

To our customers,

Old Company Name in Catalogs and Other Documents

On April 1st, 2010, NEC Electronics Corporation merged with Renesas Technology Corporation, and Renesas Electronics Corporation took over all the business of both companies. Therefore, although the old company name remains in this document, it is a valid Renesas Electronics document. We appreciate your understanding.

Renesas Electronics website: <http://www.renesas.com>

April 1st, 2010
Renesas Electronics Corporation

Issued by: Renesas Electronics Corporation (<http://www.renesas.com>)

Send any inquiries to <http://www.renesas.com/inquiry>.

Notice

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
7. Renesas Electronics products are classified according to the following three quality grades: "Standard", "High Quality", and "Specific". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as "Specific" without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as "Specific" or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is "Standard" unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.

"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.

"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.

"Specific": Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.

8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

- party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
3. All information contained in these materials, including product data, diagrams, charts, programs, and algorithms represents information on products at the time of publication of these materials, and is subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein.
The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss resulting from these inaccuracies or errors.
Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (<http://www.renesas.com>).
 4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
 5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please do not use Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor without considering the use of a product contained herein for any specific purposes, such as apparatuses or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
 6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce these materials in whole or in part these materials.
 7. If these products or technologies are subject to the Japanese export control restrictions, they may not be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.
Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
 8. Please contact Renesas Technology Corp. for further details on these materials or the products listed contained therein.

through current flows internally, and a malfunction may occur.

3. Processing before Initialization

Note: When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Be careful of your system so that it does not malfunction because of processing while it is in the undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

4. Prohibition of Access to Undefined or Reserved Addresses

Note: Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers that may have been allocated to these addresses. Do not access these registers; the operation is not guaranteed if they are accessed.

- On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each module includes notes in relation to the descriptions given, and usage notes are given, as required, in the final part of each section.

7. List of Registers
8. Electrical Characteristics
9. Appendix
10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in the manual.

11. Index

free running timer (FRT), an 8-bit timer (TMR), a watchdog timer (WDT), a serial communication interface (SCI), an I²C bus interface (IIC), an LPC interface (LPC), a D/A converter, an A/D converter, and I/O ports as on-chip peripheral modules required for system configuration.

A data transfer controller (DTC) is included as a bus master.

A flash memory (F-ZTAT^{TM*}) version is available for this LSI's 256, 384, and 512-kbyte versions. The CPU and ROM are connected to a 16-bit bus, enabling byte data and word data to be accessed in a single state. This improves the instruction fetch and process speeds.

Two operating modes are provided, offering a choice of address space and single chip emulation mode/external extended mode. Boot programming into a flash memory, on-chip emulation, and boundary scan can be selected as special operating modes.

Note: * F-ZTATTM is a trademark of Renesas Technology Corp.

Target Users: This manual was written for users who use this LSI in the design of applications systems. Target users are expected to understand the fundamentals of electrical circuits, logic circuits, and microcomputers.

Objective: This manual was written to explain the hardware functions and electrical characteristics of this LSI to the target users.
Refer to the H8S/2600 Series, H8S/2000 Series Programming Manual for a detailed description of the instruction set.

Notes on reading this manual:

- In order to understand the overall functions of the chip
Read this manual in the order of the table of contents. This manual can be roughly categorized into the descriptions on the CPU, system control functions, peripheral functions and electrical characteristics.

Rev. 3.00, 03/04, page vi of xl

RENESAS

Number notation: Binary is B'xxxx, hexadecimal is H'xxxx, decimal is D'xxxx
Signal notation: An overbar is added to a low-active signal: $\overline{\text{xxxx}}$

	SSE2I	40	Input	Input pin to halt SCI_2	
SCI with IrDA (SCI)	IrTxD	133	Output	Encoded data output pin for IrDA	
	IrRxD	134	Input	Encoded data input pin for IrDA	
I ² C bus interface (IIC)	SCL0 to SCL5	50, 48, 32, 30, 28, 60	Input/ Output	IIC clock input/output pins. These pins connect to the IIC bus directly with the NMOS open drain	
	SDA0 to SDA5	49, 47, 31, 29, 27, 59	Input/ Output	IIC data input/output pins. These pins connect to the IIC bus directly with the NMOS open drain	

D/A converter (DAC)	DA0 DA1	74 75	Output	Analog output pins
A/D converter (ADC)	AVCC	76	Input	Analog power supply pins for the A/D converter and D/A converter. When the A/D converter and D/A converter are not used, these pins should be connected to the system power supply (-V).
D/A converter (DAC)	AVref	77	Input	Reference voltage input pin for the A/D converter and D/A converter. When the A/D converter and D/A converter are not used, this pin should be connected to the system power supply (-V).
	AVSS	67	Input	Ground pins for the A/D converter and D/A converter. These pins should be connected to the system power supply (0 V).

	GA20	63	Input/ Output	GATE A20 control signal output pin. The input of an output state is enabled.
	CLKRUN	62	Input/ Output	LCLK restart request I/O pin
	LPCPD	61	Input	LPC module shutdown control input pin
Event Counter	EVENT15 to EVENT0	113 to 120, 33 to 35, 37 to 41	Input	Event counter input pins.

P67 to P60	85 to 78	Input/ Output	Eight input/output pins
P77 to P70	75 to 68	Input	Eight input pins
P87 to P80	43 to 50	Input/ Output	Eight input/output pins
P97 to P90	17 to 24	Input/ Output	Eight input/output pins (P96 input p
PA7 to PA0	33 to 35, 37 to 41	Input/ Output	Eight input/output pins
PB7 to PB0	113 to 120	Input/ Output	Eight input/output pins
PC7 to PC0	25 to 32	Input/ Output	Eight input/output pins
PD7 to PD0	59 to 66	Input/ Output	Eight input/output pins
PE7 to PE0	51 to 58	Input/ Output	Eight input/output pins
PF2 to PF0	92 to 94	Input/ Output	Three input/output pins

- Can execute H8/300 CPU and H8/300H CPU object programs
- General-register architecture
 - Sixteen 16-bit general registers also usable as sixteen 8-bit registers or eight 32-bit registers
- Sixty-five basic instructions
 - 8/16/32-bit arithmetic and logic instructions
 - Multiply and divide instructions
 - Powerful bit-manipulation instructions
- Eight addressing modes
 - Register direct [Rn]
 - Register indirect [@ERn]
 - Register indirect with displacement [@(d:16,ERn) or @(d:32,ERn)]
 - Register indirect with post-increment or pre-decrement [@ERn+ or @-ERn]
 - Absolute address [@aa:8, @aa:16, @aa:24, or @aa:32]
 - Immediate [#xx:8, #xx:16, or #xx:32]
 - Program-counter relative [@(d:8,PC) or @(d:16,PC)]
 - Memory indirect [@@aa:8]
- 16 Mbytes address space
 - Program: 16 Mbytes
 - Data: 16 Mbytes
- High-speed operation
 - All frequently-used instructions are executed in one or two states
 - 8/16/32-bit register-register add/subtract: 1 state
 - 8×8 -bit register-register multiply: 12 states (MULXU.B), 13 states (MULXS.B)
 - $16 \div 8$ -bit register-register divide: 12 states (DIVXU.B)
 - 16×16 -bit register-register multiply: 20 states (MULXU.W), 21 states (MULXS.W)
 - $32 \div 16$ -bit register-register divide: 20 states (DIVXU.W)

- Register configuration

The MAC register is supported only by the H8S/2600 CPU.

- Basic instructions

The four instructions MAC, CLRMAC, LDMAC, and STMAC are supported only by H8S/2600 CPU.

- The number of execution states of the MULXU and MULXS instructions

Instruction	Mnemonic	Execution States	
		H8S/2600	H8S/2000
MULXU	MULXU.B Rs, Rd	3	12
	MULXU.W Rs, ERd	4	20
MULXS	MULXS.B Rs, Rd	4	13
	MULXS.W Rs, ERd	5	21

In addition, there are differences in address space, CCR and EXR register functions, power modes, etc., depending on the model.

space.

- Enhanced instructions
 - Addressing modes of bit-manipulation instructions have been enhanced.
 - Signed multiply and divide instructions have been added.
 - Two-bit shift and two-bit rotate instructions have been added.
 - Instructions for saving and restoring multiple registers have been added.
 - A test and set instruction has been added.
- Higher speed
 - Basic instructions are executed twice as fast.

2.1.3 Differences from H8/300H CPU

In comparison to the H8/300H CPU, the H8S/2000 CPU has the following enhancements:

- Additional control register
 - One 8-bit control register has been added.
- Enhanced instructions
 - Addressing modes of bit-manipulation instructions have been enhanced.
 - Two-bit shift and two-bit rotate instructions have been added.
 - Instructions for saving and restoring multiple registers have been added.
 - A test and set instruction has been added.
- Higher speed
 - Basic instructions are executed twice as fast.

Linear access to a maximum address space of 64 kbytes is possible.

- Extended registers (En)

The extended registers (E0 to E7) can be used as 16-bit registers, or as the upper 16-bit segments of 32-bit registers.

When extended register En is used as a 16-bit register it can contain any value, even when the corresponding general register (Rn) is used as an address register. (If general register Rn is referenced in the register indirect addressing mode with pre-decrement (@-Rn) or post-increment (@Rn+) and a carry or borrow occurs, the value in the corresponding extended register (En) will be affected.)

- Instruction set

All instructions and addressing modes can be used. Only the lower 16 bits of effective addresses (EA) are valid.

- Exception vector table and memory indirect branch addresses

In normal mode, the top area starting at H'0000 is allocated to the exception vector table. A branch address is stored per 16 bits. The exception vector table in normal mode is shown in figure 2.1. For details of the exception vector table, see section 4, Exception Handling.

The memory indirect addressing mode (@@aa:8) employed in the JMP and JSR instructions uses an 8-bit absolute address included in the instruction code to specify a memory operand that contains a branch address. In normal mode, the operand is a 16-bit (word) operand providing a 16-bit branch address. Branch addresses can be stored in the top area from H'0000 to H'00FF. Note that this area is also used for the exception vector table.

- Stack structure

In normal mode, when the program counter (PC) is pushed onto the stack in a subroutine call, the PC and condition-code register (CCR) are pushed onto the stack. During exception handling, they are stored as shown in figure 2.2. The extended control register (EXR) is not pushed onto the stack. For details, see section 4, Exception Handling.

Note: Normal mode is not available in this LSI.

Figure 2.1 Exception Vector Table (Normal Mode)

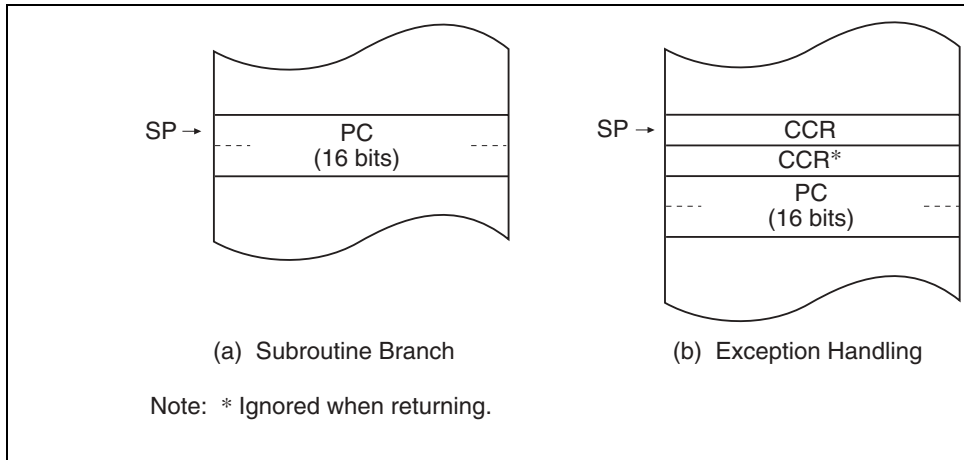

Figure 2.2 Stack Structure in Normal Mode

table in 32-bit units. In each 32 bits, the upper eight bits are ignored and a branch address is stored in the lower 24 bits (see figure 2.3). For details of the exception vector table, see section 4, Exception Handling.

Control Registers

[Legend]

- | | | | |
|-----------|--------------------------------|----|-----------------|
| SP: | Stack pointer | H: | Half-carry flag |
| PC: | Program counter | U: | User bit |
| EXR: | Extended control register | N: | Negative flag |
| T: | Trace bit | Z: | Zero flag |
| I2 to I0: | Interrupt mask bits | V: | Overflow flag |
| CCR: | Condition-code register | C: | Carry flag |
| I: | Interrupt mask bit | | |
| UI: | User bit or interrupt mask bit | | |

Note: * Does not affect operation in this LSI.

Figure 2.6 CPU Internal Registers

When the general registers are used as 8-bit registers, the R registers are divided into 8-bit registers designated by the letters RH (R0H to R7H) and RL (R0L to R7L). These registers are functionally equivalent, providing sixteen 8-bit registers at the maximum.

The usage of each register can be selected independently.

General register ER7 has the function of the stack pointer (SP) in addition to its general-purpose function, and is used implicitly in exception handling and subroutine calls. Figure 2.8 shows the stack.

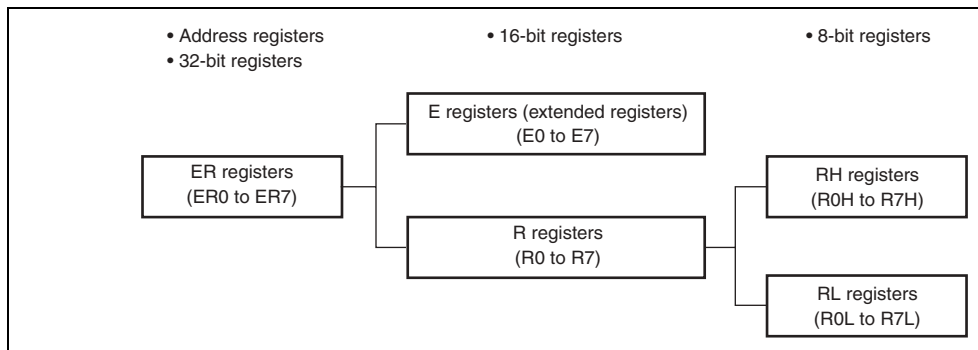

Figure 2.7 Usage of General Registers

2.4.2 Program Counter (PC)

This 24-bit counter indicates the address of the next instruction the CPU will execute. The address of all CPU instructions is 2 bytes (one word), so the least significant PC bit is ignored. (When an instruction is fetched for read, the least significant PC bit is regarded as 0.)

2.4.3 Extended Control Register (EXR)

EXR does not affect operation in this LSI.

Bit	Bit Name	Initial Value	R/W	Description
7	T	0	R/W	Trace Bit Does not affect operation in this LSI.
6 to 3	–	All 1	R	Reserved These bits are always read as 1.
2 to 0	I2	1	R/W	Interrupt Mask Bits 2 to 0
	I1	1		Do not affect operation in this LSI.
	I0	1		

at the start of an exception-handling sequence. For more information, see section 5, Interrupt Controller.

6	UI	Undefined	R/W	User Bit or Interrupt Mask Bit Can be written to and read from by software using LDC, STC, ANDC, ORC, and XORC instructions.
5	H	Undefined	R/W	Half-Carry Flag When the ADD.B, ADDX.B, SUB.B, SUBX.B, CMPL.B, or NEG.B instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 3, and cleared to 0 otherwise. When the ADD.W, SUB.W, CMP.W, or NEG.W instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 11, and cleared to 0 otherwise. When the ADD.L, SUB.L, CMP.L, or NEG.L instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 27, and cleared to 0 otherwise.
4	U	Undefined	R/W	User Bit Can be written to and read from by software using LDC, STC, ANDC, ORC, and XORC instructions.
3	N	Undefined	R/W	Negative Flag Stores the value of the most significant bit of data. Set to 1 if the bit is 1, and cleared to 0 otherwise.
2	Z	Undefined	R/W	Zero Flag Set to 1 to indicate zero data, and cleared to 0 to indicate non-zero data.
1	V	Undefined	R/W	Overflow Flag Set to 1 when an arithmetic overflow occurs, and cleared to 0 otherwise.

Reset exception handling loads the CPU's program counter (PC) from the vector table, clears the trace (T) bit in EXR to 0, and sets the interrupt mask (I) bits in CCR and EXR to 1. The CCR bits and the general registers are not initialized. Note that the stack pointer (ER7) is undefined. The stack pointer should therefore be initialized by an MOV.L instruction executed immediately after a reset.

Notes: B: Byte size; W: Word size; L: Longword size.

1. POP.W Rn and PUSH.W Rn are identical to MOV.W @SP+, Rn and MOV.W SP. POP.L ERn and PUSH.L ERn are identical to MOV.L @SP+, ERn and MOV.L @-SP.
2. Since register ER7 functions as the stack pointer in an STM/LDM instruction, it cannot be used as an STM/LDM register.
3. Cannot be used in this LSI.
4. B_{cc} is the general name for conditional branch instructions.

(EAs)	Destination operand
(EAs)	Source operand
EXR	Extended control register
CCR	Condition-code register
N	N (negative) flag in CCR
Z	Z (zero) flag in CCR
V	V (overflow) flag in CCR
C	C (carry) flag in CCR
PC	Program counter
SP	Stack pointer
#IMM	Immediate data
disp	Displacement
+	Addition
-	Subtraction
×	Multiplication
÷	Division
^	Logical AND
∨	Logical OR
⊕	Logical exclusive OR
→	Move
~	NOT (logical complement)
:8/:16/:24/:32	8-, 16-, 24-, or 32-bit length

Note: * General registers include 8-bit registers (R0H to R7H, R0L to R7L), 16-bit registers (R8 to R7, E0 to E7), and 32-bit registers (ER0 to ER7).

PUSH.W Rn is identical to MOV.W Rn, @-SP. PUSH.L ERn is identical to MOV.L ERn, @-SP.

LDM* ²	L	@SP+ → Rn (register list) Pops two or more general registers from the stack.
STM* ²	L	Rn (register list) → @-SP Pushes two or more general registers onto the stack.

- Notes:
1. Size refers to the operand size.
 - B: Byte
 - W: Word
 - L: Longword
 2. Since register ER7 functions as the stack pointer in an STM/LDM instruction, it cannot be used as an STM/LDM register.

(Only the value 1 can be added to or subtracted from byte oper

ADDS	L	$Rd \pm 1 \rightarrow Rd, Rd \pm 2 \rightarrow Rd, Rd \pm 4 \rightarrow Rd$
SUBS		Adds or subtracts the value 1, 2, or 4 to or from data in a 32-bit
DAA	B	Rd (decimal adjust) $\rightarrow Rd$
DAS		Decimal-adjusts an addition or subtraction result in a general re referring to CCR to produce 4-bit BCD data.
MULXU	B/W	$Rd \times Rs \rightarrow Rd$ Performs unsigned multiplication on data in two general registers: 8-bit \times 8-bit \rightarrow 16-bit or 16-bit \times 16-bit \rightarrow 32-bit.
MULXS	B/W	$Rd \times Rs \rightarrow Rd$ Performs signed multiplication on data in two general registers: bit \times 8-bit \rightarrow 16-bit or 16-bit \times 16-bit \rightarrow 32-bit.
DIVXU	B/W	$Rd \div Rs \rightarrow Rd$ Performs unsigned division on data in two general registers: eit \div 8-bit \rightarrow 8-bit quotient and 8-bit remainder or 32-bit \div 16-bit \rightarrow quotient and 16-bit remainder.

[Legend]

- *: Size refers to the operand size.
- B: Byte
- W: Word
- L: Longword

EXTU	W/L	Rd (zero extension) → Rd Extends the lower 8 bits of a 16-bit register to word size, or the lower 16 bits of a 32-bit register to longword size, by padding with zeros on the left.
EXTS	W/L	Rd (sign extension) → Rd Extends the lower 8 bits of a 16-bit register to word size, or the lower 16 bits of a 32-bit register to longword size, by extending the sign.
TAS	B	@ERd – 0, 1 → (<bit 7> of @ERd) Tests memory contents, and sets the most significant bit (bit 7).

[Legend]

- *: Size refers to the operand size.
- B: Byte
- W: Word
- L: Longword

NOT B/W/L $\sim R_d \rightarrow R_d$
 Takes the one's complement (logical complement) of data in a general register.

[Legend]

*: Size refers to the operand size.
 B: Byte
 W: Word
 L: Longword

Table 2.6 Shift Instructions

Instruction	Size*	Function
SHAL	B/W/L	R_d (shift) $\rightarrow R_d$
SHAR		Performs an arithmetic shift on data in a general register. 1-bit or 2-bit shift is possible.
SHLL	B/W/L	R_d (shift) $\rightarrow R_d$
SHLR		Performs a logical shift on data in a general register. 1-bit or 2-bit shift is possible.
ROTL	B/W/L	R_d (rotate) $\rightarrow R_d$
ROTR		Rotates data in a general register. 1-bit or 2-bit rotation is possible.
ROTXL	B/W/L	R_d (rotate) $\rightarrow R_d$
ROTXR		Rotates data including the carry flag in a general register. 1-bit or 2-bit rotation is possible.

[Legend]

*: Size refers to the operand size.
 B: Byte
 W: Word
 L: Longword

number is specified by 3-bit immediate data or the lower three bits of a general register.

BTST	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow Z$ Tests a specified bit in a general register or memory operand and clears the Z flag accordingly. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BAND	B	$C \wedge (\text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ANDs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIAND	B	$C \wedge (\sim \text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ANDs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BOR	B	$C \vee (\text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIOR	B	$C \vee (\sim \text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.

[Legend]

*: Size refers to the operand size.

B: Byte

		Transfers a specified bit in a general register or memory operand to the carry flag.
BILD	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow C$ Transfers the inverse of a specified bit in a general register or operand to the carry flag. The bit number is specified by 3-bit immediate data.
BST	B	$C \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the carry flag value to a specified bit in a general register or memory operand.
BIST	B	$\sim C \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the inverse of the carry flag value to a specified bit in a general register or memory operand. The bit number is specified by 3-bit immediate data.

[Legend]

*: Size refers to the operand size.

B: Byte

	(high or same)	
BCS (BLO)	Carry set (low)	$C = 1$
BNE	Not equal	$Z = 0$
BEQ	Equal	$Z = 1$
BVC	Overflow clear	$V = 0$
BVS	Overflow set	$V = 1$
BPL	Plus	$N = 0$
BMI	Minus	$N = 1$
BGE	Greater or equal	$N \oplus V = 0$
BLT	Less than	$N \oplus V = 1$
BGT	Greater than	$Z \vee (N \oplus V) = 0$
BLE	Less or equal	$Z \vee (N \oplus V) = 1$

JMP	–	Branches unconditionally to a specified address.
BSR	–	Branches to a subroutine at a specified address
JSR	–	Branches to a subroutine at a specified address
RTS	–	Returns from a subroutine

Transfers CCR or EXR contents to a general register or memory operand. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper bits are valid.

ANDC	B	$CCR \wedge \#IMM \rightarrow CCR$, $EXR \wedge \#IMM \rightarrow EXR$ Logically ANDs the CCR or EXR contents with immediate data.
ORC	B	$CCR \vee \#IMM \rightarrow CCR$, $EXR \vee \#IMM \rightarrow EXR$ Logically ORs the CCR or EXR contents with immediate data.
XORC	B	$CCR \oplus \#IMM \rightarrow CCR$, $EXR \oplus \#IMM \rightarrow EXR$ Logically exclusive-ORs the CCR or EXR contents with immediate data.
NOP	–	$PC + 2 \rightarrow PC$ Only increments the program counter.

[Legend]

*: Size refers to the operand size.

B: Byte

W: Word

data for the number of bytes set in R4L or R4 to the address set in ER6.

Execution of the next instruction begins as soon as the transfer is completed.

2.6.2 Basic Instruction Formats

The H8S/2000 CPU instructions consist of 2-byte (1-word) units. An instruction consists of an operation field (op), a register field (r), an effective address extension (EA), and a condition code field (cc).

Figure 2.11 shows examples of instruction formats.

- **Operation field**
Indicates the function of the instruction, the addressing mode, and the operation to be performed on the operand. The operation field always includes the first four bits of the instruction. Some instructions have two operation fields.
- **Register field**
Specifies a general register. Address registers are specified by 3-bit, and data registers by 4-bit. Some instructions have two register fields, and some have no register field.
- **Effective address extension**
8-, 16-, or 32-bit specifying immediate data, an absolute address, or a displacement.
- **Condition field**
Specifies the branching condition of Bcc instructions.

Figure 2.11 Instruction Formats (Examples)

No.	Addressing mode	Symbol
1	Register direct	Rn
2	Register indirect	@ERn
3	Register indirect with displacement	@(d:16,ERn)/@(d:32,ERn)
4	Register indirect with post-increment	@ERn+
	Register indirect with pre-decrement	@-ERn
5	Absolute address	@aa:8/@aa:16/@aa:24/@aa:32
6	Immediate	#xx:8/#xx:16/#xx:32
7	Program-counter relative	@(d:8,PC)/@(d:16,PC)
8	Memory indirect	@@aa:8

2.7.1 Register Direct—Rn

The register field of the instruction code specifies an 8-, 16-, or 32-bit general register which contains the operand. R0H to R7H and R0L to R7L can be specified as 8-bit registers. R0 and E0 to E7 can be specified as 16-bit registers. ER0 to ER7 can be specified as 32-bit

Register Indirect with Post-Increment—@ERn+: The register field of the instruction specifies an address register (ERn) which contains the address of a memory operand. After the operand is accessed, 1, 2, or 4 is added to the address register contents and the sum is stored in the address register. The value added is 1 for byte access, 2 for word access, and 4 for longword access. For word or longword transfer instructions, the register value should be even.

Register Indirect with Pre-Decrement—@-ERn: The value 1, 2, or 4 is subtracted from the address register (ERn) specified by the register field in the instruction code, and the result becomes the address of a memory operand. The result is also stored in the address register. The value subtracted is 1 for byte access, 2 for word access, and 4 for longword access. For word or longword transfer instructions, the register value should be even.

2.7.5 Absolute Address—@aa:8, @aa:16, @aa:24, or @aa:32

The instruction code contains the absolute address of a memory operand. The absolute address may be 8 bits long (@aa:8), 16 bits long (@aa:16), 24 bits long (@aa:24), or 32 bits long (@aa:32). Table 2.12 indicates the accessible absolute address ranges.

To access data, the absolute address should be 8 bits (@aa:8), 16 bits (@aa:16), or 32 bits (@aa:32) long. For an 8-bit absolute address, the upper 16 bits are all assumed to be 1 (H'FFFF). For a 16-bit absolute address, the upper 16 bits are a sign extension. For a 32-bit absolute address, the entire address space is accessed.

A 24-bit absolute address (@aa:24) indicates the address of a program instruction. The upper 8 bits are all assumed to be 0 (H'00).

The 8-bit (#xx:8), 16-bit (#xx:16), or 32-bit (#xx:32) immediate data contained in a instruction code can be used directly as an operand.

The ADDS, SUBS, INC, and DEC instructions implicitly contain immediate data in their instruction codes. Some bit manipulation instructions contain 3-bit immediate data in their instruction code, specifying a bit number. The TRAPA instruction contains 2-bit immediate data in its instruction code, specifying a vector address.

2.7.7 Program-Counter Relative—@(d:8, PC) or @(d:16, PC)

This mode can be used by the Bcc and BSR instructions. An 8-bit or 16-bit displacement contained in the instruction code is sign-extended to 24-bit and added to the 24-bit address indicated by the PC value to generate a 24-bit branch address. Only the lower 24-bit of the address are valid; the upper eight bits are all assumed to be 0 (H'00). The PC value to which the displacement is added is the address of the first byte of the next instruction, so the possible branching range is –126 to +128-byte (–63 to +64 words) or –32766 to +32768-byte (–16383 to +16384 words) from the branch instruction. The resulting value should be an even number.

If an odd address is specified in word or longword memory access, or as a branch address, the least significant bit is regarded as 0, causing data to be accessed or the instruction code to be fetched at the address preceding the specified address. (For further information, see section Memory Data Formats.)

Note: * Not available in this LSI.

