# **RF3183**

### QUAD-BAND/GSM850/EGSM900 /DCS/PCS/POWER AMPLIFIER MODULE

Package Style: Module (5mmx5mmx1mm)

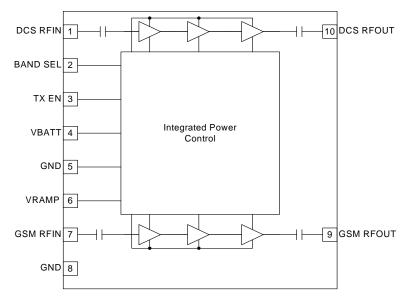

#### **Features**

- Typical GMSK Efficiency GSM850/900 48/53% DCS/PCS 50/53%
- Auto V<sub>BATT</sub> Tracking Circuit avoids Switching Transients at Low Supply Voltage
- Integrated Power Flattening Circuit Reduces Power and Current into Mismatch
- Integrated V<sub>RAMP</sub> Rejection Filter Eliminates External Components

### **Applications**

- Quad-Band GSM Handsets
- GSM Transmitter Line-ups
- Portable Battery-Powered Equipment
- GSM850/EGSM900/DCS/ PCS Products
- GPRS Class 12 Compatible Products
- Mobile EDGE/GPRS Data Products

Functional Block Diagram

### **Product Description**

The RF3183 is a high power amplifier module with integrated power control. The input and output terminals are internally matched to  $50\,\Omega$ . The amplifier devices are manufactured on an advanced Gallium Arsenide Heterojunction Bipolar Transistor (GaAs HBT) process. The module is designed to be the final amplification stage in a dual-mode GSM/EDGE mobile transmit lineup operating in the 824MHz to 915MHz (low) and 1710MHz to 1910MHz (high) bands (such as a cellular handset). Band selection is controlled by an input on the module which selects either the low or high band. The device is packaged on a 5mmx5mm laminate module with a protective plastic over-mold. The RF3183 features RFMD's latest integrated power flattening circuit, which significantly reduces current and power variation into load mismatch. The RF3183 provides excellent ESD protection at all the pins. The RF3183 also provides integrated  $V_{RAMP}$  rejection filter which improves noise performance and transient spectrum.

#### **Ordering Information**

### **Absolute Maximum Ratings**

Parameter	Rating	Unit
Supply Voltage (V <sub>BATT</sub> )	-0.5 to +6.0	V
Power Control Voltage (V <sub>RAMP</sub> )	-0.5 to +3.0	V
Band Select	3.0	V
TX Enable	3.0	V
RF - Input Power	10.0	dBm
Max Duty Cycle	50	%
Output Load VSWR	10:1	
Operating Temperature	-30 to +85	°C
Storage Temperature	-55 to +150	°C

#### Caution! ESD sensitive device.

Exceeding any one or a combination of the Absolute Maximum Rating conditions may cause permanent damage to the device. Extended application of Absolute Maximum Rating conditions to the device may reduce device reliability. Specified typical performance or functional operation of the device under Absolute Maximum Rating conditions is not implied.

RoHS status based on EUDirective 2002/95/EC (at time of this document revision).

Pin **Function Description** DCS\_RFIN RF input to the high-band PA. It is DC-blocked within the part. 1 2 **BANDSEL** Digital input enables either the low band or high band amplifier die within the module. A logic low selects Low Band (GSM850/EGSM900), a logic high selects High Band (DCS1800/PCS1900). This pin is a high impedance CMOS input with no pull-up or pull-down resistors. Digital input enables or disables the internal circuitry. When disabled, the module is in the OFF state, and 3 TX\_EN draws virtually zero current. This pin is a high impedance CMOS input with no pull-up or pull-down resistors. Main DC power supply for all circuitry in the RF3183. Traces to this pin will have high current pulses during 4 **VBATT** operation so proper decoupling and routing should be observed. Ground. 5 **GND** Analog signal used to control the output power. The signal also ramps the output power up and down. An inter-6 **VRAMP** nal 300kHz filter reduces switching ORFS resulting from transitions between DAC steps. Most systems will have no need for external  $V_{RAMP}$  filtering. This pin provides an impedance of approximately  $60\,k\Omega$ . 7 RF input to the low-band PA. It is DC-blocked within the part. **GSMIN** 8 **GND** Ground. **GSMOUT** RF output from the low-band PA. It is DC-blocked within the part. 9 RF output from the high-band PA. It is DC-blocked within the part. 10 **DCSOUT** Main ground pad in center of part. This pad should be tied to the main ground plane with as little loss as pos-11 **GND** sible for optimum linearity.

