rate 0 001 CAN Physical Layer slew rate 1 010 CAN Physical Layer slew rate 2 011 Reserved 100 CAN Physical Layer slew rate 4 101 CAN Physical Layer slew rate 5 110 CAN Physical Layer slew rate 6 111 Reserved

21.4.2.3 Reserved Register

Module Base + 0x0002

Access: User read/write⁽¹⁾

Figure 21-4. Reserved Register

- 1. Read: Anytime
Write: Only in special mode

NOTE

This reserved register is designed for factory test purposes only and is not intended for general user access. Writing to this register when in special modes can alter the modules functionality.

21.4.2.4 CAN Physical Layer Status Register (CPSR)

Module Base + 0x0003

Access: User read/write⁽¹⁾

Figure 21-5. CAN Physical Layer Status Register (CPSR)

- 1. Read: Anytime
Write: Never

Table 21-6. CPSR Register Field Descriptions

Field	Description
7 CPCHVH	CANH Voltage Failure High Status Bit This bit reflects the CANH voltage failure high monitor status. 0 Condition $V_{CANH} < V_{H5}$ 1 Condition $V_{CANH} \geq V_{H5}$
6 CPCHVL	CANH Voltage Failure Low Status Bit This bit reflects the CANH voltage failure low monitor status. 0 Condition $V_{CANH} > V_{H0}$ 1 Condition $V_{CANH} \leq V_{H0}$
5 CPCLVH	CANL Voltage Failure High Status Bit This bit reflects the CANL voltage failure high monitor status. 0 Condition $V_{CANL} < V_{L5}$ 1 Condition $V_{CANL} \geq V_{L5}$

Table 21-6. CPSR Register Field Descriptions

Field	Description
4 CPCLVL	<p>CANL Voltage Failure Low Status Bit This bit reflects the CANL voltage failure low monitor status.</p> <p>0 Condition $V_{CANL} > V_{L0}$ 1 Condition $V_{CANL} \leq V_{L0}$</p>
3 CPDT	<p>CPTXD-Dominant Timeout Status Bit This bit is set to 1, if CPTXD is dominant for longer than $t_{CPTXDDT}$. It signals a timeout event and remains set until CPTXD returns to recessive level for longer than 1 μs.</p> <p>0 No CPTXD-timeout occurred or CPTXD has ceased to be dominant after timeout 1 CPTXD-dominant timeout occurred and CPTXD is still dominant</p>

21.4.2.5 Reserved Register

Module Base + 0x0004

Access: User read/write⁽¹⁾

Figure 21-6. Reserved Register

- 1. Read: Anytime
Write: Only in special mode

NOTE

This reserved register is designed for factory test purposes only and is not intended for general user access. Writing to this register when in special modes can alter the modules functionality.

21.4.2.6 Reserved Register

Module Base + 0x0005

Access: User read/write⁽¹⁾

Figure 21-7. Reserved Register

- 1. Read: Anytime
Write: Only in special mode

NOTE

This reserved register is designed for factory test purposes only and is not intended for general user access. Writing to this register when in special modes can alter the modules functionality.

21.4.2.7 CAN Physical Layer Interrupt Enable Register (CPIE)

Module Base + 0x0006

Access: User read/write⁽¹⁾

Figure 21-8. CAN Physical Layer Interrupt Enable Register (CPIE)

- 1. Read: Anytime
Write: Anytime

Table 21-7. CPIE Register Field Descriptions

Field	Description
4 CPVFIE	CAN Physical Layer Voltage-Failure Interrupt Enable If enabled, the CAN Physical Layer generates an interrupt if any of the CAN Physical Layer voltage failure interrupt flags assert. 0 Voltage failure interrupt is disabled 1 Voltage failure interrupt is enabled
3 CPDTIE	CPTXD-Dominant Timeout Interrupt Enable If enabled, the CAN Physical Layer generates an interrupt if the CPTXD-dominant timeout interrupt flag asserts. 0 CPTXD-dominant timeout interrupt is disabled 1 CPTXD-dominant timeout interrupt is enabled
0 CPOCIE	CAN Physical Layer Over-current Interrupt Enable If enabled, the CAN Physical Layer generates an interrupt if any of the CAN Physical Layer over-current interrupt flags assert. 0 Over-current interrupt is disabled 1 Over-current interrupt is enabled

21.4.2.8 CAN Physical Layer Interrupt Flag Register (CPIF)

Module Base + 0x0007

Access: User read/write⁽¹⁾

Figure 21-9. CAN Physical Layer Interrupt Flag Register (CPIF)

1. Read: Anytime
Write: Anytime, write 1 to clear

If any of the flags is asserted an error interrupt is pending if enabled. A flag can be cleared by writing a logic level 1 to the corresponding bit location. Writing a 0 has no effect.

Table 21-8. CPIF Register Field Descriptions

Field	Description
7 CHVHIF	CANH Voltage Failure High Interrupt Flag This flag is set to 1 when the CPCHVH bit in the CAN Physical Layer Status Register (CPSR) changes. 0 No change in CPCHVH 1 CPCHVH has changed
6 CHVLIF	CANH Voltage Failure Low Interrupt Flag This flag is set to 1 when the CPCHVL bit in the CAN Physical Layer Status Register (CPSR) changes. 0 No change in CPCHVL 1 CPCHVL has changed

Table 21-8. CPIF Register Field Descriptions

Field	Description
5 CLVHIF	<p>CANL Voltage Failure High Interrupt Flag This flag is set to 1 when the CPCLVH bit in the CAN Physical Layer Status Register (CPSR) changes.</p> <p>0 No change in CPCLVH 1 CPCLVH has changed</p>
4 CLVLIF	<p>CANL Voltage Failure Low Interrupt Flag This flag is set to 1 when the CPCLVL bit in the CAN Physical Layer Status Register (CPSR) changes.</p> <p>0 No change in CPCLVL 1 CPCLVL has changed</p>
3 CPDTIF	<p>CAN CPTXD-Dominant Timeout Interrupt Flag This flag is set to 1 when CPTXD is dominant longer than $t_{CPTXDDT}$. It signals a timeout event and entry of listen-only mode disabling the transmitter. Exit of listen-only mode which was entered at timeout is requested by clearing CPDTIF when CPDT is clear after setting CPTXD to recessive state. It takes 1 to 2 μs to return to normal mode. If CPTXD is dominant or dominant timeout status is still active (CPDT=1) when clearing the flag, the CAN Physical Layer remains in listen-only mode and this flag is set again after a delay (see 21.5.4.2, "CPTXD-Dominant Timeout Interrupt").</p> <p>0 No CPTXD-dominant timeout has occurred 1 CPTXD-dominant timeout has occurred</p>
1 CHOCIF	<p>CANH Over-Current Interrupt Flag This flag is set to 1 if an over current condition was detected on CANH when driving a dominant bit to the CAN bus. While this flag is asserted the CAN Physical Layer remains in listen-only mode.</p> <p>0 Normal current level $I_{CANH} < I_{CANHOC}$ 1 Error event $I_{CANH} \geq I_{CANHOC}$ occurred</p>
0 CLOCIF	<p>CANL Over-Current Interrupt Flag This flag is set to 1 if an over current condition was detected on CANL when driving a dominant bit to the CAN bus. While this flag is asserted the CAN Physical Layer remains in listen-only mode.</p> <p>0 Normal current level $I_{CANL} < I_{CANLOC}$ 1 Error event $I_{CANL} \geq I_{CANLOC}$ occurred</p>

21.5 Functional Description

21.5.1 General

The CAN Physical Layer provides an interface for the SoC-integrated MSCAN controller.

21.5.2 Modes

Figure 21-10 shows the possible mode transitions depending on control bit CPE, device reduced performance mode (“RPM”; refer to “Low Power Modes” section in device overview) and bus error conditions.

1: A delay after clearing CPDTIF must be accounted for (see description)

Figure 21-10. CAN Physical Layer Mode Transitions

21.5.2.1 Shutdown Mode

Shutdown mode is a low power mode and entered out of reset. The transceiver, wake-up, bus error diagnostic, dominant timeout and interrupt functionality are disabled. CANH and CANL lines are pulled

to VSSC via high-ohmic input resistors of the receiver. The SPLIT pin as well as the internal mid-point reference are set to high-impedance.

Shutdown mode cannot be re-entered until reset.

21.5.2.2 Normal Mode

In normal mode the full transceiver functionality is available. In this mode, the CAN bus is controlled by the CPTXD input and the CAN bus state (recessive, dominant) is reported on the CPRXD output. The voltage failure, over-current and CPTXD-dominant timeout monitors are enabled. The SPLIT pin is driving a 2.5 V bias if enabled. The internal mid-point reference is set to 2.5 V.

If CPTXD is high, the transmit driver is set into recessive state, and CANH and CANL lines are biased to the voltage set at VDDC divided by 2, approx. 2.5 V.

If CPTXD is low, the transmit driver is set into dominant state, and CANH and CANL drivers are active. CANL is pulled low and CANH is pulled high.

The receiver reports the bus state on CPRXD. If the differential voltage V_{CANH} minus V_{CANL} at CANH and CANL is below the internal threshold, the bus is recessive and CPRXD is set high, otherwise a dominant bus is detected and CPRXD is set low.

When detecting a voltage high failure, over-current or CPTXD-dominant timeout event the CAN Physical Layer enters listen-only mode. A voltage low failure on CANL results in entering pseudo-normal mode. A voltage low failure on CANH maintains normal mode.

NOTE

After entering normal mode from shutdown or standby mode a settling time of t_{CP_set} must have passed until flags can be considered as valid.

21.5.2.3 Pseudo-Normal Mode

Pseudo-normal mode is identical to normal mode except for CANL driver being disabled as a result of a voltage low failure that has been detected on the CANL bus line (CPCLVL=1). CANH remains functional in this mode to allow transmission. Normal mode will automatically be re-entered after the error condition has ceased.

21.5.2.4 Listen-only Mode

Listen-only mode is entered upon detecting a CAN bus error condition (except for CPCLVL=1) or CPTXD-dominant timeout event. The entire transmitter is forced off. All other functions of the normal mode are maintained.

Application software action is required to re-enter normal mode by clearing the related flags if the bus error condition was caused by an over-current (refer to 21.6.3). In case of a voltage failure, normal mode will automatically be re-entered if the condition has passed. If the listen-only mode was caused by CPTXD-dominant timeout event, the related flag can only be cleared after the CPTXD has returned to recessive level.

21.5.2.5 Standby Mode

Standby is a reduced current consumption mode and is entered during RPM following a stop mode request. The transceiver and bus error diagnostics are disabled. The CPTXD-dominant timeout counter is stopped. CANH and CANL lines are pulled to VSSC via high-ohmic input resistors of the receiver. The SPLIT pin is set to high-impedance. The internal mid-point reference is set to 0V. All voltage failure and over-current monitors are disabled.

Standby is left as soon as the device returns from RPM.

21.5.3 Configurable Wake-Up

If the wake-up function is enabled, the CAN Physical Layer provides an asynchronous path through CPRXD to the MSCAN to support wake-up from stop mode. The CPRXD signal is switched from precision receiver to the low-power wake-up receiver as long as the device resides in RPM.

In order to avoid false wake-up after entering stop mode, a pulse filter can be enabled and configured to mask the first or first two wake-up events from the MSCAN input. The CPRXD output is held at recessive level until the selected number of wake-up events have been detected as shown in [Figure 21-11](#).

A valid wakeup-event is defined as a dominant level with a length of min. t_{CPWUP} followed by a recessive level of length t_{CPWUP} .

The wake-up filter specification t_{WUP} of the MSCAN applies to wake-up the MSCAN from sleep mode. Refer to MSCAN chapter. After wake-up the CAN Physical Layer automatically returns to the mode where stop mode was requested.

Refer to [21.6.2, “Wake-up Mechanism”](#) for setup information.

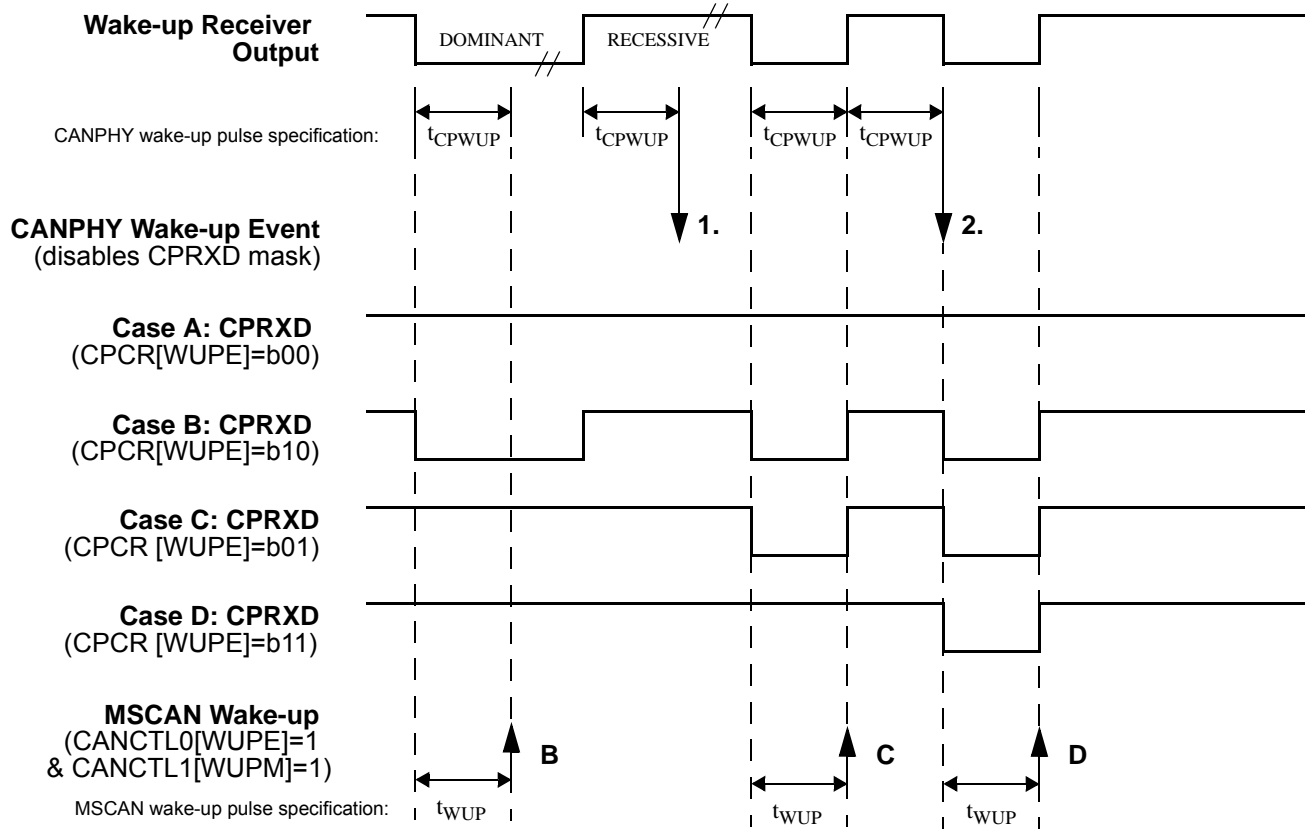

Figure 21-11. Wake-up Event Filtering

21.5.4 Interrupts

This section describes the interrupt generated by the CAN Physical Layer and its individual sources.

Vector addresses and interrupt priorities are defined at MCU level. The module internal interrupt sources are combined (OR-ed) into one module interrupt output CPI with a single local enable bit each for voltage failure and over-current errors.

Table 21-9. CAN Physical Layer Interrupt Sources

Module Interrupt Source	Module Internal Interrupt Source	Local Enable
CAN Physical Layer Interrupt (CPI)	CANH Voltage Failure High Interrupt (CHVHIF)	CPVFIE = 1
	CANH Voltage Failure Low Interrupt (CHVLIF)	
	CANL Voltage Failure High Interrupt (CLVHIF)	
	CANL Voltage Failure Low Interrupt (CLVLIF)	
	CPTXD-Dominant Timeout Interrupt (CPDTIF)	CPDTIE = 1
	CANH Over-Current Interrupt (CHOCIF)	CPOCIE = 1
CANL Over-Current Interrupt (CLOCIF)		

21.5.4.1 Voltage Failure Interrupts

A voltage failure error is detected if voltage levels on the CAN bus lines exceed the specified limits.

The voltages on both lines CANH and CANL are monitored continuously for crossing the lower and higher thresholds, V_{H0} , V_{H5} and V_{L0} , V_{L5} , respectively.

A comparator output transition to error level results in setting the corresponding status bit in CAN Physical Layer Status Register (CPSR). A change of a status bit sets the related interrupt flag in CAN Physical Layer Interrupt Flag Register (CPIF).

The flags are used as interrupt sources of which either of the four can generate a CPI interrupt if the common enable bit CPVFIE in CAN Physical Layer Interrupt Enable Register (CPIE) is set.

21.5.4.2 CPTXD-Dominant Timeout Interrupt

For network lock-up protection of the CAN bus, the CAN physical layer features a permanent CPTXD-dominant timeout monitor. When the CPTXD signal has been dominant for more than $t_{CPTXDDT}$ the transmitter is disabled by entering listen-only mode and the bus is released to recessive state. The CPDT status and CPDTIF interrupt flags are both set.

To re-enable the transmitter, the CPDTIF flag must be cleared. If the CPTXD input is dominant or dominant timeout status is still active (CPDT=1), the CAN Physical Layer stays in listen-only mode and CPDTIF is set again after some microseconds to indicate that the attempt has failed. If CPTXD is recessive and CPDT=0 it takes 1 to 2 μ s after clearing CPDTIF for returning to normal mode.

The flag is used as an interrupt source to generate a CPI interrupt if the enable bit CPDTIE in CAN Physical Layer Interrupt Enable Register (CPIE) is set.

21.5.4.3 Over-Current Interrupt

An over-current error is detected if current levels on the CAN bus lines exceed the specified limits while driving a dominant bit.

The current levels on both lines CANH and CANL are monitored continuously for crossing the thresholds I_{CANHOC} and I_{CANLOC} , respectively.

A comparator output transition to error level results in setting the corresponding interrupt flag in CAN Physical Layer Interrupt Flag Register (CPIF).

The flags are the direct interrupt sources of which either of the two can generate a CPI interrupt if the common enable bit CPOCIE in CAN Physical Layer Interrupt Enable Register (CPIE) is set.

21.6 Initialization/Application Information

21.6.1 Initialization Sequence

Setup for immediate CAN communication:

1. Enable and configure MSCAN

2. Configure CAN Physical Layer slew rate
3. Enable CAN Physical Layer interrupts
4. Optionally enable SPLIT pin
5. Configure wake-up filter or disable wake-up receiver in case of other wake-up sources
6. Enable CAN Physical Layer to enter normal mode
7. Start CAN communication

21.6.2 Wake-up Mechanism

In stop mode the CAN Physical Layer passes CAN bus states to CPRXD if the wake-up function is enabled (CPCR[WUPE1:WUPE0]≠0). In order to wake up the device from stop mode, the wake-up interrupt of the connected MSCAN module is used.

If CPCR[WUPE1:WUPE0]=b10 the CAN Physical Layer is transparent in stop mode and the MSCAN can be used with or without its integrated low-pass filter for wake-up. Refer to the MSCAN chapter for details on configuring and enabling the wake-up function.

For increased robustness against false wake-up, a CAN Physical Layer pulse filter can optionally be enabled to mask the first (CPCR[WUPE1:WUPE0]=b01) or first two (CPCR[WUPE1:WUPE0]=b11) wake-up events after entering stop mode. The appropriate number of masked pulses depends on the individual CAN bus network topology.