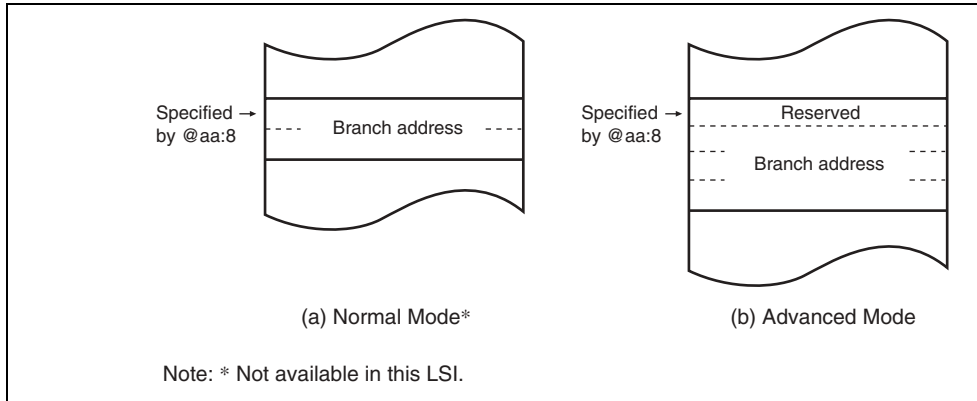

Figure 2.12 Branch Address Specification in Memory Indirect Addressing M

Note: * Not available in this LSI.

- Exception-handling state

The exception-handling state is a transient state that occurs when the CPU alters the processing flow due to an exception source, such as, a reset, trace, interrupt, or trap instruction. The CPU fetches a start address (vector) from the exception vector table and branches to that address. For further details, see section 4, Exception Handling.

- Program execution state

In this state the CPU executes program instructions in sequence.

- Bus-released state

In a product which has a bus master other than the CPU, such as a data transfer controller (DTC), the bus-released state occurs when the bus has been released in response to a request from a bus master other than the CPU. While the bus is released, the CPU has no bus operations.

- Program stop state

This is a power-down state in which the CPU stops operating. The program stop state occurs when a SLEEP instruction is executed or the CPU enters hardware standby mode. For details, see section 23, Power-Down Modes.

- Notes:
1. From any state except hardware standby mode, a transition to the reset state occurs whenever \overline{RES} goes low. A transition can also be made to the reset state when the watchdog timer overflows.
 2. From any state, a transition to hardware standby mode occurs when \overline{STBY} goes low.
 3. The power-down state also includes watch mode, subactive mode, subsleep mode, etc. For details, refer to section 23, Power-Down Modes.

Figure 2.13 State Transitions

manipulated for a port.

In addition, the BCLR instruction can be used to clear the flag of the internal I/O register. In case, if the flag to be cleared has been set to 1 by an interrupt processing routine, the flag should be read before executing the BCLR instruction.

- Set $R4^*$ and $ER6$ so that the end address of the destination address (value of $ER6 + R4^*$) not exceed $H'00FFFFFF$ (the value of $ER6$ must not change from $H'00FFFFFF$ to $H'0$ during execution).

Note: * For byte transfer $R4L$ is used.

Mode 2 is single-chip mode after a reset. The CPU can switch to extended mode by setting EXPE in MDCR to 1.

Modes 0, 1, 3, 5, and 7 are not available in this LSI. Modes 4 and 6 are operating mode for special purpose. Thus, mode pins should be set to enable mode 2 in normal program execution state. Mode pins should not be changed during operation.

MDCR is used to set an operating mode and to monitor the current operating mode.

Bit	Bit Name	Initial Value	R/W	Description
7	EXPE	0	R/W	Extended Mode Enable Specifies extended mode. 0: Single-chip mode 1: Extended mode
6 to 3	—	All 0	R	Reserved
2	MDS2	—*	R	Mode Select 2 to 0
1	MDS1	—*	R	These bits indicate the input levels at mode pin MD1, and MD0 (the current operating mode). MDS2, MDS1, and MDS0 correspond to $\overline{MD2}$ and MD0, respectively. MDS2 to MDS0 are read-only bits and they cannot be written to. The mode pin MD1, and MD0) input levels are latched into the MDCR when MDCR is read. These latches are cancelled on reset.
0	MDS0	—*	R	

Note: * The initial values are determined by the settings of the $\overline{MD2}$, MD1, and MD0 pins.

				1: CS256 pin Outputs low when a 256-kbyte expansion addresses H'F80000 to H'FBFFFF is accessed
6	IOSE	0	R/W	IOS Enable Enables or disables $\overline{AS}/\overline{IOS}$ pin function in expansion mode. 0: \overline{AS} pin Outputs low when an external area is accessed 1: \overline{IOS} pin Outputs low when an IOS expansion area addresses H'FFF000 to H'FFF7FF is accessed
5	INTM1	0	R	These bits select the control mode of the interrupt controller. For details on the interrupt control modes, see section 5.6, Interrupt Control Modes and Operation. 00: Interrupt control mode 0 01: Interrupt control mode 1 10: Setting prohibited 11: Setting prohibited
4	INTM0	0	R/W	
3	XRST	1	R	External Reset This bit indicates the reset source. A reset is caused by an external reset input, or when the watchdog timer overflows. 0: A reset is caused when the watchdog timer overflows. 1: A reset is caused by an external reset.
2	NMIEG	0	R/W	NMI Edge Select Selects the valid edge of the NMI interrupt input. 0: An interrupt is requested at the falling edge of the input 1: An interrupt is requested at the rising edge of the input

control register of the \overline{KINn} pin in an area from H'FFFFFF0 to H'FFFFFF7 and from H'FFFFFF8 to H'FFFFFFF.

0	RAME	1	R/W	RAM Enable Enables or disables on-chip RAM. The RAME is initialized when the reset state is released. 0: On-chip RAM is disabled 1: On-chip RAM is enabled
---	------	---	-----	---

3.2.3 Serial Timer Control Register (STCR)

STCR enables or disables register access, IIC operating mode, and on-chip flash memory. STCR selects the input clock of the timer counter.

Bit	Bit Name	Initial Value	R/W	Description
7	IICX2	0	R/W	IIC Transfer Rate Select 2, 1 and 0
6	IICX1	0	R/W	These bits control the IIC operation. These bits select a transfer rate in master mode together with bits CKS2 to CKS0 in the I ² C bus mode register (ICMR). For details on the transfer rate, see Section 15.3. The IICXn bit controls IIC_n. (n = 0 to 2)
5	IICX0	0	R/W	

H'FFFFDF.
 1: IIC_1 registers are accessed in an area
 H'FFFF88 to H'FFFF89 and from H'FFFF
 H'FFFF8F.
 PWMX registers are accessed in an area
 H'FFFA0 to H'FFFA1 and from H'FFF
 H'FFFA7.
 IIC_0 registers are accessed in an area
 H'FFFD8 to H'FFFD9 and from H'FFF
 H'FFFD7.

3	FLSHE	0	R/W	Flash Memory Control Register Enable Enables or disables CPU access for flash memory control registers (FCCS, FPCS, FECS, FKEY, FMC, FTDAR), control registers of power-down states (SBYCR, LPWRCR, MSTPCR, MSTPCR), control registers of on-chip peripheral modules (BCR2, WSCR2, PCSR, SYSCR2). 0: Area from H'FFFE88 to H'FFFE8F is reserved. Control registers of power-down states of on-chip peripheral modules are accessed in an area from H'FFFF80 to H'FFFF87. 1: Control registers of flash memory are accessed in an area from H'FFFE88 to H'FFFE8F. Area from H'FFFF80 to H'FFFF87 is reserved.
2	—	0	R/W	Reserved The initial value should not be changed.
1	ICKS1	0	R/W	Internal Clock Source Select 1, 0
0	ICKS0	0	R/W	These bits select a clock to be input to the counter (TCNT) and a count condition together with bits CKS2 to CKS0 in the timer control register (TCR). For details, see section 12.3.4, Timer Register (TCR).

Port 6 functions as a data bus port when the ABW bit in WSCR is cleared to 0.

Multiplex extended mode:

When 8-bit bus is specified, port 2 functions as the port for address output and data input, regardless of the setting of the data direction register (DDR). Port 1 can be used as a general purpose I/O port.

When 16-bit bus is specified, ports 1 and 2 function as the port for address output and data input/output regardless of the setting of the data direction register (DDR).

3.3.2 Pin Functions in Each Operating Mode

Pin functions of ports 1 to 3, 6, 9, and A depend on the extended mode. Table 3.2 shows pin functions in each operating mode.

I/O port95 to I/O port93	I/O port* or Control signal output	I/O port* or Control signal
I/O port92	I/O port* or Control signal output	I/O port* or Control signal
I/O port91	I/O port* or Control signal output	I/O port* or Control signal
I/O port90	I/O port* or Control signal output	I/O port* or Control signal
Port A	I/O port* or Address bus output	I/O port*

pin, or when the watchdog timer overflows.

Interrupt	Starts when execution of the current instruction or handling ends, if an interrupt request has been issued. Interrupt detection is not performed on completion of ORC, XORC, or LDC instruction execution, or on completion of reset exception handling.
Direct transition	Starts when a direct transition occurs as the result of SLEEP instruction execution.
Trap instruction	Started by execution of a trap (TRAPA) instruction. Instruction exception handling requests are accepted any number of times in program execution state.

Note: * For details on the internal interrupt vector table, see section 5.5, Interrupt Exception Handling Vector Table.

exception handling as follows:

1. The internal state of the CPU and the registers of the on-chip peripheral modules are i and the I bit in CCR is set to 1.
2. The reset exception handling vector address is read and transferred to the PC, and pro execution starts from the address indicated by the PC.

Figure 4.1 shows an example of the reset sequence.

Figure 4.1 Reset Sequence

4.3.2 Interrupts after Reset

If an interrupt is accepted after a reset and before the stack pointer (SP) is initialized, the CCR will not be saved correctly, leading to a program crash. To prevent this, all interrupts including NMI, are disabled immediately after a reset. Since the first instruction of a program is always executed immediately after the reset state ends, make sure that this instruction initializes the stack pointer (example: `MOV.L #xx: 32, SP`).

4.3.3 On-Chip Peripheral Modules after Reset is Cancelled

After a reset is cancelled, the module stop control registers (MSTPCR, MSTPCRA, SUBMSTPCR, and SUBMSTPA) are initialized, and all modules except the DTC operate in module stop mode. Therefore, the registers of on-chip peripheral modules cannot be read from or written to. To read from and write to these registers, clear module stop mode.

4.5 Trap Instruction Exception Handling

Trap instruction exception handling starts when a TRAPA instruction is executed. Trap instruction exception handling can be executed at all times in the program execution state.

Trap instruction exception handling is conducted as follows:

1. The values in the program counter (PC) and condition code register (CCR) are saved on the stack.
2. A vector address corresponding to the interrupt source is generated, the start address is fetched from the vector table to the PC, and program execution starts from that address.

The TRAPA instruction fetches a start address from a vector table entry corresponding to the interrupt number from 0 to 3, as specified in the instruction code.

Table 4.3 shows the status of CCR after execution of trap instruction exception handling.

Table 4.3 Status of CCR after Trap Instruction Exception Handling

Interrupt Control Mode	CCR	
	I	UI
0	Set to 1	Retains value prior to execution
1	Set to 1	Set to 1

Figure 4.2 Stack Status after Exception Handling

POP.W Rn (or MOV.W @SP+, Rn)
 POP.L ERn (or MOV.L @SP+, ERn)

Setting SP to an odd value may lead to a malfunction. Figure 4.3 shows an example of what happens when the SP value is odd.

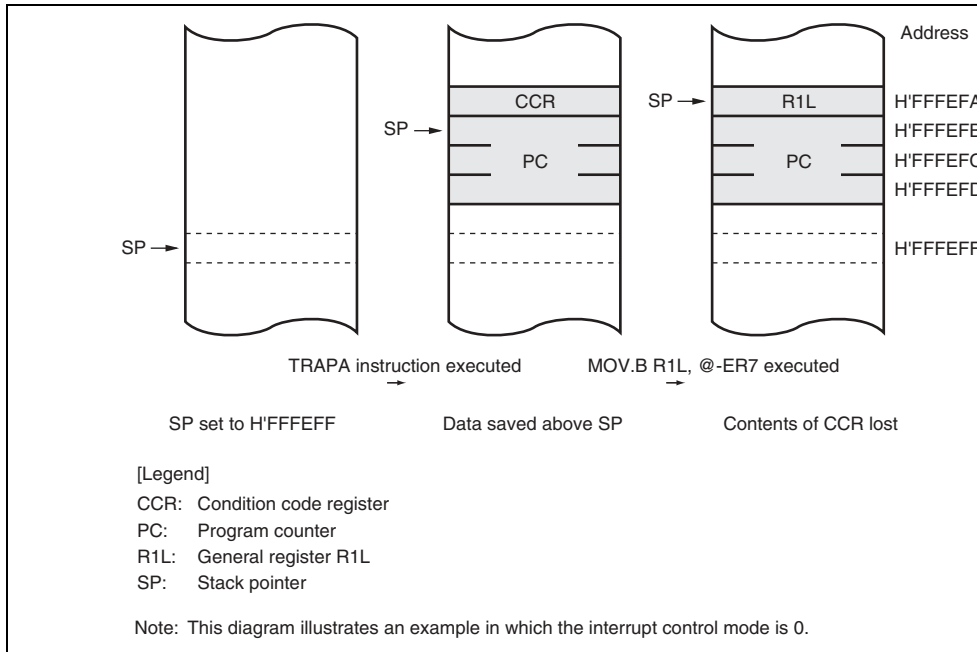

Figure 4.3 Operation when SP Value Is Odd

By means of the interrupt control mode, I and UI bits in CCR, and ICR, 3-level interrupt control is performed.

- Independent vector addresses

All interrupt sources are assigned independent vector addresses, making it unnecessary for each source to be identified in the interrupt handling routine.

- Forty-one external interrupts

NMI is the highest-priority interrupt, and is accepted at all times. Rising edge or falling-edge detection can be selected for NMI. Falling-edge, rising-edge, or both-edge detection. Edge sensing, can be selected for $\overline{\text{IRQ15}}$ to $\overline{\text{IRQ0}}$. An interrupt is requested at the falling edge of $\overline{\text{KIN15}}$ to $\overline{\text{KIN0}}$ and $\overline{\text{WUE15}}$ to $\overline{\text{WUE8}}$.

- DTC control

The DTC can be activated by an interrupt request.

IRQ15 to IRQ0 interrupts. Interrupts IRQ15 to IRQ0 are requested by an input signal at pins $\overline{\text{IRQ15}}$ to $\overline{\text{IRQ0}}$ or pins $\overline{\text{ExIRQ15}}$ to $\overline{\text{ExIRQ2}}$. Interrupts IRQ15 to IRQ0 have the following features:

- The interrupt exception handling for interrupt requests IRQ15 to IRQ0 can be started at an independent vector address.
- Using ISCR, it is possible to select whether an interrupt is generated by a low level, falling edge, rising edge, or both edges, at pins $\overline{\text{IRQ15}}$ to $\overline{\text{IRQ0}}$ or pins $\overline{\text{ExIRQ15}}$ to $\overline{\text{ExIRQ2}}$.
- Enabling or disabling of interrupt requests IRQ15 to IRQ0 can be selected with IER.
- The status of interrupt requests IRQ15 to IRQ0 is indicated in ISR. ISR flags can be cleared to 0 by software.

The detection of IRQ15 to IRQ0 interrupts does not depend on whether the relevant pin is configured as input or output. However, when a pin is used as an external interrupt input pin, the corresponding port DDR to 0 so that it is not used as an I/O pin for another function.

A block diagram of interrupts IRQ15 to IRQ0 is shown in figure 5.2.

Figure 5.2 Block Diagram of Interrupts IRQ15 to IRQ0

The detection of KIN15 to KIN0 and WUE15 to WUE8 interrupts does not depend on whether the relevant pin has been set for input or output. However, when a pin is used as an external input pin, clear the corresponding port DDR to 0 so that it is not used as an I/O pin for a function.

A block diagram of interrupts KIN15 to KIN0 and WUE15 to WUE8 is shown in figure

Figure 5.4 Block Diagram of Interrupt Control Operation

1	0	*	All interrupts (interrupt control level 1 NMI priority)
	1	0	NMI, address break, and interrupt control interrupts
		1	NMI and address break interrupts

[Legend]

*: Don't care

Default Priority Determination: The priority is determined for the selected interrupt, and the vector number is generated.

If the same value is set for ICR, acceptance of multiple interrupts is enabled, and so only one interrupt source with the highest priority according to the preset default priorities is selected and has a vector number generated.

Interrupt sources with a lower priority than the accepted interrupt source are held pending.

Table 5.6 shows operations and control signal functions in each interrupt control mode.

5.6.1 Interrupt Control Mode 0

In interrupt control mode 0, interrupts other than NMI are masked by ICR and the I bit of CCR in the CPU. Figure 5.5 shows a flowchart of the interrupt acceptance operation.

1. If an interrupt source occurs when the corresponding interrupt enable bit is set to 1, an interrupt request is sent to the interrupt controller.
2. According to the interrupt control level specified in ICR, the interrupt controller accepts an interrupt request with interrupt control level 1 (priority), and holds pending an interrupt request with interrupt control level 0 (no priority). If several interrupt requests are issued, an interrupt request with the highest priority is accepted according to the priority order, an interrupt request for handling is requested to the CPU, and other interrupt requests are held pending.
3. If the I bit in CCR is set to 1, only NMI and address break interrupt requests are accepted by the interrupt controller, and other interrupt requests are held pending. If the I bit is cleared, any interrupt request is accepted. KIN, WUE, and EVENTI interrupts are enabled or disabled by the I bit.
4. When the CPU accepts an interrupt request, it starts interrupt exception handling after the execution of the current instruction has been completed.
5. The PC and CCR are saved to the stack area by interrupt exception handling. The PC on the stack shows the address of the first instruction to be executed after returning from the interrupt handling routine.
6. Next, the I bit in CCR is set to 1. This masks all interrupts except for NMI and address break interrupts.
7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address register in the vector table.

Figure 5.5 Flowchart of Procedure up to Interrupt Acceptance in Interrupt Control

set to interrupt control level 1, and other interrupts are set to interrupt control level 0) is shown below. Figure 5.6 shows a state transition diagram.

1. All interrupt requests are accepted when $I = 0$. (Priority order: $NMI > IRQ2 > IRQ3 > IRQ1 > address\ break \dots$)
2. Only NMI, $IRQ2$, $IRQ3$, and address break interrupt requests are accepted when $I = 1$ and $UI = 0$.
3. Only NMI and address break interrupt requests are accepted when $I = 1$ and $UI = 1$.

Figure 5.6 State Transition in Interrupt Control Mode 1

Figure 5.7 shows a flowchart of the interrupt acceptance operation.

When the I bit is cleared to 0, the UI bit is not affected.

4. When the CPU accepts an interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
5. The PC and CCR are saved to the stack area by interrupt exception handling. The PC on the stack shows the address of the first instruction to be executed after returning from the interrupt handling routine.
6. The I and UI bits in CCR are set to 1. This masks all interrupts except for NMI and a break interrupts.
7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address vector table.

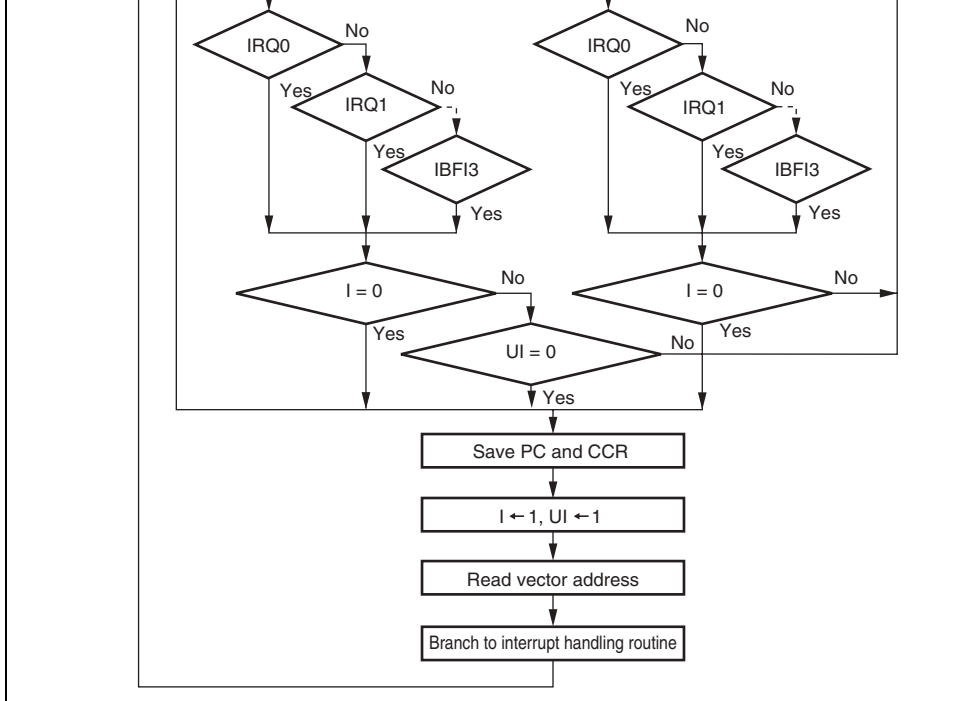

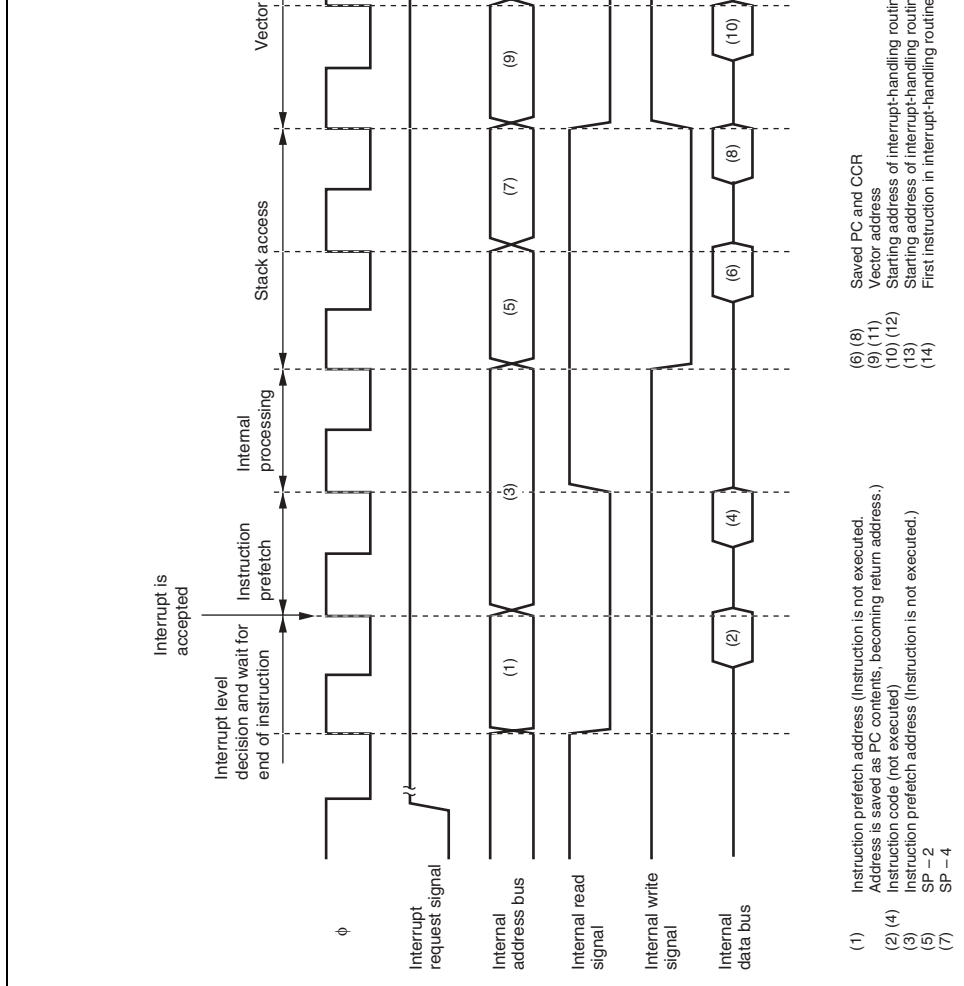

Figure 5.7 Flowchart of Procedure Up to Interrupt Acceptance in Interrupt Control Mode 1

5.6.3 Interrupt Exception Handling Sequence

Figure 5.8 shows the interrupt exception handling sequence. The example shown is for the case where interrupt control mode 0 is set in advanced mode, and the program area and stack are located in on-chip memory.

- (1) Instruction prefetch address (Instruction is not executed.)
- (2) (4) Address is saved as PC contents, becoming return address.)
- (3) Instruction code (not executed)

Branch address read S _j					
Stack manipulation S _k					

[Legend]

m: Number of wait states in external device access.

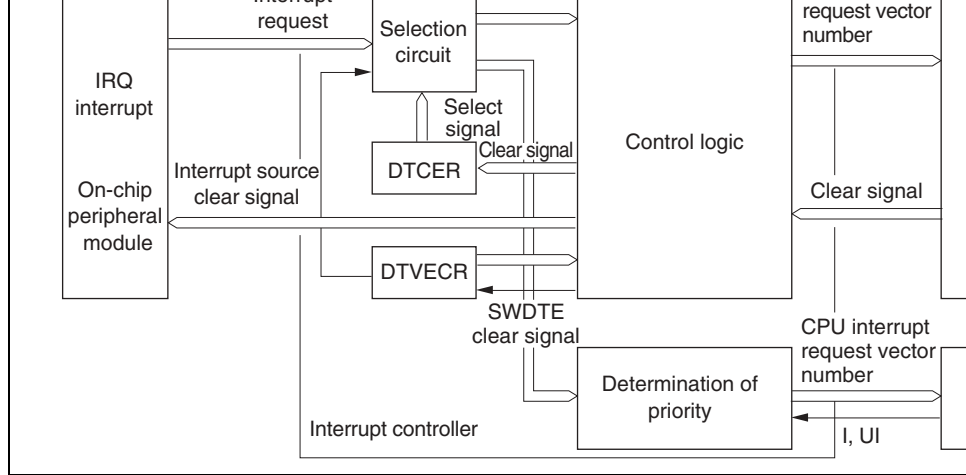

Figure 5.9 Interrupt Control for DTC

The interrupt controller has three main functions in DTC control.

Selection of Interrupt Source: It is possible to select DTC activation request or CPU interrupt request with the DTCE bit of DTCERA to DTCERE in the DTC. After a DTC data transfer, the DTCE bit can be cleared to 0 and an interrupt request sent to the CPU in accordance with the specification of the DISEL bit of MRB in the DTC. When the DTC performs the specification of data transfers and the transfer counter reaches 0, following the DTC data transfer the DTCE bit is cleared to 0 and an interrupt request is sent to the CPU.

Determination of Priority: The DTC activation source is selected in accordance with the priority order, and is not affected by mask or priority levels. See section 7.5, Location of Information and DTC Vector Table, for the respective priorities.

0	*	×	Δ
1	0	Δ	×
	1	○	Δ

[Legend]

- Δ: The relevant interrupt is used. Interrupt source clearing is performed.
(The CPU should clear the source flag in the interrupt handling routine.)
- : The relevant interrupt is used. The interrupt source is not cleared.
- ×: The relevant interrupt cannot be used.
- *: Don't care

shows an example in which the CMIEA bit in the TMR's TCR register is cleared to 0.

The above conflict will not occur if an enable bit or interrupt source flag is cleared to 0 or the interrupt is masked.

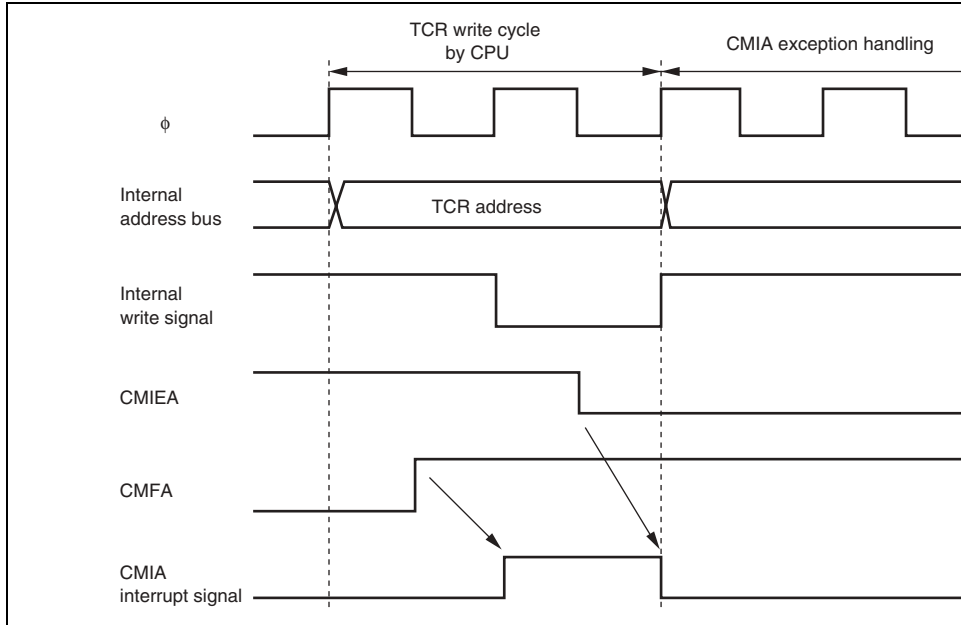

Figure 5.10 Conflict between Interrupt Generation and Disabling

is not accepted until the move is completed.

