## General Description

The 889474 is a high speed 2-to-1 differential multiplexer with integrated 2 output LVDS fanout buffer and internal termination and is a member of the family of high performance clock solutions from IDT. The 889474 is optimized for high speed and very low output skew, making it suitable for use in demanding applications such as SONET, 1 Gigabit and 10 Gigabit Ethernet, and Fibre Channel. The internally terminated differential input and Vref_AC pins allow other differential signal families such as LVPECL, LVDS, LVHSTL and CML to be easily interfaced to the input with minimal use of external components. The 889474 is packaged in a small $4 \mathrm{~mm} \times 4 \mathrm{~mm} 24$-pin VFQFN package which makes it ideal for use in space-constrained applications.

## Features

- Two differential LVDS outputs
- INx, nINx pair can accept the following differential input levels: LVPECL, LVDS, LVHSTL, CML
- $50 \Omega$ internal input termination to $\mathrm{V}_{T}$
- Maximum output frequency: 2GHz (maximum)
- Additive phase jitter, RMS: 0.06ps (typical)
- Output skew: 20ps (maximum)
- Propagation delay: 700ps (maximum)
- 2.5 V operating supply
- $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ ambient operating temperature
- Available in lead-free RoHS-complaint package

NOTE: All parameters are characterized at $\leq 1 \mathrm{GHz}$ unless otherwise noted.
NOTE 1: Measured from the differential input crossing point to the differential output crossing point.
NOTE 2: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at the output differential cross points.
NOTE 3: Defined as skew between outputs on different devices operating at the same supply voltages and with equal load conditions. Using the same type of inputs on each device, the outputs are measured at the differential cross points.
NOTE 4: This parameter is defined in accordance with JEDEC Standard 65.
NOTE 5: Driving only one input clock.

## Additive Phase Jitter

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the $\boldsymbol{d B c}$ Phase Noise. This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1 Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels
(dBm) or a ratio of the power in the 1 Hz band to the power in the fundamental. When the required offset is specified, the phase noise is called a $\boldsymbol{d B} \boldsymbol{c}$ value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

As with most timing specifications, phase noise measurements has issues relating to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the device.

This is illustrated above. The device meets the noise floor of what is shown, but can actually be lower. The phase noise is dependent on the input source and measurement equipment.

## Parameter Measurement Information

## Application Information

## LVPECL Input with Built-In $50 \Omega$ Terminations Interface

The IN /nIN with built-in $50 \Omega$ terminations accepts LVDS, LVPECL, CML and other differential signals. The signal must meet the $\mathrm{V}_{\mathrm{PP}}$ and $\mathrm{V}_{\mathrm{CMP}}$ input requirements. Figures $1 A$ to $1 E$ show interface examples for the HiPerClockS $\mathrm{IN} / \mathrm{nIN}$ input with built-in $50 \Omega$ terminations driven by the most common driver types. The

Figure 1A. HiPerClockS IN/nIN Input with Built-in 50 Driven by an LVDS Driver

Figure 1C. HiPerClockS IN/nIN Input with Built-in 50 5 Driven by a CML Driver

Figure 1E. HiPerClockS in/niN Input with Buit-in $50 \Omega$ Driven by an SSTL Driver
input interfaces suggested here are examples only. If the driver is from another vendor, use their termination recommendation. Please consult with the vendor of the driver component to confirm the driver termination requirements.

Figure 1B. HiPerClockS in/nin Input with Buit-in $50 \Omega$ Driven by an LVPECL Driver

[^0]
## Recommendations for Unused Output Pins

## InPUTS:

IN/nIN Inputs
For applications not requiring the use of the differential input, both IN and nIN can be left floating. Though not required, but for additional protection, a $1 \mathrm{k} \Omega$ resistor can be tied from IN to ground.

## Outputs:

## LVDS Outputs

All unused LVDS output pairs can be either left floating or terminated with $100 \Omega$ across. If they are left floating, there should be no trace attached.

### 2.5V LVDS Driver Termination

Figure 2 shows a typical termination for LVDS driver in transmission line environment. For buffer with multiple LVDS characteristic impedance of $100 \Omega$ differential ( $50 \Omega$ single) driver, it is recommended to terminate the unused outputs.

Figure 2. Typical LVDS Driver Termination

### 2.5V Differential Input with Bulit-In $50 \Omega$ Termination Unused Input Handling

To prevent oscillation and to reduce noise, it is recommended to have pull up and pull down connect to true and compliment of the unused input as shown in Figure 3.