Note that the MSCAN can generate a wake-up interrupt immediately after it acknowledges sleep mode (CANCTL1[SPLAK]=1) whereas the CAN Physical Layer pulse filter takes effect only after entering stop mode. To avoid a false wake-up in between these two events, the MSCAN low-pass filter should also be activated (CANCTL1[WUPM]=1). After sleep mode acknowledge the CPU STOP instruction should be executed before the expiration of $t_{WUP}(\text{min})$ to enable the CAN Physical Layer pulse filter in time.

21.6.3 Bus Error Handling

Upon CAN bus error voltage high failures and over-current events listen-only is entered immediately and the transmitter is turned off. This mode is maintained as long as voltage failure conditions persist or, in case of over-current events, application software re-enables the transmit driver by clearing the related flags.

All high and low voltage levels for both CAN bus lines are continuously reflected in their related voltage failure status bits. A change in a status bit sets the corresponding flag and generates an interrupt if enabled. As long as any of the voltage failure high status bits is set, the transmit driver remains off. It will be turned on again automatically as soon as all voltage failure conditions have disappeared. In case of a voltage failure low condition on CANL only the CANL driver is disabled. A voltage failure low condition on CANH has no effect on the transmitter.

Voltage failure errors have informational purpose. If the application detects frequent CAN protocol errors it is advisable to take the appropriate action. No software action is need to re-enable the transmit driver.

An over-current event on either CAN bus line sets the related flag and turns off the transmit driver. This error can only be detected while driving the bus dominant. In contrast to the voltage failure the over-current

condition instantaneously disappears as soon as the transmit driver is automatically being turned off. This state is locked and the application software must account for re-enabling the driver.

The recommended procedure to handle an over-current related bus error is:

1. On interrupt abort any scheduled transmissions
2. Read interrupt flag register to determine over-current source(s)
3. Clear related interrupt flag(s)
4. Retry CAN transmission
5. On interrupt abort any scheduled transmissions
6. Read interrupt flag register to determine over-current source(s)
7. If the same over-current error persists do not retry and run appropriate custom diagnostics

21.6.4 CPTXD-Dominant Timeout Recovery

Recovery from a CPTXD-dominant timeout error is attempted with the following sequence:

1. On CPTXD-dominant timeout interrupt set CPTXD input to recessive state
2. Wait until CPDT clear; exit loop if waiting for longer than 3 μ s and report malfunction
3. Clear CPDTIF
4. Wait for min. 2 μ s before attempting new transmission

Chapter 22

Pulse-Width Modulator (S12PWM8B8CV2)

Table 22-1. Revision History

Revision Number	Revision Date	Sections Affected	Description of Changes
v02.00	Feb. 20, 2009	All	Initial revision of scalable PWM. Started from pwm_8b8c (v01.08).

22.1 Introduction

The Version 2 of S12 PWM module is a channel scalable and optimized implementation of S12 PWM8B8C Version 1. The channel is scalable in pairs from PWM0 to PWM7 and the available channel number is 2, 4, 6 and 8. The shutdown feature has been removed and the flexibility to select one of four clock sources per channel has improved. If the corresponding channels exist and shutdown feature is not used, the Version 2 is fully software compatible to Version 1.

22.1.1 Features

The scalable PWM block includes these distinctive features:

- Up to eight independent PWM channels, scalable in pairs (PWM0 to PWM7)
- Available channel number could be 2, 4, 6, 8 (refer to device specification for exact number)
- Programmable period and duty cycle for each channel
- Dedicated counter for each PWM channel
- Programmable PWM enable/disable for each channel
- Software selection of PWM duty pulse polarity for each channel
- Period and duty cycle are double buffered. Change takes effect when the end of the effective period is reached (PWM counter reaches zero) or when the channel is disabled.
- Programmable center or left aligned outputs on individual channels
- Up to eight 8-bit channel or four 16-bit channel PWM resolution
- Four clock sources (A, B, SA, and SB) provide for a wide range of frequencies
- Programmable clock select logic

22.1.2 Modes of Operation

There is a software programmable option for low power consumption in wait mode that disables the input clock to the prescaler.

In freeze mode there is a software programmable option to disable the input clock to the prescaler. This is useful for emulation.

Wait: The prescaler keeps on running, unless PSWAI in PWMCTL is set to 1.

Freeze: The prescaler keeps on running, unless PFRZ in PWMCTL is set to 1.

22.1.3 Block Diagram

Figure 22-1 shows the block diagram for the 8-bit up to 8-channel scalable PWM block.

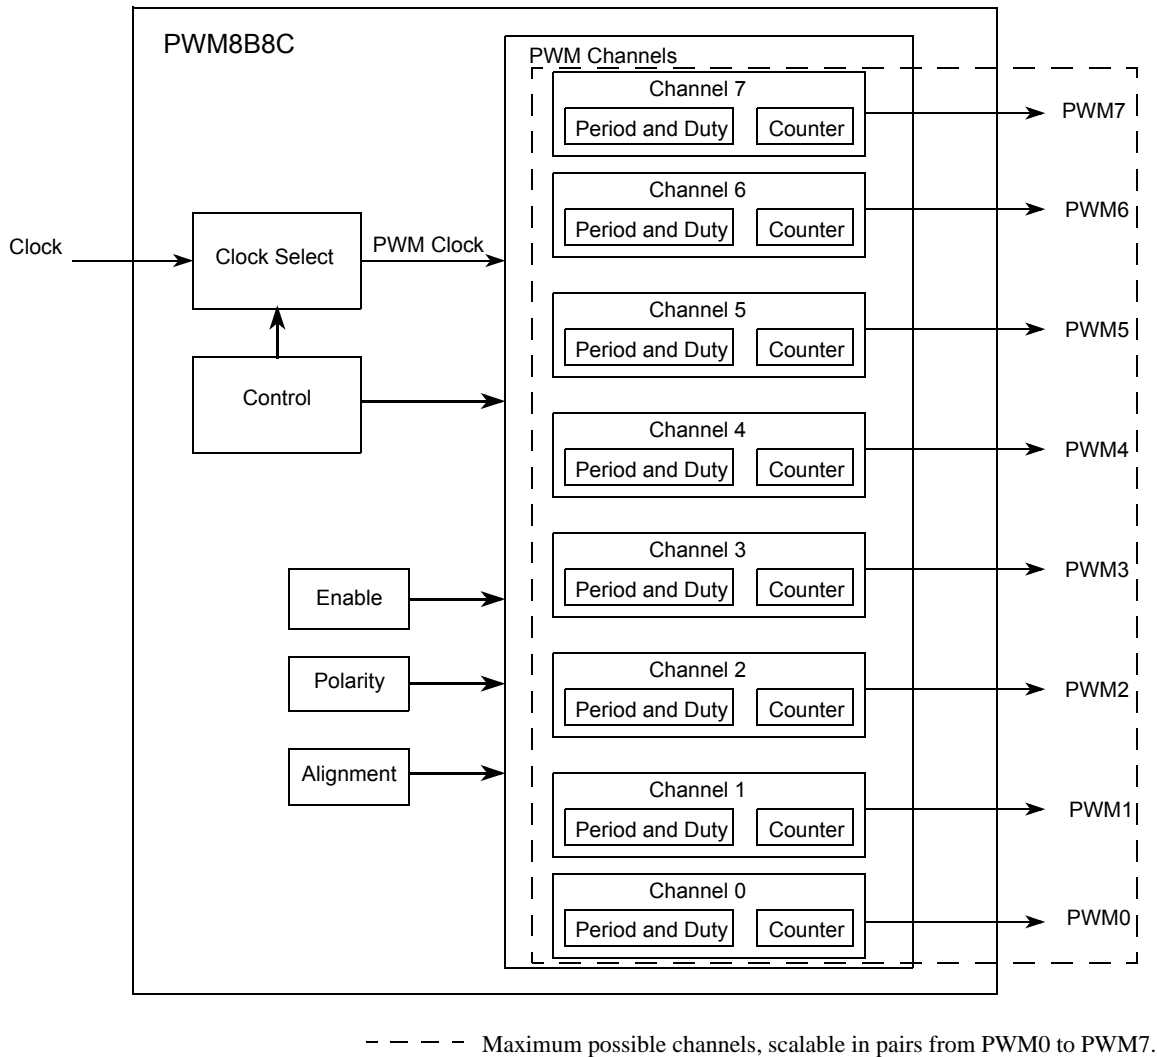

Figure 22-1. Scalable PWM Block Diagram

22.2 External Signal Description

The scalable PWM module has a selected number of external pins. Refer to device specification for exact number.

22.2.1 PWM7 - PWM0 — PWM Channel 7 - 0

Those pins serve as waveform output of PWM channel 7 - 0.

22.3 Memory Map and Register Definition

22.3.1 Module Memory Map

This section describes the content of the registers in the scalable PWM module. The base address of the scalable PWM module is determined at the MCU level when the MCU is defined. The register decode map is fixed and begins at the first address of the module address offset. The figure below shows the registers associated with the scalable PWM and their relative offset from the base address. The register detail description follows the order they appear in the register map.

Reserved bits within a register will always read as 0 and the write will be unimplemented. Unimplemented functions are indicated by shading the bit.

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level.

22.3.2 Register Descriptions

This section describes in detail all the registers and register bits in the scalable PWM module.

Register Name	Bit 7	6	5	4	3	2	1	Bit 0

Figure 22-2. The scalable PWM Register Summary (Sheet 4 of 4)

1. The related bit is available only if corresponding channel exists.
2. The register is available only if corresponding channel exists.

22.3.2.1 PWM Enable Register (PWME)

Each PWM channel has an enable bit (PWME_x) to start its waveform output. When any of the PWME_x bits are set (PWME_x = 1), the associated PWM output is enabled immediately. However, the actual PWM waveform is not available on the associated PWM output until its clock source begins its next cycle due to the synchronization of PWME_x and the clock source.

NOTE

The first PWM cycle after enabling the channel can be irregular.

An exception to this is when channels are concatenated. Once concatenated mode is enabled (CON_{xx} bits set in PWMCTL register), enabling/disabling the corresponding 16-bit PWM channel is controlled by the low order PWME_x bit. In this case, the high order bytes PWME_x bits have no effect and their corresponding PWM output lines are disabled.

While in run mode, if all existing PWM channels are disabled (PWME_{x-0} = 0), the prescaler counter shuts off for power savings.

Table 22-2. PWME Field Descriptions

Note: Bits related to available channels have functional significance. Writing to unavailable bits has no effect. Read from unavailable bits return a zero

Field	Description
7 PWME7	Pulse Width Channel 7 Enable 0 Pulse width channel 7 is disabled. 1 Pulse width channel 7 is enabled. The pulse modulated signal becomes available at PWM output bit 7 when its clock source begins its next cycle.
6 PWME6	Pulse Width Channel 6 Enable 0 Pulse width channel 6 is disabled. 1 Pulse width channel 6 is enabled. The pulse modulated signal becomes available at PWM output bit 6 when its clock source begins its next cycle. If CON67=1, then bit has no effect and PWM output line 6 is disabled.
5 PWME5	Pulse Width Channel 5 Enable 0 Pulse width channel 5 is disabled. 1 Pulse width channel 5 is enabled. The pulse modulated signal becomes available at PWM output bit 5 when its clock source begins its next cycle.
4 PWME4	Pulse Width Channel 4 Enable 0 Pulse width channel 4 is disabled. 1 Pulse width channel 4 is enabled. The pulse modulated signal becomes available at PWM, output bit 4 when its clock source begins its next cycle. If CON45 = 1, then bit has no effect and PWM output line 4 is disabled.
3 PWME3	Pulse Width Channel 3 Enable 0 Pulse width channel 3 is disabled. 1 Pulse width channel 3 is enabled. The pulse modulated signal becomes available at PWM, output bit 3 when its clock source begins its next cycle.
2 PWME2	Pulse Width Channel 2 Enable 0 Pulse width channel 2 is disabled. 1 Pulse width channel 2 is enabled. The pulse modulated signal becomes available at PWM, output bit 2 when its clock source begins its next cycle. If CON23 = 1, then bit has no effect and PWM output line 2 is disabled.
1 PWME1	Pulse Width Channel 1 Enable 0 Pulse width channel 1 is disabled. 1 Pulse width channel 1 is enabled. The pulse modulated signal becomes available at PWM, output bit 1 when its clock source begins its next cycle.
0 PWME0	Pulse Width Channel 0 Enable 0 Pulse width channel 0 is disabled. 1 Pulse width channel 0 is enabled. The pulse modulated signal becomes available at PWM, output bit 0 when its clock source begins its next cycle. If CON01 = 1, then bit has no effect and PWM output line 0 is disabled.

22.3.2.2 PWM Polarity Register (PWMPOL)

The starting polarity of each PWM channel waveform is determined by the associated PPOLx bit in the PWMPOL register. If the polarity bit is one, the PWM channel output is high at the beginning of the cycle and then goes low when the duty count is reached. Conversely, if the polarity bit is zero, the output starts low and then goes high when the duty count is reached.

Module Base + 0x0001

Figure 22-4. PWM Polarity Register (PWMPOL)

Read: Anytime

Write: Anytime

NOTE

PPOLx register bits can be written anytime. If the polarity is changed while a PWM signal is being generated, a truncated or stretched pulse can occur during the transition

Table 22-3. PWMPOL Field Descriptions

Field	Description
7-0 PPOL[7:0]	<p>Pulse Width Channel 7-0 Polarity Bits</p> <p>0 PWM channel 7-0 outputs are low at the beginning of the period, then go high when the duty count is reached.</p> <p>1 PWM channel 7-0 outputs are high at the beginning of the period, then go low when the duty count is reached.</p>

22.3.2.3 PWM Clock Select Register (PWMCLK)

Each PWM channel has a choice of four clocks to use as the clock source for that channel as described below.

Module Base + 0x0002

Figure 22-5. PWM Clock Select Register (PWMCLK)

Read: Anytime

Write: Anytime

NOTE

Register bits PCLK0 to PCLK7 can be written anytime. If a clock select is changed while a PWM signal is being generated, a truncated or stretched pulse can occur during the transition.

Table 22-4. PWMCLK Field Descriptions

Note: Bits related to available channels have functional significance. Writing to unavailable bits has no effect. Read from unavailable bits return a zero

Field	Description
7-0 PCLK[7:0]	Pulse Width Channel 7-0 Clock Select 0 Clock A or B is the clock source for PWM channel 7-0, as shown in Table 22-5 and Table 22-6 . 1 Clock SA or SB is the clock source for PWM channel 7-0, as shown in Table 22-5 and Table 22-6 .

The clock source of each PWM channel is determined by PCLKx bits in PWMCLK and PCLKABx bits in PWMCLKAB (see [Section 22.3.2.7, “PWM Clock A/B Select Register \(PWMCLKAB\)”](#)). For Channel 0, 1, 4, 5, the selection is shown in [Table 22-5](#); For Channel 2, 3, 6, 7, the selection is shown in [Table 22-6](#).

Table 22-5. PWM Channel 0, 1, 4, 5 Clock Source Selection

PCLKAB[0,1,4,5]	PCLK[0,1,4,5]	Clock Source Selection
0	0	Clock A
0	1	Clock SA
1	0	Clock B
1	1	Clock SB

Table 22-6. PWM Channel 2, 3, 6, 7 Clock Source Selection

PCLKAB[2,3,6,7]	PCLK[2,3,6,7]	Clock Source Selection
0	0	Clock B
0	1	Clock SB
1	0	Clock A
1	1	Clock SA

22.3.2.4 PWM Prescale Clock Select Register (PWMPRCLK)

This register selects the prescale clock source for clocks A and B independently.

Module Base + 0x0003

**Figure 22-6. PWM Prescale Clock Select Register (PWMPRCLK)**

Read: Anytime

Write: Anytime

NOTE

PCKB2–0 and PCKA2–0 register bits can be written anytime. If the clock pre-scale is changed while a PWM signal is being generated, a truncated or stretched pulse can occur during the transition.

Table 22-7. PWMPCLK Field Descriptions

Field	Description
6–4 PCKB[2:0]	Prescaler Select for Clock B — Clock B is one of two clock sources which can be used for all channels. These three bits determine the rate of clock B, as shown in Table 22-8 .
2–0 PCKA[2:0]	Prescaler Select for Clock A — Clock A is one of two clock sources which can be used for all channels. These three bits determine the rate of clock A, as shown in Table 22-8 .

Table 22-8. Clock A or Clock B Prescaler Selects

PCKA/B2	PCKA/B1	PCKA/B0	Value of Clock A/B
0	0	0	bus clock
0	0	1	bus clock / 2
0	1	0	bus clock / 4
0	1	1	bus clock / 8
1	0	0	bus clock / 16
1	0	1	bus clock / 32
1	1	0	bus clock / 64
1	1	1	bus clock / 128

22.3.2.5 PWM Center Align Enable Register (PWMCAE)

The PWMCAE register contains eight control bits for the selection of center aligned outputs or left aligned outputs for each PWM channel. If the CAEx bit is set to a one, the corresponding PWM output will be center aligned. If the CAEx bit is cleared, the corresponding PWM output will be left aligned. See [Section 22.4.2.5, “Left Aligned Outputs”](#) and [Section 22.4.2.6, “Center Aligned Outputs”](#) for a more detailed description of the PWM output modes.

22.3.2.6 PWM Control Register (PWMCTL)

The PWMCTL register provides for various control of the PWM module.

Module Base + 0x0005

Figure 22-8. PWM Control Register (PWMCTL)

Read: Anytime

Write: Anytime

There are up to four control bits for concatenation, each of which is used to concatenate a pair of PWM channels into one 16-bit channel. If the corresponding channels do not exist on a particular derivative, then writes to these bits have no effect and reads will return zeroes. When channels 6 and 7 are concatenated, channel 6 registers become the high order bytes of the double byte channel. When channels 4 and 5 are concatenated, channel 4 registers become the high order bytes of the double byte channel. When channels 2 and 3 are concatenated, channel 2 registers become the high order bytes of the double byte channel. When channels 0 and 1 are concatenated, channel 0 registers become the high order bytes of the double byte channel.

See [Section 22.4.2.7, “PWM 16-Bit Functions”](#) for a more detailed description of the concatenation PWM Function.

NOTE

Change these bits only when both corresponding channels are disabled.