With the EEPMOV.W instruction, if an interrupt request is issued during the transfer, into exception handling starts at a break in the transfer cycle. The PC value saved on the stack in this case is the address of the next instruction. Therefore, if an interrupt is generated during execution of an EEPMOV.W instruction, the following coding should be used.

```
L1:   EEPMOV.W
      MOV.W   R4, R4
      BNE    L1
```

5.7.4 IRQ Status Registers (ISR16, ISR)

Since IRQnF may be set to 1 according to the pin status after a reset, the ISR16 and the ISR should be read after a reset, and then write 0 in IRQnF (n = 15 to 0).

- Extended area division

Possible in normal extended mode

The external address space can be accessed as basic extended areas.

A 256-kbyte extended area can be set and controlled independently of basic extended areas.

A CP extended area can be set and controlled independently of basic extended areas.

- Address pin reduction

In normal extended mode:

A 256-kbyte extended area from H'F80000 to H'FBFFFF can be selected using 18 address pins and the $\overline{CS256}$ signal.

A CP extended area (8 kbytes, basic mode) from H'FFC000 to H'FFDFFF can be selected using 13 address pins and the $\overline{CPCS1}$ signal.

A 2-kbyte area from H'FFF000 to H'FFF7FF can be selected using six to eleven address pins and the \overline{IOS} signal.

In address-data multiplex extended mode:

The external address space can be accessed as the following three extended areas.

H'F80000 to H'F8FFFF	64 kbytes	256-kbyte extended area
----------------------	-----------	-------------------------

H'FFC000 to H'FFDFFF	8 kbytes	CP extended area
----------------------	----------	------------------

H'FFF000 to H'FFF7FF	2 kbytes	IOS extended area
----------------------	----------	-------------------

These areas can be selected using 8 pins or 16 pins, which is a total of address pins and input/output pins.

- Control address hold signal and area select signal polarity

The output polarity of \overline{IOS} , $\overline{CS256}$, $\overline{CPCS1}$, and \overline{AH} can be inverted by the PNCCS and PNCAH bits in LPWRCR.

Program wait states can be inserted for each area.

- Burst ROM interface

In normal extended mode

A burst ROM interface can be set for basic extended areas.

1-state access or 2-state access can be selected for burst access.

- Idle cycle insertion

In normal extended mode

An idle cycle can be inserted for external write cycles immediately after external read

- Bus arbitration function

Includes a bus arbiter that arbitrates bus mastership between the CPU and DTC.

Figure 6.1 Block Diagram of Bus Controller

\overline{IOS}	Output	Chip select signal indicating that the IOS extended area is being accessed (when the IOSE bit in SYSCR is 1).
$\overline{CPCS1}$	Output	Chip select signal indicating that the CP extended area is being accessed (when the CPCSE bit in BCR2 is 1).
$\overline{CS256}$	Output	Chip select signal indicating that the 256-kbyte external memory area is being accessed (when the CS256E bit in SYSCR is 1).
\overline{RD}	Output	Strobe signal indicating that the external address space is being read.
\overline{HWR}	Output	Strobe signal indicating that the external address space is being written to, and the upper half (D15 to D8, AD15 to AD8) of the data bus is enabled.
\overline{LWR}	Output	Strobe signal indicating that the external address space is being written to, and the lower half (D7 to D0, AD7 to AD0) of the data bus is enabled.
\overline{WAIT}	Input	Wait request signal when accessing the external address space.
\overline{AH}	Output	Signal indicating address fetch timing when the bus is in the address-data multiplex bus state.
AD15 to AD0	Input/Output	Address output and data input/output pins for address/data multiplex extension.

BCR is used to specify the access mode for the external address space and the I/O area and the $\overline{AS}/\overline{IOS}$ pin is specified as an I/O strobe pin.

Bit	Bit Name	Initial Value	R/W	Description
7	—	1	R/W	Reserved The initial value should not be changed.
6	ICIS	1	R/W	Idle Cycle Insertion Selects whether or not to insert 1-state of the idle cycle between successive external read and external write. 0: Idle cycle not inserted 1: 1-state idle cycle inserted
5	BRSTRM	0	R/W	Valid only in the normal extended mode. Burst ROM Enable Selects the bus interface for the external address space. 0: Basic bus interface 1: Burst ROM interface When the CS256E bit in SYSCR and the CPCSE bit in SYSCR are set to 1, burst ROM interface cannot be selected for the 256-kbyte extended area and CP extended area.
4	BRSTS1	1	R/W	Valid only in the normal extended mode. Burst Cycle Select 1 Selects the number of states in the burst cycle of the ROM interface. 0: 1 state 1: 2 states

6.3.2 Bus Control Register 2 (BCR2)

BCR2 is used to specify the access mode for the CP extended area.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R/W	Reserved The initial value should not be changed.
5	ABWCP	1	R/W	CP Extended Area Bus Width Control Selects the bus width for access to the CP extended area when the CPCSE bit is set to 1 0: 16-bit bus 1: 8-bit bus
4	ASTCP	1	R/W	CP Extended Area Access State Control Selects the number of states for access to the CP extended area when the CPCSE bit is set to 1. This bit also enables/disables wait-state insertion. [ADMXE = 0] Normal extension 0: 2-state access space. Wait state insertion disabled 1: 3-state access space. Wait state insertion enabled [ADMXE = 1] Address-data multiplex extension 0: 2-state data access space. Wait state insertion disabled 1: 3-state data access space. Wait state insertion enabled

external extended area access.

1	—	1	R/W	Reserved The initial value should not be changed.
0	CPCSE	0	R/W	CP Extended Area Enable Selects the extended area to be accessed. 0: External address space 1: CP extended area

0: 16-bit bus

1: 8-bit bus

Bit	Bit Name	Initial Value	R/W	Description
2	WC22	1	R/W	Address-Data Multiplex Extended Area Address Cycle Count 2 Selects the number of program wait states to be inserted into the address cycle for access to the address-data multiplex extended area. 0: Program wait state is not inserted 1: 1 program wait state is inserted in the address cycle
1	WC21	1	R/W	CP Extended Area Data Cycle Wait Count 1 and 0
0	WC20	1	R/W	Selects the number of program wait states to be inserted in the data cycle for access to the CP extended area wait states. The CPCSE and ASTCP bits in BCR2 are set to 1. 00: Program wait state is not inserted in the data cycle 01: 1 program wait state is inserted in the data cycle 10: 2 program wait states are inserted in the data cycle 11: 3 program wait states are inserted in the data cycle

(b) Number of Access States: Two or three access states can be selected via the AST and AST256 bits in WSCR, and the ASTCP bit in BCR2. When the 2-state access space is selected, wait-state insertion is disabled.

In the burst ROM interface, the number of access states for the basic extended area is determined regardless of the AST bit setting.

(c) Wait Mode and Number of Program Wait States: When the basic extended area is specified as a 3-state access space by the AST bit in WSCR, the wait mode and the number of program wait states to be inserted automatically is selected by the WMS1, WMS0, WC1, and WC0 bits in WSCR. From 0 to 3 program wait states can be selected.

When the 256-kbyte extended area is specified as a 3-state access space by the AST256 bit in WSCR, the wait mode and the number of program wait states to be inserted automatically is selected by the WMS10, WC11, and WC10 bits in WSCR2. From 0 to 3 program wait states can be selected.

When the CP extended area is specified as a 3-state access space by the ASTCP bit in BCR2, the wait mode and the number of program wait states to be inserted automatically is selected by the WMS21, WMS20, WC21, and WC20 bits in WSCR2. From 0 to 3 program wait states can be selected.

The wait function for external extension is effective for connecting low-speed devices to the external address space. However, this wait function may cause some problems when the number of bus masters other than the CPU, such as the DTC are to be delayed.

Tables 6.2 to 6.6 show each bit setting and external address space division in the address space, the external address space, and the bus specifications for the basic bus interface of each area.

H'FF0800 to H'FFBFFF (46 kbytes)	△ When RAME = 0, used as basic extended area.	—

wait mode and the number of program wait states to be inserted automatically is selected by the WMS1, WMS0, WC1, and WC0 bits in WSCR. Zero or one program wait state can be inserted into address cycle. From zero to three program wait states can be selected for data cycle.

ii) 256-kbyte Extended Area

When the 256-kbyte extended area is specified as a 3-state access space by the AST256 bit in WSCR, the wait mode and the number of program wait states to be inserted automatically is selected by the WMS10, WC11, and WC10 bits in WSCR2. Zero or one program wait state can be inserted into address cycle. From zero to three program wait states can be selected for data cycle.

iii) CP Extended Area

When the CP extended area is specified as a 3-state access space by the ASTCP bit in WSCR, the wait mode and the number of program wait states to be inserted automatically is selected by the WMS21, WMS20, WC22, WC21, and WC20 bits in WSCR2. Zero or one program wait state can be inserted into address cycle. From zero to three program wait states can be selected for data cycle.

The wait function for external extension is effective for connecting low-speed devices to external address space. However, this wait function may cause some problems when the operation of bus masters other than the CPU, such as the DTC, are to be delayed.

Tables 6.7 to 6.14 show address-data multiplex address space and the bus specifications for the basic bus interface of each area.

6.4.2 Advanced Mode

The external address space (H'FFF000 to H'FFF7FF) can be accessed by specifying the \overline{A} pin as an I/O strobe pin. The 256-kbyte extended area (H'F80000 to H'FBFFFF) and CP e area (H'FFC000 to H'FFDFFF) can be accessed by the $\overline{CS256}$ pin and $\overline{CPCS1}$ pin functions respectively.

The external address space is initialized as the basic bus interface and a 3-state access space mode 2, the address space other than on-chip ROM, on-chip RAM, internal I/O registers, reserved areas is specified as the external address space. The on-chip RAM and its reserved areas are enabled when the RAME bit in SYSCR is set to 1, and disabled when the RAME bit is set to 0. Addresses H'FF0800 to H'FFBFFF, H'FFE080 to H'FFEFFF, and H'FFFF00 to H'FFFF00 are the on-chip RAM area and its reserved area are always specified as the external address space.

Figure 6.2 $\overline{\text{IOS}}$ Signal Output Timing

Enabling or disabling $\overline{\text{IOS}}$ signal output is performed by the IOSE bit in SYSCR. In the mode, the $\overline{\text{IOS}}$ pin functions as an $\overline{\text{AS}}$ pin by a reset. To use this pin as an $\overline{\text{IOS}}$ pin, set the bit to 1. For details, see section 8, I/O Ports.

The address ranges of the $\overline{\text{IOS}}$ signal output can be specified by the IOS1 and IOS0 bits as shown in table 6.15.

Table 6.15 Address Range for $\overline{\text{IOS}}$ Signal Output

IOS1	IOS0	$\overline{\text{IOS}}$ Signal Output Range
0	0	H'FFF000 to H'FFF03F
	1	H'FFF000 to H'FFF0FF
1	0	H'FFF000 to H'FFF3FF
	1	H'FFF000 to H'FFF7FF (Ini

Data sizes for the CPU and other internal bus masters are byte, word, and longword. This block controls the data alignment function, and controls whether the upper data bus (D15 to D8/AD15 to AD8) or the lower data bus (D7 to D0/AD7 to AD0) is used when the external address space is accessed, according to the bus specifications for the area being accessed (8-bit access space or 16-bit access space) and the data size.

(1) 8-Bit Access Space: Figure 6.3 illustrates data alignment control for the 8-bit access space. With the 8-bit access space, the upper data bus (D15 to D8/AD15 to AD8) is always used for byte accesses. The amount of data that can be accessed at one time is one byte: a word access is performed as two byte accesses, and a longword access, as four byte accesses.

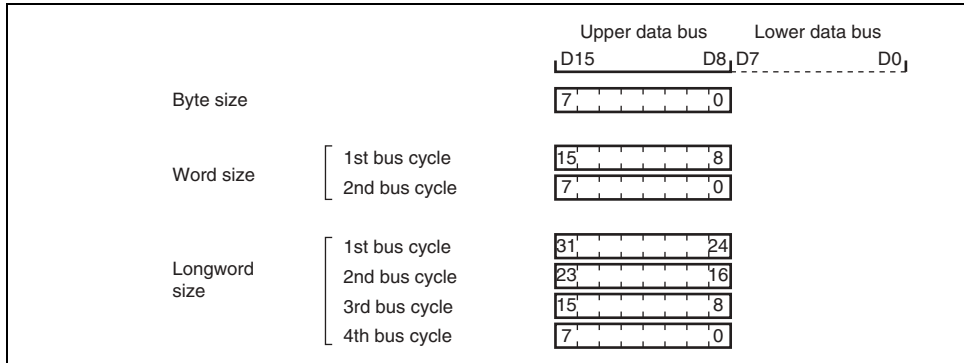

Figure 6.3 Access Sizes and Data Alignment Control (8-bit Access Space)

Figure 6.4 Access Sizes and Data Alignment Control (16-bit Access Space)

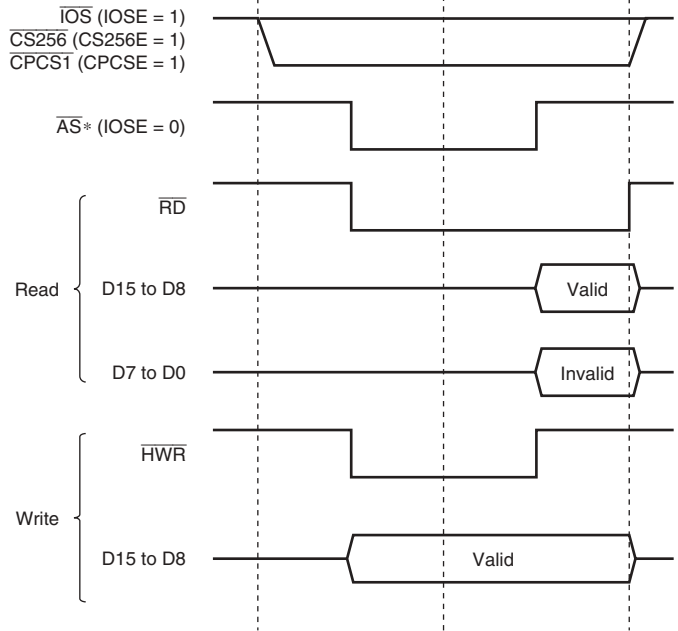

Access	Space	Mode	Condition	Input	Output	Notes
16-bit access space	Byte	Read	Even	\overline{RD}	Valid	Invalid
			Odd		Invalid	Valid
		Write	Even	\overline{HWR}	Valid	Undefined
			Odd	\overline{LWR}	Undefined	Valid
	Word	Read	—	\overline{RD}	Valid	Valid
		Write	—	$\overline{HWR}, \overline{LWR}$	Valid	Valid

[Legend]

Undefined: Undefined data is output.

Invalid: Input state with the input value ignored.

Ports or others: Used as ports or I/O pins for on-chip peripheral modules, and are not used as data bus.

Note: * For external address space access, this signal is not output when the 256-kbyte expansion area is accessed with CS256E = 1 and when the CP expansion area is accessed with CPCSE = 1.

Figure 6.5 Bus Timing for 8-Bit, 2-State Access Space

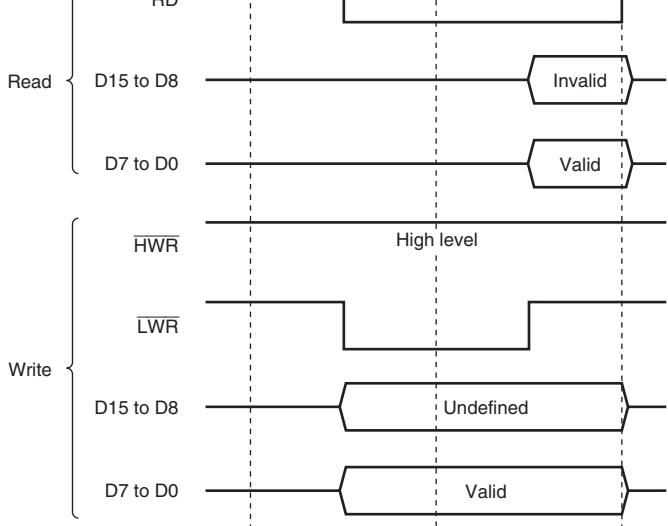

Note: * For external address space access, this signal is not output when the 256-kbyte expansion area is accessed with CS256E = 1 and when the CP expansion area is accessed with CPCSE = 1.

Figure 6.6 Bus Timing for 8-Bit, 3-State Access Space

Note: * For external address space access, this signal is not output when the 256-kbyte expansion area is accessed with CS256E = 1 and when the CP expansion area is accessed with CPCSE = 1.

Figure 6.7 Bus Timing for 16-Bit, 2-State Access Space (Even Byte Access)

Note: * For external address space access, this signal is not output when the 256-kbyte expansion area is accessed with CS256E = 1 and when the CP expansion area is accessed with CPCSE = 1.

Figure 6.8 Bus Timing for 16-Bit, 2-State Access Space (Odd Byte Access)

Note: * For external address space access, this signal is not output when the 256-kbyte expansion area is accessed with CS256E = 1 and when the CP expansion area is accessed with CPCSE = 1.

Figure 6.24 Bus Timing for 16-Bit, 3-State Access Space (3) (Word Access)

6.5.5 Wait Control

When accessing the external address space, this LSI can extend the bus cycle by inserting more wait states (T_w). There are three ways of inserting wait states: Program wait insertion, pin wait insertion using the $\overline{\text{WAIT}}$ pin, and the combination of program wait and the $\overline{\text{WAIT}}$ pin.

(1) In Normal Extended Mode

(a) Program Wait Mode: A specified number of wait states T_w are always inserted between T_2 state and T_3 state when accessing the external address space. The number of wait states is specified by the settings of the WC1 and WC0 bits in WSCR (the WC11 and WC10 bits in WSCR1 for the 128-kbyte extended area, and the WC21 and WC20 bits in WSCR2 for the 256-kbyte extended area).

(b) Pin Wait Mode: A specified number of wait states T_w are always inserted between T_2 and T_3 state when accessing the external address space. The number of wait states T_w is specified by the settings of the WC1 and WC0 bits (the WC21 and WC20 bits for the CP extended area). If the $\overline{\text{WAIT}}$ pin is low at the falling edge of ϕ in the last T_2 or T_w state, another T_w state is inserted. If the $\overline{\text{WAIT}}$ pin is held low, T_w states are inserted until it goes high.

Pin wait mode is useful when inserting four or more T_w states, or when changing the number of wait states to be inserted for each external device.

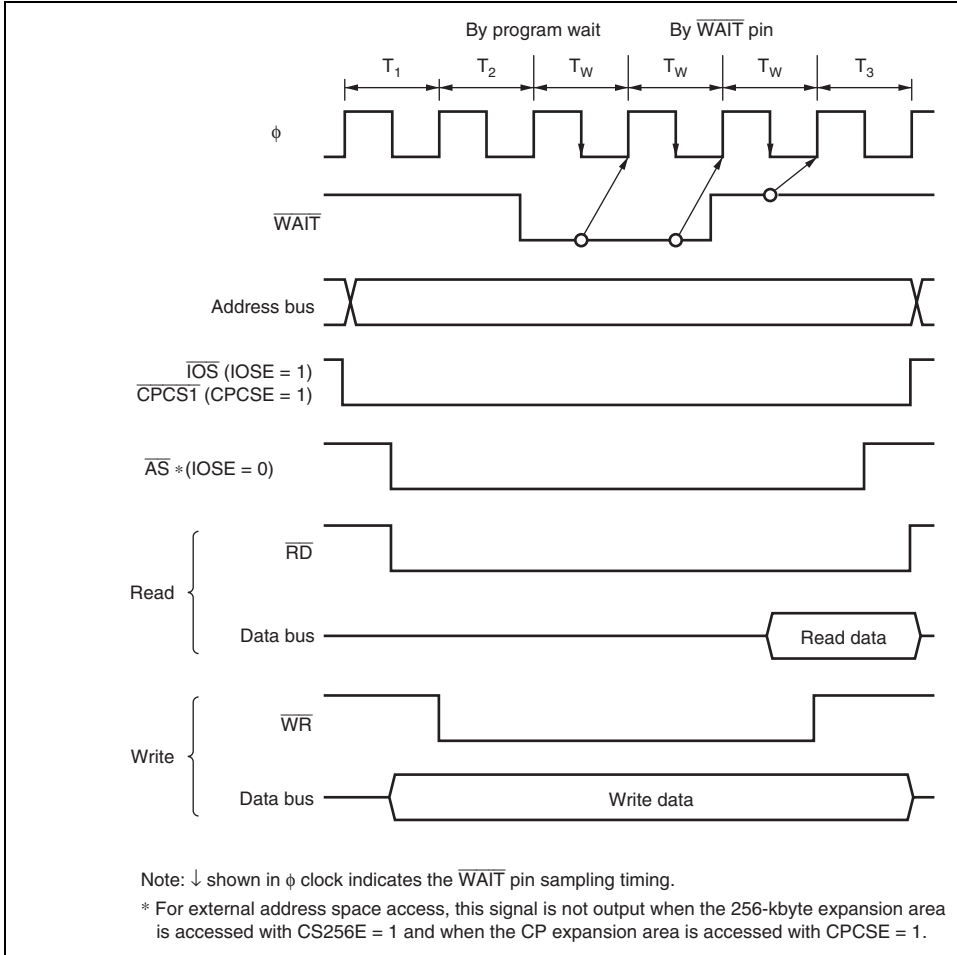

Figure 6.25 Example of Wait State Insertion Timing (Pin Wait Mode)

(b) Pin Wait Mode: When accessing the external address space, a specified number of T_{DSW} can be inserted between the T_4 state and T_5 state of data state. The number of wait states is specified by the settings of the WC1 and WC0 bits (the WC21 and WC20 bits for the extended area). If the \overline{WAIT} pin is low at the falling edge of ϕ in the last T_4 , T_{DSW} , or T_{DOW} another T_{DOW} state is inserted. If the \overline{WAIT} pin is held low, T_{DOW} states are inserted until high.

Pin wait mode is useful when inserting four or more T_{DOW} states, or when changing the number of T_{DOW} states to be inserted for each external device.

(c) Pin Auto-Wait Mode: A specified number of wait states T_{DOW} are inserted between T_4 and T_5 state when accessing the external address space if the \overline{WAIT} pin is low at the falling edge of ϕ in the last T_4 state. The number of wait states T_{DOW} is specified by the settings of the WC0 bits (the WC21 and WC20 bits for the CP extended area). Even if the \overline{WAIT} pin is held low, T_{DOW} states are inserted only up to the specified number of states.

Pin auto-wait mode enables the low-speed memory interface only by inputting the chip select signal to the \overline{WAIT} pin.

Figure 6.26 shows an example of wait state insertion timing in pin wait mode.

Figure 6.26 Example of Wait State Insertion Timing

wait states cannot be inserted in a burst cycle. Burst accesses of a maximum four words is performed when the BRSTS0 bit in BCR is cleared to 0, and burst accesses of a maximum of 16 words is performed when the BRSTS0 bit in BCR is set to 1.

The basic access timing for the burst ROM space is shown in figures 6.27 and 6.28.

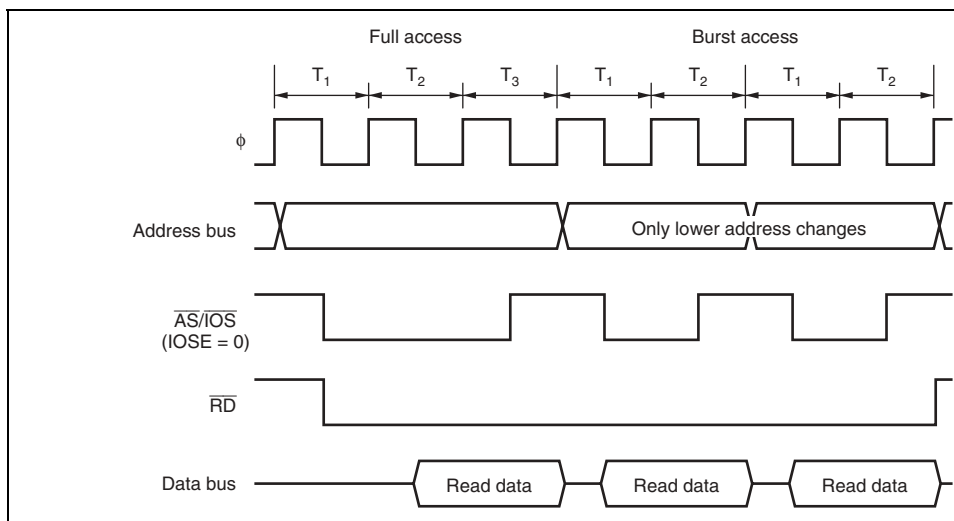

Figure 6.27 Access Timing Example in Burst ROM Space (AST = BRSTS1)

Figure 6.28 Access Timing Example in Burst ROM Space (AST = BRSTS1 = ...)

6.6.2 Wait Control

As with the basic bus interface, program wait insertion or pin wait insertion using the \overline{WA} is possible in the initial cycle (full access) of the burst ROM interface. For details, see section Wait Control. Wait states cannot be inserted in a burst cycle.

the CPU write data. In figure 6.29 (b), an idle cycle is inserted, thus preventing data collision

Figure 6.29 Examples of Idle Cycle Operation

Table 6.17 shows the pin states in an idle cycle.

Table 6.17 Pin States in Idle Cycle

Pins	Pin State
A23 to A0	Contents of immediately following bus cycle
D15 to D0	High impedance
\overline{AS} , \overline{IOS} , $\overline{CS256}$, $\overline{CPCS1}$	High
\overline{RD}	High
\overline{HWR} , \overline{LWR}	High

designated timing. If there are bus requests from more than one bus master, the bus master with the highest priority request acknowledge signal is sent to the one with the highest priority. When a bus master with the highest priority request acknowledge signal, it takes the bus mastership until that signal is canceled. The order of bus master priority is as follows:

(High) DTC > CPU (Low)

6.8.3 Bus Mastership Transfer Timing

When a bus request is received from a bus master with a higher priority than that of the bus master that has acquired the bus mastership and is currently operating, the bus mastership is not necessarily transferred immediately. Each bus master can relinquish the bus mastership at the timings given below.

CPU: The CPU is the lowest-priority bus master, and if a bus mastership request is received from the DTC, the bus arbiter transfers the bus mastership to the DTC. The timing for transferring bus mastership is as follows:

- Bus mastership is transferred at a break between bus cycles. However, if bus cycle is in discrete operations, as in the case of a long-word size access, the bus is not transferred at a break between the operations. For details see section 2.7, Bus States During Instruction Execution in the H8S/2600 Series, H8S/2000 Series Programming Manual.
- If the CPU is in sleep mode, it transfers the bus mastership immediately.

DTC: The DTC sends the bus arbiter a request for the bus mastership when a request for bus activation occurs. The DTC releases the bus mastership after a series of processes has completed.

- Transfer is possible over any number of channels
- Three transfer modes
 - Normal, repeat, and block transfer modes are available
- One activation source can trigger a number of data transfers (chain transfer)
- Direct specification of 16 Mbytes address space is possible
- Activation by software is possible
- Transfer can be set in byte or word units
- A CPU interrupt can be requested for the interrupt that activated the DTC
- Module stop mode can be set
- DTC operates in high-speed mode even when the LSI is in medium-speed mode

Figure 7.1 Block Diagram of DTC

source occurs, the DTC reads a set of register information that is stored in on-chip RAM. After the data transfer, it writes a set of register information back to on-chip RAM.

- DTC enable registers (DTCER)
- DTC vector register (DTVECR)
- Keyboard comparator control register (KBCOMP)
- Event counter control register (ECCR)
- Event counter status register (ECS)

6	DISEL	Undefined	—	DTC Interrupt Select	DTCER are not performed.
					When this bit is set to 1, a CPU interrupt request is generated every time data transfer ends. When this bit is cleared to 0, a CPU interrupt request is generated only when the specified number of data transfers has occurred.
5 to 0	—	Undefined	—	Reserved	These bits have no effect on DTC operation. The value should always be 0.

