## Power Management Unit Automotive, Battery-Connected, Multi-Output

## NCV97311

## Description

The NCV97311 is a 3-output regulator consisting of a low-Iq battery-connected $3 \mathrm{~A}, 2 \mathrm{MHz}$ non-synchronous switcher and two low-voltage $1.5 \mathrm{~A}, 2 \mathrm{MHz}$ synchronous switchers; all using integrated power transistors.

The high-voltage switcher is capable of converting a 4.1 V to 18 V battery input to a 5 V or 3.3 V output at a constant 2 MHz switching frequency, delivering up to 3 A . In overvoltage conditions up to 37 V , the switching frequency folds back to 1 MHz ; in load dump conditions up to 45 V the regulator shuts down.

The output of the battery-connected buck regulator serves as the low voltage input for the 2 downstream synchronous switchers. Each downstream output is adjustable from 1.2 V to 3.3 V , with a 1.5 A average current limit and a constant 2 MHz switching frequency. Each switcher has an independent enable and reset pin, giving extra power management flexibility.

For low-Iq operating mode, the low-voltage switchers are disabled and the standby rail is supplied by a low-Iq LDO (up to 150 mA ) with a typical Iq of $30 \mu \mathrm{~A}$. The LDO regulator is in parallel to the high-voltage switcher, and is activated when the switcher is forced in standby mode.

All 3 SMPS outputs use peak current mode control with internal slope compensation, internally-set soft-start, battery undervoltage lockout, battery overvoltage protection, cycle-by-cycle current limiting, hiccup mode short-circuit protection and thermal shutdown. An error flag is available for diagnostics.

## ORDERING INFORMATION

See detailed ordering, marking and shipping information on page 23 of this data sheet.

## Features

- 5.0 V and 3.3 V Versions Available
- Low Quiescent Current in Standby Mode
- Programmable Spread Spectrum for EMI Reduction
- 2 Microcontroller Enabled Low Voltage Synchronous Buck Converters
- Large Conversion Ratio of 18 V to 3.3 V Battery Connected Switcher
- Wide Input of 4.1 to 45 V with Undervoltage Lockout (UVLO)
- Fixed Frequency Operation Adjustable from 2.0 to 2.6 MHz
- Internal 1.5 ms Soft-starts
- Cycle-by-cycle Current Limit Protections
- Hiccup Overcurrent Protections (OCP)
- Individual Reset Pins with Adjustable Delays
- QFN Package with Wettable Flanks (pin edge plating)
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These Devices are $\mathrm{Pb}-$ Free, Halogen Free/BFR Free and are RoHS Compliant

## Typical Applications

- Infotainment, Body Electronics, Telematics, ECU

Table 1. MAXIMUM RATINGS

| Rating | Symbol | Value | Unit |
| :---: | :---: | :---: | :---: |
| Min/Max Voltage VBAT, VINL |  | -0.3 to 45 | V |
| Max Voltage VBAT to SW1 |  | 45 | V |
| Min/Max Voltage SW1 |  | -0.7 to 40 | V |
| Min Voltage SW1, SW2, SW3 - 20 ns |  | -3.0 | V |
| Min/Max Voltage BST1, STBYB, EN |  | -0.3 to 40 | V |
| Min/Max Voltage VIN2, VIN3, BST2, BST3, SW2, SW3H, SW3L, VOUT, RMIN |  | -0.3 to 12 | V |
| Min/Max Voltage on RSTB1, RSTB2, RSTB3, ERRB, EN2, EN3, FB2, FB3 |  | -0.3 to 6 | V |
| Max Voltage BST1 to SW1, BST2 to SW2, BST3 to SW3x |  | 3.6 | V |
| Min/Max Voltage VDRV1, VDRV2, COMP1, ROSC, RMOD, RDEPTH |  | -0.3 to 3.6 | V |
| Thermal Resistance, $5 \times 5$ QFN Junction - to - Ambient (Note 1) | $\mathrm{R}_{\theta \mathrm{JA}}$ | 25 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| Storage Temperature Range |  | -55 to +150 | ${ }^{\circ} \mathrm{C}$ |
| Operating Junction Temperature Range | TJ | -40 to +150 | ${ }^{\circ} \mathrm{C}$ |
| ESD Withstand VoltageHuman Body Model <br> Machine Model | $\mathrm{V}_{\text {ESD }}$ | $\begin{aligned} & 2.0^{\star} \\ & 200 \end{aligned}$ | $\begin{aligned} & \mathrm{kV} \\ & \mathrm{~V} \end{aligned}$ |
| Moisture Sensitivity | MSL | Level 1 |  |
| Peak Reflow Soldering Temperature |  | 260 | ${ }^{\circ} \mathrm{C}$ |