Table 22-10. PWMCTL Field Descriptions

Note: Bits related to available channels have functional significance. Writing to unavailable bits has no effect. Read from unavailable bits return a zero

Field	Description
7 CON67	Concatenate Channels 6 and 7 0 Channels 6 and 7 are separate 8-bit PWMs. 1 Channels 6 and 7 are concatenated to create one 16-bit PWM channel. Channel 6 becomes the high order byte and channel 7 becomes the low order byte. Channel 7 output pin is used as the output for this 16-bit PWM (bit 7 of port PWMP). Channel 7 clock select control-bit determines the clock source, channel 7 polarity bit determines the polarity, channel 7 enable bit enables the output and channel 7 center aligned enable bit determines the output mode.
6 CON45	Concatenate Channels 4 and 5 0 Channels 4 and 5 are separate 8-bit PWMs. 1 Channels 4 and 5 are concatenated to create one 16-bit PWM channel. Channel 4 becomes the high order byte and channel 5 becomes the low order byte. Channel 5 output pin is used as the output for this 16-bit PWM (bit 5 of port PWMP). Channel 5 clock select control-bit determines the clock source, channel 5 polarity bit determines the polarity, channel 5 enable bit enables the output and channel 5 center aligned enable bit determines the output mode.
5 CON23	Concatenate Channels 2 and 3 0 Channels 2 and 3 are separate 8-bit PWMs. 1 Channels 2 and 3 are concatenated to create one 16-bit PWM channel. Channel 2 becomes the high order byte and channel 3 becomes the low order byte. Channel 3 output pin is used as the output for this 16-bit PWM (bit 3 of port PWMP). Channel 3 clock select control-bit determines the clock source, channel 3 polarity bit determines the polarity, channel 3 enable bit enables the output and channel 3 center aligned enable bit determines the output mode.
4 CON01	Concatenate Channels 0 and 1 0 Channels 0 and 1 are separate 8-bit PWMs. 1 Channels 0 and 1 are concatenated to create one 16-bit PWM channel. Channel 0 becomes the high order byte and channel 1 becomes the low order byte. Channel 1 output pin is used as the output for this 16-bit PWM (bit 1 of port PWMP). Channel 1 clock select control-bit determines the clock source, channel 1 polarity bit determines the polarity, channel 1 enable bit enables the output and channel 1 center aligned enable bit determines the output mode.
3 PSWAI	PWM Stops in Wait Mode — Enabling this bit allows for lower power consumption in wait mode by disabling the input clock to the prescaler. 0 Allow the clock to the prescaler to continue while in wait mode. 1 Stop the input clock to the prescaler whenever the MCU is in wait mode.
2 PFRZ	PWM Counters Stop in Freeze Mode — In freeze mode, there is an option to disable the input clock to the prescaler by setting the PFRZ bit in the PWMCTL register. If this bit is set, whenever the MCU is in freeze mode, the input clock to the prescaler is disabled. This feature is useful during emulation as it allows the PWM function to be suspended. In this way, the counters of the PWM can be stopped while in freeze mode so that once normal program flow is continued, the counters are re-enabled to simulate real-time operations. Since the registers can still be accessed in this mode, to re-enable the prescaler clock, either disable the PFRZ bit or exit freeze mode. 0 Allow PWM to continue while in freeze mode. 1 Disable PWM input clock to the prescaler whenever the part is in freeze mode. This is useful for emulation.

22.3.2.7 PWM Clock A/B Select Register (PWMCLKAB)

Each PWM channel has a choice of four clocks to use as the clock source for that channel as described below.

Module Base + 0x00006

Figure 22-9. PWM Clock Select Register (PWMCLK)

Read: Anytime

Write: Anytime

NOTE

Register bits PCLKAB0 to PCLKAB7 can be written anytime. If a clock select is changed while a PWM signal is being generated, a truncated or stretched pulse can occur during the transition.

Table 22-11. PWMCLK Field Descriptions

Note: Bits related to available channels have functional significance. Writing to unavailable bits has no effect. Read from unavailable bits return a zero

Field	Description
7 PCLKAB7	Pulse Width Channel 7 Clock A/B Select 0 Clock B or SB is the clock source for PWM channel 7, as shown in Table 22-6 . 1 Clock A or SA is the clock source for PWM channel 7, as shown in Table 22-6 .
6 PCLKAB6	Pulse Width Channel 6 Clock A/B Select 0 Clock B or SB is the clock source for PWM channel 6, as shown in Table 22-6 . 1 Clock A or SA is the clock source for PWM channel 6, as shown in Table 22-6 .
5 PCLKAB5	Pulse Width Channel 5 Clock A/B Select 0 Clock A or SA is the clock source for PWM channel 5, as shown in Table 22-5 . 1 Clock B or SB is the clock source for PWM channel 5, as shown in Table 22-5 .
4 PCLKAB4	Pulse Width Channel 4 Clock A/B Select 0 Clock A or SA is the clock source for PWM channel 4, as shown in Table 22-5 . 1 Clock B or SB is the clock source for PWM channel 4, as shown in Table 22-5 .
3 PCLKAB3	Pulse Width Channel 3 Clock A/B Select 0 Clock B or SB is the clock source for PWM channel 3, as shown in Table 22-6 . 1 Clock A or SA is the clock source for PWM channel 3, as shown in Table 22-6 .
2 PCLKAB2	Pulse Width Channel 2 Clock A/B Select 0 Clock B or SB is the clock source for PWM channel 2, as shown in Table 22-6 . 1 Clock A or SA is the clock source for PWM channel 2, as shown in Table 22-6 .
1 PCLKAB1	Pulse Width Channel 1 Clock A/B Select 0 Clock A or SA is the clock source for PWM channel 1, as shown in Table 22-5 . 1 Clock B or SB is the clock source for PWM channel 1, as shown in Table 22-5 .
0 PCLKAB0	Pulse Width Channel 0 Clock A/B Select 0 Clock A or SA is the clock source for PWM channel 0, as shown in Table 22-5 . 1 Clock B or SB is the clock source for PWM channel 0, as shown in Table 22-5 .

The clock source of each PWM channel is determined by PCLKx bits in PWMCLK (see [Section 22.3.2.3](#), “PWM Clock Select Register (PWMCLK)”) and PCLKABx bits in PWMCLKAB as shown in [Table 22-5](#) and [Table 22-6](#).

22.3.2.8 PWM Scale A Register (PWMSCLA)

PWMSCLA is the programmable scale value used in scaling clock A to generate clock SA. Clock SA is generated by taking clock A, dividing it by the value in the PWMSCLA register and dividing that by two.

$$\text{Clock SA} = \text{Clock A} / (2 * \text{PWMSCLA})$$

NOTE

When PWMSCLA = \$00, PWMSCLA value is considered a full scale value of 256. Clock A is thus divided by 512.

Any value written to this register will cause the scale counter to load the new scale value (PWMSCLA).

Module Base + 0x0008

Figure 22-10. PWM Scale A Register (PWMSCLA)

Read: Anytime

Write: Anytime (causes the scale counter to load the PWMSCLA value)

22.3.2.9 PWM Scale B Register (PWMSCLB)

PWMSCLB is the programmable scale value used in scaling clock B to generate clock SB. Clock SB is generated by taking clock B, dividing it by the value in the PWMSCLB register and dividing that by two.

$$\text{Clock SB} = \text{Clock B} / (2 * \text{PWMSCLB})$$

NOTE

When PWMSCLB = \$00, PWMSCLB value is considered a full scale value of 256. Clock B is thus divided by 512.

Any value written to this register will cause the scale counter to load the new scale value (PWMSCLB).

Module Base + 0x0009

Figure 22-11. PWM Scale B Register (PWMSCLB)

Write: Anytime (causes the scale counter to load the PWMSCLB value).

22.3.2.10 PWM Channel Counter Registers (PWMCNTx)

Each channel has a dedicated 8-bit up/down counter which runs at the rate of the selected clock source. The counter can be read at any time without affecting the count or the operation of the PWM channel. In left aligned output mode, the counter counts from 0 to the value in the period register - 1. In center aligned output mode, the counter counts from 0 up to the value in the period register and then back down to 0.

Any value written to the counter causes the counter to reset to \$00, the counter direction to be set to up, the immediate load of both duty and period registers with values from the buffers, and the output to change according to the polarity bit. The counter is also cleared at the end of the effective period (see [Section 22.4.2.5, “Left Aligned Outputs”](#) and [Section 22.4.2.6, “Center Aligned Outputs”](#) for more details). When the channel is disabled ($PWME_x = 0$), the PWMCNTx register does not count. When a channel becomes enabled ($PWME_x = 1$), the associated PWM counter starts at the count in the PWMCNTx register. For more detailed information on the operation of the counters, see [Section 22.4.2.4, “PWM Timer Counters”](#).

In concatenated mode, writes to the 16-bit counter by using a 16-bit access or writes to either the low or high order byte of the counter will reset the 16-bit counter. Reads of the 16-bit counter must be made by 16-bit access to maintain data coherency.

NOTE

Writing to the counter while the channel is enabled can cause an irregular PWM cycle to occur.

Module Base + 0x000C = PWMCNT0, 0x000D = PWMCNT1, 0x000E = PWMCNT2, 0x000F = PWMCNT3
Module Base + 0x0010 = PWMCNT4, 0x0011 = PWMCNT5, 0x0012 = PWMCNT6, 0x0013 = PWMCNT7

Figure 22-12. PWM Channel Counter Registers (PWMCNTx)

¹ This register is available only when the corresponding channel exists and is reserved if that channel does not exist. Writes to a reserved register have no functional effect. Reads from a reserved register return zeroes.

Read: Anytime

Write: Anytime (any value written causes PWM counter to be reset to \$00).

22.3.2.11 PWM Channel Period Registers (PWMPERx)

There is a dedicated period register for each channel. The value in this register determines the period of the associated PWM channel.

The period registers for each channel are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends

- The counter is written (counter resets to \$00)
- The channel is disabled

In this way, the output of the PWM will always be either the old waveform or the new waveform, not some variation in between. If the channel is not enabled, then writes to the period register will go directly to the latches as well as the buffer.

NOTE

Reads of this register return the most recent value written. Reads do not necessarily return the value of the currently active period due to the double buffering scheme.

See [Section 22.4.2.3, “PWM Period and Duty”](#) for more information.

To calculate the output period, take the selected clock source period for the channel of interest (A, B, SA, or SB) and multiply it by the value in the period register for that channel:

- Left aligned output (CAEx = 0)

$$\text{PWMx Period} = \text{Channel Clock Period} * \text{PWMPERx}$$
- Center Aligned Output (CAEx = 1)

$$\text{PWMx Period} = \text{Channel Clock Period} * (2 * \text{PWMPERx})$$

For boundary case programming values, please refer to [Section 22.4.2.8, “PWM Boundary Cases”](#).

Module Base + 0x0014 = PWMPER0, 0x0015 = PWMPER1, 0x0016 = PWMPER2, 0x0017 = PWMPER3
 Module Base + 0x0018 = PWMPER4, 0x0019 = PWMPER5, 0x001A = PWMPER6, 0x001B = PWMPER7

¹ This register is available only when the corresponding channel exists and is reserved if that channel does not exist. Writes to a reserved register have no functional effect. Reads from a reserved register return zeroes.

Read: Anytime

Write: Anytime

22.3.2.12 PWM Channel Duty Registers (PWMDTYx)

There is a dedicated duty register for each channel. The value in this register determines the duty of the associated PWM channel. The duty value is compared to the counter and if it is equal to the counter value a match occurs and the output changes state.

The duty registers for each channel are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to \$00)

- The channel is disabled

In this way, the output of the PWM will always be either the old duty waveform or the new duty waveform, not some variation in between. If the channel is not enabled, then writes to the duty register will go directly to the latches as well as the buffer.

NOTE

Reads of this register return the most recent value written. Reads do not necessarily return the value of the currently active duty due to the double buffering scheme.

See [Section 22.4.2.3, “PWM Period and Duty”](#) for more information.

NOTE

Depending on the polarity bit, the duty registers will contain the count of either the high time or the low time. If the polarity bit is one, the output starts high and then goes low when the duty count is reached, so the duty registers contain a count of the high time. If the polarity bit is zero, the output starts low and then goes high when the duty count is reached, so the duty registers contain a count of the low time.

To calculate the output duty cycle (high time as a% of period) for a particular channel:

- Polarity = 0 (PPOL_x = 0)

$$\text{Duty Cycle} = [(\text{PWMPER}_x - \text{PWMDTY}_x) / \text{PWMPER}_x] * 100\%$$
- Polarity = 1 (PPOL_x = 1)

$$\text{Duty Cycle} = [\text{PWMDTY}_x / \text{PWMPER}_x] * 100\%$$

For boundary case programming values, please refer to [Section 22.4.2.8, “PWM Boundary Cases”](#).

Module Base + 0x001C = PWMDTY0, 0x001D = PWMDTY1, 0x001E = PWMDTY2, 0x001F = PWMDTY3

22.4 Functional Description

22.4.1 PWM Clock Select

There are four available clocks: clock A, clock B, clock SA (scaled A), and clock SB (scaled B). These four clocks are based on the bus clock.

Clock A and B can be software selected to be 1, 1/2, 1/4, 1/8,..., 1/64, 1/128 times the bus clock. Clock SA uses clock A as an input and divides it further with a reloadable counter. Similarly, clock SB uses clock B as an input and divides it further with a reloadable counter. The rates available for clock SA are software selectable to be clock A divided by 2, 4, 6, 8,..., or 512 in increments of divide by 2. Similar rates are available for clock SB. Each PWM channel has the capability of selecting one of four clocks, clock A, Clock B, clock SA or clock SB.

The block diagram in [Figure 22-15](#) shows the four different clocks and how the scaled clocks are created.

22.4.1.1 Prescale

The input clock to the PWM prescaler is the bus clock. It can be disabled whenever the part is in freeze mode by setting the PFRZ bit in the PWMCTL register. If this bit is set, whenever the MCU is in freeze mode (freeze mode signal active) the input clock to the prescaler is disabled. This is useful for emulation in order to freeze the PWM. The input clock can also be disabled when all available PWM channels are disabled (PWME_{x-0} = 0). This is useful for reducing power by disabling the prescale counter.

Clock A and clock B are scaled values of the input clock. The value is software selectable for both clock A and clock B and has options of 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, or 1/128 times the bus clock. The value selected for clock A is determined by the PCKA2, PCKA1, PCKA0 bits in the PWMPRCLK register. The value selected for clock B is determined by the PCKB2, PCKB1, PCKB0 bits also in the PWMPRCLK register.

22.4.1.2 Clock Scale

The scaled A clock uses clock A as an input and divides it further with a user programmable value and then divides this by 2. The scaled B clock uses clock B as an input and divides it further with a user programmable value and then divides this by 2. The rates available for clock SA are software selectable to be clock A divided by 2, 4, 6, 8,..., or 512 in increments of divide by 2. Similar rates are available for clock SB.

Figure 22-15. PWM Clock Select Block Diagram

Clock A is used as an input to an 8-bit down counter. This down counter loads a user programmable scale value from the scale register (PWMSCLA). When the down counter reaches one, a pulse is output and the 8-bit counter is re-loaded. The output signal from this circuit is further divided by two. This gives a greater range with only a slight reduction in granularity. Clock SA equals clock A divided by two times the value in the PWMSCLA register.

NOTE

$$\text{Clock SA} = \text{Clock A} / (2 * \text{PWMSCLA})$$

When PWMSCLA = \$00, PWMSCLA value is considered a full scale value of 256. Clock A is thus divided by 512.

Similarly, clock B is used as an input to an 8-bit down counter followed by a divide by two producing clock SB. Thus, clock SB equals clock B divided by two times the value in the PWMSCLB register.

NOTE

$$\text{Clock SB} = \text{Clock B} / (2 * \text{PWMSCLB})$$

When PWMSCLB = \$00, PWMSCLB value is considered a full scale value of 256. Clock B is thus divided by 512.

As an example, consider the case in which the user writes \$FF into the PWMSCLA register. Clock A for this case will be bus clock divided by 4. A pulse will occur at a rate of once every 255x4 bus cycles. Passing this through the divide by two circuit produces a clock signal at an bus clock divided by 2040 rate. Similarly, a value of \$01 in the PWMSCLA register when clock A is bus clock divided by 4 will produce a clock at an bus clock divided by 8 rate.

Writing to PWMSCLA or PWMSCLB causes the associated 8-bit down counter to be re-loaded. Otherwise, when changing rates the counter would have to count down to \$01 before counting at the proper rate. Forcing the associated counter to re-load the scale register value every time PWMSCLA or PWMSCLB is written prevents this.

NOTE

Writing to the scale registers while channels are operating can cause irregularities in the PWM outputs.

22.4.1.3 Clock Select

Each PWM channel has the capability of selecting one of four clocks, clock A, clock SA, clock B or clock SB. The clock selection is done with the PCLKx control bits in the PWMCLK register and PCLKABx control bits in PWMCLKAB register. For backward compatibility consideration, the reset value of PWMCLK and PWMCLKAB configures following default clock selection.

For channels 0, 1, 4, and 5 the clock choices are clock A.

For channels 2, 3, 6, and 7 the clock choices are clock B.

NOTE

Changing clock control bits while channels are operating can cause irregularities in the PWM outputs.

22.4.2 PWM Channel Timers

The main part of the PWM module are the actual timers. Each of the timer channels has a counter, a period register and a duty register (each are 8-bit). The waveform output period is controlled by a match between the period register and the value in the counter. The duty is controlled by a match between the duty register and the counter value and causes the state of the output to change during the period. The starting polarity of the output is also selectable on a per channel basis. Shown below in [Figure 22-16](#) is the block diagram for the PWM timer.

Figure 22-16. PWM Timer Channel Block Diagram

22.4.2.1 PWM Enable

Each PWM channel has an enable bit (PWME_x) to start its waveform output. When any of the PWME_x bits are set (PWME_x = 1), the associated PWM output signal is enabled immediately. However, the actual PWM waveform is not available on the associated PWM output until its clock source begins its next cycle due to the synchronization of PWME_x and the clock source. An exception to this is when channels are concatenated. Refer to [Section 22.4.2.7, “PWM 16-Bit Functions”](#) for more detail.

NOTE

The first PWM cycle after enabling the channel can be irregular.

On the front end of the PWM timer, the clock is enabled to the PWM circuit by the PWME_x bit being high. There is an edge-synchronizing circuit to guarantee that the clock will only be enabled or disabled at an edge. When the channel is disabled (PWME_x = 0), the counter for the channel does not count.

22.4.2.2 PWM Polarity

Each channel has a polarity bit to allow starting a waveform cycle with a high or low signal. This is shown on the block diagram [Figure 22-16](#) as a mux select of either the Q output or the \bar{Q} output of the PWM output flip flop. When one of the bits in the PWMPOL register is set, the associated PWM channel output is high at the beginning of the waveform, then goes low when the duty count is reached. Conversely, if the polarity bit is zero, the output starts low and then goes high when the duty count is reached.

22.4.2.3 PWM Period and Duty

Dedicated period and duty registers exist for each channel and are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to \$00)
- The channel is disabled

In this way, the output of the PWM will always be either the old waveform or the new waveform, not some variation in between. If the channel is not enabled, then writes to the period and duty registers will go directly to the latches as well as the buffer.

A change in duty or period can be forced into effect “immediately” by writing the new value to the duty and/or period registers and then writing to the counter. This forces the counter to reset and the new duty and/or period values to be latched. In addition, since the counter is readable, it is possible to know where the count is with respect to the duty value and software can be used to make adjustments

NOTE

When forcing a new period or duty into effect immediately, an irregular PWM cycle can occur.

Depending on the polarity bit, the duty registers will contain the count of either the high time or the low time.

22.4.2.4 PWM Timer Counters

Each channel has a dedicated 8-bit up/down counter which runs at the rate of the selected clock source (see [Section 22.4.1, “PWM Clock Select”](#) for the available clock sources and rates). The counter compares to two registers, a duty register and a period register as shown in [Figure 22-16](#). When the PWM counter matches the duty register, the output flip-flop changes state, causing the PWM waveform to also change state. A match between the PWM counter and the period register behaves differently depending on what output mode is selected as shown in [Figure 22-16](#) and described in [Section 22.4.2.5, “Left Aligned Outputs”](#) and [Section 22.4.2.6, “Center Aligned Outputs”](#).

Each channel counter can be read at anytime without affecting the count or the operation of the PWM channel.

Any value written to the counter causes the counter to reset to \$00, the counter direction to be set to up, the immediate load of both duty and period registers with values from the buffers, and the output to change according to the polarity bit. When the channel is disabled ($PWME_x = 0$), the counter stops. When a channel becomes enabled ($PWME_x = 1$), the associated PWM counter continues from the count in the $PWMCNT_x$ register. This allows the waveform to continue where it left off when the channel is re-enabled. When the channel is disabled, writing “0” to the period register will cause the counter to reset on the next selected clock.