7.2.3 DTC Source Address Register (SAR)

SAR is a 24-bit register that designates the source address of data to be transferred by the DTC. For word-size transfer, specify an even source address.

7.2.4 DTC Destination Address Register (DAR)

DAR is a 24-bit register that designates the destination address of data to be transferred by the DTC. For word-size transfer, specify an even destination address.

CRB is a 16-bit register that designates the number of times data is to be transferred by the block transfer mode. It functions as a 16-bit transfer counter (1 to 65536) that is decremented every time data is transferred, and transfer ends when the count reaches H'0000.

7.2.7 DTC Enable Registers (DTCER)

DTCER specifies DTC activation interrupt sources. DTCER is comprised of five registers DTCERA to DTCERE. The correspondence between interrupt sources and DTCE bits is shown in tables 7.1 and 7.4. For DTCE bit setting, use bit manipulation instructions such as BSET and BCLR. Multiple DTC activation sources can be set at one time (only at the initial setting). To mask all interrupts and writing data after executing a dummy read on the relevant register.

Bit	Bit Name	Initial Value	R/W	Description

	5 to 0	—	B'000000
SAR	23 to 0	—	Identical optional RAM address. Its lower five bits are
DAR	23 to 0	—	The start address of 16 words is this address. They are incremented every time an event is detected in EVENT0 to EVENT15.
CRAH	7 to 0	—	H'FF
CRAL	7 to 0	—	H'FF
CRBH	7 to 0	—	H'FF
CRBL	7 to 0	—	H'FF
DTCERC	4	DTCEC4	1: DTC function of the event counter is enabled
KBCOMP	7	EVENTE	1: Event counter enable
RAM	—	—	(SAR, DAR) : Result of EVENT0 count (SAR, DAR) + 2: Result of EVENT 1 count (SAR, DAR) + 4: Result of EVENT 2 count ↓ (SAR, DAR) + 30: Result of EVENT 15 count

The corresponding flag to ECS input pin is set to 1 when the event pins that are specified by ECSB3 to ECSB0 in ECCR detect the edge events specified by the EDSB in ECCR. For each event, state, status/address codes are generated.

An EVENTI interrupt request is generated even if only one bit in ECS is set to 1.

The EVENTI interrupt request activates the DTC and transfers data from RAM to RAM at the same address. Data is incremented in the DTC. The lower five bits of SAR and DAR are incremented with address code that is generated by the ECS flag status.

7.3.1 Event Counter Handling Priority

EVENT0 to EVENT15 count handling is operated in the priority shown as below.

High

Low

EVENT0 > EVENT1 EVENT14 > EVENT15

7.4 Activation Sources

The DTC is activated by an interrupt request or by a write to DTVECR by software. The request source to activate the DTC is selected by DTCER. At the end of a data transfer (or consecutive transfer in the case of chain transfer), the interrupt flag that became the activation source or the corresponding DTCER bit is cleared. The activation source flag, in the case of RXI0, for example, is the RDRF flag in SCI_0.

When an interrupt has been designated as a DTC activation source, the existing CPU mask and interrupt controller priorities have no effect. If there is more than one activation source at the same time, the DTC operates in accordance with the default priorities. Figure 7.2 shows a block diagram of DTC activation source control. For details on the interrupt controller, see Section 10.1, Interrupt Controller.

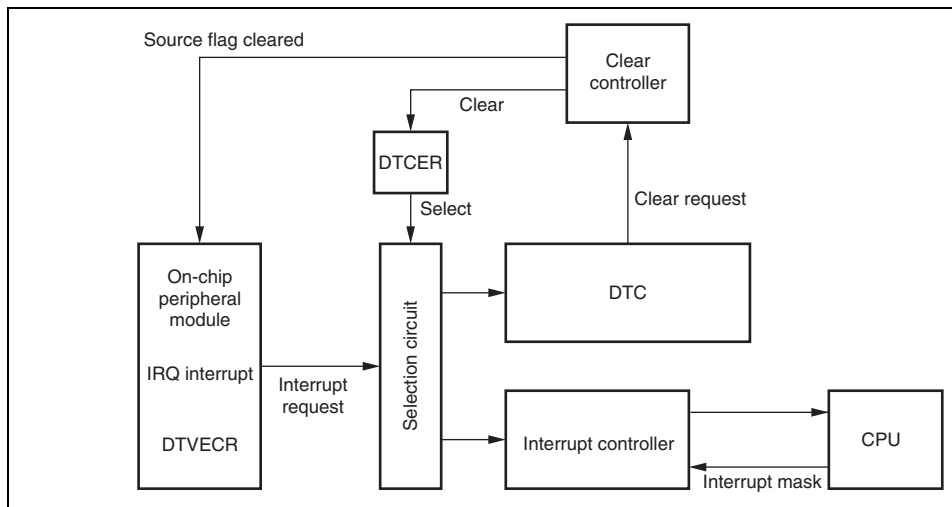

Figure 7.2 Block Diagram of DTC Activation Source Control

(DTVECR[6:0] × 2). For example, if DTVECR is H'10, the vector address is H'0420.

The configuration of the vector address is a 2-byte unit. Specify the lower two bytes of the information start address.

at the end of the specified number of transfers or by setting of the DISEL bit to 1, and the source flag for the activation source is not affected.

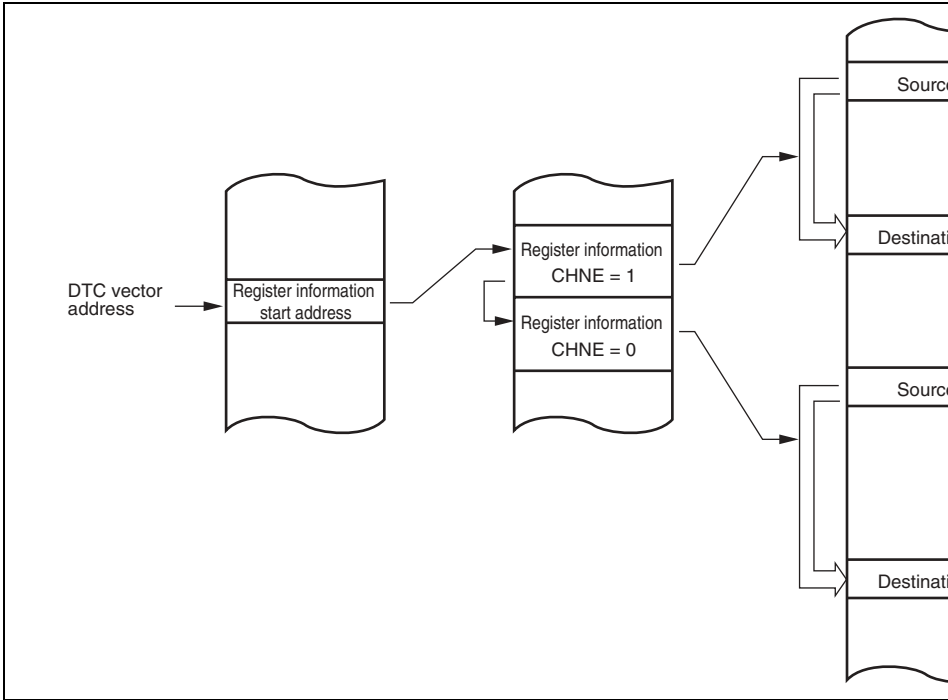

Figure 7.8 Chain Transfer Operation

to 0.

When the DTC is activated by software, an SWDTEND interrupt is not generated during transfer wait or during data transfer even if the SWDTE bit is set to 1.

7.6.6 Operation Timing

Figure 7.9 DTC Operation Timing (Example in Normal Mode or Repeat Mode)

Figure 7.11 DTC Operation Timing (Example of Chain Transfer)

7.6.7 Number of DTC Execution States

Table 7.8 lists the execution status for a single DTC data transfer, and table 7.9 shows the number of states required for each execution status.

Table 7.8 DTC Execution Status

Mode	Vector Read I	Register Information	Data Read K	Data Write L	Inter- Op M
		Read/Write J			
Normal	1	6	1	1	3
Repeat	1	6	1	1	3
Block transfer	1	6	N	N	3

[Legend]

N: Block size (initial setting of CRAH and CRAL)

Word data read	1	1	1	4	2	4	6 + 2m	2
S_K								
Byte data write	S_L	1	1	2	2	2	3 + m	2
Word data write	1	1	1	4	2	4	6 + 2m	2
S_L								
Internal operation	1	1	1	1	1	1	1	1
S_M								

The number of execution states is calculated from using the formula below. Note that Σ is the sum of all transfers activated by one activation source (the number in which the CHNE bit is set plus 1).

$$\text{Number of execution states} = I \cdot S_I + \Sigma (J \cdot S_J + K \cdot S_K + L \cdot S_L) + M \cdot S_M$$

For example, when the DTC vector address table is located in on-chip ROM, normal mode is used, and data is transferred from on-chip ROM to an internal I/O register, then the time required for DTC operation is 13 states. The time from activation to the end of data write is 10 states.

been completed, the DTCE bit is cleared to 0 and a CPU interrupt is requested. If the continue transferring data, set the DTCE bit to 1.

7.7.2 Activation by Software

The procedure for using the DTC with software activation is as follows:

- [1] Set the MRA, MRB, SAR, DAR, CRA, and CRB register information in on-chip RA
- [2] Set the start address of the register information in the DTC vector address.
- [3] Check that the SWDTE bit is 0.
- [4] Write 1 to the SWDTE bit and the vector number to DTVECR.
- [5] Check the vector number written to DTVECR.
- [6] After one data transfer has been completed, if the DISEL bit is 0 and a CPU interrupt requested, the SWDTE bit is cleared to 0. If the DTC is to continue transferring data, SWDTE bit to 1. When the DISEL bit is 1 or after the specified number of data transfer been completed, the SWDTE bit is held at 1 and a CPU interrupt is requested.

- [3] Set the corresponding bit in DTCER to 1.
- [4] Set the SCI to the appropriate receive mode. Set the RIE bit in SCR to 1 to enable the complete (RXI) interrupt. Since the generation of a receive error during the SCI reception operation will disable subsequent reception, the CPU should be enabled to accept receive interrupts.
- [5] Each time the reception of one byte of data has been completed on the SCI, the RDRF flag is set to 1, an RXI interrupt is generated, and the DTC is activated. The receive data is transferred from RDR to RAM by the DTC. DAR is incremented and CRA is decremented. The RDRF flag is automatically cleared to 0.
- [6] When CRA becomes 0 after 128 data transfers have been completed, the RDRF flag is set to 1, the DTCE bit is cleared to 0, and an RXI interrupt request is sent to the CPU. The interrupt handling routine will perform wrap-up processing.

7.8.2 Software Activation

An example is shown in which the DTC is used to transfer a block of 128 bytes of data by software activation. The transfer source address is H'1000 and the transfer destination address is H'2000. The vector number is H'60, so the vector address is H'04C0.

- [1] Set MRA to incrementing source address (SM1 = 1, SM0 = 0), incrementing destination address (DM1 = 1, DM0 = 0), block transfer mode (MD1 = 1, MD0 = 0), and byte size (BS = 0). The DTS bit can have any value. Set MRB for one block transfer by one interrupt (MRB = 0). Set the transfer source address (H'1000) in SAR, the transfer destination address (H'2000) in DAR, and 128 (H'8080) in CRA. Set 1 (H'0001) in CRB.
- [2] Set the start address of the register information at the DTC vector address (H'04C0).
- [3] Check that the SWDTE bit in DTVECR is 0. Check that there is currently no transfer by software.
- [4] Write 1 to the SWDTE bit and the vector number (H'60) to DTVECR. The write data is H'0001.

the RAME bit in SYSCR should not be cleared to 0.

7.9.3 DTCE Bit Setting

For DTCE bit setting, use bit manipulation instructions such as BSET and BCLR, for reading and writing. Multiple DTC activation sources can be set at one time (only at the initial setting). After setting, mask all interrupts and write data after executing a dummy read on the relevant register.

7.9.4 Setting Required on Entering Subactive Mode or Watch Mode

Set the MSTP14 bit in MSTPCRH to 1 to make the DTC enter module stop mode, then clear the bit that is set to 1 before making a transition to subactive mode or watch mode.

7.9.5 DTC Activation by Interrupt Sources of SCI, IIC, or A/D Converter

Interrupt sources of the SCI, IIC, or A/D converter which activate the DTC are cleared when the DTC reads from or writes to the respective registers, and they cannot be cleared by the DISL or MRB.

can drive a Darlington transistor in output mode. Ports 8, C0 to C5 and D6 to D7 are NMOS pull output.

Table 8.1 Port Functions

Port	Description	Extended Mode (EXPE = 1)	Single-Chip Mode (EXPE = 0)	I/O S

8.2.5 Port 2 Input Pull-Up MOS

Port 2 has a built-in input pull-up MOS that can be controlled by software. This input pull-up MOS can be used regardless of the operating mode. Table 8.3 summarizes the input pull-up states.

Table 8.3 Port 2 Input Pull-Up MOS States

Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
Off	Off	On/Off	On/Off

[Legend]

Off: Always off.

On/Off: On when P2DDR = 0 and P2PCR = 1; otherwise off.

The individual bits of P3DDR specify input or output for the pins of port 3.

Bit	Bit Name	Initial Value	R/W	Description
7	P37DDR	0	W	In normal extended mode:
6	P36DDR	0	W	Bidirectional data bus
5	P35DDR	0	W	In other mode:
4	P34DDR	0	W	The corresponding port 3 pins are output ports
3	P33DDR	0	W	the P3DDR bits are set to 1, and input ports v
2	P32DDR	0	W	cleared to 0.
1	P31DDR	0	W	
0	P30DDR	0	W	

8.3.2 Port 3 Data Register (P3DR)

P3DR stores output data for the port 3 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P37DR	0	R/W	In normal extended mode (ADMXE = 0):
6	P36DR	0	R/W	If a port 3 read is performed while the P3DDR
5	P35DR	0	R/W	set to 1, the P3DR values are read. When the
4	P34DR	0	R/W	bits are cleared to 0, 1 is read.
3	P33DR	0	R/W	In other mode:
2	P32DR	0	R/W	If a port 3 read is performed while the P3DDR
1	P31DR	0	R/W	set to 1, the P3DR values are read. If a port 3
0	P30DR	0	R/W	performed while the P3DDR bits are cleared t
				pin states are read.

8.3.4 Pin Functions

Normal Extended Mode:

Port 3 pins automatically function as the bidirectional data bus.

Address/Data Multiplex Mode:

Same operation as the single-chip mode.

Single-Chip Mode:

- P37/ $\overline{\text{WUE15}}$

The pin function is switched as shown below according to the P37DDR bit.

When the $\overline{\text{WUEM15}}$ bit in WUEMR3 of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{WUE15}}$ input pin. To use this pin as the $\overline{\text{WUE15}}$ input pin, clear the P37DDR to 0.

P37DDR	0		1
WUEM15	0	1	—
Pin Function	$\overline{\text{WUE15}}$ input pin	P37 input pin	P37 output

When the $\overline{\text{WUEM13}}$ bit in WUEMR3 of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{WUE13}}$ input pin. To use this pin as the $\overline{\text{WUE13}}$ input pin, clear the P35DDR bit to 0.

P35DDR	0		1
WUEM13	0	1	—
Pin function	$\overline{\text{WUE13}}$ input pin	P35 input pin	P35 output pin

- $\text{P34}/\overline{\text{WUE12}}$

The pin function is switched as shown below according to the P34DDR bits.

When the $\overline{\text{WUEM12}}$ bit in WUEMR3 of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{WUE12}}$ input pin. To use this pin as the $\overline{\text{WUE12}}$ input pin, clear the P34DDR bit to 0.

P34DDR	0		1
WUEM12	0	1	—
Pin function	$\overline{\text{WUE12}}$ input pin	P34 input pin	P34 output pin

- $\text{P33}/\overline{\text{WUE11}}$

The pin function is switched as shown below according to the P33DDR bits.

When the $\overline{\text{WUEM11}}$ bit in WUEMR3 of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{WUE11}}$ input pin. To use this pin as the $\overline{\text{WUE11}}$ input pin, clear the P33DDR bit to 0.

P33DDR	0		1
WUEM11	0	1	—
Pin function	$\overline{\text{WUE11}}$ input pin	P33 input pin	P33 output pin

When the WUEM9 bit in WUEMR3 of the interrupt controller is cleared to 0, this pin is used as the $\overline{WUE9}$ input pin. To use this pin as the $\overline{WUE9}$ input pin, clear the P31DDR to 0.

P31DDR	0		1
WUEM9	0	1	—
Pin function	$\overline{WUE9}$ input pin	P31 input pin	P31 output pin

- P30/ $\overline{WUE8}$

The pin function is switched as shown below according to the P30DDR bits.

When the WUEM8 bit in WUEMR3 of the interrupt controller is cleared to 0, this pin is used as the $\overline{WUE8}$ input pin. To use this pin as the $\overline{WUE8}$ input pin, clear the P30DDR to 0.

P30DDR	0		1
WUEM8	0	1	—
Pin function	$\overline{WUE8}$ input pin	P30 input pin	P30 output pin

(EXPE = 0)

Address-data
multiplex extended
mode (EXPE = 1,
ADMXE = 1)

[Legend]

Off : Always off.

On/Off : On when input state and P3PCR = 1; otherwise off.

7	P47DDR	0	W	If port 4 pins are specified for use as the general output port, the corresponding port 4 pins are output pins when the P4DDR bits are set to 1, and input pins are cleared to 0.
6	P46DDR	0	W	
5	P45DDR	0	W	
4	P44DDR	0	W	
3	P43DDR	0	W	
2	P42DDR	0	W	
1	P41DDR	0	W	
0	P40DDR	0	W	

8.4.2 Port 4 Data Register (P4DR)

P4DR stores output data for the port 4 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P47DR	0	R/W	P4DR stores output data for the port 4 pins that are used as the general output port.
6	P46DR	0	R/W	
5	P45DR	0	R/W	If a port 4 read is performed while the P4DDR bits are set to 1, the P4DR values are read. If a port 4 read is performed while the P4DDR bits are cleared to 0, the pin states are read.
4	P44DR	0	R/W	
3	P43DR	0	R/W	
2	P42DR	0	R/W	
1	P41DR	0	R/W	
0	P40DR	0	R/W	

Pin function	P47 input pin	P47 output pin	TMOY output
	$\overline{\text{IRQ7}}$ input pin		

- P46/ $\overline{\text{IRQ6}}$ /TMOX

The pin function is switched as shown below according to the combination of the OS3 to OS0 bits in TCSR of TMR_X and the P46DDR bit.

When the ISS6 bit in ISSR is cleared to 0 and the IRQ6E bit in IER of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{IRQ6}}$ input pin. To use this pin as the $\overline{\text{IRQ6}}$ input pin, clear the P46DDR bit to 0.

OS3 to OS0	All 0		One bit is set to 1
P46DDR	0	1	—
Pin function	P46 input pin	P46 output pin	TMOX output
	$\overline{\text{IRQ6}}$ input pin		

- P44/ $\overline{\text{IRQ4}}$ /TMIX

The pin function is switched as shown below according to the P44DDR bits.

When the TMIXS bit in PTCNT0 is cleared to 0 and the external clock is selected by the CKS0 bits in TCR of TMR_X, this bit is used as the TMCIX input pin. When the C and CCLR0 bits in TCR of TMR_X are set to 1, this pin is used as the TMRIX input pin.

When the ISS4 bit in ISSR is cleared to 0 and the IRQ4E bit in IER of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{IRQ4}}$ input pin. To use this pin as the $\overline{\text{IRQ4}}$ input pin, clear the P44DDR bit to 0.

P44DDR	0	1
Pin function	P44 input pin	P44 output pin
	TMIY (TMCIX/TMRIY) input pin	
	$\overline{\text{IRQ4}}$ input pin	

- P43/ $\overline{\text{IRQ3}}$ /TMO1

The pin function is switched as shown below according to the OS3 to OS0 bits in TCR of TMR_1 and the P43DDR bit. When the ISS3 bit in ISSR is cleared to 0 and the IRQ3E bit in IER of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{IRQ3}}$ input pin. To use this pin as the $\overline{\text{IRQ3}}$ input pin, clear the P43DDR bit to 0.

OS3 to OS0	All 0		One bit is set as 1
P43DDR	0	1	—
Pin function	P43 input pin	P43 output pin	TMO1 output pin
	$\overline{\text{IRQ3}}$ input pin		

- P41/ $\overline{\text{IRQ1}}$ /TMI1

The pin function is switched as shown below according to the P41DDR bits.

When the TMI1S bit in PTCNT0 is cleared to 0 and the external clock is selected by the CKS0 bits in TCR of TMR_1, this bit is used as the TMC11 input pin. When the CCLR0 and CCLR0 bits in TCR of TMR_1 are set to 1, this pin is used as the TMRI1 input pin. When the ISS1 bit in ISSR is cleared to 0 and the IRQ1E bit in IER of the interrupt control register is set to 1, this pin can be used as the $\overline{\text{IRQ1}}$ input pin. To use this pin as the $\overline{\text{IRQ1}}$ input pin, clear the P41DDR bit to 0.

P41DDR	0	1
Pin function	P41 input pin	P41 output pin
	TMI1(TMC11/TMRI1) input pin	
	$\overline{\text{IRQ1}}$ input pins	

- P40/ $\overline{\text{IRQ0}}$ /TMI0

The pin function is switched as shown below according to the P40DDR bits.

When the TMI0S bit in PTCNT0 is cleared to 0 and the external clock is selected by the CKS0 bits in TCR of TMR_0, this bit is used as the TMC10 input pin. When the CCLR0 and CCLR0 bits in TCR of TMR_0 are set to 1, this pin is used as the TMRI0 input pin. When the ISS0 bit in ISSR is cleared to 0 and the IRQ0E bit in IER of the interrupt control register is set to 1, this pin can be used as the $\overline{\text{IRQ0}}$ input pin. To use this pin as the $\overline{\text{IRQ0}}$ input pin, clear the P40DDR bit to 0.

P40DDR	0	1
Pin function	P40 input pin	P40 output pin
	TMI0(TMC10/TMRI0) input pin	
	$\overline{\text{IRQ0}}$ input pin	

7	P57DDR	0	W	If port 5 pins are specified for use as the general output port, the corresponding port 5 pins are output when the P5DDR bits are set to 1, and input when cleared to 0.
6	P56DDR	0	W	
5	P55DDR	0	W	
4	P54DDR	0	W	
3	P53DDR	0	W	
2	P52DDR	0	W	
1	P51DDR	0	W	
0	P50DDR	0	W	

8.5.2 Port 5 Data Register (P5DR)

P5DR stores output data for the port 5 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P57DR	0	R/W	P5DR stores output data for the port 5 pins that are used as the general output port.
6	P56DR	0	R/W	
5	P55DR	0	R/W	If a port 5 read is performed while the P5DDR bit is set to 1, the P5DR values are read. If a port 5 read is performed while the P5DDR bits are cleared to 0, the pin states are read.
4	P54DR	0	R/W	
3	P53DR	0	R/W	
2	P52DR	0	R/W	
1	P51DR	0	R/W	
0	P50DR	0	R/W	

Pin function	P57 input pin	P57 output pin	PWX1 out
	$\overline{\text{IRQ15}}$ input pin		

- P56/ $\overline{\text{IRQ14}}$ /PWX0

The pin function is switched as shown below according to the combination of the OEACR of PWMX and the P56DDR bit.

When the ISS14 bit in ISSR16 is cleared to 0 and the $\overline{\text{IRQ14E}}$ bit in IER16 of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{IRQ14}}$ input pin. To use this pin as the output pin, clear the P56DDR bit to 0.

OEA	0		1
P56DDR	0	1	—
Pin function	P56 input pin	P56 output pin	PWX0 out
	$\overline{\text{IRQ14}}$ input pin		

- P55/ $\overline{\text{IRQ13}}$ /RxD2

The pin function is switched as shown below according to the combination of the REACR of SCI_2 and the P55DDR bit.

When the ISS13 bit in ISSR16 is cleared to 0 and the $\overline{\text{IRQ13E}}$ bit in IER16 of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{IRQ13}}$ input pin. To use this pin as the output pin, clear the P55DDR bit to 0.

- Noise cancel cycle setting register (P6NCCS)

8.6.1 Port 6 Data Direction Register (P6DDR)

The individual bits of P6DDR specify input or output for the pins of port 6.

Bit	Bit Name	Initial Value	R/W	Description
7	P67DDR	0	W	Normal extended mode (16-bit data bus):
6	P66DDR	0	W	The port functions as the data bus regardless
5	P65DDR	0	W	values in these bits.
4	P64DDR	0	W	Other mode:
3	P63DDR	0	W	If port 6 pins are specified for use as the gen
2	P62DDR	0	W	port, the corresponding port 6 pins are output
1	P61DDR	0	W	when the P6DDR bits are set to 1, and input
0	P60DDR	0	W	when cleared to 0.

1	P61DR	0	R/W	If a port 6 read is performed while the P6DDR is set to 1, the P6DR values are read. If a port 6 write is performed while the P6DDR bits are cleared, the P6DR pin states are read.
0	P60DR	0	R/W	

8.6.3 Port 6 Pull-Up MOS Control Register (KMPCR6)

KMPCR6 controls the port 6 built-in input pull-up MOSs. This register is accessible when KINWUE is 1. See section 3.2.2, System Control Register (SYSCR).

Bit	Bit Name	Initial Value	R/W	Description
7	KM7PCR	0	R/W	Normal extended mode (16-bit data bus):
6	KM6PCR	0	R/W	Operation is not affected.
5	KM5PCR	0	R/W	Other mode:
4	KM4PCR	0	R/W	When the pins are in input state, the corresponding input pull-up MOS is turned on when a KMPDR bit is set to 1.
3	KM3PCR	0	R/W	
2	KM2PCR	0	R/W	
1	KM1PCR	0	R/W	
0	KM0PCR	0	R/W

2 to 0	—	All 0	R/W	Reserved The initial value should not be changed.

8.6.5 Noise Canceler Enable Register (P6NCE)

P6NCE enables or disables the noise canceler circuit at port 6.

Bit	Bit Name	Initial Value	R/W	Description
7	P67NCE	0	R/W	In 16 bit bus mode in extended mode:
6	P66NCE	0	R/W	Port 6 operates as the data pin (D7 to D0).
5	P65NCE	0	R/W	In other mode:
4	P64NCE	0	R/W	Noise canceler circuit is enabled and the pin
3	P63NCE	0	R/W	fetches in the P6DR in the sampling cycle se
2	P62NCE	0	R/W	P6NCCS.
1	P61NCE	0	R/W	The operating state changes according to the
0	P60NCE	0	R/W	control bits. Check the pin functions.

1	P61NCCM	1	R/W
0	P60NCCM	1	R/W

8.6.7 Noise Canceler Cycle Setting Register (P6NCCS)

P6NCCS controls the sampling cycles of the noise canceler.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All undefined	R/W	Reserved. The read data is undefined. The value should not be changed.
2	NCCK2	0	R/W	These bits set the sampling cycles of the noise canceler.
1	NCCK1	0	R/W	
0	NCCK0	0	R/W	
				000: 0.06 μ s $\phi/2$
				001: 0.97 μ s $\phi/32$
				010: 15.5 μ s $\phi/512$
				011: 248.2 μ s $\phi/8192$
				100: 993.0 μ s $\phi/32768$
				101: 2.0 ms $\phi/65536$

				111: 7.9 ms $\phi/262144$

Figure 8.1 Noise Canceler Circuit

Figure 8.2 Noise Canceler Operation

- P67/ $\overline{\text{KIN7}}$

The function of port 6 pins is switched as shown below according to the P67DDR bit.

When the KMIM7 bit in KMIMR6 of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{KIN7}}$ input pin. To use this pin as the $\overline{\text{KIN7}}$ input pin, clear the P67DDR

Mode	Port		
P67DDR	0	0	1
P67NCE	0	1	—
Pin function	P67 input pin	P67 input pin (noise canceling)	P67 output pin
	$\overline{\text{KIN7}}$ input pin		

- P66/FTOB/ $\overline{\text{KIN6}}$

The function of port 6 pins is switched as shown below according to the combination of the OEB bit in TOCR of FRT and the P66DDR bit.