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. Mounted on 1 sq . in. of a 4-layer PCB with 1 oz . copper thickness.
*BST2, BST3 HBM 1.5 kV
Table 2. RECOMMENDED OPERATING CONDITIONS

| Rating | Value |
| :--- | :---: |
| VIN Range | 4.5 V to 34 V |
| Ambient Temperature Range | $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ |

Functional operation above the stresses listed in the Recommended Operating Ranges is not implied. Extended exposure to stresses beyond the Recommended Operating Ranges limits may affect device reliability.

## NCV97311

Table 3. PIN FUNCTION DESCRIPTIONS

| Pin No. | Symbol | Description |
| :---: | :---: | :--- |
| 1 | VBAT | Input voltage from battery. Place an input filter capacitor in close proximity to this pin. Must be tied to Pin 29 - <br> VINL. |
| 2 | EN | High-voltage (battery), TTL-compatible, master enable signal. Grounding this input stops all outputs and <br> reduces Iq to a minimum (shutdown mode). |
| 3 | STBYB | High-voltage (battery), TTL-compatible, mode selection signal. Grounding this input activates the low-Iq <br> mode of operation for switcher 1 (standby mode). |
| 4 | RDEPTH | Modulation depth adjustment (\% of FSW) for spread spectrum. Set with a resistor to GND. |
| 5 | RMOD | Modulation frequency adjustment for spread spectrum. Set with a resistor to GND. |
| 6 | RSTB1 | Reset with adjustable delay. Goes low when the output is out of regulation. When using Low-Iq LDO Mode, <br> connect a pull-up resistor to a permanent external supply (e.g. VouT1). |
| 7 | COMP1 | Output of the error amplifier for switcher 1 |
| 8 | ROSC | Provides Frequency Adjustment |
| 9 | ERRB | Error flag combining temperature and input and output voltage sensing |
| 10 | EN2 | TTL compatible low voltage input. Grounding this input stops switcher 2. |
| 11 | RSTB2 | Reset with adjustable delay. Goes low when the output is out of regulation. |
| 12 | GND1 | Ground reference for the IC. |
| 13 | RSTB3 | Reset with adjustable delay. Goes low when the output is out of regulation. |
| 14 | FB3 | Output voltage sensing, provides adjustability. |
| 15 | EN3 | TTL compatible low voltage input. Grounding this input stops switcher 3. |
| 16 | BST3 | Bootstrap input provides drive voltage higher than VIN3 to the high-side N-channel Switch for optimum <br> switch R |
| 27 | FBS(on) and highest efficiency. |  |

## NCV97311

## APPLICATION INFORMATION

## General Description

The NCV97311 consists of one 2 MHz battery-connected 2.5 A switcher (switcher 1) with a parallel low-Iq 150 mA LDO, and two low-voltage 2 MHz 1.5 A switchers (switchers 2 and 3).

Figure 24. NCV97311 Block Schematic

## Input Voltage

The main supply for the part is taken from the VBAT pin, which much always be tied to a voltage source between 4.1 V and 37 V .

- Below 4.1 V an Undervoltage Lockout (UVLO) circuit inhibits all switching, resets the Soft-start circuits, and turns off the LDO.
- Above 40 V, an Overvoltage Shutdown circuit inhibits all switching and allows the NCV97311 to survive a 45 V load dump. Normal operation resumes when VBAT goes back down below 37 V .
Although the LDO has its own input pin VINL (that can also survive a 45 V load dump), it must always be connected to VBAT for proper operation.

