APPLICATION INFORMATION

Crystal Input Interface

Figure 5 shows the NB3N51034 device crystal oscillator interface using a typical parallel resonant crystal. The device crystal connections should include pads for small capacitors from X1 to ground and from X2 to ground. These capacitors, C_1 and C_2, need to consider the stray capacitances of the board and are used to match the nominally required crystal load capacitance C_L. A parallel crystal with loading capacitance C_L = 18 pF would use C_1 = 26 pF and C_2 = 26 pF as nominal values, assuming approximately 2 pF of stray capacitance per trace and approximately 8 pF of internal capacitance.

$C_L = (C_1 + C_{stray} + C_{in}) / 2$; $C_1 = C_2$

The frequency accuracy and duty cycle skew can be fine-tuned by adjusting the C_1 and C_2 values. For example, increasing the C_1 and C_2 values will reduce the operational frequency.

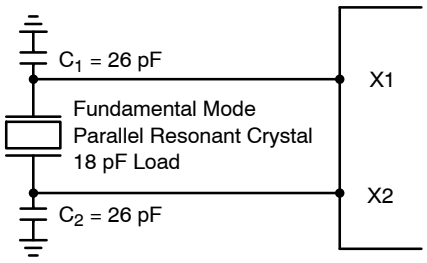

Figure 5. Crystal Interface Loading

Power Supply Filter

In order to isolate the NB3N51034 from system power supply, noise decoupling is required. The 10 μF and a 0.1 μF cap from supply pins to GND decoupling capacitor has to be connected between V_{DD} (pins 1 and 15) and GND (pins 9 and 6). It is recommended to place decoupling capacitors as close as possible to the device to minimize lead inductance.

Termination

The output buffer structure is shown in the Figure 6.

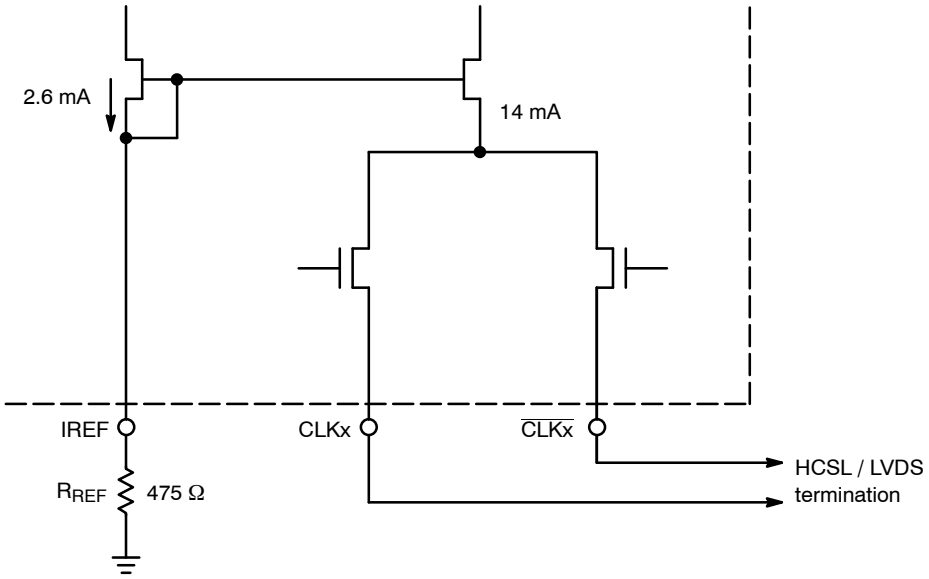

Figure 6. Simplified Output Structure

The outputs can be terminated to drive HCSL receiver (see Figure 7) or LVDS receiver (see Figure 8). HCSL output interface requires 49.9 Ω termination resistors to GND for generating the output levels. LVDS output interface may not require the 100 Ω near the LVDS receiver if the receiver has internal 100 Ω termination. An optional series resistor R_L may be connected to reduce the overshoots in case of impedance mismatch.