When the KMIM6 bit in KMIMR6 of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{KIN6}}$ input pin. To use this pin as the $\overline{\text{KIN6}}$ input pin, clear the P66DDR

Mode	Port			FRT
OEB	0	0	0	1
P66DDR	0	0	1	—
P66NCE	0	1	—	—
Pin function	P66 input pin	P66 input pin (noise canceling)	P66 output pin	FTOB output pin
	$\overline{\text{KIN6}}$ input pin			

- P64/FTIC/ $\overline{\text{KIN4}}$

The function of port 6 pins is switched as shown below according to the P64DDR bit.

When the ICICE bit in TIER of FRT is set to 1, this pin can be used as the FTIC input.

When the $\overline{\text{KMIM4}}$ bit in KMIMR6 of the interrupt controller is cleared to 0, this pin can be used as the $\overline{\text{KIN4}}$ input pin. To use this pin as the $\overline{\text{KIN4}}$ input pin, clear the P64DDR bit.

Mode	Port			FRT
P64DDR	0	0	1	0
P64NCE	0	1	—	0
Pin function	P64 input pin	P64 input pin (noise canceling)	P64 output pin	FTIC input
	$\overline{\text{KIN4}}$ input pin			

- P62/FTIA/ $\overline{\text{KIN2}}$

The function of port 6 pins is switched as shown below according to the P62DDR bit.

When the ICIAE bit in TIER of FRT is set to 1, this pin can be used as the FTIA input pin.

When the $\overline{\text{KMIM2}}$ bit in KMIMR6 of the interrupt controller is cleared to 0, this pin can be used as the $\overline{\text{KIN2}}$ input pin. To use this pin as the $\overline{\text{KIN2}}$ input pin, clear the P62DDR bit.

Mode	Port			FRT
	P62DDR	0	0	1
P62NCE	0	1	—	0
Pin function	P62 input pin	P62 input pin (noise canceling)	P62 output pin	FTIA input pin
	$\overline{\text{KIN2}}$ input pin			

		canceling)	
	KIN1 input pin		

- P60/FTCI/ $\overline{\text{KIN0}}$

The function of port 6 pins is switched as shown below according to the P60DDR bit.

When the CKS1 and CKS0 bits in TCR of FRT are both set to 1, this pin can be used as FTCLI input pin. When the $\overline{\text{KMIM0}}$ bit in KMIMR6 of the interrupt controller is cleared, this pin can be used as the $\overline{\text{KIN0}}$ input pin. To use this pin as the $\overline{\text{KIN0}}$ input pin, clear P60DDR bit to 0.

Mode	Port			FRT
P60DDR	0	0	1	0
P60NCE	0	1	—	0
Pin function	P60 input pin	P60 input pin (noise canceling)	P60 output pin	FTCLI input
	$\overline{\text{KIN0}}$ input pin			

On/Off : On when input state and KMPCR = 1; otherwise off.

8.7 Port 7

Port 7 is an 8-bit input port. Port 7 pins also function as the A/D converter analog input converter analog output pins, and interrupt input pins. Port 7 has the following register.

- Port 7 input data register (P7PIN)

8.7.1 Port 7 Input Data Register (P7PIN)

P7PIN indicates the pin states.

Bit	Bit Name	Initial Value	R/W	Description
7	P77PIN	Undefined*	R	When a P7PIN read is performed, the pin state is always read. This register is assigned to the address as that of PBDDR. When the register is programmed, data is programmed in the PE register. When the setting of port B is changed.
6	P76PIN	Undefined*	R	
5	P75PIN	Undefined*	R	
4	P74PIN	Undefined*	R	
3	P73PIN	Undefined*	R	
2	P72PIN	Undefined*	R	
1	P71PIN	Undefined*	R	
0	P70PIN	Undefined*	R	

Note: The initial value is determined in accordance with the pin states of P77 to P70.

values than those shown in the following table.

CH2 to CH0	B'111	Other than B'111		
DAOE1	0	0		1

The port 7 function changes as shown in the following table, depending on the combination of the CH2 to CH0 bits of ADCSR of the A/D converter and the ISS3 bit of ISSR of the interrupt controller. Do not set these bits to other values than those shown in the following table.

CH2 to CH0	B'011	Other than B'011	
ISS3	0	0	1
Pin function	AN3 input pin	P73 input pin	$\overline{\text{ExIRQ3}}$ input pin

Don't care

- P71/AN1

The port 7 function changes as shown in the following table, depending on the combination of the SCAN bit and the CH2 to CH0 bits of ADCSR of the A/D converter. Do not set the bits to other values than those shown in the following table.

SCAN	0		1	
CH2 to CH0	B'001	Other than B'001	B'001, B'01*	Other than B'001 and B'01*
Pin function	AN1 input pin	P71 input pin	AN1 input pin	P71 input pin

[Legend]

*: Don't care

- P70/AN0

The port 7 function changes as shown in the following table, depending on the combination of the SCAN bit and the CH2 to CH0 bits of ADCSR of the A/D converter. Do not set the bits to other values than those shown in the following table.

SCAN	0		1	
CH2 to CH0	B'000	Other than B'000	B'0**	Other than B'0**
Pin function	AN0 input pin	P70 input pin	AN0 input pin	P70 input pin

[Legend]

*: Don't care

The individual bits of P8DDR specify input or output for the pins of port 8.

Bit	Bit Name	Initial Value	R/W	Description
7	P87DDR	0	W	This register is assigned to the same address of PBPIN. When this register is read, the ports are read.
6	P86DDR	0	W	
5	P85DDR	0	W	If port 8 pins are specified for use as the general output port, the corresponding port 8 pins are output when the P8DDR bits are set to 1, and input when cleared to 0.
4	P84DDR	0	W	
3	P83DDR	0	W	
2	P82DDR	0	W	
1	P81DDR	0	W	
0	P80DDR	0	W	

8.8.2 Port 8 Data Register (P8DR)

P8DR stores output data for the port 8 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P87DR	0	R/W	P8DR stores output data for the port 8 pins used as the general output port.
6	P86DR	0	R/W	
5	P85DR	0	R/W	If a port 8 read is performed while the P8DDR bits are set to 1, the P8DR values are read. If a port 8 read is performed while the P8DDR bits are cleared, the port 8 pin states are read.
4	P84DR	0	R/W	
3	P83DR	0	R/W	
2	P82DR	0	R/W	
1	P81DR	0	R/W	
0	P80DR	0	R/W	

P87DDR	0	1
Pin function	P87 input pin	P87 output pin
	$\overline{\text{ExIRQ15}}$ input pin $\overline{\text{/ADTRG}}$ input pin $\overline{\text{/ExTMIY}}$ input pin	

- P86/ $\overline{\text{ExIRQ14}}$ /SCK2/ExTMIX

The pin function is switched as shown below according to the combination of the C/\overline{A} SMR of SCI_2, the CKE1 and CKE0 bits in SCR, and the P86DDR bit.

When the ISS14 bit in ISSR16 of the interrupt controller is set to 1, this pin can be used as $\overline{\text{ExIRQ14}}$ input pin. When the TMIXS bit in PTCNT0 is set to 1, this pin can be used as TMIX (TMCIX/TMRIX) input pin. To use this pin as the $\overline{\text{ExIRQ14}}$ input pin, clear the P86DDR bit to 0.

When this pin is used as the P86 output pin, the output format is NMOS push-pull output.

CKE1	0				
C/\overline{A}	0			1	
CKE0	0		1	—	
P86DDR	0	1	—	—	
Pin function	P86 input pin	P86 output pin	SCK2 output pin	SCK2 output pin	SCK2 output pin
	$\overline{\text{ExIRQ14}}$ input pin $\overline{\text{/ExTMIX}}$ input pin				

P85DDR	0	1	—	—	SC
Pin function	P85 input pin	P85 output pin	SCK1 output pin	SCK1 output pin	SC
	ExIRQ13 input pin /ExTMI1 input pin				

- P84/ $\overline{\text{ExIRQ12}}$ /SCK0/ExTMI0

The pin function is switched as shown below according to the combination of the C/ $\overline{\text{A}}$ SMR of SCI_0, the CKE1 and CKE0 bits in SCR, and the P84DDR bit.

When the ISS12 bit in ISSR16 of the interrupt controller is set to 1, this pin can be used as $\overline{\text{ExIRQ12}}$ input pin. When the TMI0S bit in PTCNT0 is set to 1, this pin can be used as TMI0 (TMI0/TMRI0) input pin. To use this pin as the $\overline{\text{ExIRQ12}}$ input pin, clear the bit to 0.

When this pin is used as the P84 output pin, the output format is NMOS push-pull output.

CKE1	0				
C/ $\overline{\text{A}}$	0		1		
CKE0	0		1	—	
P84DDR	0	1	—	—	
Pin function	P84 input pin	P84 output pin	SCK0 output pin	SCK0 output pin	SC
	$\overline{\text{ExIRQ12}}$ input pin /ExTMI0 input pin				

- P82/ $\overline{\text{ExIRQ10}}$ /SCL1

The pin function is switched as shown below according to the combination of the ICE ICCR of IIC_1 and the P82DDR bit.

When the ISS10 bit in ISSR16 of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{ExIRQ10}}$ input pin. To use this pin as the $\overline{\text{ExIRQ10}}$ input pin, clear the P82DDR bit to 0.

When this pin is used as the P82 output pin, the output format is NMOS push-pull output. When this pin is used as the P82 input pin, the output format for SCL1 is NMOS open-drain output, and direct bus drive is possible.

ICE	0		1
P82DDR	0	1	—
Pin function	P82 input pin	P82 output pin	SCL1 input/output pin
	$\overline{\text{ExIRQ10}}$ input pin		

- P81/ $\overline{\text{ExIRQ9}}$ /SDA0

The pin function is switched as shown below according to the combination of the ICE ICCR of IIC_0 and the P81DDR bit.

When the ISS9 bit in ISSR16 of the interrupt controller is set to 1, this pin can be used as the $\overline{\text{ExIRQ9}}$ input pin. To use this pin as the $\overline{\text{ExIRQ9}}$ input pin, clear the P81DDR bit to 0.

When this pin is used as the P81 output pin, the output format is NMOS push-pull output. When this pin is used as the P81 input pin, the output format for SDA0 is NMOS open-drain output, and direct bus drive is possible.

ICE	0		1
P81DDR	0	1	—
Pin function	P81 input pin	P81 output pin	SDA0 input/output pin
	$\overline{\text{ExIRQ9}}$ input pin		

Bit	Bit Name	Initial Value	R/W	Description
7	P97DDR	0	W	If port 9 pins are specified for use as the general purpose I/O port, the corresponding port 9 pins are output when the P9DDR bits are set to 1, and input when cleared to 0.
6	P96DDR	0	W	When this bit is set to 1, the corresponding pin is the system clock output pin (ϕ), and as a general purpose I/O input port when cleared to 0.
5	P95DDR	0	W	If port 9 pins are specified for use as the general purpose I/O port, the corresponding port 9 pins are output when the P9DDR bits are set to 1, and input when cleared to 0.
4	P94DDR	0	W	
3	P93DDR	0	W	If port 9 pins are specified for use as the general purpose I/O port, the corresponding port 9 pins are output when the P9DDR bits are set to 1, and input when cleared to 0.
2	P92DDR	0	W	
1	P91DDR	0	W	If port 9 pins are specified for use as the general purpose I/O port, the corresponding port 9 pins are output when the P9DDR bits are set to 1, and input when cleared to 0.
0	P90DDR	0	W	

1	P97DR	0	R/W
0	P90DR	0	R/W

Note: The initial value of bit 6 is determined in accordance with the P96 pin state.

8.9.3 Pin Functions

The relationship between the operating mode, register setting values, and pin functions is as follows.

- $P97/\overline{WAIT}/\overline{CS256}$

The pin function is switched as shown below according to the combination of the operating mode, the CS256E bit in SYSCR, the WMS1 bit in WSCR, the WMS21 bit in WSCR, and the P97DDR bit.

Operating Mode	Extended Mode				Single-Chip Mode	
	WMS1, WMS21	All 0			One bit is set as 1	—
CS256E	0		1	—	—	
P97DDR	0	1	—	—	0	—
Pin function	P97 input pin	P97 output pin	$\overline{CS256}$ output pin	\overline{WAIT} input pin	P97 input pin	—

Operating Mode	Extended Mode		Single-Chip Mode	
	P95DDR	—		0
IOSE	0	1	—	
Pin function	\overline{AS} output pin	\overline{IOS} output pin	P95 input pin	P95 output pin

- P94/ \overline{HWR}

The pin function is switched as shown below according to the combination of the operating mode and the P94DDR bit.

Operating Mode	Extended Mode	Single-Chip Mode	
	P94DDR	—	0
Pin function	\overline{HWR} output pin	P94 input pin	P94 output pin

- P93/ \overline{RD}

The pin function is switched as shown below according to the combination of the operating mode and the P93DDR bit.

Operating Mode	Extended Mode	Single-Chip Mode	
	P93DDR	—	0
Pin function	\overline{RD} output pin	P93 input pin	P93 output pin

mode, the ADMXE bit of SYSCR2, and the P91DDR bit.

Operating Mode	Extended Mode			Single-Chip Mode	
ADMXE	0		1	—	
P91DDR	0	1	—	0	
Pin function	P91 input pin	P91 output pin	\overline{AH} output pin	P91 input pin	P91 output pin

- P90/ \overline{LWR}

The pin function is switched as shown below according to the combination of the operating mode, the ABW and ABW256 bits in WSCR, the ABWCP bit in BCR2, and the P90DDR bit.

Operating Mode	Extended Mode			Single-Chip Mode	
ABW, ABW256, ABWCP	All 1		One bit is set as 0	—	
P90DDR	0	1	—	0	
Pin function	P90 input pin	P90 output pin	\overline{LWR} output pin	P90 input pin	P90 output pin

The individual bits of PADDR specify input or output for the pins of port A.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7DDR	0	W	In normal extended mode:
6	PA6DDR	0	W	The corresponding port A pins are address o ports when the PADDR bits are set to 1, and ports when cleared to 0. Pins function as the output port depending on the setting of bits I CS256E, CPCSE, ADFULLE in bus controlle
5	PA5DDR	0	W	
4	PA4DDR	0	W	
3	PA3DDR	0	W	
2	PA2DDR	0	W	In other mode:
1	PA1DDR	0	W	The corresponding port A pins are output por the PADDR bits are set to 1, and input ports cleared to 0.
0	PA0DDR	0	W	

1	PA1ODR	0	R/W
0	PA0ODR	0	R/W

8.10.3 Port A Input Data Register (PAPIN)

PAPIN indicates the pin states.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7PIN	Undefined*	R	When a PAPIN read is performed, the pin s always read.
6	PA6PIN	Undefined*	R	
5	PA5PIN	Undefined*	R	
4	PA4PIN	Undefined*	R	
3	PA3PIN	Undefined*	R	
2	PA2PIN	Undefined*	R	
1	PA1PIN	Undefined*	R	
0	PA0PIN	Undefined*	R	

Note: The initial values are determined in accordance with the pin states of PA7 to PA0

The function of port A pins is switched according to the combination of address 18 set the PAnDDR bit. When the $\overline{\text{KMIM}}$ bit in KMIMRA of the interrupt controller is clear this pin can be used as the $\overline{\text{KIN}}$ input pin. To use this pin as the $\overline{\text{KIN}}$ input pin, clear the PAnDDR bit to 0. When this pin is used as EVENT input pin according to bits ECSB0 to ECSB7 in ECCR of the data transfer controller settings, clear the PAnDDR bit to 0. Though this pin has been set to the EVENT input pin, to use as the PAn or A1 output pin, set the PAnDDR bit to 1.

PAnDDR	0	1	1
Address 18	1	1	0
Pin function	PAn input pins	PAn output pin	A1 output pin
	$\overline{\text{KIN}}_m$ input pin EVENT _n input pin		

[Legend]

n = 7 to 2

m = 15 to 10

l = 23 to 18

- PA1/ $\overline{\text{KIN}}_9$ /EVENT1/A17/SSE2I

The function of port A pins is switched as shown below according to the combination of SSE bit in SEMR of SCI_2, the $\overline{\text{C/A}}$ bit in SMR, the CKE1 bit in SCR, address 13 set the PA1DDR bit.

When the $\overline{\text{KMIM}}_9$ bit in KMIMRA of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{KIN}}_9$ input pin. To use this pin as the $\overline{\text{KIN}}_9$ input pin, clear the PA1DDR bit to 0. When this pin is used as EVENT1 input pin according to bits ECSB3 to ECSB0 in ECCR of the data transfer controller settings, clear the PA1DDR bit to 0. Though this pin has been set to the EVENT1 input pin, to use as the PA1 or A17 output pin, set the PA1DDR bit to 1.

SSE bit in SEMR of SCI_0, the C/A bit in SMR, the CKE1 bit in SCR, address 13 set the PA0DDR bit.

When the KMIM8 bit in KMIMRA of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{KIN8}}$ input pin. To use this pin as the $\overline{\text{KIN8}}$ input pin, clear the PA0DDR bit. When this pin is used as EVENT0 input pin according to bits ECSB3 to ECSB0 in EDCR, the data transfer controller settings, clear the PA0DDR bit to 0. Though this pin has the EVENT0 input pin, to use as the PA0 or A16 output pin, set the PA0DDR bit to 1.

SSE	0				
C/A	—				
CKE1	—				
PA0DDR	0	1	1		
Address 13	1		0		
Pin function	PA0 input pin	PA0 output pin	A16 output pin	SSE0	
	$\overline{\text{KIN8}}$ input pin /EVENT0 input pin				

Single-Chip Mode and Address-Data Multiplex Extended Mode: Port A functions as input, external control input of SCI_0 and SCI_2, and also as an I/O port, and input or output pin. The pin functions to be specified in bit units.

- PA7/ $\overline{\text{KIN15}}$ /EVENT7, PA6/ $\overline{\text{KIN14}}$ /EVENT6, PA5/ $\overline{\text{KIN13}}$ /EVENT5, PA4/ $\overline{\text{KIN12}}$ /EVENT4, PA3/ $\overline{\text{KIN11}}$ /EVENT3, PA2/ $\overline{\text{KIN10}}$ /EVENT2

When the KMIM bit in KMIMRA of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{KIN}}$ input pin. To use this pin as the $\overline{\text{KIN}}$ input pin, clear the PAnDDR bit. When this pin is used as the EVENT input pin according to bits ECSB3 to ECSB0 in EDCR, the data transfer controller settings, clear the PAnDDR bit to 0. Though this pin has the EVENT input pin, to use as the PAn output pins, set the PAnDDR bit to 1.

When this pin is used as the EVENT1 input pin according to bits ECSB3 to ECSB0 in of the data transfer controller settings, clear the PA1DDR bit to 0. Though this pin has to the EVENT1 input pin, to use as the PA1 output pin, set the PA1DDR bit to 1.

SSE	0		1
C/ \bar{A}	—		1
CKE1	—		1
PA1DDR	0	1	—
Pin function	PA1 input pin	PA1 output pin	SSE2I input pin
	$\overline{\text{KIN9}}$ input pin /EVENT1 input pin		

- PA0/ $\overline{\text{KIN8}}$ /EVENT0/SSE0I

The function of port A pins is switched as shown below according to the combination of the SSE bit in SEMR of SCI_0, the C/ \bar{A} bit in SMR, the CKE1 bit in SCR, and the PA0DDR bit in PA0DDR. When the KMIM8 bit in KMIMRA of the interrupt controller is cleared to 0, this pin is used as the $\overline{\text{KIN8}}$ input pin. To use this pin as the $\overline{\text{KIN8}}$ input pin, clear the PA0DDR bit to 0. When this pin is used as the EVENT0 input pin according to bits ECSB3 to ECSB0 in of the data transfer controller settings, clear the PA0DDR bit to 0. Though this pin has to the EVENT0 input pin, to use as the PA0 output pin, set the PA0DDR bit to 1.

MOS can be used in any operating mode, and can be specified as on or off on a bit-by-bit

PAnDDR	0		1
PAnODR	1	0	—
PAn pull-up MOS	ON	OFF	OFF

[Legend]

n = 7 to 0

The input pull-up MOS is in the off state after a reset and in hardware standby mode. The state is retained in software standby mode.

Table 8.6 summarizes the input pull-up MOS states.

Table 8.6 Port A Input Pull-Up MOS States

Reset	Hardware Standby Mode	Software Standby Mode	In Other Operat
Off	Off	On/Off	On/Off

[Legend]

Off: Always off.

On/Off: On when PADDR = 0 and PAODR = 1; otherwise off.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7DDR	0	W	The corresponding port B pins are output ports when the PBDDR bits are set to 1, and input ports when cleared to 0.
6	PB6DDR	0	W	
5	PB5DDR	0	W	
4	PB4DDR	0	W	
3	PB3DDR	0	W	
2	PB2DDR	0	W	
1	PB1DDR	0	W	
0	PB0DDR	0	W	

8.11.2 Port B Output Data Register (PBODR)

PBODR stores output data for the port B pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7ODR	0	R/W	The PBODR register stores the output data for the port B pins that are used as a general output port.
6	PB6ODR	0	R/W	
5	PB5ODR	0	R/W	
4	PB4ODR	0	R/W	
3	PB3ODR	0	R/W	
2	PB2ODR	0	R/W	
1	PB1ODR	0	R/W	
0	PB0ODR	0	R/W	

Note: The initial value of these pins is determined in accordance with the state of pins P... PB0.

8.11.4 Pin Functions

Port B is a multi-function port that can function as an event counter input pin. The relation between the operating mode setup and pin functions is described below.

When this pin is used as the EVENT input pin according to bits ECSB3 to ECSB0 in EC... data transfer controller settings, clear the PBnDDR bit to 0. (n = 7 to 0)

- PB7/EVENT15

PB7DDR	0		1
Event counter*1	Disable	Enable	—
Pin function	PB7 input pin	EVENT15 input pin	PB7 output pin

- PB6/EVENT14

PB6DDR	0		1
Event counter*1	Disable	Enable	—
Pin function	PB6 input pin	EVENT14 input pin	PB6 output pin

- PB3/EVENT11

PB3DDR	0		1
Event counter* ¹	Disable	Enable	—
Pin function	PB3 input pin	EVENT11 input pin	PB3 output pin

- PB2/EVENT10

PB2DDR	0		1
Event counter* ¹	Disable	Enable	—
Pin function	PB2 input pin	EVENT10 input pin	PB2 output pin

- PB1/EVENT9

PB1DDR	0		1
Event counter* ¹	Disable	Enable	—
Pin function	PB1 input pin	EVENT9 input pin	PB1 output pin

- PB0/EVENT8

PB0DDR	0		1
Event counter* ¹	Disable	Enable	—
Pin function	PB0 input pin	EVENT8 input pin	PB0 output pin

Note: For event counter setting, refer to section 7, Data Transfer Controller (DTC).

PCDDR is used to specify the input/output attribute of each pin of port C.

Bit	Bit Name	Initial Value	R/W	Description
7	PC7DDR	0	W	When a given bit is set to 1, the corresponding function as an output port, and when cleared functions as an input port.
6	PC6DDR	0	W	
5	PC5DDR	0	W	This register is assigned to the same address of PCPIN. When this address is read, the port states are returned.
4	PC4DDR	0	W	
3	PC3DDR	0	W	
2	PC2DDR	0	W	
1	PC1DDR	0	W	
0	PC0DDR	0	W	

8.12.2 Port C Output Data Register (PCODR)

PCODR stores output data for port C.

Bit	Bit Name	Initial Value	R/W	Description
7	PC7ODR	0	R/W	The PCODR register stores the output data of pins that are used as a general output port.
6	PC6ODR	0	R/W	
5	PC5ODR	0	R/W	
4	PC4ODR	0	R/W	
3	PC3ODR	0	R/W	
2	PC2ODR	0	R/W	
1	PC1ODR	0	R/W	
0	PC0ODR	0	R/W	

Note: The initial values are determined in accordance with the states of PC7 to PC0 pins.

8.12.4 Pin Functions

Port C is capable of functioning as the input and output of IIC_2, IIC_3, and IIC_4, and the PWMX output. The relationship between the register settings and pin function is described below.

- PC7/PWX3

The pin function is switched as shown below according to the combination of the OE and the 14-bit PWMX DACR and the PC7DDR.

OEB	0		1
PC7DDR	0	1	—
Pin Function	PC7 input pin	PC7 output pin	PWX3 output pin

- PC6/PWX2

The pin function is switched as shown below according to the combination of the OE and the 14-bit PWMX DACR and the PC6DDR.

OEA	0		1
PC6DDR	0	1	—
Pin Function	PC6 input pin	PC6 output pin	PWX2 output pin

ICE	0		1
PC4DDR	0	1	—
Pin Function	PC4 input pin	PC4 output pin	SCL4 input/ou

- PC3/SDA3

The pin function is switched as shown below according to the combination of the IC the IIC_3 ICCR and the PC3DDR.

ICE	0		1
PC3DDR	0	1	—
Pin Function	PC3 input pin	PC3 output pin	SDA3 input/ou

- PC2/SCL3

The pin function is switched as shown below according to the combination of the IC the IIC_3 ICCR and the PC2DDR.

ICE	0		1
PC2DDR	0	1	—
Pin Function	PC2 input pin	PC2 output pin	SCL3 input/ou

- PC1/SDA2

The pin function is switched as shown below according to the combination of the IC the IIC_2 ICCR and the PC1DDR.

ICE	0		1
PC1DDR	0	1	—
Pin Function	PC1 input pin	PC1 output pin	SDA2 input/ou

- Port D data direction register (PDDDR)
- Port D output data register (PDODR)
- Port D input data register (PDPIN)

8.13.1 Port D Data Direction Register (PDDDR)

PDDDR is used to specify the input/output attribute of each pin of port D.

Bit	Bit Name	Initial Value	R/W	Description
7	PD7DDR	0	W	When the general input/output port function is selected, and the given bit is set to 1, the corresponding pin will function as an output port. When the bit is cleared to 0, the pin will function as an input port.
6	PD6DDR	0	W	
5	PD5DDR	0	W	
4	PD4DDR	0	W	
3	PD3DDR	0	W	This register is assigned to the same address as PDPIN. When this address is read, the port D states are returned.
2	PD2DDR	0	W	
1	PD1DDR	0	W	
0	PD0DDR	0	W	

1	PD1ODR	0	R/W
0	PD0ODR	0	R/W

8.13.3 Port D Input Data Register (PDPIN)

PDPIN indicates the pin states of port D.

Bit	Bit Name	Initial Value	R/W	Description
7	PD7PIN	Undefined*	R	Pin states can be read by performing a read of this register.
6	PD6PIN	Undefined*	R	
5	PD5PIN	Undefined*	R	This register is assigned to the same address of PDDDR. When this register is written to, written to PDDDR and the port D setting is then changed.
4	PD4PIN	Undefined*	R	
3	PD3PIN	Undefined*	R	
2	PD2PIN	Undefined*	R	
1	PD1PIN	Undefined*	R	
0	PD0PIN	Undefined*	R	

Note: The initial value of these pins is determined in accordance with the state of pins PD0.

PD7DDR	0	1	—
Pin Function	PD7 input pin	PD7 output pin	SDA5 input/output

- PD6/SCL5

The pin function is switched as shown below according to the combination of the ICE and the IIC_5 ICCR and the PD6DDR.

ICE	0		1
PD6DDR	0	1	—
Pin Function	PD6 input pin	PD6 output pin	SCL5 input/output

- PD5/ $\overline{\text{LPCPD}}$

The pin function is switched as shown below according to the combination of LPC enabled/disabled and the PD5DDR.

LPC	Disabled		Enabled
PD5DDR	0	1	0
Pin Function	PD5 input pin	PD5 output pin	$\overline{\text{LPCPD}}$ input/output

- PD4/ $\overline{\text{CLKRUN}}$

The pin function is switched as shown below according to the combination of LPC enabled/disabled and the PD4DDR.

LPC	Disabled		Enabled
PD4DDR	0	1	0
Pin Function	PD4 input pin	PD4 output pin	$\overline{\text{CLKRUN}}$ input/output

PMEE	0		1
PD2DDR	0	1	0
Pin Function	PD2 input pin	PD2 output pin	$\overline{\text{PME}}$ output

- PD1/ $\overline{\text{LSMI}}$

The pin function is switched as shown below according to the combination of the LS
LPC HICR0 and the PD1DDR.

LSMIE	0		1
PD1DDR	0	1	0
Pin Function	PD1 input pin	PD1 output pin	$\overline{\text{LSMI}}$ output

- PD0/LSCI

The pin function is switched as shown below according to the combination of the LS
LPC HICR0 and the PD0DDR.

LSCIE	0		1
PD0DDR	0	1	0
Pin Function	PD0 input pin	PD0 output pin	LSCI output

The input pull-up MOS is in the off state after a reset and in hardware standby mode. The state is retained in software standby mode.