Switcher 2 and switcher 3 each have a dedicated input pin, VIN2 and VIN3. VIN2 and VIN3 should be shorted together right at the pin because they share a common drive pin, VDRV2. Please note that VIN2 and VIN3 are strictly low voltage (up to 12 V when disabled and 9.5 V when switching) and there is no voltage sensing present.

It is recommended to connect VIN2 (and VIN3) to VOUT1, although a different rail could be used to supply switchers 2 and 3, as long as VBAT is powered and switcher 1 enabled (see Oscillator section for details).

## Oscillator

All three switchers share the same oscillator, which defaults to 2.0 MHz and can be adjusted from 2.0 to 2.6 MHz using an external resistor ( $\mathrm{R}_{\mathrm{OSC}}$ ) to ground. The range of ROSC value for this range of frequency adjustment is between $12.5 \mathrm{k} \Omega$ and $50 \mathrm{k} \Omega$ (see Figure 25). For resistor values below $10 \mathrm{k} \Omega$, the frequency is safely clamped to 2.8 MHz.

Instead of a resistor, one can force a current out of the ROSC pin, between $20 \mu \mathrm{~A}$ (corresponding to 2 MHz ) and $80 \mu \mathrm{~A}$ (corresponding to 2.5 MHz ), typical.

Figure 25. Oscillator Frequency vs. ROSC Value

Manually adjusting the oscillator frequency using the ROSC pin changes the switching frequency of all 3 switchers, since they share a common oscillator. When switcher 1 enters maximum duty cycle frequency foldback, though, switchers 2 and 3 remain at their nominal switching frequency. The foldback for switcher 1 takes place in logic outside of the oscillator. The same applies for both switcher 2 and switcher 3 . When switcher 2, for example, enters maximum duty cycle frequency foldback, the other two switchers remain at their nominal switching frequency.

## Spread Spectrum

In SMPS devices, switching translates to higher efficiency. Unfortunately, the switching leads to a much noisier EMI profile. We can greatly decrease some of the radiated emissions with some spread spectrum techniques. Spread spectrum is used to reduce the peak electromagnetic emissions of a switching regulator.

Figure 26.
The spread spectrum used in the NCV97311 is an "up-spread" technique, meaning the switching frequency is spread upward from the 2.0 MHz base frequency. For example, a $5 \%$ spread means that the switching frequency is swept (spread) from 2.0 MHz up to 2.1 MHz in a linear fashion - this is called the modulation depth. The rate at which this spread takes place is called the modulation frequency. For example, a 10 kHz modulation frequency means that the frequency is swept from 2.0 MHz to 2.1 MHz in $50 \mu \mathrm{~s}$ and then back down from 2.1 MHz to 2.0 MHz in $50 \mu \mathrm{~s}$.

Figure 27.

The modulation depth and modulation frequency are each set by an external resistor to GND. The modulation frequency can be set from 5 kHz up to 50 kHz using a resistor from the RMOD pin to GND. The modulation depth can be set from $3 \%$ up to $30 \%$ of the nominal switching frequency using a resistor from the RDEPTH pin to GND. Please see the curves below for typical values:

Figure 28. Modulation Frequency vs. RMOD Value

Figure 29. Modulation Depth vs. RDEPTH Value

Spread spectrum is automatically turned off when there is a short to GND or an open circuit on either the RMOD pin or the RDEPTH pin. Please be sure that the ROSC pin is an open circuit when using spread spectrum.

## Master Enable

The NCV97311 can be completely disabled (shutdown mode) by connecting the EN pin to ground. As a result, all outputs are stopped and the internal current consumption drops below $10 \mu \mathrm{~A}$.
The EN pin is designed to accept either a logic level signal or the battery voltage.