## **Theory of Operation**

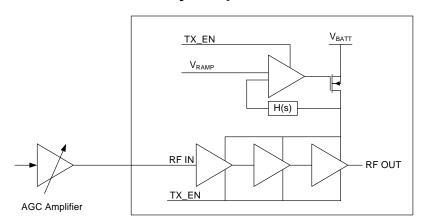

Figure 1. RF3183 Power Amplifier Simplified Block Diagram of a Single Band

#### Overview

The RF3183 is designed for use as the final RF amplifier in GSM850, EGSM900, DCS and PCS handheld digital cellular equipment, and other applications operating in the 824MHz to 915MHz, and 1710MHz to 1910MHz bands. The RF3183 is a high power, power amplifier module with PowerStar® integrated power control. The integrated power control circuitry provides reliable control of saturated power by a single analog voltage ( $V_{RAMP}$ ). This control voltage can be driven directly from a DAC output. PowerStar®'s predictable power versus  $V_{RAMP}$  relationship allows single-point calibration in each band. Single-point calibration enables handset manufacturers to achieve simple and efficient phone calibration in production.

The RF3183 also features an integrated saturation detection circuit, which is an industry first for standard PA module products. The saturation detection circuit automatically monitors battery voltage, and adjusts the power control loop to reduce transient spectrum degradation that would otherwise occur at low battery voltage conditions. Prior to the implementation of the saturation detection circuit, handset designers were required to adjust the ramp voltage within the system software. RFMD's saturation detection circuit reduces handset design time and ensures robust performance over broad operating conditions.

#### **Power and Current Into Mismatch**

Transmitters are often designed to operate only under perfect  $50\Omega$  loads. In the real application when a PA is subjected to mismatch conditions, performance degrades most likely in a reduction of output power, increased harmonic levels, increased transient spectrum, and catastrophic failures.

RF3183 has an integrated power flattening circuit that reduces the amount of current variation under load mismatch. When a mismatch is presented to the output of the PA, its output impedance is varied and could present a load that will increase output power. As the output power increases, so does current consumption. The current consumption can become very high if not monitored and limited. The power-flattening circuit is integrated onto the CMOS controller and requires no input from the user.

Into a mismatch, current varies as phase changes. The power-flattening circuit monitors current through an internal sense resistor. As current changes, the loop is adjusted in order to maintain current. Under nominal conditions, this loop is not activated and is seemingly transparent. The result is flatter power and reduced current into mismatch as shown in the following figures.

Test Condition: V<sub>BATT</sub>=3.6V, RF<sub>IN</sub>=1dBm, Temperature=25°C, Tx Frequency=915MHz

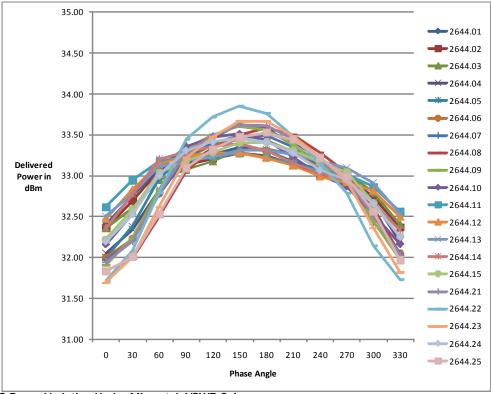

Figure 2. RF3183 Power Variation Under Mismatch VSWR 3:1

Test Condition: V<sub>BATT</sub>=3.6V, RF<sub>IN</sub>=1dBm, Temperature=25 °C, Tx Frequency=915MHz

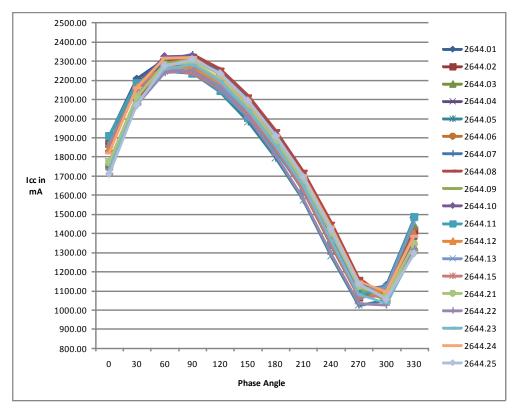

Figure 3. RF3183 Current Variation Under Mismatch VSWR 3:1

RF3183 operates as a traditional PowerStar® module. The incorporated control loop regulates the collector voltage of the amplifiers while the stages are held at a constant bias. The basic circuit diagram is shown in Figure 2.