NOTE

If the user wants to start a new “clean” PWM waveform without any “history” from the old waveform, the user must write to channel counter ($PWMCNT_x$) prior to enabling the PWM channel ($PWME_x = 1$).

Generally, writes to the counter are done prior to enabling a channel in order to start from a known state. However, writing a counter can also be done while the PWM channel is enabled (counting). The effect is similar to writing the counter when the channel is disabled, except that the new period is started immediately with the output set according to the polarity bit.

NOTE

Writing to the counter while the channel is enabled can cause an irregular PWM cycle to occur.

The counter is cleared at the end of the effective period (see [Section 22.4.2.5, “Left Aligned Outputs”](#) and [Section 22.4.2.6, “Center Aligned Outputs”](#) for more details).

Table 22-12. PWM Timer Counter Conditions

Counter Clears (\$00)	Counter Counts	Counter Stops
When $PWMCNT_x$ register written to any value	When PWM channel is enabled ($PWME_x = 1$). Counts from last value in $PWMCNT_x$.	When PWM channel is disabled ($PWME_x = 0$)
Effective period ends		

22.4.2.5 Left Aligned Outputs

The PWM timer provides the choice of two types of outputs, left aligned or center aligned. They are selected with the CAEx bits in the $PWMC_{AE}$ register. If the CAEx bit is cleared ($CAE_x = 0$), the corresponding PWM output will be left aligned.

In left aligned output mode, the 8-bit counter is configured as an up counter only. It compares to two registers, a duty register and a period register as shown in the block diagram in [Figure 22-16](#). When the PWM counter matches the duty register the output flip-flop changes state causing the PWM waveform to also change state. A match between the PWM counter and the period register resets the counter and the output flip-flop, as shown in [Figure 22-16](#), as well as performing a load from the double buffer period and duty register to the associated registers, as described in [Section 22.4.2.3, “PWM Period and Duty”](#). The counter counts from 0 to the value in the period register – 1.

NOTE

Changing the PWM output mode from left aligned to center aligned output (or vice versa) while channels are operating can cause irregularities in the PWM output. It is recommended to program the output mode before enabling the PWM channel.

Figure 22-17. PWM Left Aligned Output Waveform

To calculate the output frequency in left aligned output mode for a particular channel, take the selected clock source frequency for the channel (A, B, SA, or SB) and divide it by the value in the period register for that channel.

- PWMx Frequency = Clock (A, B, SA, or SB) / PWMPERx
- PWMx Duty Cycle (high time as a% of period):
 - Polarity = 0 (PPOLx = 0)

$$\text{Duty Cycle} = [(PWMPERx - PWMDTYx) / PWMPERx] * 100\%$$
 - Polarity = 1 (PPOLx = 1)

$$\text{Duty Cycle} = [PWMDTYx / PWMPERx] * 100\%$$

As an example of a left aligned output, consider the following case:

Clock Source = bus clock, where bus clock = 10 MHz (100 ns period)

PPOLx = 0

PWMPERx = 4

PWMDTYx = 1

PWMx Frequency = 10 MHz / 4 = 2.5 MHz

PWMx Period = 400 ns

PWMx Duty Cycle = 3/4 * 100% = 75%

The output waveform generated is shown in [Figure 22-18](#).

Figure 22-18. PWM Left Aligned Output Example Waveform

22.4.2.6 Center Aligned Outputs

For center aligned output mode selection, set the CAEx bit (CAEx = 1) in the PWMCAE register and the corresponding PWM output will be center aligned.

The 8-bit counter operates as an up/down counter in this mode and is set to up whenever the counter is equal to \$00. The counter compares to two registers, a duty register and a period register as shown in the block diagram in [Figure 22-16](#). When the PWM counter matches the duty register, the output flip-flop changes state, causing the PWM waveform to also change state. A match between the PWM counter and the period register changes the counter direction from an up-count to a down-count. When the PWM counter decrements and matches the duty register again, the output flip-flop changes state causing the PWM output to also change state. When the PWM counter decrements and reaches zero, the counter direction changes from a down-count back to an up-count and a load from the double buffer period and duty registers to the associated registers is performed, as described in [Section 22.4.2.3, “PWM Period and Duty”](#). The counter counts from 0 up to the value in the period register and then back down to 0. Thus the effective period is $PWMPER_x * 2$.

NOTE

Changing the PWM output mode from left aligned to center aligned output (or vice versa) while channels are operating can cause irregularities in the PWM output. It is recommended to program the output mode before enabling the PWM channel.

Figure 22-19. PWM Center Aligned Output Waveform

To calculate the output frequency in center aligned output mode for a particular channel, take the selected clock source frequency for the channel (A, B, SA, or SB) and divide it by twice the value in the period register for that channel.

- PWMx Frequency = Clock (A, B, SA, or SB) / (2*PWMPER_x)
- PWMx Duty Cycle (high time as a% of period):
 - Polarity = 0 (PPOL_x = 0)

$$\text{Duty Cycle} = [(PWMPER_x - PWMDTY_x) / PWMPER_x] * 100\%$$
 - Polarity = 1 (PPOL_x = 1)

$$\text{Duty Cycle} = [PWMDTY_x / PWMPER_x] * 100\%$$

As an example of a center aligned output, consider the following case:

Clock Source = bus clock, where bus clock = 10 MHz (100 ns period)

PPOL_x = 0

PWMPER_x = 4

PWMDTY_x = 1

PWM_x Frequency = 10 MHz/8 = 1.25 MHz

PWM_x Period = 800 ns

PWM_x Duty Cycle = 3/4 * 100% = 75%

Shown in [Figure 22-20](#) is the output waveform generated.

Figure 22-20. PWM Center Aligned Output Example Waveform

22.4.2.7 PWM 16-Bit Functions

The scalable PWM timer also has the option of generating up to 8-channels of 8-bits or 4-channels of 16-bits for greater PWM resolution. This 16-bit channel option is achieved through the concatenation of two 8-bit channels.

The PWMCTL register contains four control bits, each of which is used to concatenate a pair of PWM channels into one 16-bit channel. Channels 6 and 7 are concatenated with the CON67 bit, channels 4 and 5 are concatenated with the CON45 bit, channels 2 and 3 are concatenated with the CON23 bit, and channels 0 and 1 are concatenated with the CON01 bit.

NOTE

Change these bits only when both corresponding channels are disabled.

When channels 6 and 7 are concatenated, channel 6 registers become the high order bytes of the double byte channel, as shown in [Figure 22-21](#). Similarly, when channels 4 and 5 are concatenated, channel 4 registers become the high order bytes of the double byte channel. When channels 2 and 3 are concatenated, channel 2 registers become the high order bytes of the double byte channel. When channels 0 and 1 are concatenated, channel 0 registers become the high order bytes of the double byte channel.

When using the 16-bit concatenated mode, the clock source is determined by the low order 8-bit channel clock select control bits. That is channel 7 when channels 6 and 7 are concatenated, channel 5 when channels 4 and 5 are concatenated, channel 3 when channels 2 and 3 are concatenated, and channel 1 when channels 0 and 1 are concatenated. The resulting PWM is output to the pins of the corresponding low order 8-bit channel as also shown in [Figure 22-21](#). The polarity of the resulting PWM output is controlled by the PPOL_x bit of the corresponding low order 8-bit channel as well.

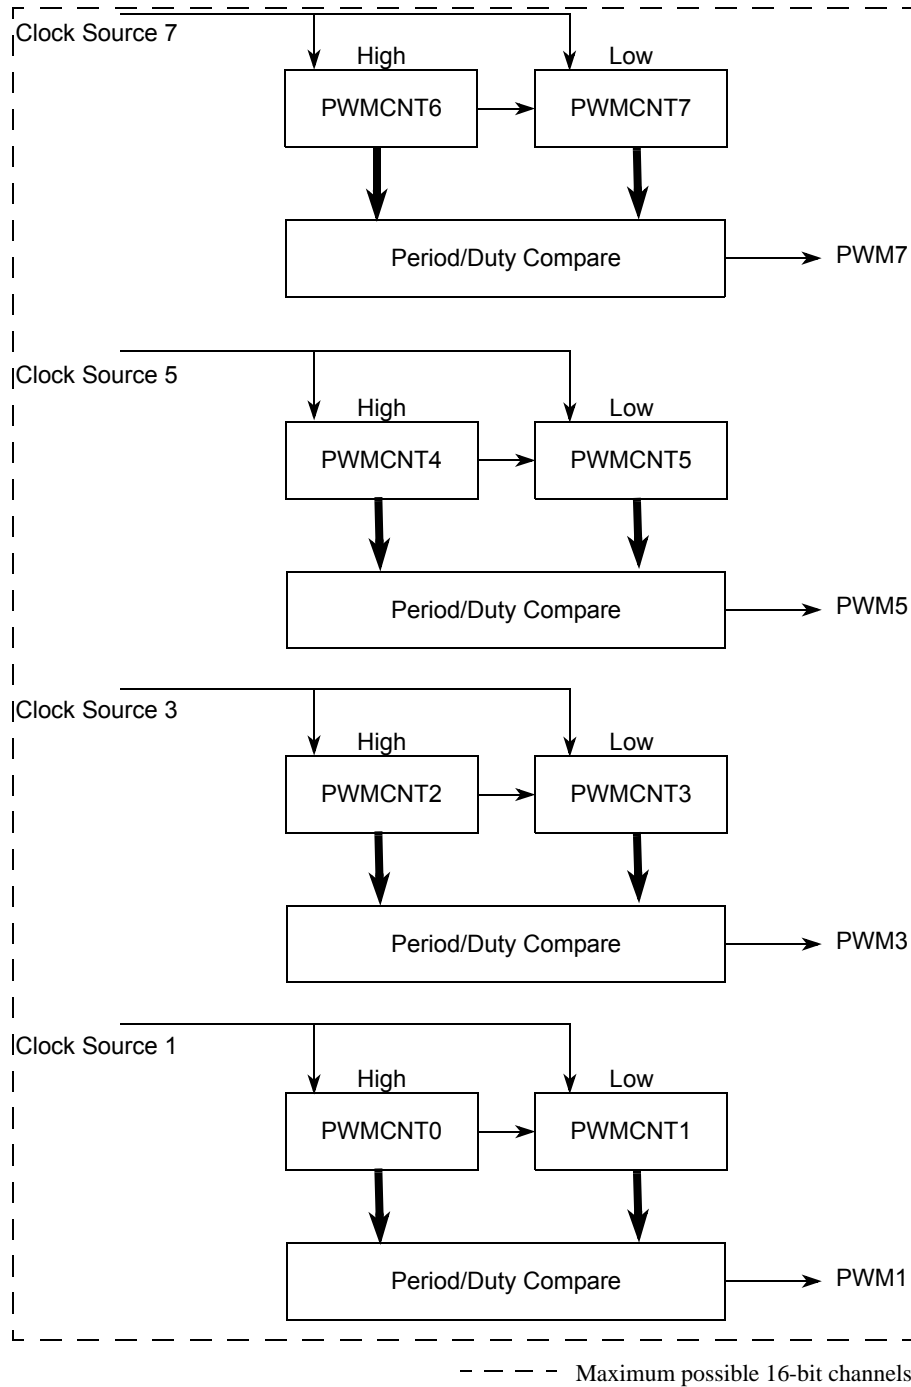

Figure 22-21. PWM 16-Bit Mode

Once concatenated mode is enabled (CONxx bits set in PWMCTL register), enabling/disabling the corresponding 16-bit PWM channel is controlled by the low order PWME_x bit. In this case, the high order bytes PWME_x bits have no effect and their corresponding PWM output is disabled.

In concatenated mode, writes to the 16-bit counter by using a 16-bit access or writes to either the low or high order byte of the counter will reset the 16-bit counter. Reads of the 16-bit counter must be made by 16-bit access to maintain data coherency.

Either left aligned or center aligned output mode can be used in concatenated mode and is controlled by the low order CAEx bit. The high order CAEx bit has no effect.

Table 22-13 is used to summarize which channels are used to set the various control bits when in 16-bit mode.

Table 22-13. 16-bit Concatenation Mode Summary

Note: Bits related to available channels have functional significance.

CONxx	PWMEx	PPOLx	PCLKx	CAEx	PWMx Output
CON67	PWME7	PPOL7	PCLK7	CAE7	PWM7
CON45	PWME5	PPOL5	PCLK5	CAE5	PWM5
CON23	PWME3	PPOL3	PCLK3	CAE3	PWM3
CON01	PWME1	PPOL1	PCLK1	CAE1	PWM1

22.4.2.8 PWM Boundary Cases

Table 22-14 summarizes the boundary conditions for the PWM regardless of the output mode (left aligned or center aligned) and 8-bit (normal) or 16-bit (concatenation).

Table 22-14. PWM Boundary Cases

PWMDTYx	PWMPERx	PPOLx	PWMx Output
\$00 (indicates no duty)	>\$00	1	Always low
\$00 (indicates no duty)	>\$00	0	Always high
XX	\$00 ⁽¹⁾ (indicates no period)	1	Always high
XX	\$00 ¹ (indicates no period)	0	Always low
>= PWMPERx	XX	1	Always high
>= PWMPERx	XX	0	Always low

1. Counter = \$00 and does not count.

22.5 Resets

The reset state of each individual bit is listed within the [Section 22.3.2, “Register Descriptions”](#) which details the registers and their bit-fields. All special functions or modes which are initialized during or just following reset are described within this section.

- The 8-bit up/down counter is configured as an up counter out of reset.
- All the channels are disabled and all the counters do not count.

- For channels 0, 1, 4, and 5 the clock choices are clock A.
- For channels 2, 3, 6, and 7 the clock choices are clock B.

22.6 Interrupts

The PWM module has no interrupt.

Appendix A

MCU Electrical Specifications

A.1 General

This section contains the most accurate electrical information available at the time of publication.

A.1.1 Parameter Classification

The electrical parameters shown in the appendices are guaranteed by various methods.

The parameter classification is documented in the PPAP.

The parameter classification columns are for NXP internal use only.

Table A-1. Power Supplies

Mnemonic	Nominal Voltage	Description
VDD	1.8 V	1.8V core supply voltage generated by on chip voltage regulator
VSS1	0 V	Ground pin for 2.8V flash supply voltage generated by on chip voltage regulator
VSS2	0 V	Ground pin for 1.8V core supply voltage generated by on chip voltage regulator
VDDF	2.8 V	2.8V flash supply voltage generated by on chip voltage regulator
VDDX1 ⁽¹⁾	5.0 V	5V power supply output for I/O drivers generated by on chip voltage regulator
VSSX ₁	0 V	Ground pin for I/O drivers
VDDX2	5.0 V	5V power supply output for I/O drivers generated by on chip voltage regulator
VDDA	5.0 V	5V Power supply for the analog-to-digital converter and for the reference circuit of the internal voltage regulator
VSSA	0 V	Ground pin for VDDA analog supply
LGND	0 V	Ground pin for LIN physical interface
HD	12 V	GDU Highside Drain. Also used as LIN supply, VLINSUP.
VSUP	12 V/18 V	External power supply for voltage regulator
VDDC	5 V	Power supply output for CANPHY
VDDS2	5 V	Power supply output (5V) for external sensors
VDDS1	5 V	Power supply output (5V) for external sensors
VLS_OUT	11 V	GDU voltage regulator output for low side FET-predriver power supply.
VSSB	0 V	Ground pin for boost supply.

1. All VDDX pins are internally connected by metal

NOTE

VDDA is connected to VDDX pins by diodes for ESD protection such that VDDX must not exceed VDDA by more than a diode voltage drop. VSSA and VSSX are connected by anti-parallel diodes for ESD protection.

A.1.2 Pins

There are 4 groups of functional pins.

A.1.2.1 General Purpose I/O Pins (GPIO)

The I/O pins have a level in the range of 4.5V to 5.5V. This class of pins is comprised of all port I/O pins, BKGD and the RESET pins.

A.1.2.2 High Voltage Pins

These consist of the LIN, BST, HD, VCP, CP, VLS_OUT, VLS[2:0], VBS[2:0], HG[2:0], HS[2:0], LG[2:0], LD[2:0], PL0, CANH0, CANL0, SPLIT0, VDDS1, VDDS2, BCTLS1, BCTLS2, SNPS1,

SNPS2 pins. These pins are intended to interface to external components operating in the automotive battery range. They have nominal voltages above the standard 5V I/O voltage range.

A.1.2.3 Oscillator

If the designated EXTAL and XTAL pins are configured for external oscillator operation then these pins have a nominal voltage of 1.8 V.

A.1.2.4 TEST

This pin is used for production testing only. The TEST pin must be tied to ground in all applications.

A.1.3 Current Injection

Power supply must maintain regulation within operating V_{DDX} or V_{DD} range during instantaneous and operating maximum current conditions. **Figure A-1.** shows a 5 V GPIO pad driver and the on chip voltage regulator with VDDX output. It shows also the power and ground pins VSUP, VDDX, VSSX and VSSA. Px represents any 5 V GPIO pin. Assume Px is configured as an input. The pad driver transistors P1 and N1 are switched off (high impedance). If the voltage V_{in} on Px is greater than V_{DDX} a positive injection current I_{in} will flow through diode D1 into VDDX node. If this injection current I_{in} is greater than I_{Load} , the internal power supply VDDX may go out of regulation. Ensure the external V_{DDX} load will shunt current greater than maximum injection current. This is the greatest risk when the MCU is not consuming

power; e.g., if no system clock is present, or if the clock rate is very low which would reduce overall power consumption.

Figure A-1. Current Injection on GPIO Port if $V_{in} > V_{DDX}$

A.1.4 Absolute Maximum Ratings

Absolute maximum ratings are stress ratings only. A functional operation outside these ranges is not guaranteed. Stress beyond these limits may affect the reliability or cause permanent damage of the device.

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level.

