

Dual Operational Transconductance Amplifier

NE5517

The NE5517 contains two current-controlled transconductance amplifiers, each with a differential input and push-pull output. The NE5517 offers significant design and performance advantages over similar devices for all types of programmable gain applications. Circuit performance is enhanced through the use of linearizing diodes at the inputs which enable a 10 dB signal-to-noise improvement referenced to 0.5% THD. The NE5517 is suited for a wide variety of industrial and consumer applications.

Constant impedance of the buffers on the chip allow general use of the NE5517. These buffers are made of Darlington transistors and a biasing network that virtually eliminate the change of offset voltage due to a burst in the bias current I_{ABC} , hence eliminating the audible noise that could otherwise be heard in high quality audio applications.

Features

- Constant Impedance Buffers
- ΔV_{BE} of Buffer is Constant with Amplifier I_{BIAS} Change
- Excellent Matching Between Amplifiers
- Linearizing Diodes
- High Output Signal-to-Noise Ratio
- This is a Pb-Free Device

Applications

- Multiplexers
- Timers
- Electronic Music Synthesizers
- Dolby® HX Systems
- Current-Controlled Amplifiers, Filters
- Current-Controlled Oscillators, Impedances

MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Supply Voltage (Note 1)	V_S	44 V_{DC} or ± 22	V
Power Dissipation, $T_{amb} = 25^\circ\text{C}$ (Still Air) (Note 2)	P_D	1125	mW
Thermal Resistance, Junction-to-Ambient	$R_{\theta JA}$	140	$^\circ\text{C}/\text{W}$
Differential Input Voltage	V_{IN}	± 5.0	V
Diode Bias Current	I_D	2.0	mA
Amplifier Bias Current	I_{ABC}	2.0	mA
Output Short-Circuit Duration	I_{SC}	Indefinite	
Buffer Output Current (Note 3)	I_{OUT}	20	mA
Operating Temperature Range	T_{amb}	0°C to $+70^\circ\text{C}$	$^\circ\text{C}$
Operating Junction Temperature	T_J	150	$^\circ\text{C}$
DC Input Voltage	V_{DC}	$+V_S$ to $-V_S$	
Storage Temperature Range	T_{stg}	-65°C to $+150^\circ\text{C}$	$^\circ\text{C}$
Lead Soldering Temperature (10 sec max)	T_{slid}	230	$^\circ\text{C}$

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. For selections to a supply voltage above ± 22 V, contact factory.
2. The following derating factors should be applied above 25°C
D package at $7.1\text{ mW}/^\circ\text{C}$.
3. Buffer output current should be limited so as to not exceed package dissipation.

NE5517

ELECTRICAL CHARACTERISTICS (Note 4)

Characteristic	Test Conditions	Symbol	Min	Typ	Max	Unit

APPLICATIONS

Figure 20. Unity Gain Follower

CIRCUIT DESCRIPTION

The circuit schematic diagram of one-half of the NE5517, a dual operational transconductance amplifier with linearizing diodes and impedance buffers, is shown in Figure 21.

Transconductance Amplifier

The transistor pair, Q₄ and Q₅, forms a transconductance stage. The ratio of their collector currents (I₄ and I₅, respectively) is defined by the differential input voltage, V_{IN}, which is shown in Equation 1.

$$V_{IN} = \frac{KT}{q} \ln \frac{I_5}{I_4} \quad (\text{eq. 1})$$

Where V_{IN} is the difference of the two input voltages

KT ≅ 26 mV at room temperature (300°K).

Transistors Q₁, Q₂ and diode D₁ form a current mirror which focuses the sum of current I₄ and I₅ to be equal to amplifier bias current I_B:

$$I_4 + I_5 = I_B \quad (\text{eq. 2})$$

If V_{IN} is small, the ratio of I₅ and I₄ will approach unity and the Taylor series of ln function can be approximated as

$$\frac{KT}{q} \ln \frac{I_5}{I_4} \approx \frac{KT}{q} \frac{I_5 - I_4}{I_4} \quad (\text{eq. 3})$$

$$\text{and } I_4 \cong I_5 \cong I_B$$

$$\frac{KT}{q} \ln \frac{I_5}{I_4} \approx \frac{KT}{q} \frac{I_5 - I_4}{1/2 I_B} = \frac{2KT}{q} \frac{I_5 - I_4}{I_B} = V_{IN} \quad (\text{eq. 4})$$

$$I_5 - I_4 = V_{IN} \frac{(I_B^q)}{2KT}$$

The remaining transistors (Q₆ to Q₁₁) and diodes (D₄ to D₆) form three current mirrors that produce an output current equal to I₅ minus I₄. Thus:

$$V_{IN} \left(\frac{I_B^q}{2KT} \right) = I_O \quad (\text{eq. 5})$$

The term $\frac{(I_B^q)}{2KT}$ is then the transconductance of the amplifier and is proportional to I_B.