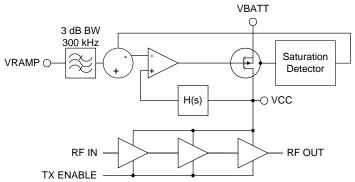

Figure 4. RF3183 Basic Circuit

By regulating the collector voltage ( $V_{CC}$ ), the stages are held in saturation across all power levels. As  $V_{CC}$  is decreased, output power decreases as described by Equation 1. The equation shows that load impedance affects output power, but to a lesser degree than  $V_{CC}$  supply variations. Since the RF3183 regulates  $V_{CC}$ , the dominant cause of power variation is eliminated.

$$P_{OUT_{dBm}} = 10\log \frac{(2 \cdot V_{CC} - V_{SAT})^2}{8 \cdot R1 \cdot 10^{-3}}$$
 (Eq. 1)

RF3183 power is ramped up and down through the  $V_{RAMP}$  control voltage which in turn controls the collector voltage of the amplifier stages. The RF signal applied at the RF $_{IN}$  pin must be a constant amplitude signal and should be high enough to saturate the amplifier in the GSM mode. The input power ( $P_{IN}$ ) range is indicated in the specifications. Power levels below this range will result in reduced maximum output power and the potential for more variation of output power over extreme conditions. Higher input power is unnecessary and will require more current in the circuitry driving the power amplifier and will increase the minimum output power of the RF3183.

The saturation detector circuit monitors the  $V_{BATT}$  and  $V_{CC}$  voltages and adjusts the power control loop to prevent the seriespass FET regulator from entering saturation. If the  $V_{CC}$  regulator were to saturate, the response time would increase dramatically. This is undesirable because the  $V_{CC}$  regulator must accurately follow the burst ramp up or ramp down applied to the  $V_{RAMP}$  pin, or the transient spectrum will degrade.

#### **Power Ramping and Timing**

The RF3183 should be powered on according to the Power-On Sequence provided in the datasheet. The power on sequence is designed to prevent operation of the amplifier under conditions that could cause damage to the device or erratic operation.

In the Power-On Sequence, there are some set-up times associated with the control signals of the RF3183. The most important of these is the settling time between TXEN going high and when  $V_{RAMP}$  can begin to increase. This time is often referred to as the "pedestal" and is required so that the internal power control loop and bias circuitry can settle after being turned on. The RF3183 requires at least 1.5  $\mu$ s or two quarter bit times for proper settling of the power control loop.

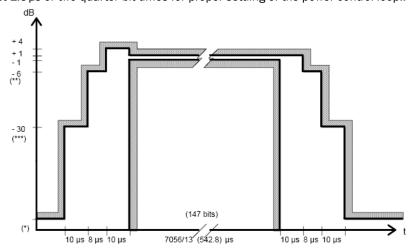

Figure 5. ETSI Time Mask for a Single GSM Time Slot

The  $V_{RAMP}$  waveform used with the RF3183 must be created such that the output power falls into this power versus time mask. The ability to ramp the RF output power to meet ETSI switching transient and time mask requirements partially depends upon the predictability of output power versus  $V_{RAMP}$  response of the power amplifier. The PowerStar® control in the RF3183 is very capable of meeting switching transient requirements with the proper raised cosine waveform applied to the  $V_{RAMP}$  input. The ramping waveform on  $V_{RAMP}$  must not start until after TX\_EN is asserted. A ramp of about 12 us is required to control switching transients at high power levels.

The  $V_{RAMP}$  voltage range should be limited to min and max values in the specifications to avoid damage or undesirable operation. At some voltage below 0.3V, the CMOS controller switches off and turns off the PA. The effect of this is a discontinuity in the response curve. In order to guarantee minimum switching transients, it is recommended that the minimum ramp voltage be set slightly above the voltage where this discontinuity occurs (See Figure 3). The  $V_{RAMP}$  voltage at which the discontinuity occurs is unique to the design of the part and does not shift significantly across process. Figure 7 shows the power versus  $V_{RAMP}$  response curve for five parts which represent typical process variation of the discontinuity

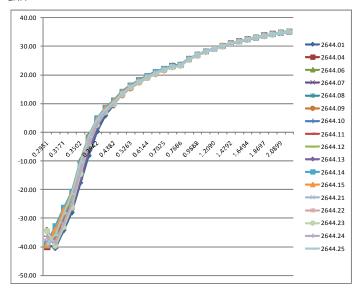

Figure 6. RF3183 LB POLIT versus VRAMP

As the  $V_{RAMP}$  voltage approaches its maximum, the linear regulator in the CMOS saturates, the output power reaches its maximum level, and the  $V_{RAMP}$  versus Output Power curve levels out. The saturation point of the linear regulator is directly proportional to the  $V_{BATT}$  supply voltage applied. The  $V_{RAMP}$  voltage can be increased above the saturation level, but the PA will not produce any higher output power. It is not recommended to apply a  $V_{RAMP}$  voltage above the absolute maximum specification, as the part could be damaged.