The CANPHY maximum ratings are specified in [Appendix H.1](#)

Table A-2. Absolute Maximum Ratings

Num	Rating	Symbol	Min	Max	Unit
1	Voltage regulator and LINPHY supply voltage	V_{SUP}	-0.3	42	V
2	DC voltage on LIN	V_{LIN}	-32	42	V
3	DC voltage on HVI pin PL0	V_{HVI}	-27	42	V
4	Core logic supply voltage	V_{DD}	-0.3	2.16	V

Table A-2. Absolute Maximum Ratings

5	Flash supply voltage	V_{DDF}	-0.3	3.6	V
6	FET-Predriver High-Side Drain	V_{HD}	-0.3	42	V
7	FET-Predriver Bootstrap Capacitor Connection	V_{VBS}	-0.3	42	V
8	FET-Predriver High-Side Gate ⁽¹⁾	V_{HG}	-5	42	V
9a	FET-Predriver High-Side Source ⁽¹⁾	V_{HS}	-5	42	V
9b	FET-Predriver High-Side Source negative pulse of up to 1us	V_{HS}	-7	—	V
10	Generated FET-Predriver Low-Side Supply	V_{VLS_OUT}	-0.3	42	V
11	FET-Predriver Low-Side Supply Inputs	V_{VLS}	-0.3	42	V
12	FET-Predriver Low-Side Gate ⁽¹⁾	V_{LG}	-5	42	V
13	FET-Predriver Low-Side Source ⁽¹⁾	V_{LS}	-5	42	V
14	FET-Predriver Low-Side Drain ⁽¹⁾	V_{LD}	-5	42	V
15	FET-Predriver Charge Pump Output	V_{CP}	-0.3	42	V
16	FET-Predriver Charge Pump Input	V_{VCP}	-0.3	42	V
17	FET-Predriver Boost Converter Connection	V_{BST}	-0.3	42	V
18	FET-Predriver Boost Converter Ground	V_{VSSB}	-0.3	0.3	V
19	Voltage Regulator Ballast Connection	V_{BCTL}	-0.3	42	V
20	Supplies VDDA, VDDC, VDDX	V_{VDDACX}	-0.3	6	V
21	Supplies VDDS1, VDDS2	V_{VDDS}	-0.3	42	V
22	Base connection of bipolar for CANPHY supply	V_{BCTLC}	-0.3	42	V
23	Voltage difference V_{DDX} to V_{DDA} ⁽²⁾	ΔV_{DDX}	-0.3	0.3	V
24	Voltage difference V_{SSX} to V_{SSA}	ΔV_{SSX}	-0.3	0.3	V
25	Digital I/O input voltage	V_{IN}	-0.3	6.0	V
26	EXTAL, XTAL ⁽³⁾	V_{ILV}	-0.3	2.16	V
27	TEST input	V_{TEST}	-0.3	10.0	V
28	Instantaneous current. Single pin limit for all digital I/O pins ⁽⁴⁾	I_D	-25	+25	mA
29	Instantaneous maximum current on EVDD1	I_{EVDD1}	-80	+25	mA
30	Instantaneous maximum current. Single pin limit for EXTAL, XTAL	I_{DL}	-25	+25	mA
31	Storage temperature range	T_{stg}	-65	155	°C

1. Negative limit for pulsed operation only.

2. VDDX and VDDA must be shorted

3. EXTAL, XTAL pins configured for external oscillator operation only

4. All digital I/O pins are internally clamped to V_{SSX} and V_{DDX} , or V_{SSA} and V_{DDA} .

A.1.5 ESD Protection and Latch-up Immunity

All ESD testing is in conformity with CDF-AEC-Q100 stress test qualification for automotive grade integrated circuits. During the device qualification ESD stresses were performed for the Human Body Model (HBM) and the Charged-Device Model.

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification. Complete DC parametric and functional testing is performed per the applicable device specification at room temperature followed by hot temperature, unless specified otherwise.

For better immunity to ESD events, the PCB test point for the BST pin should be located at a distance from the device to increase the track length to the BST pin, but the diode should be located close to the device. This may require a track branch on the PCB to ensure that the test point is further away from the device than the diode.

Table A-3. ESD and Latch-up Test Conditions

Model	Spec	Description	Symbol	Value	Unit
Human Body	JESD22-A114	Series Resistance	R	1500	Ω
		Storage Capacitance	C	100	pF
		Number of Pulses per pin positive negative	-	- 1 1	
Charged-Device	JESD22-C101	Series Resistance	R	0	Ω
		Storage Capacitance	C	4	pF
Latch-up for 5V GPIOs		Minimum Input Voltage Limit		-2.5	V
		Maximum Input Voltage Limit		+7.5	V
Latch-up for HD, VCP, BST, LIN, BCTL, BCTLC		Minimum Input Voltage Limit		-7	V
		Maximum Input Voltage Limit		+27	V
Latch-up for CANH, CANL, SPLIT		Minimum Input Voltage Limit		-7	V
		Maximum Input Voltage Limit		+21	V
Latch-up for HG, HS		Minimum Input Voltage Limit		-5	V
		Maximum Input Voltage Limit (VBS=10V)		15	V
Latch-up for LG, LS, LD		Minimum Input Voltage Limit		-5	V
		Maximum Input Voltage Limit (VLS=10V)		15	V

Table A-4. ESD Protection and Latch-up Characteristics

Num	C	Rating	Symbol	Min	Max	Unit
1		Human Body Model (HBM): - LIN versus LGND - CANH, CANL, SPLIT, PLO - All other pins	V_{HBM} V_{HBM} V_{HBM}	+/-6 +/-4 +/-2	- - -	KV
2		Charged-Device Model (CDM): Corner Pins	V_{CDM}	+/-750	-	V
3		Charged-Device Model (CDM): All other pins	V_{CDM}	+/-500	-	V
4		Direct Contact Discharge IEC61000-4-2 with and with out 220pF capacitor (R=330, C=150pF): LIN versus LGND, CANH, CANL	V_{ESDIEC}	+/-6	-	KV

Table A-4. ESD Protection and Latch-up Characteristics

5	Latch-up Current of 5V GPIOs at T=125°C positive negative	I_{LAT}	+100 -100	-	mA
6	Latch-up Current (VCP, BST, LIN, HD, HS, HG, LG, LS, LD) T=125°C positive negative	I_{LAT}	+100 -100	-	mA
7	Latch-up Current of 5V GPIOs at 27°C positive negative	I_{LAT}	+200 -200	-	mA
8	Latch-up Current (VCP, BST, LIN, HD, HS, HG, LG, LS, LD) T= 27°C positive negative	I_{LAT}	+200 -200	-	mA

A.1.6 Recommended Capacitor Values

Table A-5. Recommended Capacitor Values (nominal component values)

Num	Characteristic	Symbol	Typical	Unit
1	VDDX decoupling capacitor ⁽¹⁾ ⁽²⁾	$C_{VDDX1,2}$	100-220	nF
2	VDDA decoupling capacitor ⁽¹⁾	C_{VDDA}	100-220	nF
3	VDDX stability capacitor ⁽³⁾ ⁽⁴⁾	C_{VDD5}	4.7-10	uF
4	VDDC stability capacitor	C_{VDDC}	4.7-10	uF
5	VDDS[2:1] stability capacitor	C_{VDDS}	4.7-10	uF
6	VLS decoupling capacitor ⁽¹⁾ ⁽⁵⁾	$C_{VLS0,1,2}$	100-220	nF
7	VLS stability capacitor ⁽³⁾ ⁽⁶⁾	C_{VLS}	4.7-10	uF
8	VDD decoupling capacitor ⁽¹⁾	C_{VDD}	100-220	nF
9	VDDF decoupling capacitor ⁽¹⁾	C_{VDDF}	100-220	nF
10	LIN decoupling capacitor ⁽¹⁾	C_{LIN}	220	pF

1. X7R ceramic
2. One capacitor per VDDX pin
3. 4.7µF ceramic or 10µF tantalum
4. Can be placed anywhere on the 5V supply node (VDDA, VDDX)
5. One capacitor per each VLS[2:0] pin
6. Can be placed anywhere on the VLS node

A.1.7 Operating Conditions

This section describes the operating conditions of the device. Unless otherwise noted these conditions apply to the following electrical parameters.

NOTE

Please refer to the temperature rating of the device with regards to the ambient temperature T_A and the junction temperature T_J . For power dissipation calculations refer to [Section A.1.8, “Power Dissipation and Thermal Characteristics”](#).

Table A-6. Operating Conditions

Num	Rating	Symbol	Min	Typ	Max	Unit
1	Voltage regulator and LINPHY supply voltage ⁽¹⁾	V_{SUP}	3.5	12	40	V
2	Voltage difference V_{DDX} to V_{DDA}	ΔV_{DDX}	-0.1	—	0.1	V
3	Voltage difference V_{SSX} to V_{SSA}	ΔV_{SSX}	-0.1	—	0.1	V
	Digital logic supply voltage	V_{DD}	1.72	1.8	1.98	V
4	Oscillator	f_{osc}	4	—	20	MHz
5	Bus frequency ⁽²⁾ -40°C < T_J < 150°C 150°C < T_J < 175°C (Temp option W only)	f_{bus}	(4)	— —	50 40	MHz
6	Bus frequency without flash wait states -40°C < T_J < 150°C 150°C < T_J < 175°C (Temp option W only)	f_{WSTAT}	— —	— —	25 20	MHz
7a	Operating junction temperature range Operating ambient temperature range ⁽³⁾ (option V)	T_J T_A	-40 -40	— —	125 105	°C
7b	Operating junction temperature range Operating ambient temperature range ⁽³⁾ (option M)	T_J T_A	-40 -40	— —	150 125	°C
7c	Operating junction temperature range Operating ambient temperature range ⁽³⁾ (option W)	T_J T_A	-40 -40	— —	175 150	°C

1. Normal operating range is 5.5 V - 18 V. Continuous operation at 40 V is not allowed. Only Transient Conditions (Load Dump) single pulse $t_{max} < 400$ ms. Operation down to 3.5V is guaranteed without reset, however some electrical parameters are specified only in the range above 4.5 V. Operation in the range $20V < V_{SUP} < 26.5V$ is limited to 1 hour over lifetime of the device. In this range the device continues to function but electrical parameters are degraded.
2. The flash program and erase operations must configure f_{NVMOP} as specified in the NVM electrical section.
3. Please refer to [Section A.1.8, “Power Dissipation and Thermal Characteristics”](#) for more details about the relation between ambient temperature T_A and device junction temperature T_J .
4. Refer to f_{ATDCLK} for minimum ADC operating frequency. This is derived from the bus clock.

NOTE

Operation is guaranteed when powering down until low voltage reset assertion.

A.1.8 Power Dissipation and Thermal Characteristics

Power dissipation and thermal characteristics are closely related. The user must assure that the maximum operating junction temperature is not exceeded. The average chip-junction temperature (T_J) in °C can be obtained from:

$$T_J = T_A + (P_D \cdot \Theta_{JA})$$

T_J = Junction Temperature, [°C]

T_A = Ambient Temperature, [°C]

P_D = Total Chip Power Dissipation, [W]

Θ_{JA} = Package Thermal Resistance, [°C/W]

The total power dissipation P_D can be calculated from the equation below. [Table A-7](#) below lists the power dissipation components. [Figure A-2](#) provides an overview of power pin connectivity.

$$P_D = P_{VSUP} + P_{BCTL} + P_{INT} - P_{GPIO} + P_{LIN} - P_{EVDD1} + P_{GDU}$$

Table A-7. Power Dissipation Components

Power Component	Description
$P_{VSUP} = V_{SUP} I_{SUP}$	Internal Power through VSUP pin
$P_{BCTL} = V_{BCTL} I_{BCTL}$	Internal Power through BCTL pin
$P_{INT} = V_{DDX} I_{VDDX} + V_{DDA} I_{VDDA}$	Internal Power through VDDX/A pins.
$P_{GPIO} = V_{IO} I_{IO}$	Power dissipation of external load driven by GPIO Port. Assuming the load is connected between GPIO and ground. This power component is included in P_{INT} and is subtracted from overall MCU power dissipation P_D
$P_{LIN} = V_{LIN} I_{LIN}$	Power dissipation of LINPHY
$P_{GDU}^{(1)} = (-V_{VLS_OUT} I_{VLS_OUT}) + (V_{VBS} I_{VBS}) + (V_{VCP} I_{VCP}) + (V_{VI_Sn} I_{VI_Sn})$	Power dissipation of FET-Predriver without the outputs switching

1. No switching. GDU power consumption is very load dependent.

Figure A-2. Supply Currents Overview

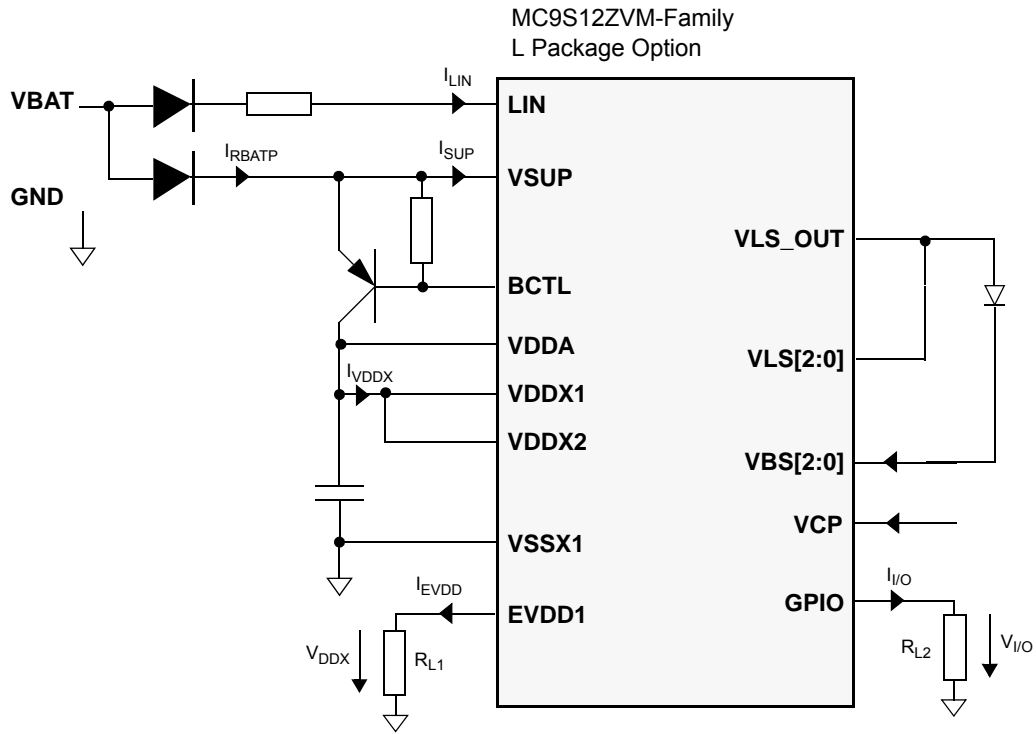

Table A-8. 80LQFP-EP Thermal Package Characteristics

Num	C ⁽¹⁾	Rating	Symbol	Min	Typ	Max	Unit
1		Thermal resistance, single sided PCB ⁽²⁾ Natural Convection	θ_{JA}	—	59	—	°C/W
2		Thermal resistance, double sided PCB ⁽²⁾ with 2 internal planes. Natural Convection.	θ_{JA}	—	26	—	°C/W
3		Thermal resistance, single sided PCB ⁽³⁾ (@200 ft./min)	θ_{JA}	—	47	—	°C/W
4		Thermal resistance, double sided PCB ⁽³⁾ with 2 internal planes (@200 ft./min).	θ_{JA}	—	20	—	°C/W
5		Junction to Board ⁽⁴⁾	θ_{JB}	—	11	—	°C/W
6		Junction to Case Top ⁽⁵⁾	θ_{JCTop}	—	15	—	°C/W
7		Junction to Case Bottom ⁽⁶⁾	$\theta_{JCbottom}$	—	0.6	—	°C/W
8		Junction to Package Top ⁽⁷⁾	Ψ_{JT}	—	2	—	°C/W

1. The values for thermal resistance are achieved by package simulations
2. Per JEDEC JESD51-2 with natural convection for horizontally oriented board. Board meets JESD51-9 specification for 1s or 2s2p board, respectively
3. Per JEDEC JESD51-6 with forced convection for horizontally oriented board. Board meets JESD51-9 specification for 1s or 2s2p board, respectively
4. Thermal resistance between the die and the printed circuit board per JEDEC JESD51-8. Board temperature is measured on the top surface of the board near the package.

5. Thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC-883 Method 1012.1).
6. Thermal resistance between the die and the solder pad on the bottom of the package based on simulation without any interface resistance
7. Thermal characterization parameter indicating the temperature difference between package top and the junction temperature per JEDEC JESD51-2. A single layer board is used for this simulation.

Table A-9. 64LQFP-EP Typical Thermal Package Characteristics (ZVML31, ZVM32, ZVM16 devices)

Num	C ⁽¹⁾	Rating	Symbol	maskset 0N14N	maskset 1N14N	Unit
1		Thermal resistance 64LQFP-EP, single sided PCB ⁽²⁾ Natural Convection	θ_{JA}	71	60	°C/W
2		Thermal resistance 64LQFP-EP, double sided PCB ⁽²⁾ with 2 internal planes. Natural Convection.	θ_{JA}	32	29	°C/W
3		Thermal resistance 64LQFP-EP, single sided PCB ⁽³⁾ (@200 ft./min)	θ_{JA}	58	48	°C/W
4		Thermal resistance 64LQFP-EP, double sided PCB ⁽³⁾ with 2 internal planes (@200 ft./min).	θ_{JA}	27	23	°C/W
5		Junction to Board 64LQFP-EP ⁽⁴⁾	θ_{JB}	16	12	°C/W
6		Junction to Case Top 64LQFP-EP ⁽⁵⁾	θ_{JCTop}	19	15	°C/W
7		Junction to Case Bottom 64LQFP-EP ⁽⁶⁾	$\theta_{JCbottom}$	1.8	1.5	°C/W
8		Junction to Package Top 64LQFP-EP ⁽⁷⁾	Ψ_{JT}	4	3	°C/W

1. The values for thermal resistance are achieved by package simulations
2. Junction to ambient thermal resistance. Per JEDEC JESD51-2 with natural convection for horizontally oriented board. Board meets JESD51-9 specification for 1s or 2s2p board, respectively.
3. Junction to ambient thermal resistance. Per JEDEC JESD51-6 with forced convection for horizontally oriented board. Board meets JESD51-9 specification for 1s or 2s2p board, respectively.
4. Thermal resistance between the die and the printed circuit board per JEDEC JESD51-8. Board temperature is measured on the top surface of the board near the package.
5. Thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC-883 Method 1012.1).
6. Thermal resistance between the die and the solder pad on the bottom of the package based on simulation without any interface resistance
7. Thermal characterization parameter indicating the temperature difference between package top and the junction temperature per JEDEC JESD51-2. A single layer board is used for this simulation.

Table A-10. 64LQFP-EP Typical Thermal Package Characteristics (All other devices)

Num	C ⁽¹⁾	Rating	Symbol	masksets 1N95G, 2N95G	maskset 3N95G	Unit
1		Thermal resistance 64LQFP-EP, single sided PCB ⁽²⁾ Natural Convection	θ_{JA}	69	58	°C/W
2		Thermal resistance 64LQFP-EP, double sided PCB ⁽²⁾ with 2 internal planes. Natural Convection.	θ_{JA}	31	28	°C/W
3		Thermal resistance 64LQFP-EP, single sided PCB ⁽³⁾ (@200 ft./min)	θ_{JA}	56	46	°C/W
4		Thermal resistance 64LQFP-EP, double sided PCB ⁽³⁾ with 2 internal planes (@200 ft./min).	θ_{JA}	26	22	°C/W
5		Junction to Board 64LQFP-EP ⁽⁴⁾	θ_{JB}	15	11	°C/W

7. Thermal characterization parameter indicating the temperature difference between package top and the junction temperature per JEDEC JESD51-2. A single layer board is used for this simulation.