## Reset

When the voltage on the OUTx pin drops below the reset threshold ( $92.5 \%$ typically for RSTB1, $93.5 \%$ typically for RSTB2 \& RSTB3), the open-drain output RSTBx is pulled low. The RSTB1 pin is fully operational in Low-Iq mode. A pull-up resistor must be connected to RSTB1, typically from RSTB1 to VOUT1 (permanent supply voltage in low-Iq mode). The RSTB2 \& RSTB3 pins are asserted (pulled low) when the associated switcher is disabled and when in Low-Iq mode (STBYB low).

## Delay

Each of the RSTB signals can either be used as a reset with delay or a power good (no delay). The delay is determined by the current into the RSTBx pin, set by a resistor, shown in Figure 30.

Figure 30. Reset Delay Time
Use the following equation to determine the ideal reset delay time using currents less than 1 mA :

$$
\begin{equation*}
t_{\text {delay }}=\frac{3000}{I_{\text {RSTBx }}}+1.2 \tag{eq.1}
\end{equation*}
$$

where:
$\mathrm{t}_{\text {delay }}$ : ideal reset delay time [ms]
$\mathrm{I}_{\text {RSTBx }}$ : current into the RSTBx pin $[\mu \mathrm{A}]$
Using $\mathrm{I}_{\text {RSTBx }}=2 \mathrm{~mA}$ removes the delay and allows the reset to act as a "power good" pin.
The RSTBx resistor is commonly tied to VOUT1. For a 5.0 V pull-up voltage, typical delay times can be achieved with the following resistor values:

| $\mathbf{R}_{\mathbf{R S T B X}}(\mathbf{k} \mathbf{\Omega})$ | $\mathbf{t}_{\mathbf{D L Y}}(\mathbf{m s})$ |
| :---: | :---: |
| 2.5 | 0 |
| 5 | 4.4 |
| 10 | 7.3 |
| 20 | 13.0 |
| 30 | 18.8 |
| 50 | 31.5 |

For a 3.3 V pull-up voltage, typical delay times can be achieved with the following resistor values:

| $\mathbf{R}_{\mathbf{R S T B x}} \mathbf{( k \Omega )}$ | $\mathbf{t}_{\mathbf{D L Y}} \mathbf{( m s )}$ |
| :---: | :---: |
| 1.6 | 0 |
| 3.3 | 4.5 |
| 5 | 5.9 |
| 10 | 10.3 |
| 20 | 19.3 |
| 30 | 28.9 |

## Minimum Dropout Voltage

When operating at low input voltages, two parameters play a major role in imposing a minimum voltage drop across the regulator: the minimum off time (that sets the maximum duty cycle) and the on-state resistance.

When operating in continuous conduction mode (CCM), the output voltage is equal to the input voltage multiplied by the duty ratio. Because each switcher needs a sufficient bootstrap voltage to operate, its duty cycle cannot be $100 \%$ : it needs a minimum off time $\left(\mathrm{t}_{\text {off,min }}\right)$ to periodically re-fuel the bootstrap capacitor, CBST. This imposes a maximum duty ratio $\mathrm{D}_{\mathrm{MAX}}=1-\mathrm{t}_{\text {off,min }} \cdot \mathrm{F}_{\mathrm{SW}(\min )}$ with the switching frequency being folded back to $\mathrm{F}_{\mathrm{SW}(\mathrm{min})}=500 \mathrm{kHz}$ to keep regulating at the lowest input voltage possible. The drop due to the on-state resistance is simply the voltage drop across the switch at the given output current: $\mathrm{V}_{\mathrm{SW}, \text { drop }}=\mathrm{I}_{\mathrm{OUT}}$. $\mathrm{R}_{\mathrm{DS}(\mathrm{on})}$. Which leads to the maximum output voltage in low Vin condition: $\mathrm{V}_{\text {OUT }}=\mathrm{D}_{\mathrm{MAX}} \cdot \mathrm{V}_{\mathrm{IN}(\text { min })}-\mathrm{V}_{\mathrm{SW} \text {,drop }}$

## Error Flag

An open drain ERRB pin (active low) flags the status of several internal error detectors: VBAT undervoltage, VBAT overvoltage, thermal warning, switcher 1 reset, as well as the reset flags RSTB2 and RSTB3 if their respective switchers
are enabled. Note that overvoltage is not flagged in Low-Iq standby mode.