Table 8.7 summarizes the input pull-up MOS states.

Table 8.7 Port D Input Pull-Up MOS States

Reset	Hardware Standby Mode	Software Standby Mode	In Other Oper
Off	Off	On/Off	On/Off

[Legend]

Off: Always off.

On/Off: On when PDDDR = 0 and PDODR = 1; otherwise off.

Bit	Bit Name	Initial Value	R/W	Description
7	PE7DDR	0	W	When a given bit of PEDDR is set to 1, the corresponding pin will function as an output.
6	PE6DDR	0	W	
5	PE5DDR	0	W	This register is assigned to the same address of PEPIN. When this address is read, the pin states are returned.
4	PE4DDR	0	W	
3	PE3DDR	0	W	
2	PE2DDR	0	W	
1	PE1DDR	0	W	
0	PE0DDR	0	W	

8.14.2 Port E Output Data Register (PEODR)

PEODR stores output data for the port E pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PE7ODR	0	R/W	The PEODR register stores the output data of the port E pins that are used as a general output port.
6	PE6ODR	0	R/W	
5	PE5ODR	0	R/W	
4	PE4ODR	0	R/W	
3	PE3ODR	0	R/W	
2	PE2ODR	0	R/W	
1	PE1ODR	0	R/W	
0	PE0ODR	0	R/W	

Note: The initial value of these pins is determined in accordance with the state of pins PE0 to PE7.

8.14.4 Pin Functions

Port E also functions as an LPC input/output. The pin function is switched with LPC enabled/disabled. The LPC module is disabled when the LPC1E, LPC2E, and LPC3E bits in HICR are all 0.

- PE7/SERIRQ

The pin function is switched as shown below according to the LPC enabled/disabled and PE7DDR.

LPC	Disabled		Enabled
PE7DDR	0	1	—
Pin Function	PE7 input pin	PE7 output pin	SERIRQ input/output

- PE6/LCLK

The pin function is switched as shown below according to the LPC enabled/disabled and PE6DDR.

LPC	Disabled		Enabled
PE6DDR	0	1	—
Pin Function	PE6 input pin	PE6 output pin	LCLK input/output

LPC	Disabled		Enable
PE4DDR	0	1	—
Pin Function	PE4 input pin	PE4 output pin	LFRAME in

- PE3/LAD3

The pin function is switched as shown below according to the LPC enabled/disabled PE3DDR.

LPC	Disabled		Enable
PE3DDR	0	1	—
Pin Function	PE3 input pin	PE3 output pin	LAD3 input/o

- PE2/LAD2

The pin function is switched as shown below according to the LPC enabled/disabled PE2DDR.

LPC	Disabled		Enable
PE2DDR	0	1	—
Pin Function	PE2 input pin	PE2 output pin	LAD2 input/o

- PE1/LAD1

The pin function is switched as shown below according to the LPC enabled/disabled PE1DDR.

LPC	Disabled		Enable
PE1DDR	0	1	—
Pin Function	PE1 input pin	PE1 output pin	LAD1 input/o

- Port F data direction register (PFDDR)
- Port F output data register (PFODR)
- Port F input data register (PFPIN)

8.15.1 Port F Data Direction Register (PFDDR)

PFDDR is used to specify the input/output attribute of each pin of port F.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	—	—	Reserved
2	PF2DDR	0	W	When the given bit of PFDDR is set to 1, the corresponding pin of port F will function as an output port, and when the bit is cleared to 0, the port will function as an input port. This register is assigned to the same address as the register of PFPIN. When this address is read, the port F pins are returned.
1	PF1DDR	0	W	
0	PF0DDR	0	W	

8.15.2 Port F Output Data Register (PFODR)

PFODR stores output data for the port F pins.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	—	—	Reserved. When this bit is read, an undefined value is returned.
2	PF2ODR	0	R/W	The PFODR register stores the output data for the port F pins that are used as a general output port.
1	PF1ODR	0	R/W	
0	PF0ODR	0	R/W	

8.15.4 Pin Functions

Port F is a 3-bit input/output port that functions as a PWM output. The relationship between register settings and pin functions is depicted below.

- PF2/ExPW2, PF1/ExPW1, PF0/ExPW0

The pin function is switched as shown below according to the combination of the OE_n, PWOERA of PWM, the PWMS bit in PTCNT0, and PF_nDDR bit.

PF _n DDR	0		1		
PWMS	0	1	0	1	
OE _n	—	0	—	0	
Pin Function	PF _n input pin		PF _n output pin		PW _n output

[Legend]

n = 2 to 0

ISSR16 and ISSR select ports that also function as $\overline{\text{IRQ15}}$ to $\overline{\text{IRQ0}}$ input pins.

- ISSR16

Bit	Bit Name	Initial Value	R/W	Description
15	ISS15	0	R/W	0: P57/ $\overline{\text{IRQ15}}$ is selected 1: P87/ $\overline{\text{ExIRQ15}}$ is selected
14	ISS14	0	R/W	0: P56/ $\overline{\text{IRQ14}}$ is selected 1: P86/ $\overline{\text{ExIRQ14}}$ is selected
13	ISS13	0	R/W	0: P55/ $\overline{\text{IRQ13}}$ is selected 1: P85/ $\overline{\text{ExIRQ13}}$ is selected
12	ISS12	0	R/W	0: P54/ $\overline{\text{IRQ12}}$ is selected 1: P84/ $\overline{\text{ExIRQ12}}$ is selected
11	ISS11	0	R/W	0: P53/ $\overline{\text{IRQ11}}$ is selected 1: P83/ $\overline{\text{ExIRQ11}}$ is selected
10	ISS10	0	R/W	0: P52/ $\overline{\text{IRQ10}}$ is selected 1: P82/ $\overline{\text{ExIRQ10}}$ is selected
9	ISS9	0	R/W	0: P51/ $\overline{\text{IRQ9}}$ is selected 1: P81/ $\overline{\text{ExIRQ9}}$ is selected
8	ISS8	0	R/W	0: P50/ $\overline{\text{IRQ8}}$ is selected 1: P80/ $\overline{\text{ExIRQ8}}$ is selected

				1: P73/ $\overline{\text{ExIRQ3}}$ is selected
2	ISS2	0	R/W	0: P42/ $\overline{\text{IRQ2}}$ is selected 1: P72/ $\overline{\text{ExIRQ2}}$ is selected
1	ISS1	0	R/W	P41/ $\overline{\text{IRQ1}}$ is always selected
0	ISS0	0	R/W	P40/ $\overline{\text{IRQ0}}$ is always selected

4	TMIYS	0	R/W	0: P45/TMIY is selected 1: P87/ExTMIY is selected
3	—	0	R/W	Reserved The initial values should not be changed.
2	PWMS	0	R/W	0: P10/PW0, P11/PW1, P12/PW2 are selected 1: PF0/ExPW0, PF1/ExPW1, and PF2/ExPW2 are selected
1, 0	—	All 0	R/W	Reserved The initial values should not be changed.

Figure 9.1 shows a block diagram of the PWM timer.

Figure 9.1 Block Diagram of PWM Timer

Figure 3-23 shows the bit fields of the Serial Timer Control Register (STCR) in section 3.2.3, Serial Timer Control Register (STCR).

- PWM register select (PWSL)
- PWM data registers 15 to 0 (PWDR15 to PWDR0)
- PWM data polarity register A (PWDPRB)
- PWM data polarity register B (PWDPRB)
- PWM output enable register A (PWOERA)
- PWM output enable register B (PWOERB)
- Peripheral clock select register (PCSR)

from the following equations.

Resolution (minimum pulse width) = $1/\text{internal clock}$

PWM conversion period = resolution \times 256

Carrier frequency = $16/\text{PWM conversion period}$

With a 33 MHz system clock (ϕ), the resolution, PWM conversion period, and carrier frequency are as shown in Table 9.3.

5	—	1	R	Reserved This bit is always read as 1 and cannot be modified.
4	—	0	R	Reserved This bit is always read as 0 and cannot be modified.

0111: PWDR7 selected

 1111: PWDR15 selected

Table 9.2 Internal Clock Selection

PWSL		PCSR		Description	
PWCKE	PWCKS	PWCKB	PWCKA		
0	—	—	—	Clock input is disabled	(Initi
1	0	—	—	ϕ (system clock) is selected	
	1	0	0	$\phi/2$ is selected	
			1	$\phi/4$ is selected	
	1	1	0	$\phi/8$ is selected	
			1	$\phi/16$ is selected	

PWDR are 8-bit readable/writable registers. The PWM has sixteen PWM data registers. PWDR specifies the duty cycle of the basic pulse to be output, and the number of additional pulses. The value set in PWDR corresponds to a 0 or 1 ratio in the conversion period. The upper four bits specify the duty cycle of the basic pulse as 0/16 to 15/16 with a resolution of 1/16. The lower four bits specify how many extra pulses are to be added within the conversion period comprising 16 basic pulses. Thus, a specification of 0/256 to 255/256 is possible for 0/1 to 100% output within the conversion period. For 256/256 (100%) output, port output should be used.

9.3.3 PWM Data Polarity Registers A and B (PWDPRB and PWDPRB)

Each PWDPR selects the PWM output phase.

- PWDPRB

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	OS7 to OS0	All 0	R/W	Output Select 7 to 0 These bits select the PWM output phase. Bits OS7 to OS0 correspond to outputs PW7 to PW0. 0: PWM direct output (PWDR value corresponds to the width of output) 1: PWM inverted output (PWDR value corresponds to the width of output)

Each PWOER switches between PWM output and port output.

- PWOERA

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	OE7 to OE0	All 0	R/W	Output Enable 7 to 0 These bits, together with P1DDR, specify the P1n/PW state. Bits OE7 to OE0 correspond to outputs PW7 to PW0. P1nDDR OEn: Pin state 0*: Port input 10: Port output or PWM 256/256 output 11: PWM output (0 to 255/256 output)

[Legend]

n = 0 to 7

*: Don't care

m = 8 to 15

*: Don't care

To perform PWM 256/256 output when DDR = 1 and OE = 0, the corresponding pin should be set to port output. The corresponding pin can be set as port output in single-chip mode or with DDR = 1 and CS256E = 0 in SYSCR in extended mode with on-chip ROM. Otherwise, it should be noted that an address bus is output to the corresponding pin.

DR data is output when the corresponding pin is used as port output. A value corresponding to PWM 256/256 output is determined by the OS bit, so the value should have been set to 1 beforehand.

9.3.5 Peripheral Clock Select Register (PCSR)

PCSR selects the PWM input clock.

Bit	Bit Name	Initial Value	R/W	Description
7	PWCKX1B	0	R/W	See section 10.3.4, Peripheral Clock Select Register (PCSR).
6	PWCKX1A	0	R/W

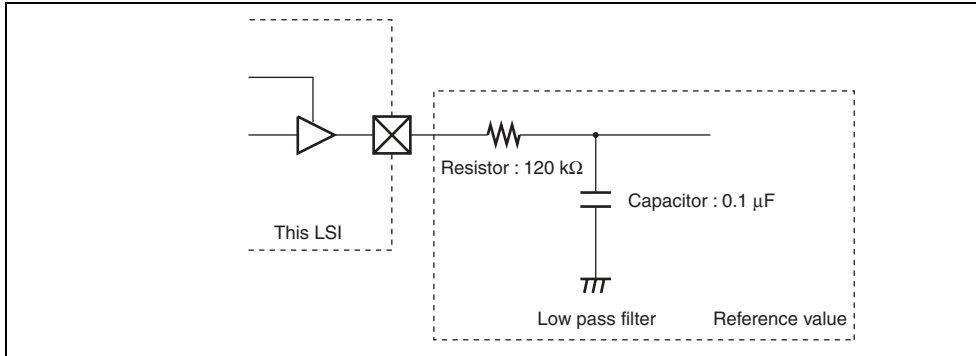

Figure 9.4 Example when PWM is Used as D/A Converter

The base cycle can be set equal to $T \times 04$ or $T \times 250$, where T is the resolution.

- Sixteen operation clocks (by combination of eight resolution settings and two base cycle settings)

Figure 10.1 shows a block diagram of the PWM (D/A) module.

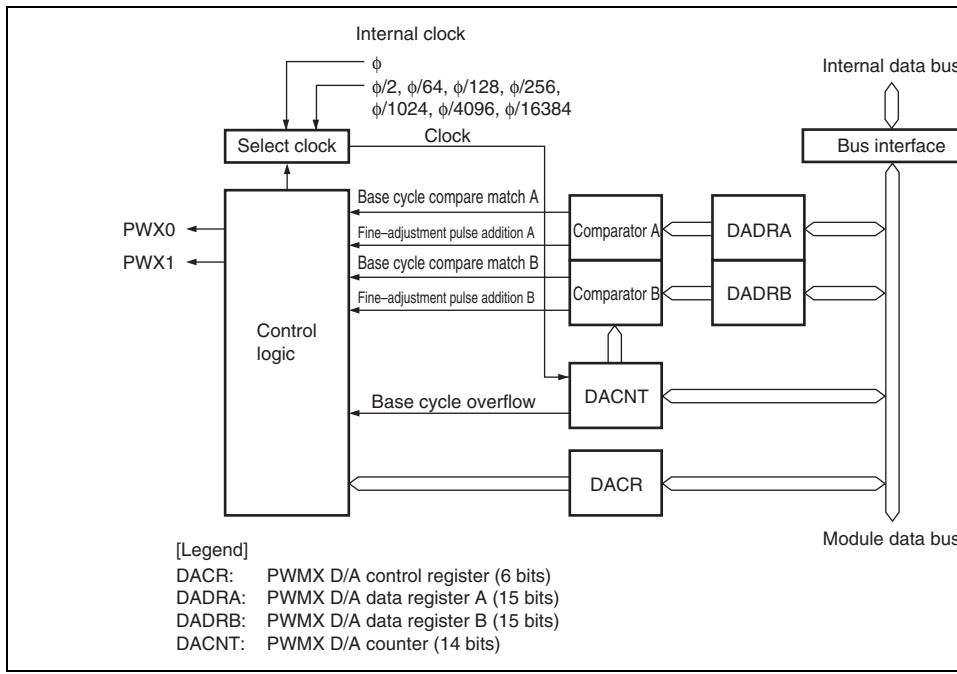

Figure 10.1 PWMX (D/A) Block Diagram

10.3 Register Descriptions

The PWMX (D/A) module has the following registers. The PWMX (D/A) registers are at the same addresses with other registers. The registers are selected by the IICE bit in the system timer control register (STCR). For details on the module stop control register, see section 10.1.2.1 Module Stop Control Register H, L, and A (MSTPCRH, MSTPCRL, MSTPCRA).

- PWMX (D/A) counter (DACNT)
- PWMX (D/A) data register A (DADRA)
- PWMX (D/A) data register B (DADRB)
- PWMX (D/A) control register (DACR)
- Peripheral clock select register (PCSR)

Note: The same addresses are shared by DADRA and DACR, and by DADRB and DACR. Switching is performed by the REGS bit in DACNT or DADRB.

15 to 8	UC7 to UC6	All 0	R/W	Lower Up-Counter
7 to 2	UC8 to UC13	All 0	R/W	Upper Up-Counter
1	—	1	R	Reserved
This bit is always read as 1 and cannot be modified.				
0	REGS	1	R/W	Register Select
DADRA and DACR, and DADRB and DACNT are located at the same addresses. The REGS bit selects which registers can be accessed. When changing the register to be accessed, set this bit in advance.				
0: DADRA and DADRB can be accessed				
1: DACR and DACNT can be accessed				

In each base cycle, the DACNT value is compared with the DADR value to determine the cycle of the output waveform, and to decide whether to output a fine-adjustment pulse equal in width to the resolution. To enable this operation, this register must be set within a range that depends on the CFS value. If the DADR value is outside this range, the PWM output is held constant.

A channel can be operated with 12-bit precision by fixing DA0 and DA1 to 0. The two data bits are compared with UC12 and UC13 of DACNT.

1	CFS	1	R/W	Carrier Frequency Select 0: Base cycle = resolution (T) × 64 The range of DA13 to DA0: H'0100 to H'3FFF 1: Base cycle = resolution (T) × 256 The range of DA13 to DA0: H'0040 to H'3FFF
0	—	1	R	Reserved This bit is always read as 1 and cannot be modified.

- Read

When the upper byte is read from, the upper-byte value is transferred to the CPU and lower-byte value is transferred to TEMP. Next, when the lower byte is read from, the byte value in TEMP is transferred to the CPU.

These registers should always be accessed 16 bits at a time with a MOV instruction, and the upper byte should always be accessed before the lower byte. Correct data will not be transferred if only the upper byte or only the lower byte is accessed. Also note that a bit manipulation instruction cannot be used to access these registers.

Example 1: Write to DACNT

```
MOV.W R0, @DACNT ; Write R0 contents to DACNT
```

Example 2: Read DADRA

```
MOV.W @DADRA, R0 ; Copy contents of DADRA to R0
```

Figure 10.2 PWMX (D/A) Operation

Table 10.3 summarizes the relationships between the CKS and CFS bit settings and the base cycle, and conversion cycle. The PWM output remains fixed unless DA13 to DA0 contain at least a certain minimum value. The relationship between the OS bit and the waveform is shown in figures 10.3 and 10.4.

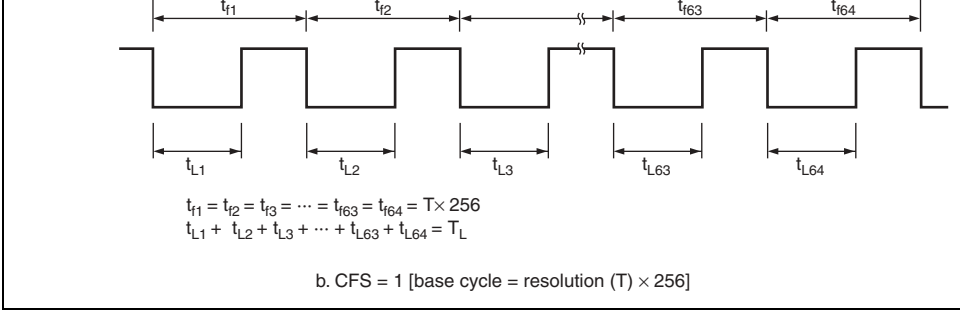

Figure 10.3 Output Waveform (OS = 0, DADR corresponds to T_L)

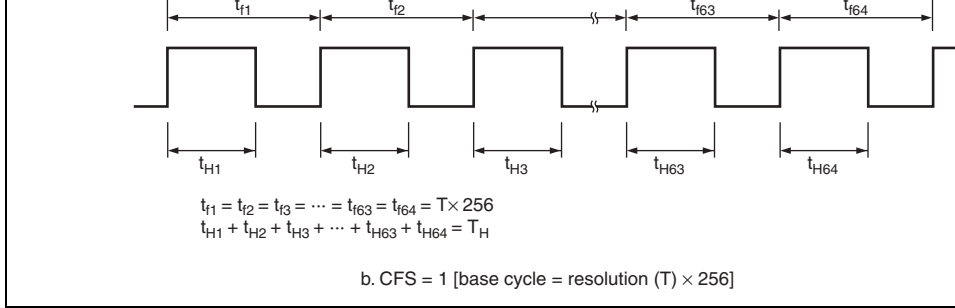

Figure 10.4 Output Waveform (OS = 1, DADR corresponds to T_H)

An example of the additional pulses when CFS = 1 (base cycle = resolution (T) × 256) and OS = 1 (inverted PWM output) is described below. When CFS = 1, the upper eight bits (DA13 to DA6) of the DADR determine the duty cycle of the base pulse while the subsequent six bits (DA5 to DA0) determine the locations of the additional pulses as shown in figure 10.5.

Table 10.4 lists the locations of the additional pulses.

Figure 10.5 D/A Data Register Configuration when CFS = 1

In this example, DADR = H'0207 (B'0000 0010 0000 0111). The output waveform is shown in figure 10.6. Since CFS = 1 and the value of the upper eight bits is B'0000 0010, the high time of the base pulse duty cycle is $2/256 \times (T)$.

Since the value of the subsequent six bits is B'0000 01, an additional pulse is output only at the location of base pulse No. 63 according to table 10.4. Thus, an additional pulse of $1/256$ of the base pulse is added to the base pulse.

However, when $CFS = 0$ (base cycle = resolution $(T) \times 64$), the duty cycle of the base pulse is determined by the upper six bits and the locations of the additional pulses by the subsequent bits with a method similar to as above.

Lower 6 bits	Base pulse No.

- Two independent waveforms can be output.
- Four independent input capture channels
 - The rising or falling edge can be selected.
 - Buffer modes can be specified.
- Counter clearing
 - The free-running counters can be cleared on compare-match A.
- Seven independent interrupts
 - Two compare-match interrupts, four input capture interrupts, and one overflow interrupt can be requested independently.
- Special functions provided by automatic addition function
 - The contents of OCRAR and OCRAF can be added to the contents of OCRA automatically, enabling a periodic waveform to be generated without software intervention. The contents of ICRD can be added automatically to the contents of OCRDM $\times 2$ during input capture operations in this interval to be restricted.

Figure 11.1 shows a block diagram of the FRT.

Figure 11.1 Block Diagram of 16-Bit Free-Running Timer

Input capture C input pin	FTIC	Input	Input capture C input
Input capture D input pin	FTID	Input	Input capture D input

11.3 Register Descriptions

The FRT has the following registers.

- Free-running counter (FRC)
- Output compare register A (OCRA)
- Output compare register B (OCRB)
- Input capture register A (ICRA)
- Input capture register B (ICRB)
- Input capture register C (ICRC)
- Input capture register D (ICRD)
- Output compare register AR (OCRAR)
- Output compare register AF (OCRAF)
- Output compare register DM (OCRDM)
- Timer interrupt enable register (TIER)
- Timer control/status register (TCSR)
- Timer control register (TCR)
- Timer output compare control register (TOCR)

Note: OCRA and OCRB share the same address. Register selection is controlled by the bit in TOCR. ICRA, ICRB, and ICRC share the same addresses with OCRAR, OCRAF, and OCRDM. Register selection is controlled by the ICRS bit in TOCR.

match, the output level selected by the OLVLA or OLVLB bit in TOCR is output at the compare output pin (FTOA or FTOB). Following a reset, the FTOA and FTOB output level is output until the first compare-match. OCR should always be accessed in 16-bit units; cannot be accessed in 8-bit units. OCR is initialized to H'FFFF.

11.3.3 Input Capture Registers A to D (ICRA to ICRD)

The FRT has four input capture registers, ICRA to ICRD, each of which is a 16-bit read-only register. When the rising or falling edge of the signal at an input capture input pin (FTIA or FTIB) is detected, the current FRC value is transferred to the corresponding input capture register (ICRA to ICRD). At the same time, the corresponding input capture flag (ICFA to ICFD) in TCSR is set to 1. The FRC contents are transferred to ICR regardless of the value of ICF. The input capture edge is selected by the input edge select bits (IEDGA to IEDGD) in TCR.

ICRC and ICRD can be used as ICRA and ICRB buffer registers, respectively, by means of the enable bits A and B (BUFEA and BUFEB) in TCR. For example, if an input capture occurs and ICRC is specified as the ICRA buffer register, the FRC contents are transferred to ICRA, and the contents of ICRC are transferred to the buffer register ICRC. When IEDGA and IEDGC bits in TCR are set to 0 and 1 values, both rising and falling edges can be specified as the change of the external input signal.

To ensure input capture, the input capture pulse width should be at least 1.5 system clock periods for a single edge. When triggering is enabled on both edges, the input capture pulse width should be at least 2.5 system clocks (ϕ).

ICRA to ICRD should always be accessed in 16-bit units; cannot be accessed in 8-bit units. ICR is initialized to H'0000.

input clock together with a set value of H'0001 or less for OCRAR (or OCRAF).

OCRAR and OCRAF should always be accessed in 16-bit units; cannot be accessed in 8-bit units. OCRAR and OCRAF are initialized to H'FFFF.

11.3.5 Output Compare Register DM (OCRDM)

OCRDM is a 16-bit readable/writable register in which the upper eight bits are fixed at 1. When the ICRDMS bit in TOCR is set to 1 and the contents of OCRDM are other than 1, the operation of ICRD is changed to include the use of OCRDM. The point at which input capture D occurs is taken as the start of a mask interval. Next, twice the contents of OCRDM is compared with the contents of ICRD, and the result is compared with the FRC value. The point at which the values match is taken as the end of the mask interval. New input capture D events are disabled during the mask interval. A mask interval is not generated when the contents of OCRDM are H'0000 while the ICRDMS bit is set to 1.

OCRDM should always be accessed in 16-bit units; cannot be accessed in 8-bit units. OCRDM is initialized to H'0000.

				<p>Selects whether to enable input capture interrupt request (ICIB) when input capture flag B (ICFB) TCSR is set to 1.</p> <p>0: ICIB requested by ICFB is disabled</p> <p>1: ICIB requested by ICFB is enabled</p>

11.3.7 Timer Control/Status Register (TCSR)

TCSR is used for counter clear selection and control of interrupt request signals.

Bit	Bit Name	Initial Value	R/W	Description
7	ICFA	0	R/(W)*	<p>Input Capture Flag A</p> <p>This status flag indicates that the FRC value transferred to ICRA by means of an input capture signal. When BUFEA = 1, ICFA indicates that ICRA value has been moved into ICRC and the FRC value has been transferred to ICRA.</p> <p>[Setting condition]</p> <p>When an input capture signal causes the FRC to be transferred to ICRA</p> <p>[Clearing condition]</p> <p>Read ICFA when ICFA = 1, then write 0 to ICFA</p>

3	ICFC	0	R/(W)*	Input Capture Flag C	<p>This status flag indicates that the FRC value has been transferred to ICRC by means of an input capture signal. When BUFEA = 1, on occurrence of an input capture signal specified by the IEDGC bit at the input pin, ICFC is set but data is not transferred to ICRC. In buffer operation, ICFC can be used as an external interrupt signal by setting the ICICE bit.</p> <p>[Setting condition] When an input capture signal is received</p> <p>[Clearing condition] Read ICFC when ICFC = 1, then write 0 to ICFC</p>
4	ICFD	0	R/(W)*	Input Capture Flag D	<p>This status flag indicates that the FRC value has been transferred to ICRD by means of an input capture signal. When BUFEA = 1, on occurrence of an input capture signal specified by the IEDGD bit at the input pin, ICFD is set but data is not transferred to ICRD. In buffer operation, ICFD can be used as an external interrupt signal by setting the ICIDE bit.</p> <p>[Setting condition] When an input capture signal is received</p> <p>[Clearing condition] Read ICFD when ICFD = 1, then write 0 to ICFD</p>

				When FRC = OCRB [Clearing condition] Read OCFB when OCFB = 1, then write 0 to
1	OVF	0	R/(W)*	Overflow Flag This status flag indicates that the FRC has overflowed. [Setting condition] When FRC overflows (changes from H'FFFF to H'0000) [Clearing condition] Read OVF when OVF = 1, then write 0 to OVF
0	CCLRA	0	R/W	Counter Clear A This bit selects whether the FRC is to be cleared at compare-match A (when the FRC and OCRA match). 0: FRC clearing is disabled 1: FRC is cleared at compare-match A

Note: * Only 0 can be written to clear the flag.

				<p>Selects the rising or falling edge of the input capture signal (FTIB).</p> <p>0: Capture on the falling edge of FTIB</p> <p>1: Capture on the rising edge of FTIB</p>
5	IEDGC	0	R/W	<p>Input Edge Select C</p> <p>Selects the rising or falling edge of the input capture signal (FTIC).</p> <p>0: Capture on the falling edge of FTIC</p> <p>1: Capture on the rising edge of FTIC</p>

Figure 11.3 Increment Timing with Internal Clock Source

Figure 11.4 Increment Timing with External Clock Source

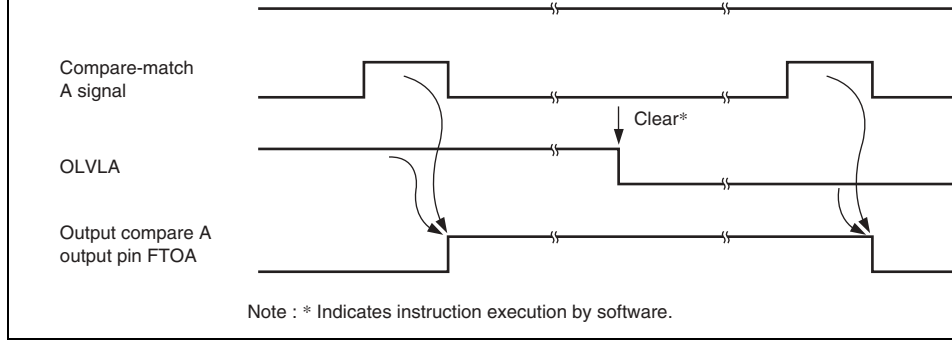

Figure 11.5 Timing of Output Compare A Output

11.5.3 FRC Clear Timing

FRC can be cleared when compare-match A occurs. Figure 11.6 shows the timing of this operation.