A.2 General Purpose I/O Characteristics

Table A-12. 5V I/O Characteristics

Conditions are $4.5\text{ V} < V_{DDX} < 5.5\text{ V}$, $-40^\circ\text{C} < T_j < 175^\circ\text{C}$ for all GPIO pins (defined in A.1.2.1/A-876) unless otherwise noted.						
Num	Rating	Symbol	Min	Typ	Max	Unit
1	Input high voltage, $3.13\text{ V} < V_{DDX} < 5.5\text{ V}$	V_{IH}	$0.65 \cdot V_{DDX}$	—	—	V
2	Input high voltage	V_{IH}	—	—	$V_{DDX} + 0.3$	V
3	Input low voltage, $3.13\text{ V} < V_{DDX} < 5.5\text{ V}$	V_{IL}	—	—	$0.35 \cdot V_{DDX}$	V
4	Input low voltage	V_{IL}	$V_{SSX} - 0.3$	—	—	V
5	Input hysteresis	V_{HYS}	—	250	—	mV
6a	Input leakage current. All cases except 6b,6c,6d. ⁽¹⁾ $V_{in} = V_{DDX}$ or V_{SSX}	I_{in}	-1	—	1	μA
6b	Input leakage current PAD[15:0], ZVMC256 ⁽¹⁾ $V_{in} = V_{DDX}$ or V_{SSX} , $T_j = 125^\circ\text{C}$	I_{in}	-0.3	—	0.3	μA
6c	Input leakage current. PAD8 (all devices except ZVMC256), PP0 ⁽¹⁾ $V_{in} = V_{DDX}$ or V_{SSX}	I_{in}	-2.5	—	2.5	μA
6d	Input leakage current. PAD8, PP0 ⁽¹⁾ $-40^\circ\text{C} < T_j < 150^\circ\text{C}$, $V_{in} = V_{DDX}$ or V_{SSX}	I_{in}	-1	—	1	μA
7	Output high voltage (All GPIO except EVDD1) $I_{OH} = -4\text{ mA}$	V_{OH}	$V_{DDX} - 0.8$	—	—	V
8a	Output high voltage (EVDD1), $V_{DDX} > 4.85\text{V}$ Partial Drive $I_{OH} = -2\text{ mA}$ Full Drive $I_{OH} = -20\text{ mA}$	V_{OH}	$V_{DDX} - 0.8$	—	—	V
8b	Output high voltage (EVDD1), $V_{DDX} > 4.85\text{V}$ Full Drive $I_{OH} = -10\text{ mA}$	V_{OH}	$V_{DDX} - 0.1$	—	—	V
9	Output low voltage (All GPIO except EVDD1) $I_{OL} = +4\text{ mA}$	V_{OL}	—	—	0.8	V
10	Output low voltage (EVDD1) Partial drive $I_{OL} = +2\text{ mA}$ or Full drive $I_{OL} = +20\text{ mA}$	V_{OL}	—	—	0.8	V
11	Maximum allowed continuous current on EVDD1	I_{EVDD1}	-20	—	10	mA
12	Over-current Detect Threshold EVDD1	I_{OCD}	-80	—	-40	mA
13	Internal pull up current (All GPIO except RESET) $V_{IH\text{ min}} > \text{input voltage} > V_{IL\text{ max}}$	I_{PUL}	-10	—	-130	μA
14	Internal pull up resistance (RESET pin)	R_{PUL}	2.5	5	10	$\text{K}\Omega$
15	Internal pull down current, $V_{IH\text{ min}} > V_{in} > V_{IL\text{ max}}$	I_{PDH}	10	—	130	μA
16	Input capacitance	C_{in}	—	7	—	pF
17a	Injection current ⁽²⁾ Single pin limit (all GPIO pins) Total device limit, sum of all injected currents	I_{ICS} I_{ICP}	-2.5 -25	—	2.5 25	mA
17b	Injection current single pin (HG,HS,LS pins) ⁽³⁾	I_{ICS}	-2.5	—	2.5	mA

1. Pins in high impedance input mode. Maximum leakage current occurs at maximum operating temperature. Current decreases by approximately one-half for each 8°C to 12°C in the temperature range from 50°C to 125°C .

- For better ADC accuracy, the application should avoid current injection into pin PAD8/VREFH. Refer to [Section A.1.3, “Current Injection”](#) for more details
- For better ADC accuracy, the application should avoid current injection into pin HS0 and HG0 during ADC conversions. This can be achieved by correct synchronization of ADC and FET switching..

Table A-13. Pin Timing Characteristics (Junction Temperature From -40°C To +175°C)

Conditions are $4.5\text{ V} < V_{DDX} < 5.5\text{ V}$ unless otherwise noted. I/O Characteristics for all GPIO pins (defined in [A.1.2.1/A-876](#)).

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		Port P, S, AD interrupt input pulse filtered (STOP mode)	t_{P_MASK}	—	—	3	μs

7		$\overline{\text{RESET}}$ pin input pulse passed	R_{P_PASS}	22	—	—	ns

A.2.1 High Voltage Input Electrical Characteristics

Table A-14. High Voltage Input Electrical Characteristics (Junction Temperature From -40°C To +175°C)

Conditions are $5.5\text{ V} < V_{SUP} < 18\text{ V}$ unless otherwise noted.

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		Digital Input Threshold • $V_{SUP} > 6.5\text{ V}$ • $5.5\text{ V} < V_{SUP} < 6.5\text{ V}$	V_{TH_HVI}	2.8 2.0	3.5 2.5	4.5 3.8	V V
2		Input Hysteresis	V_{HYS_HVI}	—	250	—	mV
3		Pin Input Divider Ratio with external series R_{EXT_HVI} Ratio = $V_{HVI} / V_{Internal(ADC)}$	$Ratio_{L_HVI}$ $Ratio_{H_HVI}$	— —	2 6	— —	— —
4		Analog Input Matching Absolute Error on V_{ADC} ⁽¹⁾ • Compared to $V_{HVI} / Ratio_{L_HVI}$, ($1\text{ V} < V_{HVI} < 7\text{ V}$) • Compared to $V_{HVI} / Ratio_{H_HVI}$, ($3\text{ V} < V_{HVI} < 21\text{ V}$) • Direct Mode (PTADIRL=1), ($0.5\text{ V} < V_{HVI} < 3.5\text{ V}$)	AIM_{L_HVI} AIM_{H_HVI} AIM_{D_HVI}	— — —	+/- 2 +/- 2 +/- 2	+/- 5 +/- 5 +/- 5	% % %
5		High Voltage Input Series Resistor	R_{EXT_HVI}	—	10	—	$\text{K}\Omega$
6		Enable Uncertainty Time	t_{UNC_HVI}	—	1	—	μs
7		Input capacitance	C_{IN_HVI}	—	8	—	pF
8		Input leakage ($-40^\circ\text{C} < T_j < 150^\circ\text{C}$)	I_{IN_HVI}	—	0.1	1.8	μA

1. Outside of the given V_{HVI} range the error is significant. The ratio can be changed, if outside of the given range.

A.2.2 HV Physical Interface Characteristics

The HV Physical Interface specification is included in the LINPHY electrical section.

A.3 Supply Currents

This section describes the current consumption characteristics of the device as well as the conditions for the measurements.

A.3.1 Measurement Conditions

Current is measured on VSUP. VDDX is connected to VDDA. It does not include the current to drive external loads. Unless otherwise noted the currents are measured in special single chip mode and the CPU code is executed from RAM. For Run and Wait current measurements PLL is on and the reference clock is the IRC1M trimmed to 1MHz. For the junction temperature range from -40°C to $+150^{\circ}\text{C}$ the bus frequency is 50MHz. For the temperature range from $+150^{\circ}\text{C}$ to $+175^{\circ}\text{C}$, the bus frequency is 40MHz. [Table A-15](#), [Table A-16](#) and [Table A-17](#) show the configuration of the CPMU module and the peripherals for Run, Wait and Stop current measurement.

Table A-15. CPMU Configuration for Pseudo Stop Current Measurement

CPMU REGISTER	Bit settings/Conditions
CPMUCLKS	PLLSEL=0, PSTP=1, CSAD=0, PRE=PCE=RTIOSCSEL=1 COPOSCSEL[1:0]=01
CPMUOSC	OSCE=1, Quartz oscillator $f_{\text{EXTAL}}=4\text{MHz}$
CPMURTI	RTDEC=0, RTR[6:4]=111, RTR[3:0]=1111
CPMUCOP	WCOP=1, CR[2:0]=111

Table A-16. CPMU Configuration for Run/Wait and Full Stop Current Measurement

CPMU REGISTER	Bit settings/Conditions
CPMUSYNR	VCOFRQ[1:0]= 3,SYNDIV[5:0] = 49
CPMUPOSTDIV	POSTDIV[4:0]=0
CPMUCLKS	PLLSEL=1, CSAD=0
CPMUOSC	OSCE=0, Reference clock for PLL is $f_{\text{ref}}=f_{\text{irc1m}}$ trimmed to 1MHz
CPMUVREGCTL	EXTXON=0, INTXON=1

Table A-16. CPMU Configuration for Run/Wait and Full Stop Current Measurement

CPMU REGISTER	Bit settings/Conditions
API settings for STOP current measurement	
CPMUAPICTL	APIEA=0, APIFE=1, APIE=0
CPMUACLKTR	trimmed to >=20Khz
CPMUAPIRH/RL	set to 0xFFFF

Table A-17. Peripheral Configurations for Run & Wait Current Measurement

Peripheral	Configuration
SCI	Continuously transmit data (0x55) at speed of 19200 baud
SPI	Configured to master mode, continuously transmit data (0x55) at 1Mbit/s
ADC	The peripheral is configured to operate at its maximum specified frequency and to continuously convert voltages on a single input channel
MSCAN	Configured in loop back mode with a bit rate of 500kbit/s.
DBG	The module is disabled, as in typical final applications
PTU	The module is enabled, bits TG1EN and TG0EN are set. PTUFRE is also set to generate automatic reload events.
PMF	The module is configured with a modulus rate of 10 kHz
TIM	The peripheral is configured to output compare mode,
GDU	LDO enabled. Charge pump enabled. Current sense0 enabled. Boost disabled. No output activity (too load dependent)
COP & RTI	Enabled
BATS	Enabled
LINPHY	Connected to SCI and continuously transmit data (0x55) at speed of 19200 baud
CANPHY (ZVMC256)	Enabled and connected to MSCAN module

Table A-18. Run and Wait Current Characteristics

Conditions see Table A-16 and Table A-17, $V_{SUP}=18\text{ V}$							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		Run Current, $-40^{\circ}\text{C} < T_J < 150^{\circ}\text{C}$, $f_{bus}=50\text{MHz}$ ZVMC256 Other devices	I_{SUPR}	— —	56 53	70 66	mA
2		Wait Current, $-40^{\circ}\text{C} < T_J < 150^{\circ}\text{C}$, $f_{bus}=50\text{MHz}$ ZVMC256 Other devices	I_{SUPW}	— —	50 42	66 55	mA
3		Run Current, $T_J = 175^{\circ}\text{C}$, $f_{bus}=40\text{MHz}$ ZVMC256 Other devices	I_{SUPR}	— —	50 45	66 55	mA
4		Wait Current, $T_J = 175^{\circ}\text{C}$, $f_{bus}=40\text{MHz}$ ZVMC256 Other devices	I_{SUPW}	— —	40 36	56 45	mA

Table A-19. Stop Current Characteristics

Conditions are: $V_{SUP}=12\text{ V}^{(1) (2)}$							
Num	C	Rating ⁽³⁾	Symbol	Min	Typ	Max	Unit
Stop Current all modules off							
1		$T_A = T_J = -40^{\circ}\text{C}$ ZVMC256 Other devices	I_{SUPS}	— —	25 20	40 35	μA
2		$T_A = T_J = 150^{\circ}\text{C}$ ZVMC256 Other devices	I_{SUPS}	— —	600 350	2400 1050	μA
3		$T_A = T_J = 25^{\circ}\text{C}$ ZVMC256 Other devices	I_{SUPS}	— —	27 25	95 40	μA
4		$T_A = T_J = 85^{\circ}\text{C}$ ZVMC256 Other devices	I_{SUPS}	— —	120 95	250 —	μA
5		$T_A = T_J = 105^{\circ}\text{C}$ ZVMC256 Other devices	I_{SUPS}	— —	140 105	600 250	μA
Stop Current API enabled & LINPHY in standby (only for devices featuring LINPHY)							
6		$T_A = T_J = 25^{\circ}\text{C}$	I_{SUPS}	—	35	45	μA
Stop Current API enabled & CANPHY in standby (only for devices featuring CANPHY)							
7		$T_A = T_J = 25^{\circ}\text{C}$	I_{SUPS}	—	50	—	μA

1. This is the total current flowing into the VSUP and HD pins, to account for mask sets where HD is the LINPHY supply.

2. Stop current values for ZVMC256 are subject to change following characterization.

3. If MCU is in Stop mode long enough then $T_A = T_J$. Die self heating due to stop current can be ignored.

Table A-20. Pseudo Stop Current Characteristics

Conditions are: $V_{SUP}=12V$, API, COP & RTI enabled							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		$T_J = 25^{\circ}C$ ZVMC256 Other devices	I_{SUPPS}	— —	430 265	660 300	μA

A.4 ADC Calibration Configuration

The reference voltage V_{BG} is measured under the conditions shown in Table A-21. The values stored in the IFR are the average of eight consecutive conversions at $T_J=150^{\circ}C$ and eight consecutive conversions at $T_J=-40^{\circ}C$. The code is executed from RAM. The result is programmed to the IFR, otherwise there is no flash activity.

Table A-21. Measurement Conditions

Description	Symbol	Value	Unit
Regulator Supply Voltage at V_{SUP}	V_{SUP}	5	V
Supply Voltage at V_{DDX} and V_{DDA}	$V_{DDX,A}$	5	V
ADC reference voltage high	V_{RH}	5	V
ADC reference voltage low	V_{RL}	0	V
ADC clock	f_{ATDCLK}	2	MHz
ADC sample time	t_{SMP}	4	ADC clock cycles
Bus clock frequency	f_{bus}	48	MHz
Junction temperature	T_J	-40 and 150	$^{\circ}C$

Appendix B

CPMU Electrical Specifications (VREG, OSC, IRC, PLL)

B.1 VREG Electrical Specifications

Table B-1. Voltage Regulator Electrical Characteristics
(Junction Temperature From -40°C To $+175^{\circ}\text{C}$ unless otherwise stated)

Note: VDDA and VDDX must be shorted on the application board.							
Num	C	Characteristic	Symbol	Min	Typical	Max	Unit
1		Input Voltages	V_{SUP}	3.5	—	40	V

11		Trimmed ACLK internal clock Δf / f _{nominal} ⁽⁸⁾	df _{ACLK}	- 6%	—	+ 6%	—
12		The first period after enabling the counter by APIFE might be reduced by API start up delay	t _{sdel}	—	—	100	μs
13		Temperature Sensor Slope	dV _{HT}	5.05	5.25	5.45	mV/°C
14		Temperature Sensor output voltage (T _J = 150°C) untrimmed	V _{HT}	—	2.4	—	V
15		High Temperature Interrupt Assert ⁽⁹⁾ High Temperature Interrupt Deassert	T _{HTIA} T _{HTID}	120 110	132 122	144 134	°C °C
16		Bandgap output voltage	V _{BG}	1.14	1.20	1.28	V
17		Bandgap output voltage V _{SUP} dependency 3.5 < V _{SUP} < 18V	ΔV _{BGV}	-5 ⁽¹⁰⁾	—	5 ⁽¹⁰⁾	mV
18		Bandgap output voltage temperature dependency V _{SUP} = 12V, -40°C < T _J < 150°C	ΔV _{BGT}	-20	—	20	mV
19a		Max. Base Current For External PNP (VDDX) ⁽¹¹⁾ -40°C < T _J < 150°C	I _{BCTLMAX}	2.3	—	—	mA
19b		Max. Base Current For External PNP (VDDX) ⁽¹¹⁾ 150°C < T _J < 175°C	I _{BCTLMAX}	1.5	—	—	mA
20a		Max. Base Current For External PNP (VDDC) ⁽¹¹⁾ -40°C < T _J < 150°C	I _{BCTLCMAX}	2.3	—	—	mA
20b		Max. Base Current For External PNP (VDDC) ⁽¹¹⁾ 150°C < T _J < 175°C	I _{BCTLCMAX}	1.5	—	—	mA

- External PNP regulator has a higher regulation point to ensure that the current flows through the PNP when the application fails to disable the internal regulator by clearing INTXON.
- Please note that the core current is derived from VDDX
- Further limitation may apply due to maximum allowable T_J
- Maximum load current depends on the current gain of the external PNP and available base current
- LVI is monitored on the VDDA supply domain
- LVRX is monitored on the VDDX supply domain only during full performance mode. During reduced performance mode (stop mode) voltage supervision is solely performed by the POR block monitoring core VDD.
- For the given maximum load currents and V_{SUP} input voltages, the MCU will stay out of reset.
- The ACLK trimming must be set that the minimum period equals to 0.2ms
- CPMUHTTR=0x88. Customer must program CPMUHTTR to 0x88. Default value is 0x0F. Junction temperature depends on system thermal performance, therefore the offset to ambient temperature must be characterized at system level.
- This parameter value is subject to change following further characterization.
- This is the minimum base current that can be guaranteed when the external PNP is delivering maximum current.

Table B-2. VDDS Regulators (ZVMC256 only)

Num	C	Characteristic	Symbol	Min	Typ	Max	Unit
1		VDDS to VDDA differential (with external PNP) ⁽¹⁾ Full Performance Mode only (disabled in RPM) -40°C < T_J < 150°C	V_{DDS}	—	0	75	mV
2a		Max. Base Current For External PNP (VDDS) ⁽²⁾ -40°C < T_J < 150°C	$I_{BCTLSMAX}$	2.3	—	—	mA
2b		Max. Base Current For External PNP (VDDS) 150°C < T_J < 175°C	$I_{BCTLSMAX}$	1.5	—	—	mA
3		VDDS monitor under voltage assert	$V_{DDSM A}$	—	VDDX-0.2	—	V
4		VDDS monitor under voltage de-assert	$V_{DDSM D}$	—	VDDX-0.2	—	V
5		SNPS monitor threshold ($V_{SNPS} - V_{DDS}$)	V_{SNPSM}	60	100	150	mV

- Measured directly at VDDS/VDDA pins. Static load current on VDDS.
- This is the minimum base current that can be guaranteed when the external PNP is delivering maximum current.

B.2 Reset and Stop Timing Characteristics

Table B-3. Reset and Stop Timing Characteristics

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1a		Startup from Reset (normal mode). ZVMC256	$n_{STARTUP}$	402	—	510	t_{bus}
1a		Startup from Reset (normal mode). All devices except ZVMC256	$n_{STARTUP}$	396	—	504	t_{bus}
1b		Startup from Reset (special mode)	$n_{STARTUP}$	555	—	555	t_{bus}
2		Recovery time from STOP	t_{STP_REC}	—	23	—	μs

B.3 IRC and OSC Electrical Specifications

Table B-4. IRC electrical characteristics

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1a		Junction Temperature - 40 to 150 Celsius Internal Reference Frequency, factory trimmed	f_{IRC1M_TRIM}	0.9895	1.002	1.0145	MHz
1b		Junction Temperature 150 to 175 Celsius Internal Reference Frequency, factory trimmed	f_{IRC1M_TRIM}	0.9855	—	1.0145	MHz

Table B-5. OSC electrical characteristics (Junction Temperature From -40°C To $+175^{\circ}\text{C}$)

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		Nominal crystal or resonator frequency	f_{OSC}	4.0	—	20	MHz
2		Startup Current	i_{OSC}	100	—	—	μA
3a		Oscillator start-up time (4MHz) ⁽¹⁾	t_{UPOSC}	—	2	10	ms
3b		Oscillator start-up time (8MHz) ¹	t_{UPOSC}	—	1.6	8	ms
3c		Oscillator start-up time (16MHz) ¹	t_{UPOSC}	—	1	5	ms
3d		Oscillator start-up time (20MHz) ¹	t_{UPOSC}	—	1	4	ms
4		Clock Monitor Failure Assert Frequency	f_{CMFA}	200	450	1200	KHz
5		Input Capacitance (EXTAL, XTAL pins)	C_{IN}	—	7	—	pF
6		EXTAL Pin Input Hysteresis	$V_{HYS,EXTAL}$	—	120	—	mV
7		EXTAL Pin oscillation amplitude (loop controlled Pierce)	$V_{PP,EXTAL}$	—	1.0	—	V
8		EXTAL Pin oscillation required amplitude ⁽²⁾	$V_{PP,EXTAL}$	0.8	—	1.5	V

1. These values apply for carefully designed PCB layouts with capacitors that match the crystal/resonator requirements.

2. Needs to be measured at room temperature on the application board using a probe with very low ($\leq 5\text{pF}$) input capacitance.