When the FET pass-device in the linear regulator saturates, the response time of the regulated voltage slows significantly. If the control voltage changes (as in ramp-down) the saturated linear regulator does not react fast enough to follow the ramp-down curve. The result is a discontinuity in the output power ramp and degraded switching transients. This usually occurs at low  $V_{BATT}$  levels where the regulated  $V_{CC}$  voltage is very near the supply voltage. The RF3183 incorporates a saturation detection circuit which senses if the FET pass-device is entering saturation and reduces  $V_{CC}$  to prevent it. This relieves the requirement of the transceiver controller to adjust the maximum  $V_{RAMP}$  when the battery voltage is low.

#### **Design Considerations**

There are several key factors to consider in the implementation of a mobile phone transmitter solution using the RF3183:

· System efficiency:

The RF output match can be designed to improve system efficiency by presenting a non  $50\Omega$  load. Output matching circuits for the RF3183 should be a compromise between system efficiency and power.

Power variation due to supply voltage:

Output power does not vary due to supply voltage under normal operating conditions. By regulating the collector voltage to the PA the voltage sensitivity is essentially eliminated. This covers most cases where the PA will be operated. However, as the battery discharges and V<sub>BATT</sub> approaches its lower operating limit, the output power from the PA will start to drop. This cannot be avoided as a certain supply voltage is required to produce full output power. System specifications must allow for this power decrease.

Switching Transients due to low battery conditions are reduced by the saturation detection circuit in RF3183. The saturation detection circuit consists of a feedback loop which detects FET saturation. As the FET approaches saturation, the circuit adjusts the  $V_{CC}$  voltage in order to ensure minimum switching transients. The saturation detection circuit is integrated into the CMOS controller and requires no additional input from the user.

#### • Power variation due to temperature

RF3183 output power variation due to temperature is largest at low power levels and decreases at the upper power levels. This follows the ETSI specification limits which allow a larger tolerance over extreme conditions at low power levels. Since output power is controlled by an analog input, factors other than the power amplifier will have an effect on total system power variation. The entire system containing the RF3183 should be tested to determine whether compensation is necessary. At high temperatures and low battery voltages, the PA cannot support as high of an output power. In this condition, increasing V<sub>RAMP</sub> will not provide more output power, so compensation may not provide the intended result.

#### · Noise Power

The bias point of the RF3183 is kept constant and the gain in the first stage is always high. This has the effect of maintaining a consistent noise power which does not increase at reduced output power levels. For that reason, noise power is at its highest when  $V_{RAMP}$  is at its maximum. The RF3183 does not create enough noise in the receive band to cause system receive band noise power failures, but it may amplify noise from other sources. Care must be taken to prevent noise from entering the power amplifier.

#### Loop Stability and Loop Bandwidth variation across power levels

The design of a proper power control loop involves trade-offs affecting stability, transient spectrum and burst timing. In non-PowerStar® architectures, backing off power causes gain variation which can affect loop bandwidth. In RF3183 the loop bandwidth is determined by  $V_{CC}$  regulator bandwidth and does not change over output power. Loop stability is maintained since amplifier bias voltage is constant.

#### Transient Spectrum

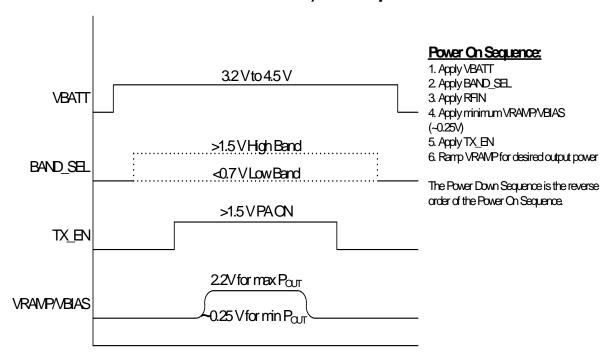

Switching transients occur when the up and down power ramps are not smooth enough, or suddenly change shape. If the control slope of a PA has an inflection point within the output power control range, or if the slope is too steep, switching transients will result. In RF3183 all stages are kept constantly biased and the output power is controlled by changing the collector voltage according to Equation 1. Inflection points are eliminated by this design. In addition, the steepness of the power control slope is reduced because  $V_{RAMP}$  actively controls output power over a larger voltage range than many other power amplifiers.