Figure 11.6 Clearing of FRC by Compare-Match A Signal

Figure 11.7 Input Capture Input Signal Timing (Usual Case)

If ICRA to ICRD are read when the corresponding input capture signal arrives, the internal capture signal is delayed by one system clock (ϕ). Figure 11.8 shows the timing for this case.

Figure 11.8 Input Capture Input Signal Timing (When ICRA to ICRD is Read)

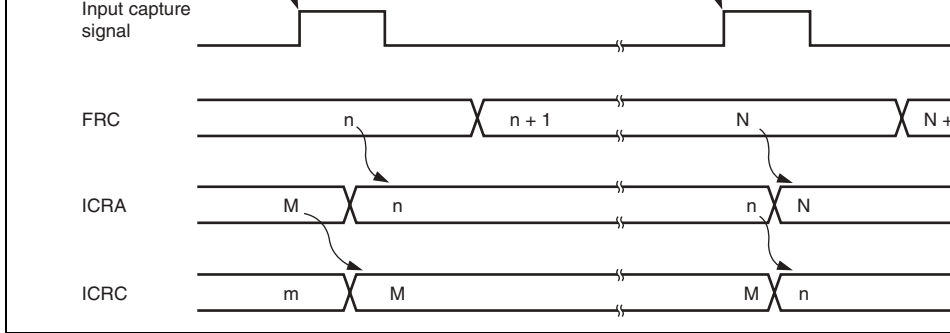

Figure 11.9 Buffered Input Capture Timing

Even when ICRC or ICRD is used as a buffer register, its input capture flag is set by the transition of its input capture signal. For example, if ICRC is used to buffer ICRA, when the transition selected by the IEDGC bit occurs on the FTIC input capture line, ICFC will be set. If the ICICE bit is set at this time, an interrupt will be requested. The FRC value will not be transferred to ICRC, however. In buffered input capture, if either set of two registers to be transferred (ICRA and ICRC, or ICRB and ICRD) is being read when the input capture signal arrives, input capture is delayed by one system clock (ϕ). Figure 11.10 shows the timing when BUFEA = 1.

11.5.6 Timing of Input Capture Flag (ICF) Setting

The input capture flag, ICFA to ICFD, is set to 1 by the input capture signal. The FRC value is simultaneously transferred to the corresponding input capture register (ICRA to ICRD). Figure 11.11 shows the timing of setting the ICFA to ICFD flag.

Figure 11.11 Timing of Input Capture Flag (ICFA to ICFD) Setting

Figure 11.12 Timing of Output Compare Flag (OCFA or OCFB) Setting

11.5.8 Timing of FRC Overflow Flag (OVF) Setting

The FRC overflow flag (OVF) is set to 1 when FRC overflows (changes from H'FFFF to H'0000). Figure 11.13 shows the timing of setting the OVF flag.

Figure 11.13 Timing of Overflow Flag (OVF) Setting

Figure 11.14 OCRA Automatic Addition Timing

11.5.10 Mask Signal Generation Timing

When the ICRDMS bit in TOCR is set to 1 and the contents of OCRDM are other than H, a signal that masks the ICRD input capture signal is generated. The mask signal is set by the capture signal. The mask signal is cleared by the sum of the ICRD contents and twice the OCRDM contents, and an FRC compare-match. Figure 11.15 shows the timing of setting the mask signal. Figure 11.16 shows the timing of clearing the mask signal.

Figure 11.15 Timing of Input Capture Mask Signal Setting

Figure 11.16 Timing of Input Capture Mask Signal Clearing

ICIB	Input capture of ICRB	ICFB	Possible	Low
ICIC	Input capture of ICRC	ICFC	Not possible	
ICID	Input capture of ICRD	ICFD	Not possible	
OCIA	Compare match of OCRA	OCFA	Possible	
OCIB	Compare match of OCRB	OCFB	Possible	
FOVI	Overflow of FRC	OVF	Not possible	

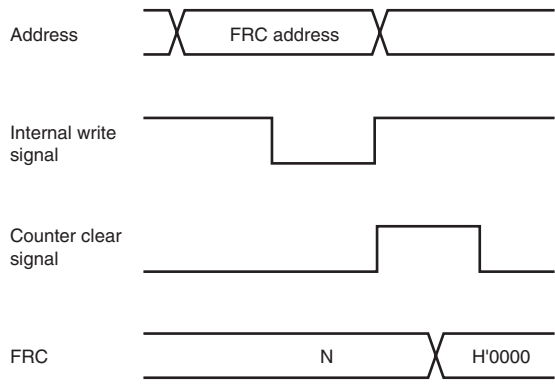

Figure 11.17 Conflict between FRC Write and Clear

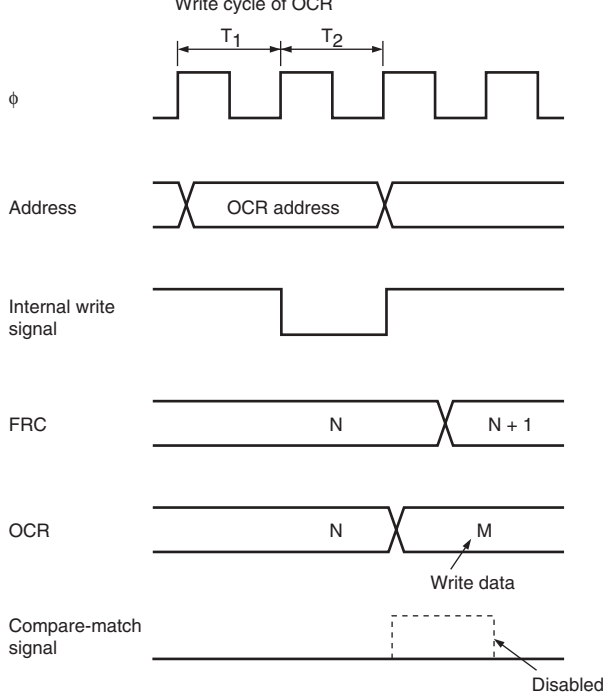

Figure 11.19 Conflict between OCR Write and Compare-Match (When Automatic Addition Function is Not Used)

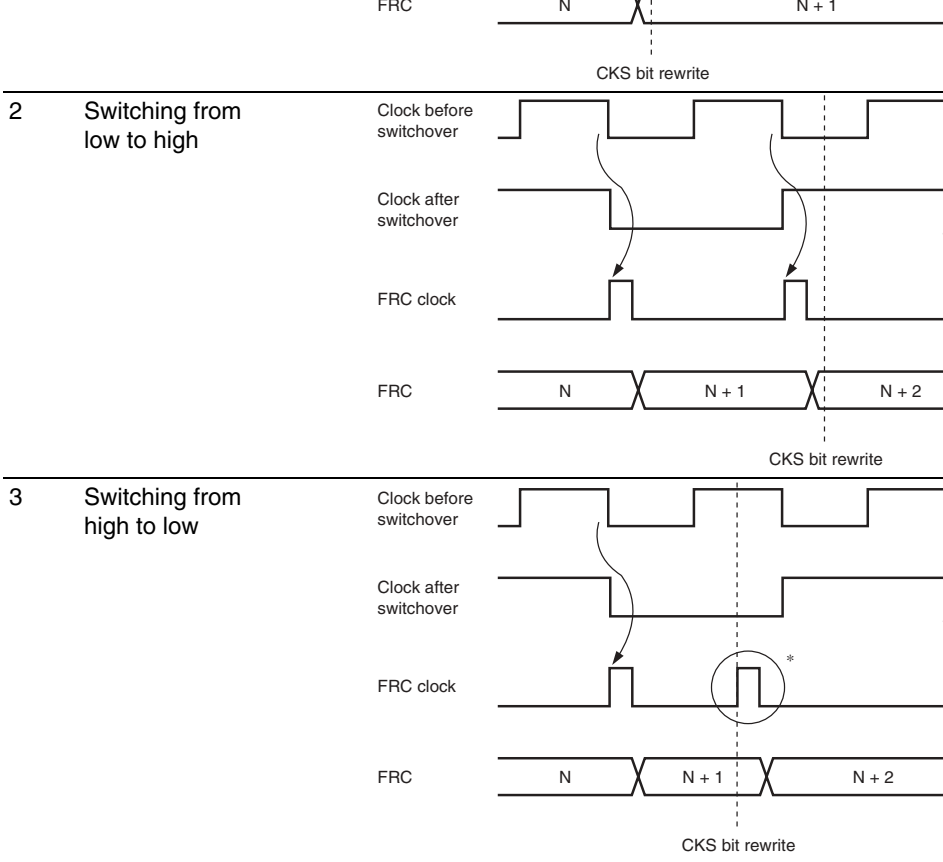

Figure 11.20 Conflict between OCR Write and Compare-Match (When Automatic Addition Function is Used)

11.7.4 Switching of Internal Clock and FRC Operation

When the internal clock is changed, the changeover may source FRC to increment. This occurs on the time at which the clock is switched (bits CKS1 and CKS0 are rewritten), as shown in Figure 11.3.

When an internal clock is used, the FRC clock is generated on detection of the falling edge of the internal clock scaled from the system clock (ϕ). If the clock is changed when the old source is high and the new source is low, as in case no. 3 in table 11.3, the changeover is regarded as a falling edge that triggers the FRC clock, and FRC is incremented. Switching between an internal and external clock can also source FRC to increment.

Note: * Generated on the assumption that the switchover is a falling edge; FRC is incr

- TMR_0, TMR_1: The counter input clock can be selected from six internal clocks or an external clock
- TMR_Y, TMR_X: The counter input clock can be selected from three internal clocks or an external clock
- Selection of three ways to clear the counters
 - The counters can be cleared on compare-match A, compare-match B, or by an external reset signal.
- Timer output controlled by two compare-match signals
 - The timer output signal in each channel is controlled by two independent compare-match signals, enabling the timer to be used for various applications, such as the generation of a pulse output or PWM output with an arbitrary duty cycle.
- Cascading of TMR_0 and TMR_1
(Cascading of TMR_Y and TMR_X is not allowed)
 - Operation as a 16-bit timer can be performed using TMR_0 as the upper half and TMR_1 as the lower half (16-bit count mode). TMR_1 can be used to count TMR_0 compare-match occurrences (compare-match count mode).
- Multiple interrupt sources for each channel
 - TMR_0, TMR_1, and TMR_Y: Three types of interrupts: Compare-match A, compare-match B, and overflow
 - TMR_X: Four types of interrupts: Compare-match A, compare-match B, overflow, and input capture

Figures 12.1 and 12.2 show block diagrams of 8-bit timers.

An input capture function is added to TMR_X.

Notes: Some of the registers of TMR_X and TMR_Y use the same address. The registers are switched by the TMRX/Y bit in TCONRS.

1. Only for the TMR_X
2. Only for the TMR_Y

12.3.1 Timer Counter (TCNT)

Each TCNT is an 8-bit readable/writable up-counter. TCNT_0 and TCNT_1 comprise a 16-bit register, so they can be accessed together by word access. The clock source is selected by the CKS2 to CKS0 bits in TCR. TCNT can be cleared by an external reset input signal, compare-match A signal or compare-match B signal. The method of clearing can be selected by the CLR0 and CCLR0 bits in TCR. When TCNT overflows (changes from H'FF to H'00), the OVF flag in TCSR is set to 1. TCNT is initialized to H'00.

TCNT_Y can be accessed when the KINWUE bit in SYSCR is 0 and the TMRX/Y bit in TCONRS is 1. TCNT_X can be accessed when the KINWUE bit in SYSCR is 0 and the TMRX/Y bit in TCONRS is 0. See section 3.2.2, System Control Register (SYSCR), and section 12.3.1, Timer Connection Register S (TCONRS).

12.3.3 Time Constant Register B (TCORB)

TCORB is an 8-bit readable/writable register. TCORB_0 and TCORB_1 comprise a single register, so they can be accessed together by word access. TCORB is continually compared to the value in TCNT. When a match is detected, the corresponding compare-match flag B (CMFB) in TCSR is set to 1. Note however that comparison is disabled during the T2 state of a TC write cycle. The timer output from the TMO pin can be freely controlled by these compare-match signals and the settings of output select bits OS3 and OS2 in TCSR. TCORB is initialized to 0xFF.

TCORB_Y can be accessed when the KINWUE bit in SYSCR is 0 and the TMRX/Y bit in TCONRS is 1. TCORB_X can be accessed when the KINWUE bit in SYSCR is 0 and the TMRX/Y bit in TCONRS is 0. See section 3.2.2, System Control Register (SYSCR), and section 12.3.11, Timer Connection Register S (TCONRS).

12.3.6 Input Capture Register (TICR)

TICR is an 8-bit register. The contents of TCNT are transferred to TICR at the rising edge of the external reset input. TICR cannot be directly accessed by the CPU.

12.3.7 Time Constant Register C (TCORC)

TCORC is an 8-bit readable/writable register. The sum of contents of TCORC and TICR is compared with TCNT. When a match is detected, a compare-match C signal is generated. However, comparison at the T2 state in the write cycle to TCORC and at the input capture event, TICR is disabled. TCORC is initialized to H'FF.

12.3.8 Input Capture Registers R and F (TICRR and TICRF)

TICRR and TICRF are 8-bit read-only registers. While the ICST bit in TCONRI is set to 1, the contents of TCNT are transferred at the rising edge and falling edge of the external reset input in that order. The ICST bit is cleared to 0 when one capture operation ends. TICRR and TICRF are initialized to H'00.

TICRR and TICRF can be accessed when the KINWUE bit in SYSCR is 0 and the TMR bit in TCONRS is 0. See section 3.2.2, System Control Register (SYSCR).

Table 12.3 Registers Accessible by TMR_X/TMR_Y

TMRX/Y	H'FFFFFF0	H'FFFFFF1	H'FFFFFF2	H'FFFFFF3	H'FFFFFF4	H'FFFFFF5	H'FFFFFF6

	TCR_Y	TCSR_Y	TCORA_Y	TCORB_Y	TCNT_Y	TISR	

can be output without the intervention of software.

Figure 12.3 Pulse Output Example

Figure 12.4 Count Timing for Internal Clock Input

Figure 12.5 Count Timing for External Clock Input

12.5.2 Timing of CMFA and CMFB Setting at Compare-Match

The CMFA and CMFB flags in TCSR are set to 1 by a compare-match signal generated when TCNT and TCOR values match. The compare-match signal is generated at the last state of the match is true, just when the timer counter is updated. Therefore, when TCNT and TCOR match, the compare-match signal is not generated until the next TCNT input clock. Figure 12.6 shows the timing of CMF flag setting.

12.5.3 Timing of Timer Output at Compare-Match

When a compare-match signal occurs, the timer output changes as specified by the OS3 to OS6 bits in TCSR. Figure 12.7 shows the timing of timer output when the output is set to toggle on compare-match A signal.

Figure 12.7 Timing of Toggled Timer Output by Compare-Match A Signal

12.5.4 Timing of Counter Clear at Compare-Match

TCNT is cleared when compare-match A or compare-match B occurs, depending on the settings of the CCLR1 and CCLR0 bits in TCR. Figure 12.8 shows the timing of clearing the counter on compare-match A.

Figure 12.8 Timing of Counter Clear by Compare-Match

Rev. 3.00, 03/04, page 324 of 830

Figure 12.9 Timing of Counter Clear by External Reset Input

12.5.6 Timing of Overflow Flag (OVF) Setting

The OVF bit in TCSR is set to 1 when the TCNT overflows (changes from H'FF to H'00). 12.10 shows the timing of OVF flag setting.

Figure 12.10 Timing of OVF Flag Setting

- The CMF flag in TCSR_0 is set to 1 when a 16-bit compare-match occurs.
- The CMF flag in TCSR_1 is set to 1 when a lower 8-bit compare-match occurs.
- Counter clear specification
 - If the CCLR1 and CCLR0 bits in TCR_0 have been set for counter clear at compare-match, the 16-bit counter (TCNT_0 and TCNT_1 together) is cleared when a 16-bit compare-match occurs. The 16-bit counter (TCNT_0 and TCNT_1 together) is also cleared when the counter clear by the TMI0 pin has been set.
 - The settings of the CCLR1 and CCLR0 bits in TCR_1 are ignored. The lower 8-bit counter is cleared independently.
- Pin output
 - Control of output from the TMO0 pin by bits OS3 to OS0 in TCSR_0 is in accordance with the 16-bit compare-match conditions.
 - Control of output from the TMO1 pin by bits OS3 to OS0 in TCSR_1 is in accordance with the lower 8-bit compare-match conditions.

12.6.2 Compare-Match Count Mode

When bits CKS2 to CKS0 in TCR_1 are B'100, TCNT_1 counts the occurrence of compare-match. A for TMR_0. TMR_0 and TMR_1 are controlled independently. Conditions such as setting the CMF flag, generation of interrupts, output from the TMO pin, and counter clearing are in accordance with the settings for each channel.

Figure 12.11 Timing of Input Capture Operation

If the input capture signal is input while TICRR and TICRF are being read, the input capture signal is delayed by one system clock (ϕ) cycle. Figure 12.12 shows the timing of this operation.

Selection of Input Capture Signal Input: TMR_{IX} (input capture input signal of TMR_{IX}) switched according to the setting of the ICST bits in TCONR1. Input capture signal selection is shown in table 12.4.

Table 12.4 Input Capture Signal Selection

TCONR1	
Bit 4	
ICST	Description
0	Input capture function not used
1	TMR _{IX} pin input selection

Channel	Name	Interrupt Source	Flag	Activation	Pri

Figure 12.14 Conflict between TCNT Write and Increment

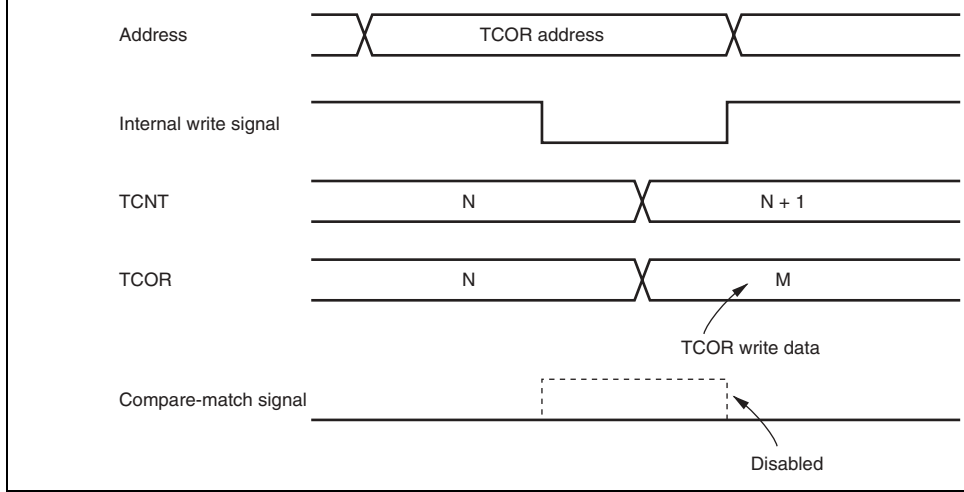

Figure 12.15 Conflict between TCOR Write and Compare-Match

12.9.5 Switching of Internal Clocks and TCNT Operation

TCNT may increment erroneously when the internal clock is switched over. Table 12.7 shows the relationship between the timing at which the internal clock is switched (by writing to the CKS1 and CKS0 bits) and the TCNT operation.

When the TCNT clock is generated from an internal clock, the falling edge of the internal clock pulse is detected. If clock switching causes a change from high to low level, as shown in table 12.7, a TCNT clock pulse is generated on the assumption that the switchover is a falling edge, and TCNT is incremented.

Erroneous incrementation can also happen when switching between internal and external

Table 12.7 Switching of Internal Clocks and TCNT Operation

No.	Timing of Switchover by Means of CKS1 and CKS0 Bits	TCNT Clock Operation
1	Clock switching from low to low level*1	<p data-bbox="639 683 756 719">Clock before switchover</p> <p data-bbox="639 759 741 796">Clock after switchover</p> <p data-bbox="639 836 699 873">TCNT clock</p> <p data-bbox="639 927 699 951">TCNT</p> <p data-bbox="876 983 1000 1002">CKS bit rewrite</p>

3 Clock switching from high to low level^{*3}

4 Clock switching from high to high level

- Notes:
1. Includes switching from low to stop, and from stop to low.
 2. Includes switching from stop to high.
 3. Includes switching from high to stop.
 4. Generated on the assumption that the switchover is a falling edge; TCNT is incremented.

- Selectable from eight (WDT_0) or 16 (WDT_1) counter input clocks.
- Switchable between watchdog timer mode and interval timer mode

Watchdog Timer Mode:

- If the counter overflows, an internal reset or an internal NMI interrupt is generated.
- When the LSI is selected to be internally reset at counter overflow, a low level signal from the $\overline{\text{RESO}}$ pin if the counter overflows.

Internal Timer Mode:

- If the counter overflows, an internal timer interrupt (WOVI) is generated.

[Legend]

- TCSR_0: Timer control/status register_0
- TCNT_0: Timer counter_0
- TCSR_1: Timer control/status register_1
- TCNT_1: Timer counter_1

- Notes: 1. The $\overline{\text{RESO}}$ signal outputs the low level signal when the internal reset signal is generated due to a TCNT overflow of either WDT_0 or WDT_1. The internal reset signal first resets the WDT in which the overflow has occurred first.
2. The internal NMI interrupt signal can be independently output from either WDT_0 or WDT_1. The interrupt controller does not distinguish the NMI interrupt request from WDT_0 from that from WDT_1.

Figure 13.1 Block Diagram of WDT

TCNT is an 8-bit readable/writable up-counter.

TCNT is initialized to H'00 when the TME bit in timer control/status register (TCSR) is cleared to 0.

13.3.2 Timer Control/Status Register (TCSR)

TCSR selects the clock source to be input to TCNT, and the timer mode.

- TCSR_0

Bit	Bit Name	Initial Value	R/W	Description

110: $\phi\text{SUB}/128$ (cycle: 1 s)

111: $\phi\text{SUB}/256$ (cycle: 2 s)

-
- Notes:
1. Only 0 can be written, to clear the flag.
 2. When OVF is polled with the interval timer interrupt disabled, OVF = 1 must be written at least twice.

RESO pin for 132 states, as shown in figure 13.2. If the RST/NMI bit is cleared to 0, when TCNT overflows, an NMI interrupt request is generated. Here, the output from the $\overline{\text{RESO}}$ remains high.

An internal reset request from the watchdog timer and a reset input from the $\overline{\text{RES}}$ pin are processed in the same vector. Reset source can be identified by the XRST bit status in SYSCR. If a reset caused by a signal input to the $\overline{\text{RES}}$ pin occurs at the same time as a reset caused by WDT overflow, the RES pin reset has priority and the XRST bit in SYSCR is set to 1.

An NMI interrupt request from the watchdog timer and an interrupt request from the NMI pin are processed in the same vector. Do not handle an NMI interrupt request from the watchdog timer and an interrupt request from the NMI pin at the same time.

Figure 13.2 Watchdog Timer Mode ($\overline{\text{RST/NMI}} = 1$) Operation

Figure 13.3 Interval Timer Mode Operation

Figure 13.4 OVF Flag Set Timing

Figure 13.5 Output Timing of $\overline{\text{RESO}}$ signal

TCNT and TCSR both have the same write address. Therefore, satisfy the relative conditions shown in figure 13.6 to write to TCNT or TCSR. To write to TCNT, the higher bytes must contain the value H'5A and the lower bytes must contain the write data. To write to TCSR, the higher bytes must contain the value H'A5 and the lower bytes must contain the write data.

Figure 13.6 Writing to TCNT and TCSR (WDT_0)

Reading from TCNT and TCSR (Example of WDT_0):

These registers are read in the same way as other registers. The read address is H'FFA8 for TCSR and H'FFA9 for TCNT.

Figure 13.7 Conflict between TCNT Write and Increment

13.6.3 Changing Values of CKS2 to CKS0 Bits

If CKS2 to CKS0 bits in TCSR are written to while the WDT is operating, errors could occur in the incrementation. Software must stop the watchdog timer (by clearing the TME bit to 0) before changing the values of CKS2 to CKS0 bits.

13.6.4 Changing Value of PSS Bit

If the PSS bit in TCSR_1 is written to while the WDT is operating, errors could occur in the incrementation. Stop the watchdog timer (by clearing the TME bit to 0) before changing the value of the PSS bit.

Figure 13.8 Sample Circuit for Resetting the System by the $\overline{\text{RESO}}$ Signal

SCI_1 can handle communication using the waveform based on the Infrared Data Association (IrDA) standard version 1.0. SCI_0 and SCI_2 provide high-speed communication at a transfer rate of a specific system clock frequency. Reliable fast data transfers are secured by an internal cyclic redundancy check (CRC) operation circuit. Since the CRC operation circuit is connected to the SCI, data is transferred to the circuit using the MOV instruction to be processed there.

14.1 Features

- Choice of asynchronous or clock synchronous serial communication mode
- Full-duplex communication capability
The transmitter and receiver are mutually independent, enabling transmission and reception to be executed simultaneously. Double-buffering is used in both the transmitter and the receiver, enabling continuous transmission and continuous reception of serial data.
- On-chip baud rate generator allows any bit rate to be selected
The external clock can be selected as a transfer clock source (except for the smart card interface).
- Choice of LSB-first or MSB-first transfer (except in the case of asynchronous mode)
- Four interrupt sources
Four interrupt sources — transmit-end, transmit-data-empty, receive-data-full, and receive-error — that can issue requests.
The transmit-data-empty and receive-data-full interrupt sources can activate DTC.
- Module stop mode availability

Clock Synchronous Mode:

- Data length: 8 bits
- Receive error detection: Overrun errors
- SCI channel selectable (SCI_0 and SCI_2): When SSE0I = 1, TxD0 = high-impedance and SCK0 = fixed to high input; when SSE2I = 1, TxD2 = high-impedance state and SCK2 = fixed to high input

Smart Card Interface:

- An error signal can be automatically transmitted on detection of a parity error during transmission
- Data can be automatically re-transmitted on detection of a error signal during transmission
- Both direct convention and inverse convention are supported

Figure 14.1 shows a block diagram of SCI_1, and figure 14.2 shows a block diagram of SCI_2.

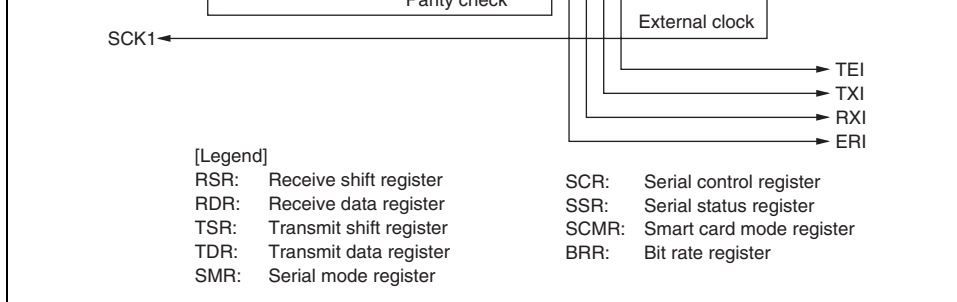

Figure 14.1 Block Diagram of SCL_1

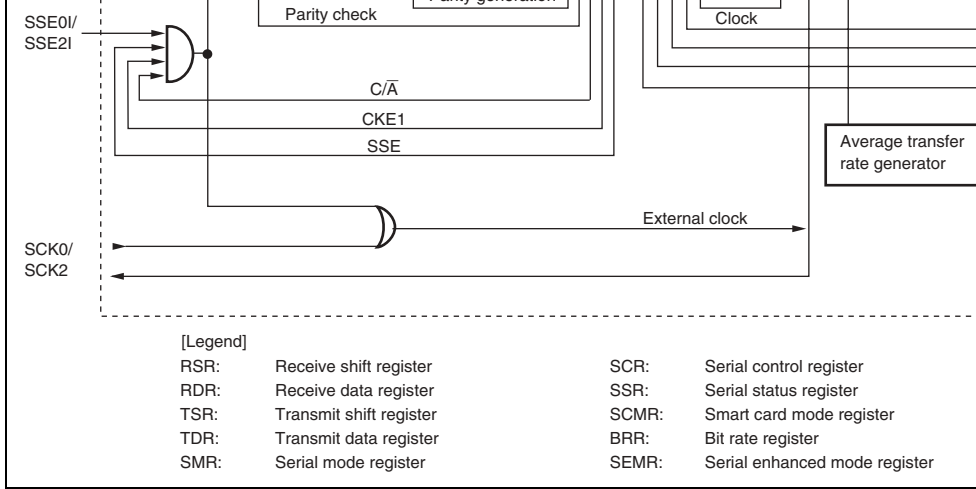

Figure 14.2 Block Diagram of SCI_0 and SCI_2

	RxD1/IrRxD	Input	Channel 1 receive data input (normal/IrDA)
	TxD1/IrTxD	Output	Channel 1 transmit data output (normal/IrDA)
2	SCK2	Input/Output	Channel 2 clock input/output
	RxD2	Input	Channel 2 receive data input
	TxD2	Output	Channel 2 transmit data output
	SSE2I	Input	Channel 2 stop input

Note: * Pin names SCK, RxD, and TxD are used in the text for all channels, omitting channel designation.