Figure 3. Unused Input Handling

## VFQFN EPAD Thermal Release Path

In order to maximize both the removal of heat from the package and the electrical performance, a land pattern must be incorporated on the Printed Circuit Board (PCB) within the footprint of the package corresponding to the exposed metal pad or exposed heat slug on the package, as shown in Figure 4. The solderable area on the PCB, as defined by the solder mask, should be at least the same size/ shape as the exposed pad/slug area on the package to maximize the thermal/electrical performance. Sufficient clearance should be designed on the PCB between the outer edges of the land pattern and the inner edges of pad pattern for the leads to avoid any shorts.

While the land pattern on the PCB provides a means of heat transfer and electrical grounding from the package to the board through a solder joint, thermal vias are necessary to effectively conduct from the surface of the PCB to the ground plane(s). The land pattern must be connected to ground through these vias. The vias act as "heat pipes". The number of vias (i.e. "heat pipes") are application
specific and dependent upon the package power dissipation as well as electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. Maximum thermal and electrical performance is achieved when an array of vias is incorporated in the land pattern. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13 mils ( 0.30 to 0.33 mm ) with $10 z$ copper via barrel plating. This is desirable to avoid any solder wicking inside the via during the soldering process which may result in voids in solder between the exposed pad/slug and the thermal land. Precautions should be taken to eliminate any solder voids between the exposed heat slug and the land pattern. Note:These recommendations are to be used as a guideline only. For further information, refer to the Application Note on the Surface Mount Assembly of Amkor's Thermally/Electrically Enhance Leadfame Base Package, Amkor Technology.

Figure 4. P.C.Assembly for Exposed Pad Thermal Release Path -Side View (Drawing not to Scale)

## Power Considerations

This section provides information on power dissipation and junction temperature for the 889474.
Equations and example calculations are also provided.

## 1. Power Dissipation.

The total power dissipation for the 889474 is the sum of the core power plus the power dissipated in the load(s).
The following is the power dissipation for $\mathrm{V}_{\mathrm{DD}}=2.625 \mathrm{~V}$, which gives worst case results.
NOTE: Please refer to Section 3 for details on calculating power dissipated in the load.

- Power (core) $)_{\text {MAX }}=\mathrm{V}_{\text {DD_MAX }}{ }^{*} I_{\text {DD_MAX }}=2.625 \mathrm{~V} * 80 \mathrm{~mA}=\mathbf{2 1 0 m W}$
- Power Dissipation at built-in terminations: Assume the input is driven by a 2.5 V SSTL driver as shown in Figure 1E and estimated approximately 1.75 V drop across IN and nIN .

Total Power Dissipation for the two $50 \Omega$ built-in terminations is: $(1.75 \mathrm{~V})^{2} /(50 \Omega+50 \Omega)=\mathbf{3 0 . 6 m W}$
Input pair for both inputs is 2 * $30.6 \mathrm{~mW}=61.2 \mathrm{~mW}$

Total Power ${ }_{\text {max }}(2.625 \mathrm{~V}$, with all outputs switching $)=210 \mathrm{~mW}+61.2 \mathrm{~mW}=271.2 \mathrm{~mW}$

## 2. Junction Temperature.

Junction temperature, Tj , is the temperature at the junction of the bond wire and bond pad and directly affects the reliability of the device. The maximum recommended junction temperature for HiPerClockS ${ }^{\text {mM }}$ devices is $125^{\circ} \mathrm{C}$.

The equation for Tj is as follows: $\mathrm{Tj}=\theta_{\mathrm{JA}}$ * Pd_total $+\mathrm{T}_{\mathrm{A}}$
$\mathrm{Tj}=$ Junction Temperature
$\theta_{\mathrm{JA}}=$ Junction-to-Ambient Thermal Resistance
Pd_total = Total Device Power Dissipation (example calculation is in section 1 above)
$T_{A}=$ Ambient Temperature
In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance $\theta_{\mathrm{jA}}$ must be used. Assuming no air flow and a multi-layer board, the appropriate value is $49.5^{\circ} \mathrm{C} / \mathrm{W}$ per Table 6 below.

Therefore, Tj for an ambient temperature of $85^{\circ} \mathrm{C}$ with all outputs switching is:
$85^{\circ} \mathrm{C}+0.271 \mathrm{~W} * 49.5^{\circ} \mathrm{C} / \mathrm{W}=98.4^{\circ} \mathrm{C}$. This is well below the limit of $125^{\circ} \mathrm{C}$.
This calculation is only an example. Tj will obviously vary depending on the number of loaded outputs, supply voltage, air flow, and the type of board (single layer or multi-layer).