When the master enable pin EN is forced low, the error flag is not active anymore.

## Thermal Shutdown

A thermal shutdown circuit inhibits switching, resets the Soft-start circuits, and removes DRVx voltages if the internal temperature exceeds a safe level. Switching is automatically restored when the temperature returns to a safer level.

## Inductor Selection

By default, a $4.7 \mu \mathrm{H}$ inductor is recommended for the primary switching output. If you'd like to choose a different value, please follow the equation, below.

$$
\mathrm{L}=\frac{\mathrm{V}_{\mathrm{out}}\left(1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}, \max }}\right)}{\delta \mathrm{I}_{\mathrm{r}} \cdot f_{\mathrm{sw}} \cdot I_{\mathrm{out}}}
$$

where:
V OUT: dc output voltage [V]
$\mathrm{V}_{\mathrm{IN}, \max }$ : maximum dc input voltage [V]
$\delta \mathrm{I}_{\mathrm{r}}$ : inductor current ripple [\%]
$\mathrm{f}_{\mathrm{SW}}$ : switching frequency [ Hz$]$
I

## Discontinuous Mode

In order to ensure continuous conduction mode, the ripple (half of the peak-to-peak ripple) needs to be less than the average current through the inductor. The limit can be found using the following equation for borderline conduction mode:

$$
\mathrm{I}_{\mathrm{BCM}}=\frac{1}{2} \cdot \frac{\left(1-\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}, \max }}\right)}{f_{\mathrm{SW}}} \cdot \frac{\mathrm{~V}_{\mathrm{OUT}}}{\mathrm{~L}}
$$

where:
$\mathrm{I}_{\mathrm{BCM}}$ : borderline conduction mode output current [A]
$V_{\text {OUT: }}$ dc output voltage [V]
$\mathrm{V}_{\mathrm{IN}, \text { max }}$ : maximum dc input voltage [V]
$\mathrm{f}_{\mathrm{SW}}$ : switching frequency [Hz]
L: inductor value $[\mathrm{H}]$
Average output currents above $\mathrm{I}_{\mathrm{BCM}}$ will operate in continuous mode while average output currents below $\mathrm{I}_{\mathrm{BCM}}$ will operate in discontinuous mode.

## Output Voltage

The NCV97311 comes in a 5.0 V version and a 3.3 V version. The output of switcher 1 , as well as the output of the low-Iq LDO, are fixed at 5.0 V and 3.3 V , respectively.

## High Voltage Frequency Foldback

To limit the power lost in generating the drive voltage for the Power Switch, the switching frequency is reduced by a factor of 2 when the input voltage exceeds the $\mathrm{V}_{\text {BAT }}$ Frequency Foldback threshold $\mathrm{V}_{\text {FL1U }}$ (see Figure 31). Frequency reduction is automatically terminated when the input voltage drops back below the $\mathrm{V}_{\text {BAT }}$ Frequency Foldback threshold $\mathrm{V}_{\text {FL1D }}$.

Figure 31. Switcher 1 Switching Frequency Reduction at High Input Voltage

## Low-IQ Mode

The NCV97311 can be put in a low-Iq regulating mode by connecting the STBYB pin to ground. As a result, Switcher 1 turns off and the low-Iq LDO turns on, maintaining regulation on VOUT (up to 150 mA ). In this mode the VOUT reset monitor is still active (RSTB1 pin), as well as the under-voltage sensing on VBAT and the thermal sensing, and they're all flagged on the ERRB pin. Switchers 2 and 3 are automatically disabled, with their respective reset pins pulled low.

Upon enabling standard switching mode again (bringing STBYB high), voltage is established at the DRV1 pin, followed by a pre-charge of the bootstrap capacitor before switcher 1 starts switching. There is no soft-start unless VOUT is below the reset threshold.

It is recommended to wait at least $200 \mu$ s after toggling STBYB before applying a load higher than 150 mA .

The STBYB pin is designed to accept either a logic level signal or the battery voltage.