#### Harmonics

Harmonics are natural products of high efficiency, saturated power amplifiers. An ideal, class 'E', saturated power amplifier will produce a perfect square wave. Looking at the Fourier transform of a square wave reveals high harmonic content. Although this is common to all saturated power amplifiers, there are other factors that contribute to harmonic content as well. With many power control methods, a peak power detector is used to rectify and sense forward power. Through the rectification process, there is additional squaring of the waveform resulting in higher harmonics. The RF3183 has no need for the detector diode; therefore, the harmonics coming out of the PA should represent maximum power of the harmonics throughout the transmit chain. This is based on proper harmonic termination of the transmit port. The receive port termination on antenna switch as well as the harmonic impedance from the switch itself will have an impact on harmonics. These terminations should be adjusted to correct problems with harmonics.

# **PCB Design Requirements**

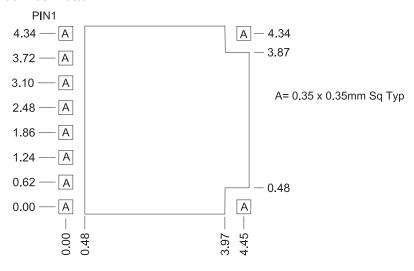

#### **PCB Surface Finish**

The PCB surface finish used for RFMD's qualification process is electroless nickel, immersion gold. Typical thickness is  $3\mu$ inch to  $8\mu$ inch gold over  $180\mu$ inch nickel.

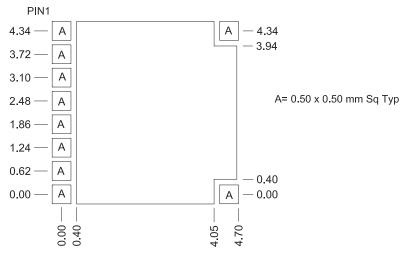

#### **PCB Land Pattern Recommendation**

PCB land patterns for RFMD components are based on IPC-7351 standards and RFMD empirical data. The pad pattern shown has been developed and tested for optimized assembly at RFMD. The PCB land pattern has been developed to accommodate lead and package tolerances. Since surface mount processes vary from company to company, careful process development is recommended.

### **Tape and Reel**

Carrier tape basic dimensions are based on EIA 481. The pocket is designed to hold the part for shipping and loading onto SMT manufacturing equipment, while protecting the body and the solder terminals from damaging stresses. The individual pocket design can vary from vendor to vendor, but width and pitch will be consistent.

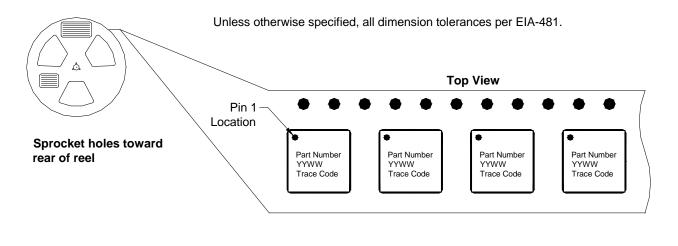

Carrier tape is wound or placed onto a shipping reel either 330mm (13 inches) in diameter or 178mm (7 inches) in diameter. The center hub design is large enough to ensure the radius formed by the carrier tape around it does not put unnecessary stress on the parts.

Prior to shipping, moisture sensitive parts (MSL level 2a-5a) are baked and placed into the pockets of the carrier tape. A cover tape is sealed over the top of the entire length of the carrier tape. The reel is sealed in a moisture barrier ESD bag with the appropriate units of desiccant and a humidity indicator card, which is placed in a cardboard shipping box. It is important to note that unused moisture sensitive parts need to be resealed in the moisture barrier bag. If the reels exceed the exposure limit and need to be rebaked, most carrier tape and shipping reels are not rated as bakeable at 125 °C. If baking is required, devices may be baked according to section 4, table 4-1, of Joint Industry Standard IPC/JEDEC J-STD-033.

The table below provides information for carrier tape and reels used for shipping the devices described in this document.

#### Tape and Reel

RFMD Part Number	Reel Diameter Inch (mm)	Hub Diameter Inch (mm)	Width (mm)	Pocket Pitch (mm)	Feed	Units per Reel
RF3183TR13	13 (330)	4 (102)	12	8	Single	2500