Figure 21. Circuit Diagram of NE5517

Linearizing Diodes

For V_{IN} greater than a few millivolts, Equation 3 becomes invalid and the transconductance increases non-linearly. Figure 22 shows how the internal diodes can linearize the transfer function of the operational amplifier. Assume D_2 and D_3 are biased with current sources and the input signal current is I_S . Since $I_4 + I_5 = I_B$ and $I_5 - I_4 = I_0$, that is: $I_4 = (I_B - I_0)$, $I_5 = (I_B + I_0)$

Figure 22. Linearizing Diode

For the diodes and the input transistors that have identical geometries and are subject to similar voltages and temperatures, the following equation is true:

$$\frac{T}{q} \ln \frac{I_D/2 + I_S}{I_D/2 - I_S} = \frac{KT}{q} \ln \frac{1/2(I_B + I_0)}{1/2(I_B - I_0)} \quad (\text{eq. 6})$$

$$I_0 = I_S \frac{2I_B}{I_D} \text{ for } |I_S| < \frac{I_D}{2}$$

The only limitation is that the signal current should not exceed I_D .

Impedance Buffer

The upper limit of transconductance is defined by the maximum value of I_B (2.0 mA). The lowest value of I_B for which the amplifier will function therefore determines the overall dynamic range. At low values of I_B , a buffer with very low input bias current is desired. A Darlington amplifier with constant-current source (Q_{14} , Q_{15} , Q_{16} , D_7 , D_8 , and R_1) suits the need.

APPLICATIONS

Voltage-Controlled Amplifier

In Figure 23, the voltage divider R_2 , R_3 divides the input-voltage into small values (mV range) so the amplifier operates in a linear manner.

It is:

$$I_{OUT} = -V_{IN} \cdot \frac{R_3}{R_2 + R_3} \cdot g_M$$

$$V_{OUT} = I_{OUT} \cdot R_L$$

$$A = \frac{V_{OUT}}{V_{IN}} = \frac{R_3}{R_2 + R_3} \cdot g_M \cdot R_L$$

$$(3) g_M = 19.2 I_{ABC}$$

(g_M in μmhos for I_{ABC} in mA)

Since g_M is directly proportional to I_{ABC} , the amplification is controlled by the voltage V_C in a simple way.

When V_C is taken relative to $-V_{CC}$ the following formula is valid:

$$I_{ABC} = \frac{(V_C - 1.2V)}{R_1}$$

The 1.2 V is the voltage across two base-emitter baths in the current mirrors. This circuit is the base for many applications of the NE5517.

- TYPICAL VALUES: $R_1 = 47k\Omega$
 $R_2 = 10k\Omega$
 $R_3 = 200\Omega$
 $R_4 = 200\Omega$
 $R_L = 100k\Omega$
 $R_S = 47k\Omega$

Figure 23.

NE5517

Stereo Amplifier With Gain Control

Figure 24 shows a stereo amplifier with variable gain via a control input. Excellent tracking of typical 0.3 dB is easy to achieve. With the potentiometer, R_P , the offset can be adjusted. For AC-coupled amplifiers, the potentiometer may be replaced with two 510 Ω resistors.

Modulators

Because the transconductance of an OTA (Operational Transconductance Amplifier) is directly proportional to I_{ABC} , the amplification of a signal can be controlled easily. The output current is the product from transconductance \times input voltage. The circuit is effective up to approximately 200 kHz. Modulation of 99% is easy to achieve.

Figure 24. Gain-Controlled Stereo Amplifier

Figure 25. Amplitude Modulator

Voltage-Controlled Resistor (VCR)

Because an OTA is capable of producing an output current proportional to the input voltage, a voltage variable resistor can be made. Figure 26 shows how this is done. A voltage presented at the R_X terminals forces a voltage at the input. This voltage is multiplied by g_M and thereby forces a current through the R_X terminals:

$$R_x = \frac{R + R_A}{g_M + R_A}$$

where g_M is approximately 19.21 μ MHOs at room temperature. Figure 27 shows a Voltage Controlled Resistor using linearizing diodes. This improves the noise performance of the resistor.

Voltage-Controlled Filters

Figure 28 shows a Voltage Controlled Low-Pass Filter. The circuit is a unity gain buffer until X_C/g_M is equal to R/R_A . Then, the frequency response rolls off at a 6dB per octave with the -3 dB point being defined by the given equations. Operating in the same manner, a Voltage Controlled High-Pass Filter is shown in Figure 29. Higher order filters can be made using additional amplifiers as shown in Figures 30 and 31.

Voltage-Controlled Oscillators

Figure 32 shows a voltage-controlled triangle-square wave generator. With the indicated values a range from 2.0 Hz to 200 kHz is possible by varying I_{ABC} from 1.0 mA to 10 μ A.

The output amplitude is determined by $I_{OUT} \times R_{OUT}$.

Please notice the differential input voltage is not allowed to be above 5.0 V.

With a slight modification of this circuit you can get the sawtooth pulse generator, as shown in Figure 33.

APPLICATION HINTS

To hold the transconductance g_M within the linear range, I_{ABC} should be chosen not greater than 1.0 mA. The current mirror ratio should be as accurate as possible over the entire current range. A current mirror with only two transistors is not recommended. A suitable current mirror can be built with a PNP transistor array which causes excellent matching and thermal coupling among the transistors. The output current range of the DAC normally reaches from 0 to -2.0 mA. In this application, however, the current range is set through R_{REF} (10 k Ω) to 0 to -1.0 mA.

$$I_{DACMAX} = 2 \cdot \frac{V_{REF}}{R_{REF}} = 2 \cdot \frac{5V}{10k\Omega} = 1mA$$