B.4 Phase Locked Loop

B.4.1 Jitter Information

With each transition of the feedback clock, the deviation from the reference clock is measured and the input voltage to the VCO is adjusted accordingly. The adjustment is done continuously with no abrupt changes in the VCOCLK frequency. Noise, voltage, temperature and other factors cause slight variations in the control loop resulting in a clock jitter. This jitter affects the real minimum and maximum clock periods as illustrated in [Figure B-1.](#)

Figure B-1. Jitter Definitions

The relative deviation of t_{nom} is at its maximum for one clock period, and decreases towards zero for larger number of clock periods (N).

Defining the jitter as:

$$J(N) = \max\left(\left|1 - \frac{t_{max}(N)}{N \cdot t_{nom}}\right|, \left|1 - \frac{t_{min}(N)}{N \cdot t_{nom}}\right|\right)$$

The following equation is a good fit for the maximum jitter:

$$J(N) = \frac{j_1}{\sqrt{N(\text{POSTDIV} + 1)}}$$

Figure B-2. Maximum Bus Clock Jitter Approximation (N = number of bus cycles)

NOTE**Peripheral module prescalers eliminate the effect of jitter to a large extent.****Table B-6. PLL Characteristics (Junction Temperature From -40°C To $+175^{\circ}\text{C}$)**

Conditions are $4.5\text{ V} < V_{\text{DDX}} < 5.5\text{ V}$ unless otherwise noted

Appendix C

ADC Electrical Specifications

NOTE: ADC1 is only tested to 10-bit accuracy in the 48LQFP-EP package options.

NOTE: VRL_0 is the preferred reference for low noise.

NOTE: (ZVMC256 only) When using VDDS2 or VDDS1 as the VRH reference, the reference is impacted by a drop of between 4mV and 15mV across the internal short circuit protection switch.

C.1 ADC Operating Characteristics

The Table C-1 shows conditions under which the ADC operates.

The following constraints exist to obtain full-scale, full range results:

$$V_{SSA} \leq V_{RL} \leq V_{IN} \leq V_{RH} \leq V_{DDA}$$

This constraint exists since the sample buffer amplifier can not drive beyond the power supply levels that it ties to. If the input level goes outside of this range it will effectively be clipped.

Table C-1. ADC Operating Characteristics

Supply voltage $4.5\text{ V} < V_{DDA} < 5.5\text{ V}$, Junction Temperature From -40°C To $+175^{\circ}\text{C}$							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		Reference potential					
		Low	V_{RL}	V_{SSA}	—	$V_{DDA}/2$	V
		High	V_{RH}	$V_{DDA}/2$	—	V_{DDA}	V
2		Voltage difference V_{DDX} to V_{DDA}	ΔV_{DDX}	-0.1	0	0.1	V
3		Voltage difference V_{SSX} to V_{SSA}	ΔV_{SSX}	-0.1	0	0.1	V
4		Differential reference voltage ⁽¹⁾	$V_{RH} - V_{RL}$	3.13	5.0	5.5	V
5		ADC Clock Frequency (derived from bus clock via the prescaler).	f_{ATDCLK}	0.25	—	8.33	MHz
6		Buffer amplifier turn on time (delay after module start/recovery from Stop mode)	t_{REC}	—	—	1	μs
7		ADC disable time	$t_{DISABLE}$	—	—	3	bus clock cycles
8		ADC Conversion Period ⁽²⁾					
		12 bit resolution:	N_{CONV12}	19	—	39	ADC clock cycles
		10 bit resolution:	N_{CONV10}	18	—	38	
	8 bit resolution:	N_{CONV8}	16	—	36		

1. Full accuracy is not guaranteed when differential voltage is less than 4.50 V

2. The minimum time assumes a sample time of 4 ATD clock cycles; maximum time assumes a sample time of 24 ATD clock cycles.

C.1.1 Factors Influencing Accuracy

Source resistance, source capacitance and current injection have an influence on the accuracy of the ADC. **Figure C-1**. A further factor is PortAD pins that are configured as output drivers.

C.1.1.1 Port AD Output Drivers Switching

PortAD output drivers switching can adversely affect the ADC accuracy whilst converting the analog voltage on other PortAD pins because the output drivers are supplied from the VDDA/VSSA ADC supply pins. Although internal design measures are implemented to minimize the effect of output driver noise, it is recommended to configure PortAD pins as outputs only for low frequency, low load outputs. The impact on ADC accuracy is load dependent and not specified. The values specified are valid under condition that no PortAD output drivers switch during conversion.

C.1.1.2 Source Resistance

Input pin leakage current in conjunction with the source resistance causes a voltage drop from the signal source to the ADC input. The maximum source resistance R_S results in an error (10-bit resolution) of less than 1/2 LSB (2.5 mV) at the maximum leakage current. If device or operating conditions are less than worst case or leakage induced error is acceptable, a larger source resistance of up to 10Kohm is allowed.

C.1.1.3 Source Capacitance

When sampling an additional internal capacitor is switched to the input. This can cause a voltage drop due to charge sharing with the external and the pin capacitance. For a maximum sampling error of the input voltage $\leq 1\text{LSB}$ (10-bit resolution), then the external filter capacitor, $C_f \geq 1024 * (C_{\text{INS}} - C_{\text{INN}})$.

C.1.1.4 Current Injection

There are two cases to consider.

1. A current is injected into the channel being converted. The channel being stressed has conversion values of 0x3FF (in 10-bit mode) for analog inputs greater than V_{RH} and 0x000 for values less than V_{RL} unless the current is higher than specified as a disruptive condition.
2. Current is injected into pins in the neighborhood of the channel being converted. A portion of this current is picked up by the channel (coupling ratio K), This additional current impacts the accuracy of the conversion depending on the source resistance.

The additional input voltage error on the converted channel can be calculated as:

$$V_{\text{ERR}} = K * R_S * I_{\text{INJ}}$$

with I_{INJ} being the sum of the currents injected into the two pins adjacent to the converted channel.

C.1.1.5 VRH reference mapped to VDDS1 or VDDS2 (ZVMC256 only)

When using VDDS2 or VDDS1 as the VRH reference, the reference is impacted by a drop of between 4mV and 15mV across the internal short circuit protection switch. This can add an error of $\leq 3\text{LSB}$ (10-bit resolution).

Table C-2. ADC Electrical Characteristics (Junction Temperature From -40°C To +175°C)

Supply voltage $3.13\text{ V} < V_{DDA} < 5.5\text{ V}$							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		Max input source resistance	R_S	—	—	1	$\text{k}\Omega$
2		Total input capacitance Non sampling Total input capacitance Sampling	C_{INN} C_{INS}	— —	— —	10 16	pF
3a		Input internal Resistance Junction temperature from -40°C to +150°C	R_{INA}	—	5	9.9	$\text{k}\Omega$
3b		Input internal Resistance Junction temperature from 150°C to +175°C	R_{INA}	—	—	12	$\text{k}\Omega$
4		Disruptive analog input current	I_{NA}	-2.5	—	2.5	mA
5		Coupling ratio positive current injection	K_p	—	—	1E-4	A/A
6		Coupling ratio negative current injection	K_n	—	—	5E-3	A/A

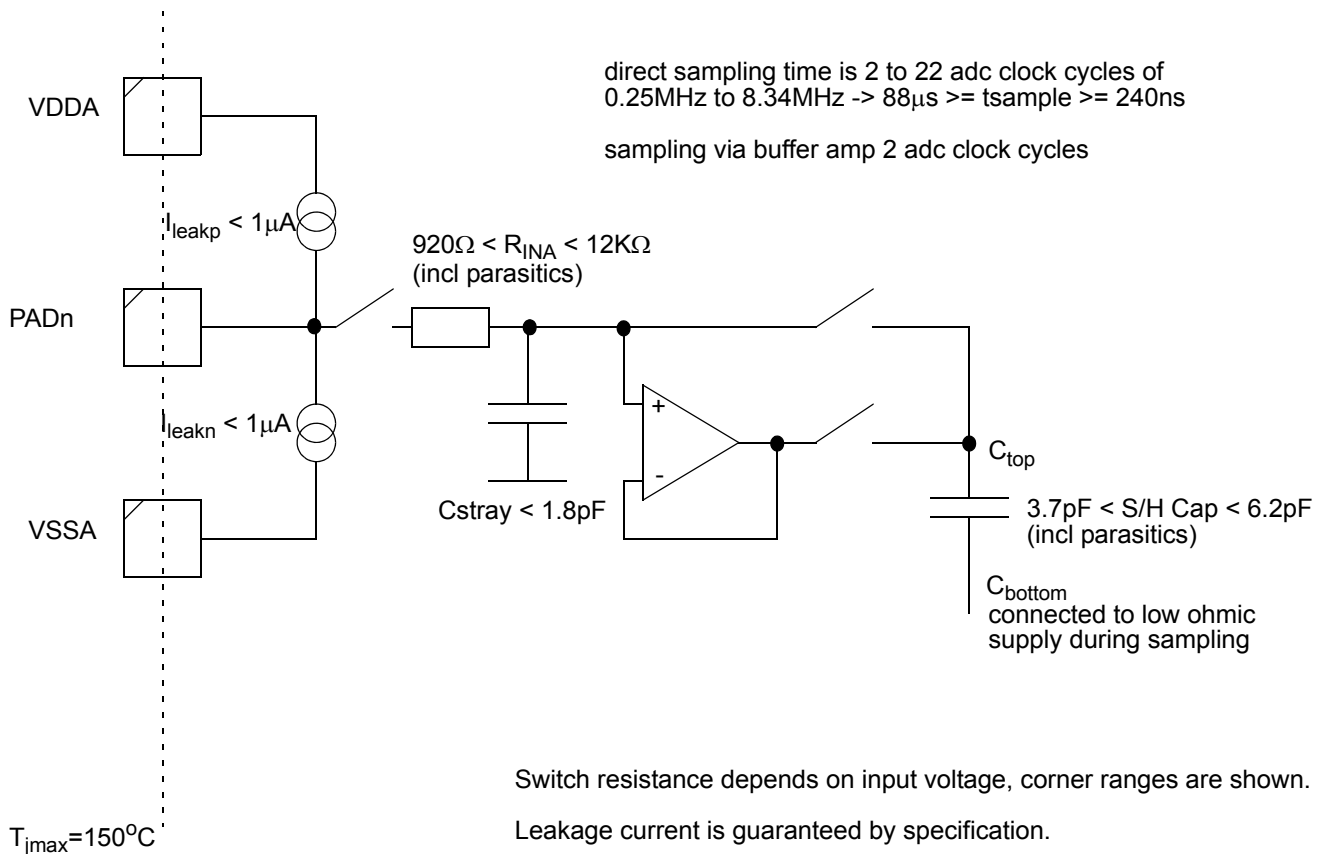

Figure C-1.

C.1.2 ADC Accuracy

Table C-3. specifies the ADC conversion performance excluding any errors due to current injection, input capacitance and source resistance.

C.1.2.1 ADC Accuracy Definitions

For the following definitions see also **Figure C-2.**

Differential non-linearity (DNL) is defined as the difference between two adjacent switching steps.

$$\text{DNL}(i) = \frac{V_i - V_{i-1}}{1\text{LSB}} - 1$$

The integral non-linearity (INL) is defined as the sum of all DNLs:

$$\text{INL}(n) = \sum_{i=1}^n \text{DNL}(i) = \frac{V_n - V_0}{1\text{LSB}} - n$$

Figure C-2. ADC Accuracy Definitions

Table C-3. ADC Conversion Performance 5 V range (Junction Temperature From –40°C To +150°C)

Supply voltage $4.5\text{ V} < V_{\text{DDA}} < 5.5\text{ V}$, $4.5\text{ V} < V_{\text{REF}} < 5.5\text{ V}$. ($V_{\text{REF}} = V_{\text{RH}} - V_{\text{RL}}$). $f_{\text{ADCCLK}} = 8.0\text{ MHz}$
 The values are tested to be valid with no PortAD output drivers switching simultaneous with conversions.

Num	C	Rating ⁽¹⁾		Symbol	Min	Typ	Max	Unit
1		Resolution ($V_{\text{REF}} = 5.12\text{V}$)	12-Bit	LSB	—	1.25	—	mV
2		Differential Nonlinearity	12-Bit	DNL	-4	± 2	4	counts
3		Integral Nonlinearity	12-Bit	INL	-5	± 2.5	5	counts
4		Absolute Error ⁽²⁾	12-Bit	AE	-7	± 4	7	counts
5		Resolution ($V_{\text{REF}} = 5.12\text{V}$)	10-Bit	LSB	—	5	—	mV
6		Differential Nonlinearity	10-Bit	DNL	-1	± 0.5	1	counts
7		Integral Nonlinearity	10-Bit	INL	-2	± 1	2	counts
8		Absolute Error	10-Bit	AE	-3	± 2	3	counts

1. The 8-bit and 10-bit mode operation is structurally tested in production test. Absolute values are tested in 12-bit mode.

2. These values include the quantization error which is inherently 1/2 count for any A/D converter.

Appendix D

LIN/HV PHY Electrical Specifications

D.1 Static Electrical Characteristics

Table D-1. Static electrical characteristics of the LIN/HV PHY (Junction Temperature From -40°C To +175°C)

Characteristics noted under conditions $5.5V \leq V_{LINSUP} \leq 18V$ unless otherwise noted ^{(1) (2) (3)} . Typical values noted reflect the approximate parameter mean at $T_A = 25^\circ C$ under nominal conditions unless otherwise noted.							
Num	C	Ratings	Symbol	Min	Typ	Max	Unit
1		V_{LINSUP} range for LIN compliant electrical characteristics	V_{LINSUP_LIN}	$5.5^{1\ 2}$	12	18	V
2		Current limitation into the LIN pin in dominant state ⁽⁴⁾ $V_{LIN} = V_{LINSUP_LIN_MAX}$	I_{LIN_LIM}	40	—	200	mA
3		Input leakage current in dominant state, driver off, internal pull-up on ($V_{LIN} = 0V$, $V_{LINSUP} = 12V$)	$I_{LIN_PAS_dom}$	-1	—	—	mA
4		Input leakage current in recessive state, driver off ($5V < V_{LINSUP} < 18V$, $5V < V_{LIN} < 18V$, $V_{LIN} \Rightarrow V_{LINSUP}$)	$I_{LIN_PAS_rec}$	—	—	20	μA
5		Input leakage current when ground disconnected ($GND_{Device} = V_{LINSUP}$, $0V < V_{LIN} < 18V$, $V_{LINSUP} = 12V$)	$I_{LIN_NO_GND}$	-1	—	1	mA
6		Input leakage current when battery disconnected ($V_{LINSUP} = GND$, $0 < V_{LIN} < 18V$)	$I_{LIN_NO_BAT}$	—	—	30	μA
7		Receiver dominant state	V_{LINdom}	—	—	0.4	V_{LINSUP}
8		Receiver recessive state	V_{LINrec}	0.6	—	—	V_{LINSUP}
9		$V_{LIN_CNT} = (V_{th_dom} + V_{th_rec})/2$	V_{LIN_CNT}	0.475	0.5	0.525	V_{LINSUP}
10		$V_{HYS} = V_{th_rec} - V_{th_dom}$	V_{HYS}	—	—	0.175	V_{LINSUP}
11		Maximum capacitance allowed on slave node	C_{slave}	—	220	250	pF
12a		Capacitance of LIN pin -40°C < T_J < 150°C, Recessive state	C_{int}	—	20	—	pF
12b		Capacitance of LIN pin -40°C < T_J < 150°C, Recessive state	C_{int}	—	—	45	pF
12c		Capacitance of LIN pin 150°C < T_J < 175°C, Recessive state	C_{int}	—	—	39	pF
13		Internal pull-up (slave)	R_{slave}	27	34	40	k Ω

- For $3.5V \leq V_{LINSUP} < 5V$, the LIN/HV PHY is still working but with degraded parametrics.
- For $5V \leq V_{LINSUP} < 5.5V$, characterization showed that all parameters generally stay within the indicated specification, except the duty cycles D2 and D4 which may increase and potentially go beyond their maximum limits for highly loaded buses.
- The V_{LINSUP} voltage is provided by the VLINSUP supply. This supply mapping is described in device level documentation.

4. At temperatures above 25°C the current may be naturally limited by the driver, in this case the limitation circuit is not engaged and the flag is not set.

D.2 Dynamic Electrical Characteristics

Table D-2. Dynamic electrical characteristics of the LIN/HV PHY

Characteristics noted under conditions $5.5V \leq V_{LINSUP} \leq 18V$ unless otherwise noted ^{(1) (2) (3)} . Typical values noted reflect the approximate parameter mean at $T_A = 25^\circ C$ under nominal conditions unless otherwise noted.							
Num	C	Ratings	Symbol	Min	Typ	Max	Unit

Characteristics noted under conditions $5.5V \leq V_{LINSUP} \leq 18V$ unless otherwise noted ^{(1) (2) (3)} . Typical values noted reflect the approximate parameter mean at $T_A = 25^\circ C$ under nominal conditions unless otherwise noted.							
Num	C	Ratings	Symbol	Min	Typ	Max	Unit
12	M	Duty cycle 4 $T_{HRec(min)} = 0.389 \times V_{LINSUP}$ $T_{HDom(min)} = 0.251 \times V_{LINSUP}$ $V_{LINSUP} = 5.5V \dots 18V$ $t_{Bit} = 96\mu s$ $D4 = t_{Bus_rec(max)} / (2 \times t_{Bit})$	D4	—	—	0.590 ⁵	
LIN PHYSICAL LAYER: DRIVER CHARACTERISTICS FOR FAST MODE SLEW RATE - 100KBIT/S UP TO 250KBIT/S							
13		Rising/falling edge time (min to max / max to min)	t_{rise}	—	0.5	—	μs
14		Over-current masking window (IRC trimmed at 1MHz)	t_{OCLIM}	5	—	6	μs

1. For $3.5V \leq V_{LINSUP} < 5V$, the LIN/HV PHY is still working but with degraded parametrics.
2. For $5V \leq V_{LINSUP} < 5.5V$, characterization showed that all parameters generally stay within the indicated specification, except the duty cycles D2 and D4 which may increase and potentially go beyond their maximum limits for highly loaded buses.
3. The V_{LINSUP} voltage is provided by the VLINSUP supply. This supply mapping is described in device level documentation.
4. Can be disabled for the HV Phy version.
5. Does not apply to the HV Phy version.

Appendix E

GDU Electrical Specifications

NOTE

It is necessary to consider the power dissipation of the FET channel versus the power dissipation in the FET-Predriver.

FET-Predriver dissipation is $\text{Power} = V_{\text{SUP}} \times f(\text{PWM}) \times C(\text{FET-GATE})$
 FET channel power dissipation is a function of channel current and voltage.

Reducing the R_{DS(on)} of the external FET to reduce the FET power dissipation increases the FET gate capacitance.

At a certain FET level, further reduction of FET R_{DS(on)} actually increases overall power consumption because the increased charging and discharging power dissipation due to increased gate capacitance outweighs the FET power reduction due to R_{DS(on)} reduction.

