Note: To reduce V_{DD} signal noise and to increase the duration of the backup battery supply, $V_{SS}1$, $V_{SS}2$, and $V_{SS}3$ should connect to each other and they should also be grounded.

Example 1: During backup in hold mode, port output 'H' level is supplied from the back-up capacitor.
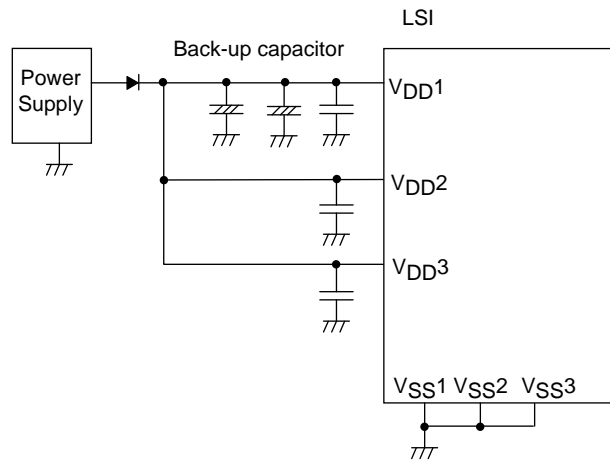

Example 2: During backup in hold mode, output is not held high and its value in unsettled.

The oscillation stabilization time refers to the time interval that is required for the oscillation to get stabilized after V_{DD} goes above the operating voltage lower limit (see Figure 4).

Characteristics of a Sample Subsystem Clock Oscillator Circuit

Given below are the characteristics of a sample subsystem clock oscillation circuit that are measured using a Our designated oscillation characteristics evaluation board and external components with circuit constant values with which the oscillator vendor confirmed normal and stable oscillation.

Table 2 Characteristics of a Sample Subsystem Clock Oscillator Circuit with a Crystal Oscillator

The oscillation stabilization time refers to the time interval that is required for the oscillation to get stabilized after the instruction for starting the subclock oscillation circuit is executed and to the time interval that is required for the oscillation to get stabilized after the HOLD mode is reset (see Figure 4).

Note: The components that are involved in oscillation should be placed as close to the IC and to one another as possible because they are vulnerable to the influences of the circuit pattern.

Figure 7 Pulse Input Timing Signal Waveform

Figure 8 Waveform observed when only POR is used (LVD not used)
(RESET pin: Pull-up resistor R_{RES} only)

• The POR function generates a reset only when power is turned on starting at the V_{SS} level.
• No stable reset will be generated if power is turned on again when the power level does not go down to the V_{SS} level as shown in (a). If such a case is anticipated, use the LVD function together with the POR function or implement an external reset circuit.
• A reset is generated only when the power level goes down to the V_{SS} level as shown in (b) and power is turned on again after this condition continues for 100μs or longer.

Figure 9 Waveform observed when both POR and LVD functions are used
(RESET pin: Pull-up resistor R_{RES} only)

• Resets are generated both when power is turned on and when the power level lowers.
• A hysteresis width (LVHYS) is provided to prevent the repetitions of reset release and entry cycles near the detection level.