For NCV97311MW33R2G and NCV97311MW50R2G, please note: - when using Low-Iq Mode in your application, it is necessary to place a resistor (between $10 \mathrm{k} \Omega$ and $1 \mathrm{M} \Omega$ ) from VDRV1 to GND to discharge CDRV1 while the LDO is operating. To avoid extra current consumption during low-Iq mode, it is also necessary to place a pull-up resistor on RSTB1 so that the internal delay timer is properly settled.

## Soft-Start

Upon being enabled or released from a fault condition, and after the DRV1 voltage is established, a soft-start circuit ramps the switching regulator error amplifier reference voltage to the final value. During soft-start, the average switching frequency is lower than its normal mode value (typically 2 MHz ) until the output voltage approaches regulation. There is no soft-start if the output is already above the reset threshold.

## Error Amplifier

The error amplifier is a transconductance type amplifier. The output voltage of the error amplifier controls the peak inductor current at which the power switch shuts off. The Current Mode control method employed allows the use of a simple, type II compensation to optimize the dynamic response according to system requirements.

The compensation components must be connected between the output of the error amplifier and the electrical ground (between pins COMP1 and GND1). For most applications, the following compensation circuitry is recommended:

Figure 32. Recommended Compensation for Primary Switcher

## Slope Compensation

A fixed slope compensation signal is generated internally and added to the sensed current to avoid increased output voltage ripple due to bifurcation of inductor ripple current at duty cycles above $50 \%$ (sub-harmonics oscillations). The fixed amplitude of the slope compensation signal requires the inductor to be greater than a minimum value, depending on output voltage, in order to avoid sub-harmonic oscillations. For both 3.3 V and 5.0 V versions, the recommended inductor value is either $2.2 \mu \mathrm{H}$ or $4.7 \mu \mathrm{H}$.
To determine the minimum inductor required to avoid sub-harmonic oscillations, please refer to the following equation:

$$
\mathrm{L}_{\text {min }}=\frac{\mathrm{V}_{\text {OUT }}}{\left(2 * \mathrm{~S}_{\text {ramp }}\right)}
$$

where:
$\mathrm{L}_{\text {min }}$ : minimum inductor required to avoid sub-harmonic oscillations $[\mu \mathrm{H}]$
$\mathrm{V}_{\text {out: }}$ : output voltage [V]
$\mathrm{S}_{\text {ramp }}$ : internal slope compensation [A/ $\mu \mathrm{s}$ ]

## Short Circuit Frequency Foldback

During severe output overloads or short circuits, switcher 1 automatically reduces its switching frequency. This creates duty cycles small enough to limit the peak current in the power components, while maintaining the ability to automatically reestablish the output voltage if the overload is removed. If the current is still too high after the switching frequency folds back to $500 \mathrm{kHz}(250 \mathrm{kHz}$ for $\mathrm{V}_{\text {IN }}>20 \mathrm{~V}$ ), the regulator enters hiccup mode ( 32 kHz ) that further reduces the dissipated power.

## Bootstrap

At the DRV1 pin an internal regulator provides a ground-referenced voltage to an external capacitor ( $\mathrm{C}_{\mathrm{DRV} 1}$ ), to allow fast recharge of the external bootstrap capacitor ( $\mathrm{C}_{\mathrm{BST}}$ ) used to supply power to the power switch gate driver. If the voltage at the DRV1 pin goes below the DRV UVLO Threshold $V_{\text {DRVSTP, }}$ switching is inhibited and the Soft-start circuit is reset, until the DRV1 pin voltage goes back up above $V_{\text {DRVSTT }}$.

In order for the bootstrap capacitor to stay charged, the Switch node needs to be pulled down to ground regularly. In very light load condition, when switcher 1 skips switching cycles to keep the output voltage in regulation, the bootstrap voltage could collapse and the regulator stop switching. To prevent this, an internal minimum load is connected on VOUT to operate correctly in all cases (it is disconnected in low Iq mode, when the STBYB pin is low).

A fast-charge circuit ensures the bootstrap capacitor is always charged prior to starting the switcher after it has been enabled.