E.1 GDU specifications for devices featuring GDU V4 or V6

Table E-1. GDU Electrical Characteristics (Junction Temperature From –40°C To +175°C)

4.85V ≤ VDDX, VDDA ≤ 5.15V

1. Without using the boost option. The minimum level can be relaxed when the boost option is used. The lower limit is sensed on VLS, the upper limit is sensed on HD.

2. Without using the boost option. The minimum level can be relaxed when the boost option is used. The lower limit is sensed on VLS, the upper limit is sensed on HD. Operation beyond 20V is limited to 1 hour over lifetime of the device

3. For high side, the performance of external diodes may influence this parameter.
4. If VSUP is lower than 11.2V, external FET gate drive will diminish and roughly follow VSUP - 2* Vbe
5. Total gate charge spec is only a recommendation. FETs with higher gate charge can be used when resulting slew rates are tolerable by the application and resulting power dissipation does not lead to thermal overload.
6. Blanking time for assert (see device level mask set dependencies)
7. (VBSx - HSx) = 10V respectively VLSx=10V, measured from 1V to 9V HGx/LGx vs HSx/LSx
8. (VBSx - HSx) = 10V respectively VLSx=10V, measured from 9V to 1V HGx/LGx vs HSx/LSx
9. The delay is dependent on slew rate configuration. The variation on a given device for a given slew setting is much less than the specified range.
10. V(VBSx) - V(VLSx) > 9V, resp VLSx > 9V
11. V(VBSx) - V(VLSx) > 9V, resp VLSx > 9V, nmos branch only
12. V(VBSx) - V(VLSx) > 9V, resp VLSx > 9V, pmos branch only
13. Not tested on the mask set 2N95G, which does not feature the BST pin function
14. VLS > 6V
15. Output current range for which the effective output resistance specification applies
16. Input resistance can be calculated from the pin input leakage because the sense amp has high impedance MOS inputs
17. Av=10, no frequency compensation in feedback network, 90% output swing
18. Low side desaturation comparator range extends to LSx <= 2.35V - V_{desatls}

E.2 Preliminary GDU specifications for devices featuring GDU V5

Table E-2. GDUV5 Electrical Characteristics (Junction Temperature From -40°C To +175°C)

4.85V<=VDDX,VDDA<=5.15V						
Num	Characteristic	Symbol	Min	Typ	Max	Unit
1	VSUP Supply range	V _{VSUP}	-0.3	—	40	V

17. Low side desaturation comparator range extends to $LSx \leq 2.35V - V_{desatls}$

Appendix F

NVM Electrical Parameters

F.1 NVM Timing Parameters

The time base for all NVM program or erase operations is derived from the bus clock using the FCLKDIV register. The frequency of this derived clock must be set within the limits specified as f_{NVMOP} . The NVM module does not have any means to monitor the frequency and will not prevent program or erase operation at frequencies above or below the specified minimum. When attempting to program or erase the NVM module at a lower frequency, a full program or erase transition is not assured.

The device bus frequency, below which the flash wait states can be disabled, f_{WSTAT} , is specified in the device operating conditions table in [Table A-6](#).

The following sections provide equations which can be used to determine the time required to execute specific flash commands. All timing parameters are a function of the bus clock frequency, f_{NVMBUS} . All program and erase times are also a function of the NVM operating frequency, f_{NVMOP} .

Timing parameters for the ZVMC128, ZVML128, ZVMC64, ZVML64 and ZVML32 devices are specified in [Table F-1](#) and [Table F-2](#).

Timing parameters for the ZVML31, ZVM32 and ZVM16 are specified in [Table F-3](#) and [Table F-4](#).

Timing parameters for the ZVMC256 are specified in [Table F-5](#).

1. Minimum times are based on maximum f_{NVMOP} and maximum f_{NVMBUS}
2. Typical times are based on typical f_{NVMOP} and typical f_{NVMBUS}
3. Maximum times are based on typical f_{NVMOP} and typical f_{NVMBUS} plus aging
4. Worst times are based on minimum f_{NVMOP} and minimum f_{NVMBUS} plus aging

F.2 NVM Reliability Parameters

The reliability of the NVM blocks is guaranteed by stress test during qualification, constant process monitors and burn-in to screen early life failures.

The data retention and program/erase cycling failure rates are specified at the operating conditions noted. The program/erase cycle count on the sector is incremented every time a sector or mass erase event is executed.

Table F-7. NVM Reliability Characteristics

NUM	Rating	Symbol	Min	Typ	Max	Unit
Program Flash Arrays						
1	Data retention at an average junction temperature of $T_{Javg} = 85^{\circ}\text{C}^{(1)}$ after up to 10,000 program/erase cycles	t_{NVMRET}	20	$100^{(2)}$	—	Years
2	Program Flash number of program/erase cycles ($-40^{\circ}\text{C} \leq T_j \leq 175^{\circ}\text{C}$)	n_{FLPE}	10K	$100\text{K}^{(3)}$	—	Cycles
EEPROM Array						
3	Data retention at an average junction temperature of $T_{Javg} = 85^{\circ}\text{C}^1$ after up to 100,000 program/erase cycles	t_{NVMRET}	5	100^2	—	Years
4	Data retention at an average junction temperature of $T_{Javg} = 85^{\circ}\text{C}^1$ after up to 10,000 program/erase cycles	t_{NVMRET}	10	100^2	—	Years
5	Data retention at an average junction temperature of $T_{Javg} = 85^{\circ}\text{C}^1$ after less than 100 program/erase cycles	t_{NVMRET}	20	100^2	—	Years
6	EEPROM number of program/erase cycles ($-40^{\circ}\text{C} \leq T_j \leq 175^{\circ}\text{C}$)	n_{FLPE}	100K	500K^3	—	Cycles

- T_{Javg} does not exceed 85°C in a typical temperature profile over the lifetime of a consumer, industrial or automotive application.
- Typical data retention values are based on intrinsic capability of the technology measured at high temperature and de-rated to 25°C using the Arrhenius equation. For additional information on the definition of Typical Data Retention, please refer to Engineering Bulletin EB618
- Spec table quotes typical endurance evaluated at 25°C for this product family. For additional information on the definition of Typical Endurance, please refer to Engineering Bulletin EB619.

F.3 NVM Factory Shipping Condition

Devices are shipped from the factory with flash and EEPROM in the erased state. Data retention specifications begin at time of this erase operation. For additional information on the definition of Typical Data Retention, please refer to Engineering Bulletin EB618.

Appendix I

SPI Electrical Specifications

This section provides electrical parametrics and ratings for the SPI.

In **Figure I-1**, the measurement conditions are listed.

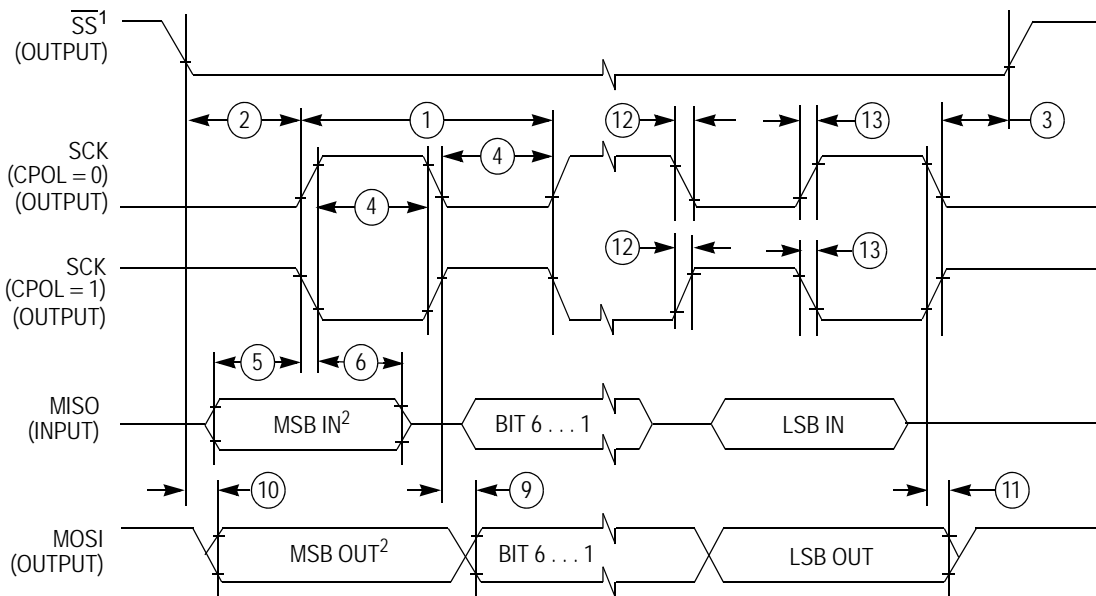

Figure I-1. Measurement Conditions

Description	Value	Unit
Drive mode	full drive mode	—
Load capacitance $C_{LOAD}^{(1)}$, on all outputs	50	pF
Thresholds for delay measurement points	(35% / 65%) VDDX	V

1. Timing specified for equal load on all SPI output pins. Avoid asymmetric load.

I.1 Master Mode

In **Figure I-2**, the timing diagram for master mode with transmission format CPHA=0 is depicted.

1. If enabled.

2. LSBFE = 0. For LSBFE = 1, bit order is LSB, bit 1, ..., bit 6, MSB.

Figure I-2. SPI Master Timing (CPHA=0)

In **Figure I-3**, the timing diagram for master mode with transmission format CPHA=1 is depicted.

Figure I-3. SPI Master Timing (CPHA=1)

Table I-1. SPI Master Mode Timing Characteristics (Junction Temperature From -40°C To +175°C)

Num	C	Characteristic	Symbol	Min			Unit
				Min	Typ	Max	
1		SCK Frequency	f_{sck}	1/2048	—	1/2 ⁽¹⁾⁽²⁾	f_{bus}
1		SCK Period	t_{sck}	2	—	2048	t_{bus}
2		Enable Lead Time	t_{lead}	—	1/2	—	t_{sck}
3		Enable Lag Time	t_{lag}	—	1/2	—	t_{sck}
4		Clock (SCK) High or Low Time	t_{wsck}	—	1/2	—	t_{sck}
5		Data Setup Time (Inputs)	t_{su}	4	—	—	ns
6		Data Hold Time (Inputs)	t_{hi}	5	—	—	ns
9		Data Valid after SCK Edge	t_{vsck}	—	—	10	ns
10		Data Valid after SS fall (CPHA=0)	t_{vss}	—	—	9	ns
11		Data Hold Time (Outputs)	t_{ho}	-1.2	—	—	ns
12		Rise and Fall Time Inputs	t_{rfi}	—	—	8	ns
13		Rise and Fall Time Outputs	t_{rfo}	—	—	8	ns

1. See Figure I-4.

2. f_{bus} max is 40MHz at temperatures above 150°C

Figure I-4. Derating of maximum f_{SCK} to f_{bus} ratio in Master Mode

In Master Mode the allowed maximum f_{SCK} to f_{bus} ratio (= minimum Baud Rate Divisor, pls. see SPI Block Guide) derates with increasing f_{bus} , please see **Figure I-4..**

I.1.1 Slave Mode

In **Figure I-1.** the timing diagram for slave mode with transmission format CPHA=0 is depicted.

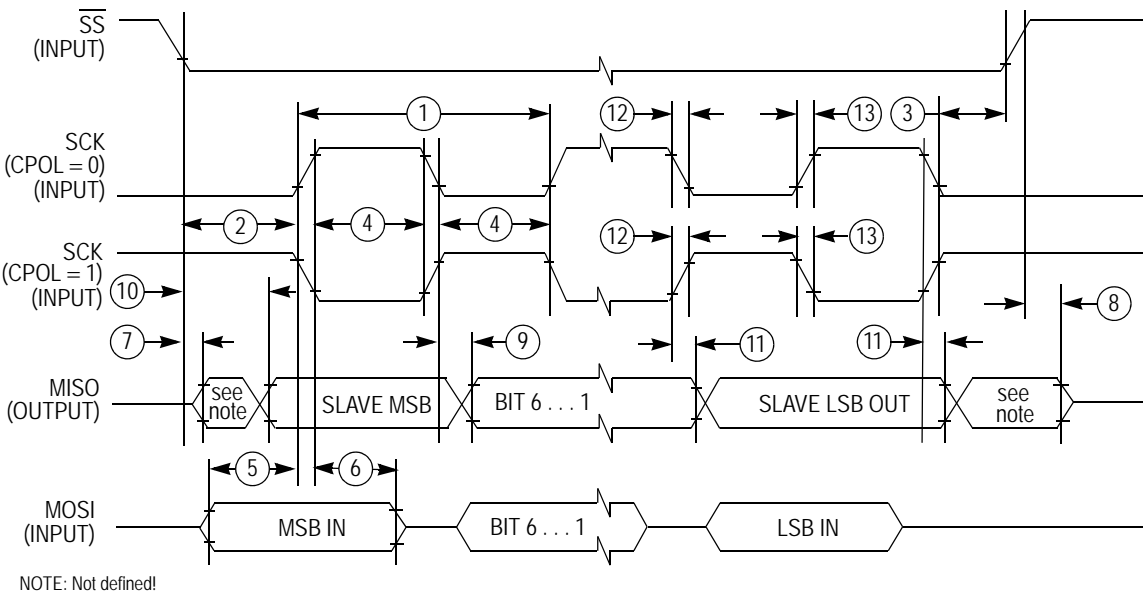

Figure I-5. SPI Slave Timing (CPHA=0)

In **Figure I-6.** the timing diagram for slave mode with transmission format CPHA=1 is depicted.

Figure I-6. SPI Slave Timing (CPHA=1)

Table I-2. SPI Slave Mode Timing Characteristics -40°C to 175°C

Num	C	Characteristic	Symbol	Min	Typ	Max	Unit
1		SCK Frequency	f_{sck}	DC	—	$1/4^{(1)}$	f_{bus}
1		SCK Period	t_{sck}	4	—	∞	t_{bus}
2		Enable Lead Time	t_{lead}	4	—	—	t_{bus}
3		Enable Lag Time	t_{lag}	4	—	—	t_{bus}
4		Clock (SCK) High or Low Time	t_{wsck}	$2t_{bus} - (t_{rfl} + t_{rfo})$	—	—	ns
5		Data Setup Time (Inputs)	t_{su}	3	—	—	ns
6		Data Hold Time (Inputs)	t_{hi}	2	—	—	ns
7		Slave Access Time (time to data active)	t_a	—	—	28	ns
8		Slave MISO Disable Time	t_{dis}	—	—	26	ns
9a		Data Valid after SCK Edge (-40°C < T_j < 150°C)	t_{vsck}	—	—	$23 + 0.5 \cdot t_{bus}^{(2)}$	ns
9b		Data Valid after SCK Edge (150°C < T_j < 175°C) ⁽¹⁾	t_{vsck}	—	—	$25 + 0.5 \cdot t_{bus}^{(2)}$	ns
10a		Data Valid after SS fall (-40°C < T_j < 150°C)	t_{vss}	—	—	$23 + 0.5 \cdot t_{bus}^{(2)}$	ns
10b		Data Valid after SS fall (150°C < T_j < 175°C) ⁽¹⁾	t_{vss}	—	—	$25 + 0.5 \cdot t_{bus}^{(2)}$	ns
11		Data Hold Time (Outputs)	t_{ho}	22	—	—	ns
12		Rise and Fall Time Inputs	t_{rfl}	—	—	8	ns
13		Rise and Fall Time Outputs	t_{rfo}	—	—	8	ns

1. f_{bus} max is 40MHz at temperatures above 150°C

2. $0.5t_{bus}$ added due to internal synchronization delay

Appendix J

MSCAN Electrical Specifications

J.1 MSCAN Wake-up Pulse Timing

Table J-1. MSCAN Wake-up Pulse Characteristics (Junction Temperature From -40°C To $+175^{\circ}\text{C}$)

Conditions are $4.5\text{ V} < V_{\text{DDX}} < 5.5\text{ V}$, unless otherwise noted.							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1		MSCAN wake-up dominant pulse filtered	t_{WUP}	—	—	1.5	μs
2		MSCAN wake-up dominant pulse pass	t_{WUP}	5	—	—	μs

Appendix K Package Information

The Package Reflow capability meets Pb-free requirements for JEDEC standard J-STD-020C. For Peak Package Reflow Temperature and Moisture Sensitivity Levels (MSL), Go to www.nxp.com, search by part number and review parametrics.

NOTES:

1. DIMENSIONS ARE IN MILLIMETERS.
2. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994.
3. DATUMS A, B AND D TO BE DETERMINED AT DATUM PLANE H.
4. DIMENSION TO BE DETERMINED AT SEATING PLANE C.
5. THIS DIMENSION DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL NOT CAUSE THE LEAD WIDTH TO EXCEED THE UPPER LIMIT BY MORE THAN 0.08MM AT MAXIMUM MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT. MINIMUM SPACE BETWEEN PROTRUSION AND ADJACENT LEAD SHALL NOT BE LESS THAN 0.07MM.
6. THIS DIMENSION DOES NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25MM PER SIDE. THIS DIMENSION IS MAXIMUM PLASTIC BODY SIZE DIMENSION INCLUDING MOLD MISMATCH.
7. EXACT SHAPE OF EACH CORNER IS OPTIONAL.
8. THESE DIMENSIONS APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.1MM AND 0.25MM FROM THE LEAD TIP.
9. HATCHED AREA TO BE KEEP OUT ZONE FOR PCB ROUTING.

SHEET:	2

TITLE: LQFP, 10 X 10 X 1.4 PKG,
0.5 PITCH, 64LD,
6.1 x 6.1 EXPOSED PAD

CASE NUMBER:	1899-03
STANDARD:	JEDEC MS-026 BCD
SHEET:	3

NOTES:

1. DIMENSIONS ARE IN MILLIMETERS.
2. INTERPRET DIMENSIONS AND TOLERANCES PER ASME Y14.5M-1994.
3. DATUMS A, B AND D TO BE DETERMINED AT DATUM PLANE H.
4. DIMENSIONS TO BE DETERMINED AT SEATING PLANE C.
5. DIMENSION DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL NOT CAUSE THE LEAD WIDTH TO EXCEED THE MAXIMUM DIMENSION BY MORE THAN 0.08 MM. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT. MINIMUM SPACE BETWEEN PROTRUSION AND ADJACENT LEAD OR PROTRUSION 0.07 MM.
6. DIMENSIONS DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 MM PER SIDE. DIMENSIONS ARE MAXIMUM PLASTIC BODY SIZE DIMENSIONS INCLUDING MOLD MISMATCH.
7. EXACT SHAPE OF EACH CORNER IS OPTIONAL.
8. THESE DIMENSIONS APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.10 MM AND 0.25 MM FROM THE LEAD TIP.
9. HATCHED AREA TO BE KEEP OUT ZONE FOR PCB ROUTING.

Appendix L Ordering Information

Customers can choose either the mask-specific partnumber or the generic, mask-independent partnumber. Ordering a mask-specific partnumber enables the customer to specify which particular maskset they receive whereas ordering the generic partnumber means that the currently preferred maskset (which may change over time) is shipped. In either case, the marking on the device always shows the generic, mask-independent partnumber and the mask set number. The below figure illustrates the structure of a typical mask-specific ordering number.

NOTES

Not every combination is offered. [Table 1.2.1](#) lists available derivatives.

The mask identifier suffix and the Tape & Reel suffix are always both omitted from the partnumber which is actually marked on the device.

Appendix M

Detailed Register Address Map

Registers listed are a superset of all registers in the S12ZVM-Family.

The device overview section specifies module (version) assignment to individual devices.