## Minimum Load

For a 3.3 V output, an external minimum load is not required. The internal minimum load ensures stability under low-battery conditions. For a 5.0 V output, an external minimum load is required when not using a pre-boost that maintains a minimum 6.8 V on the input. The following chart describes the ways in which the RMIN pin is recommended to be used:

| VOUT1 | Pre- <br> boost? | VBAT <br> Condition | RMIN <br> Resistor | Configuration |
| :---: | :---: | :---: | :---: | :---: |
| 5.0 V | No | VBAT < <br> 6.8 V | Populated | Resistor connected <br> from VOUT1 to <br> RMIN pin |
| 5.0 V | Yes | VBAT set to <br> 6.8 V from <br> pre- boost | Not <br> Populated | RMIN not <br> connected |
| 3.3 V | No | VBAT < <br> 6.8 V | Not <br> Populated | RMIN not <br> connected |
| 3.3 V | Yes | VBAT set to <br> 6.8 V from <br> pre- boost | Not <br> Populated | RMIN not <br> connected |

The RMIN resistance (from VOUT1 to RMIN) should be between 27 and $35 \Omega$. When using an external minimum load, $3 \times 100 \Omega, 1 / 4 \mathrm{~W}$ resistors are recommended to be placed in parallel from VOUT1 to the RMIN pin of the IC.

Figure 33. Internal Control for Minimum Load Circuit

## Current Limiting

Due to the ripple on the inductor current, the average output current of a buck converter is lower than the peak current setpoint of the regulator. Figure 34 shows - for a $4.7 \mu \mathrm{H}$ inductor - how the variation of inductor peak current with input voltage affects the maximum DC current switcher 1 can deliver to a load. Figure 35 shows the same for $2.2 \mu \mathrm{H}$ inductor.

Figure 34. Switcher 1 Load Current Capability with a $4.7 \mu \mathrm{H}$ Inductor

Figure 35. Switcher 1 Load Current Capability with a $2.2 \mu \mathrm{H}$ Inductor

## Enable

When a dc logic high (CMOS/TTL compatible) voltage is applied to the EN2 or EN3 pin and the STBYB pin is high Switcher 2 or Switcher 3, respectively, are allowed to operate. Switcher 1 soft start needs to complete before Switcher 2 or Switcher 3 is allowed to turn on. A dc logic low on EN2 or EN3 shuts off the respective regulators.

## Soft-Start

Upon being enabled or released from a fault condition, voltage is first established on the VDRV2 pin (for the first of switcher 2 or 3 to be enabled). Then a soft-start circuit ramps the switching regulator error amplifier reference voltage to the final value, for a duration $t_{S S}$ independent of the switching frequency ( 1.4 ms typically).

The low-side switch is always turned on first to ensure a proper charge of the bootstrap capacitor.

## Error Amplifier

The error amplifier is a voltage type amplifier with fixed internal compensation, optimized for the range of input and output voltage combinations. The output voltage of the error amplifier controls the peak inductor current at which the power shuts off (current-mode operation).

Because the compensation is internally fixed, the value of the upper feedback resistor (in series between the output and the feedback pin) must be $10 \mathrm{k} \Omega$ to ensure stability, including in the case of a 1.2 V output, when no lower feedback resistor is used. In addition, it is recommended to use 1 or $210 \mu \mathrm{~F}$ capacitors on the output, depending on your ripple requirement; and an inductor value between $1 \mu \mathrm{H}$ and $4.7 \mu \mathrm{H}$ (see slope compensation section).

## Slope Compensation

A fixed slope compensation signal is generated internally and added to the sensed current to avoid increased output voltage ripple due to bifurcation of inductor ripple current at duty cycles above $50 \%$ (sub-harmonic oscillations). The fixed amplitude of the slope compensation signal requires the inductor to be greater than a minimum value, dependent on the output voltage, in order to avoid sub-harmonic oscillations.

- For a 5 V output, the recommended inductor value is $4.7 \mu \mathrm{H}$.
- For 3.3 V or 2.5 V output, the recommended inductor value is $2.2 \mu \mathrm{H}$.
- For 1.2 V or 1.5 V output, the recommended inductor value is $1.0 \mu \mathrm{H}$.

## Short Circuit Frequency Foldback

During severe output overloads or short circuits, switchers 2 and 3 (independently) automatically enter an auto-recovery burst mode in order to self-protect. When a short-circuit is detected, the switcher disables its output and remains off for the hiccup time and then goes through the
power-on reset procedure. If the short has been removed then the output re-enables and operates normally; if, however, the short is still present the cycle begins again. The hiccup mode is continuous until the short is removed.

## Current Limiting

Due to the ripple on the inductor current, the average output current of a buck converter is lower than the peak current setpoint of the regulator. Figure 36 shows how the variation of inductor peak current with input voltage affects the maximum DC current switcher 2 or 3 can deliver to a load.

Figure 36. Switcher 2 or 3 Load Current Capability vs. Input Voltage

## Output Voltage Selection

The voltage outputs for switcher 2 and switcher 3 are adjustable and can be set with a resistor divider. The FB reference for both switchers is 1.2 V .

Figure 37. Output Voltage Selection with Feedback Divider

The upper resistor is set to $10 \mathrm{k} \Omega$ and is part of the feedback loop. To maintain stability over all conditions, it is recommended to change the only the lower feedback resistor to set the output voltage. Use the following equation:

$$
R_{\text {LOWER }}=R_{\text {UPPER }} \frac{V_{F B}}{V_{O U T}-V_{F B}}
$$

Some common setups are listed below:

| Desired <br> Output (V) | VREF (V) | $\mathbf{R}_{\text {UPPER }}$ <br> $\mathbf{( k \Omega , 1 \% )}$ | $\mathbf{R}_{\text {LOWER }}$ <br> $\mathbf{( k \Omega , 1 \% )}$ |
| :---: | :---: | :---: | :---: |
| 1.2 | 1.2 | 10.0 | NP |
| 1.5 | 1.2 | 10.0 | 40.0 |
| 1.8 | 1.2 | 10.0 | 20.0 |
| 2.5 | 1.2 | 10.0 | 9.31 |
| 3.3 | 1.2 | 10.0 | 5.76 |

## Noise Performance for Heavy Load

For heavy load conditions (> 1 A ) on the downstream switching outputs, a snubber circuit is recommended for improved noise performance. The following circuit can be used for all output voltage combinations:

Figure 38. RC Snubber Circuit for Noise Performance at Heavy Loads

## ORDERING INFORMATION

| Device | Package | Shipping $^{\dagger}$ |
| :---: | :---: | :---: |
| NCV97311MW50R2G (5.0 V) | QFN32 <br> (Pb-Free) | $5000 /$ Tape \& Reel |
| NCV97311MW33R2G (3.3 V) |  |  |

$\dagger$ For information on tape and reel specifications, including part orientation and tape sizes, please refer to our Tape and Reel Packaging Specifications Brochure, BRD8011/D.

QFN32 5x5, 0.5P
CASE 488AM ISSUE A

DATE 23 OCT 2013
SCALE 2:1

1. DIMENSIONS AND TOLERANCING PER ASME Y14.5M, 1994
2. CONTROLLING DIMENSION: MILLIMETERS.
3. DIMENSION b APPLIES TO PLATED

TERMINAL AND IS MEASURED BETWEEN
0.15 AND 0.30MM FROM THE TERMINAL TIP.
4. COPLANARITY APPLIES TO THE EXPOSED PAD AS WELL AS THE TERMINALS.

| DIM | MILLIMETERS |  |
| :---: | :---: | :---: |
|  | MIN | MAX |
| A | 0.80 | 1.00 |
| A1 | --- | 0.05 |
| A3 | 0.20 REF |  |
| b | 0.18 | 0.30 |
| D | 5.00 BSC |  |
| D2 | 2.95 | 3.25 |
| E | 5.00 BSC |  |
| E2 | 2.95 | 3.25 |
| e | 0.50 BSC |  |
| K | 0.20 | --- |
| L | 0.30 | 0.50 |
| L1 | --- | 0.15 |