- Transmit shift register (TSR)
- Serial mode register (SMR)
- Serial control register (SCR)
- Serial status register (SSR)
- Smart card mode register (SCMR)
- Bit rate register (BRR)
- Serial interface control register (SCICR)*¹
- Serial enhanced mode register (SEMR)*²

Notes: 1. SCICR is not available in SCI_0 or SCI_2.

2. SEMR is not available in SCI_1.

14.3.1 Receive Shift Register (RSR)

RSR is a shift register used to receive serial data that converts it into parallel data. When a frame of data has been received, it is transferred to RDR automatically. RSR cannot be directly accessed by the CPU.

14.3.2 Receive Data Register (RDR)

RDR is an 8-bit register that stores receive data. When the SCI has received one frame of data, it transfers the received serial data from RSR to RDR where it is stored. After this, RSR can receive the next data. Since RSR and RDR function as a double buffer in this way, continuous receive operations can be performed. After confirming that the RDRF bit in SSR is set to 1, RDR can be read only once. RDR cannot be written to by the CPU.

TSR is a shift register that transmits serial data. To perform serial data transmission, the transfers transmit data from TDR to TSR, then sends the data to the TxD pin. TSR cannot be directly accessed by the CPU.

14.3.5 Serial Mode Register (SMR)

SMR is used to set the SCI's serial transfer format and select the baud rate generator clock. Some bits in SMR have different functions in normal mode and smart card interface mode.

				bits is used.
5	PE	0	R/W	Parity Enable (enabled only in asynchronous mode) When this bit is set to 1, the parity bit is added to the data to be transmitted before transmission, and the parity is checked in reception. For a multiprocessor mode, parity bit addition and checking are not performed regardless of the PE bit setting.
4	O \bar{E}	0	R/W	Parity Mode (enabled only when the PE bit is set to 1 in asynchronous mode) 0: Selects even parity. 1: Selects odd parity.
3	STOP	0	R/W	Stop Bit Length (enabled only in asynchronous mode) Selects the stop bit length in transmission. 0: 1 stop bit 1: 2 stop bits In reception, only the first stop bit is checked. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.
2	MP	0	R/W	Multiprocessor Mode (enabled only in asynchronous mode) When this bit is set to 1, the multiprocessor communication function is enabled. The PE bit and O \bar{E} bit settings are invalid in multiprocessor mode.

- Bit Functions in Smart Card Interface Mode (when SMIF in SCMR = 1)

Bit	Bit Name	Initial Value	R/W	Description
7	GM	0	R/W	<p>GSM Mode</p> <p>Setting this bit to 1 allows GSM mode operation. In GSM mode, the TEND set timing is put forward by 11.0 etu* from the start and the clock output function is appended. For details, see section 14.7.3, Clock Output Control.</p>
6	BLK	0	R/W	<p>Setting this bit to 1 allows block transfer mode operation. For details, see section 14.7.3, Block Transfer Mode.</p>
5	PE	0	R/W	<p>Parity Enable (valid only in asynchronous mode)</p> <p>When this bit is set to 1, the parity bit is added to the transmit data before transmission, and the parity is checked in reception. Set this bit to 1 in smart card interface mode.</p>
4	O/ \bar{E}	0	R/W	<p>Parity Mode (valid only when the PE bit is 1 in asynchronous mode)</p> <p>0: Selects even parity 1: Selects odd parity</p> <p>For details on the usage of this bit in smart card interface mode, see section 14.7.2, Data Format (Except in Block Transfer Mode).</p>

1	CKS1	0	R/W	Clock Select 1 and 0
0	CKS0	0	R/W	These bits select the clock source for the baud rate generator.
				00: ϕ clock (n = 0)
				01: $\phi/4$ clock (n = 1)
				10: $\phi/16$ clock (n = 2)
				11: $\phi/64$ clock (n = 3)
				For the relation between the bit rate register value and the baud rate, see section 14.3.9, Bit Rate Register (BRR). n is the decimal display of the value of n in BRR (see section 14.3.9, Bit Rate Register (BRR)).

Note: * etu: Element Time Unit (time taken to transfer one bit)

6	RIE	0	R/W	Receive Interrupt Enable When this bit is set to 1, RXI and ERI interrupt requests are enabled.
5	TE	0	R/W	Transmit Enable When this bit is set to 1, transmission is enabled.
4	RE	0	R/W	Receive Enable When this bit is set to 1, reception is enabled.
3	MPIE	0	R/W	Multiprocessor Interrupt Enable (enabled only when the MP bit in SMR is 1 in asynchronous mode) When this bit is set to 1, receive data in which the multiprocessor bit is 0 is skipped, and settings of RDRF, FER, and ORER status flags in SSF are disabled. On receiving data in which the multiprocessor bit is 1, this bit is automatically set to 1 and normal reception is resumed. For details, see section 14.5, Multiprocessor Communication Function.
2	TEIE	0	R/W	Transmit End Interrupt Enable When this bit is set to 1, a TEI interrupt request is enabled.

(input a clock with a frequency 10 times
rate from the SCK pin.)

Clock synchronous mode:

0*: Internal clock (SCK pin functions as clock)

1*: External clock (SCK pin functions as clock)

[Legend]

*: Don't care

3	MPIE	0	R/W	Multiprocessor Interrupt Enable (enabled or disabled by the MP bit in SMR is 1 in asynchronous mode) Write 0 to this bit in smart card interface mode
2	TEIE	0	R/W	Transmit End Interrupt Enable Write 0 to this bit in smart card interface mode
1	CKE1	0	R/W	Clock Enable 1 and 0
0	CKE0	0	R/W	These bits control the clock output from the SCK pin in GSM mode, clock output can be dynamically enabled or disabled. For details, see section 14.7.8, Clock Output Control. When GM in SMR = 0 00: Output disabled (SCK pin functions as I/O pin) 01: Clock output 1*: Reserved When GM in SMR = 1 00: Output fixed to low 01: Clock output 10: Output fixed to high 11: Clock output

Assuming values of $F = 0$ and $D = 0.5$ in formula (1), the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 16)\} \times 100 \quad [\%] = 46.875 \%$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

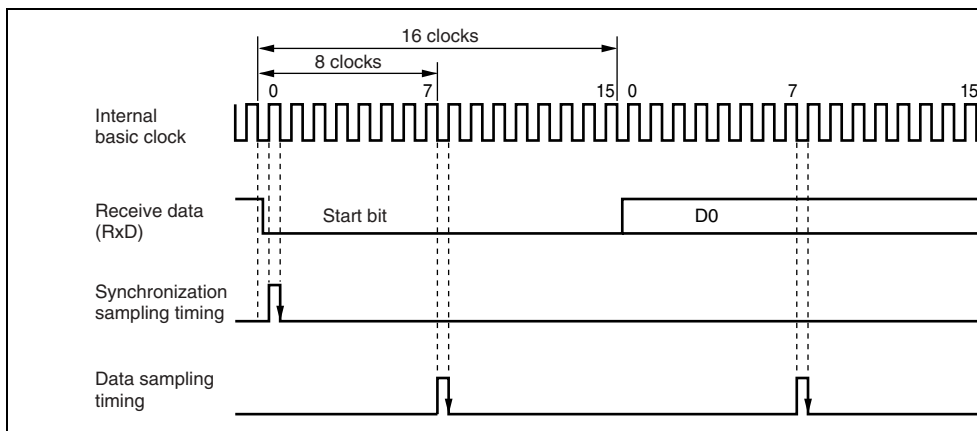

Figure 14.4 Receive Data Sampling Timing in Asynchronous Mode

Figure 14.5 Relation between Output Clock and Transmit Data Phase (Asynchronous Mode)

14.4.4 Serial Enhanced Mode Clock

SCI_0 and SCI_2 can be operated not only based on the clocks described in section 14.4 but based on the following clocks, which are specified by the serial enhanced mode register SEMR_0 and SEMR_2.

Double-Speed Operation: Operations that are usually achieved using the clock with frequency 8 times the normal bit rate can be achieved using the clock with frequency 8 times the bit rate mode. That is, double transfer rate can be achieved using a single basic clock.

Double-speed operation can be specified by the ABCS bit in SEMR and is available for sources of an internal clock generated by the on-chip baud rate generator and an external input at the SCK pin. However, double-speed operation cannot be specified when the average transfer rate operation is selected.

Average Transfer Rate Operation: The SCI can be operated based on the clock with average transfer rate generated from the system clock instead of the external clock input at the SCK pin. In this case, the SCK pin is fixed to input.

Average transfer rate operation can be specified by the ACS4 and ACS2 to ACS0 bits in SEMR. Double-speed operation may be selected by clearing the ACS4 and ACS2 to ACS0 bits in SEMR.

Figures 14.6 and 14.7 show some examples of internal basic clock operations when average transfer rate operation is selected.

Note: * 1-bit length depends on the changes in basic clock synchronization.

Figure 14.6 Basic Clock Examples When Average Transfer Rate is Selected

Figure 14.7 Basic Clock Examples When Average Transfer Rate is Selected

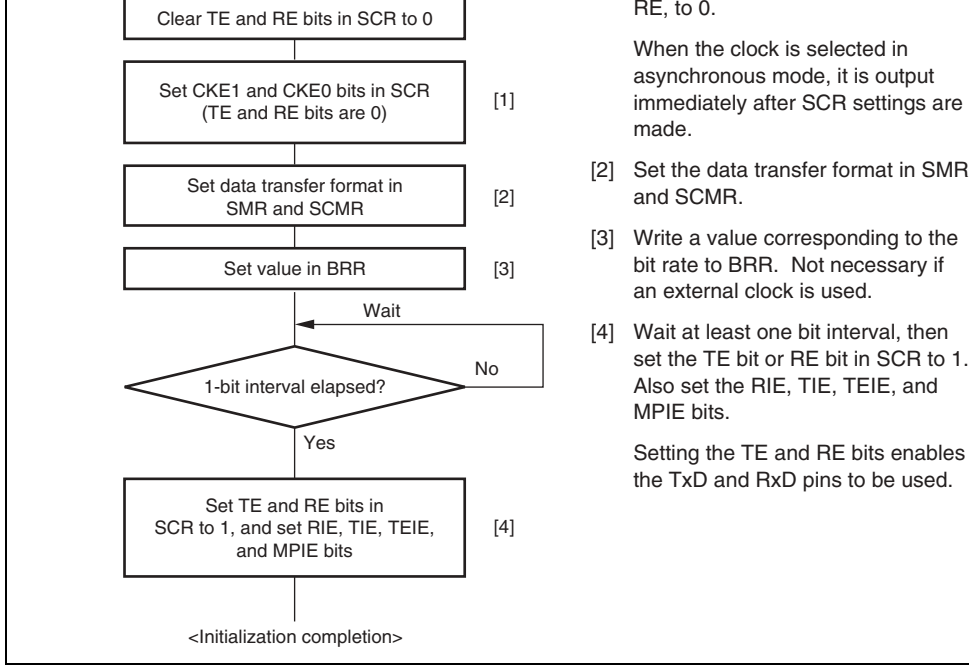

Figure 14.8 Sample SCI Initialization Flowchart

3. Data is sent from the TXD pin in the following order: start bit, transmit data, parity multiprocessor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks the TDRE flag at the timing for sending the stop bit.
5. If the TDRE flag is 0, the data is transferred from TDR to TSR, the stop bit is sent, and a serial transmission of the next frame is started.
6. If the TDRE flag is 1, the TEND flag in SSR is set to 1, the stop bit is sent, and then "state" is entered in which 1 is output. If the TEIE bit in SCR is set to 1 at this time, a interrupt request is generated.

Figure 14.10 shows a sample flowchart for transmission in asynchronous mode.

Figure 14.9 Example of Operation in Transmission in Asynchronous Mode (Example of 8-Bit Data, Parity, One Stop Bit)

To continue serial transmission, read 1 from the TDRE flag to confirm that writing is possible, then write data to TDR, and clear the TDRE flag to 0. However, the TDRE flag is checked and cleared automatically when the DTC is initiated by a transmit data empty interrupt (TXI) request and writes data to TDR.

- [4] Break output at the end of serial transmission:
To output a break in serial transmission, set DDR for the port corresponding to the TxD pin to 1, clear DR to 0, then clear the TE bit in SCR to 0.

Figure 14.10 Sample Serial Transmission Flowchart

- RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
- If a framing error (when the stop bit is 0) is detected, the FER bit in SSR is set to 1 and data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
 - If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt routine reads the receive data transferred to RDR, reception of the next receive data has finished, continuous reception can be enabled.

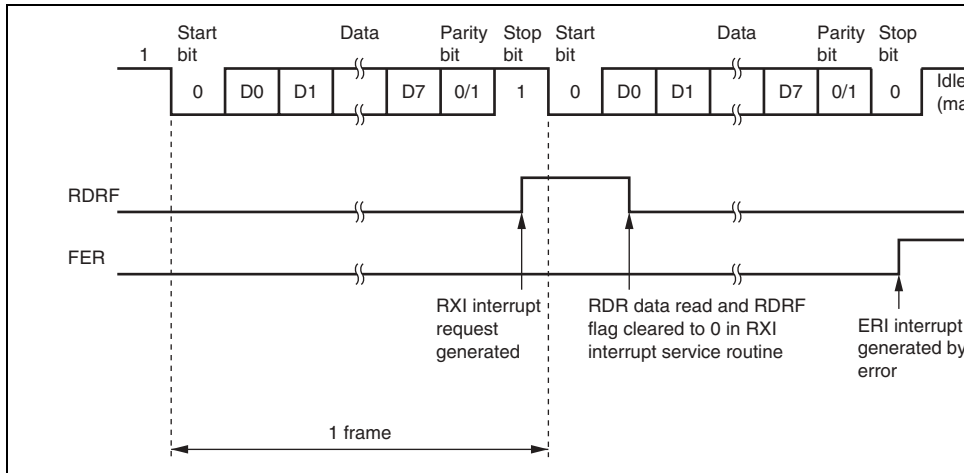

Figure 14.11 Example of SCI Operation in Reception (Example with 8-Bit Data One Stop Bit)

1	1	1	0	Lost	Overrun error + framing error
1	1	0	1	Lost	Overrun error + parity error
0	0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	1	Lost	Overrun error + framing error + parity error

Note: * The RDRF flag retains the state it had before data reception.

- the RxD pin.
- [4] SCI status check and receive data. Read SSR and check that RDRF is 1. Then read the receive data in RDR and clear the RDRF flag to 0. Transitioning the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [5] Serial reception continuation procedure. To continue serial reception, before the stop bit for the current frame is received, read the RDRF flag, read the RDR, and clear the RDRF flag to 0. However, the RDRF flag is cleared automatically when the DTC is initiated by an RXI interrupt and reads data from RDR.

Legend
 ∨ : Logical add (OR)

Figure 14.12 Sample Serial Reception Flowchart (1)

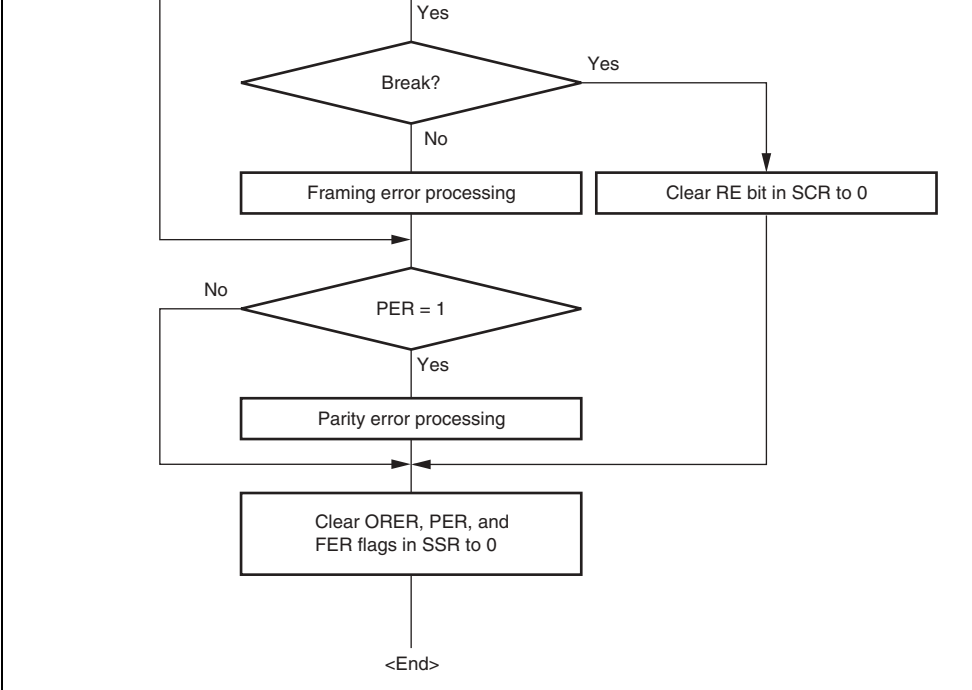

Figure 14.12 Sample Serial Reception Flowchart (2)

transmitting station first sends the ID code of the receiving station with which it wants to communicate as data with a 1 multiprocessor bit added. It then sends transmit data with a 0 multiprocessor bit added. When data with a 1 multiprocessor bit is received, the station compares that data with its own ID. The station whose ID matches then receives data sent next. Stations whose ID does not match continue to skip data until data with a 1 multiprocessor bit is again received.

The SCI uses the MPIE bit in SCR to implement this function. When the MPIE bit is set, the transfer of receive data from RSR to RDR, error flag detection, and setting the RDRF, FERR, and ORER status flags in SSR to 1 are prohibited until data with a 1 multiprocessor bit is received. After reception of a receive character with a 1 multiprocessor bit, the MPB bit in SSR is set to 1. The MPIE bit is automatically cleared, thus normal reception is resumed. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt is generated.

When the multiprocessor format is selected, the parity bit setting is invalid. All other bits are the same as those in normal asynchronous mode. The clock used for multiprocessor communication is the same as that in normal asynchronous mode.

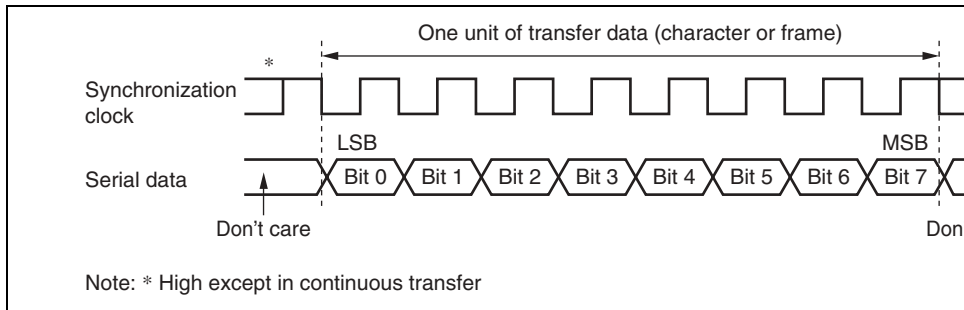

Figure 14.17 Data Format in Synchronous Communication (LSB-First)

14.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCK pin can be selected, according to the setting of the SCKE0 and CKE0 bits in SCR. When the SCI is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is fixed high.

- [2] Set the data transfer format in SMR and SCMR.
- [3] Write a value corresponding to the bit rate to BRR. This step is not necessary if an external clock is used.
- [4] Wait at least one bit interval, then set the TE bit or RE bit in SCR to 1. Also set the RIE, TIE, TEIE, and MPIE bits. Setting the TE and RE bits enables the TxD and RxD pins to be used.

Note: In simultaneous transmit and receive operations, the TE and RE bits should both be cleared to 0 or set to 1 simultaneously.

Figure 14.18 Sample SCI Initialization Flowchart

mode has been specified and synchronized with the input clock when use of an external clock has been specified.

4. The SCI checks the TDRE flag at the timing for sending the last bit.
5. If the TDRE flag is cleared to 0, data is transferred from TDR to TSR, and serial transmission of the next frame is started.
6. If the TDRE flag is set to 1, the TEND flag in SSR is set to 1, and the TxD pin main output state of the last bit. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt is generated. The SCK pin is fixed high.

Figure 14.20 shows a sample flowchart for serial data transmission. Even if the TDRE flag is cleared to 0, transmission will not start while a receive error flag (ORER, FER, or PER) is set. Make sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

Figure 14.19 Sample SCI Transmission Operation in Clock Synchronous Mode

TDRE flag to 0. However, the TDRE flag is checked and cleared automatically when the DTC is initiated by a transmit data empty interrupt (TXI) request and writes data to TDR.

Figure 14.20 Sample Serial Transmission Flowchart

transferred to RDR. If the RXIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt routine reads the receive data transferred to RDR, reception of the next receive data has finished, continuous reception can be enabled.

Figure 14.21 Example of SCI Receive Operation in Clock Synchronous Mode

Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the FER, PER, and RDRF bits to 0 before resuming reception. Figure 14.22 shows a sample for serial data reception.

data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 1 to 0 can also be identified by an RXI interrupt.

[5] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, reading the RDRF flag, reading RDR, and clearing the RDRF flag to 0 should be finished. However, the RDRF flag is cleared automatically when the DTC is initiated by a receive data full interrupt (RXI) and reads data from RDR.

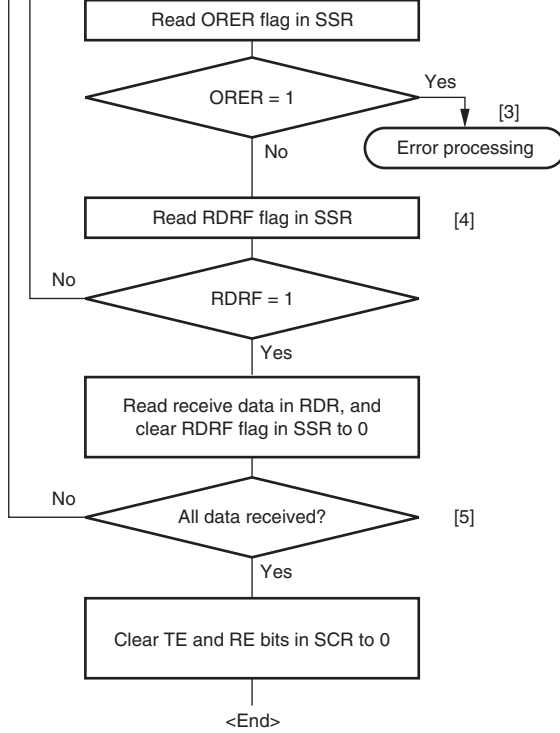

Figure 14.22 Sample Serial Reception Flowchart

14.6.6 SCI Selection in Serial Enhanced Mode

SCI_0 and SCI_2 provide the following capability according to the serial enhanced mode (SEMR_0 and SEMR_2) settings.

If the SCI is used in clock synchronous mode with clock input, the SCI channel can be enabled/disabled using the input at the external pins. The external pins include PA0/SSE1 (SCI_0) and PA1/SSE2I (SCI_2); therefore, this capability is not available in modes where PA0 and PA1 pins are automatically set for address output.

When the SCI operation is disabled (not selected) by input at the external pins, TxD output is fixed to the high-impedance state and SCK input is internally fixed to high. One-to-multiple communication is possible if the master device, which outputs SCK, controls these external pins for chip selection. SCI selection capability is selected using the SSE bits in SEMR.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first clear the TE bit and RE bit to 0, then set both these bits to 1 simultaneously.

ORER flag in SSR, and after performing the appropriate error processing, clear the ORER flag. Transmission/reception cannot be resumed if the ORER flag is set.

[4] SCI status check and receive read:

Read SSR and check that the flag is set to 1, then read the data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by interrupt.

[5] Serial transmission/reception continuation procedure:

To continue serial transmission/reception, before the MSB (bit 7) of the current frame is received, read the RDRF flag, read the data in RDR, and clearing the RDRF flag to 0 before the MSB (bit 7) of the next frame is transmitted, read 1 from the TDRE flag to confirm that writing data to TDR is possible. Then write data to TDR and clear the TDRE flag to 0. However, the TDRE flag is cleared automatically when the DTC is initiated by a transmit empty interrupt (TXI) request.

Similarly, when the DTC is initiated by a data full interrupt (RXI) and receive data from RDR.

Figure 14.23 Sample Flowchart of Simultaneous Serial Transmission and Reception

the SCK pin output to the CLK pin of the IC card. A reset signal can be supplied via the port of this LSI.

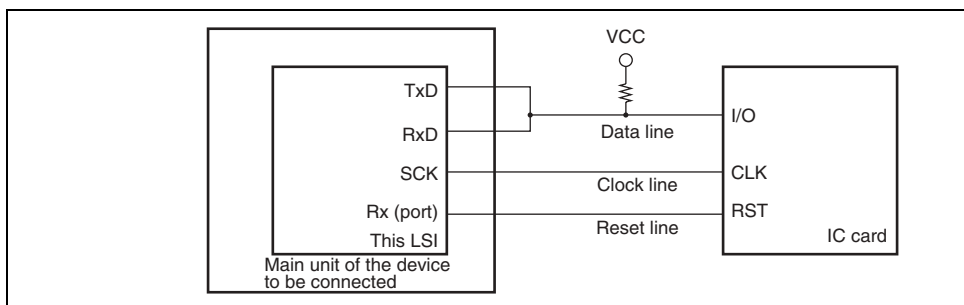

Figure 14.24 Pin Connection for Smart Card Interface

14.7.2 Data Format (Except in Block Transfer Mode)

Figure 14.25 shows the data transfer formats in smart card interface mode.

- One frame contains 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time after the end of the parity bit before the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after the error has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically re-transmitted after two or more etu.

Ds: Start bit
 D0 to D7: Data bits
 Dp: Parity bit
 DE: Error signal

Figure 14.25 Data Formats in Normal Smart Card Interface Mode

For communication with the IC cards of the direct convention and inverse convention type, follow the procedure below.

Figure 14.26 Direct Convention (SDIR = SINV = $O/\bar{E} = 0$)

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB-first as the start character, as shown in figure 14.26. Therefore, the start character in the figure is H'3B. When using the direct convention type, write 0 to the SDIR and SINV bits in SCMR. Write 0 to the O/\bar{E} bit in SMR in order to use even parity, which is prescribed by the smart card standard.

Figure 14.27 Inverse Convention (SDIR = SINV = $O/\bar{E} = 1$)

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively, and data is transferred with MSB-first as the start character, as shown in figure 14.27. Therefore, the start character in the figure is H'3F. When using the inverse convention type, write 1 to both the SDIR and SINV bits in SCMR. The parity bit is logic level 0 to produce even parity.

etu after transmission start.

- Although the ERS flag in block transfer mode displays the error signal status as in normal smart card interface mode, the flag is always read as 0 because no error signal is transmitted.

14.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the internal baud rate generator can be used as a communication clock in smart card interface mode. In this mode, the SCI can operate using an internal clock with a frequency of 32, 64, 372, or 256 times the bit rate according to the BCP1 and BCP2 register settings (the frequency is always 16 times the bit rate in normal asynchronous mode). At the start of reception, the falling edge of the start bit is sampled using the internal basic clock in order to perform internal synchronization. Receive data is sampled at the 16th, 32nd, 186th and 202nd rising edges of the basic clock pulses so that it can be latched at the center of each bit as shown in figure 14.28. The reception margin here is determined by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 [\%] \quad \dots \text{Formula (1)}$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock rate deviation

Assuming values of F = 0, D = 0.5, and N = 372 in formula (1), the reception margin is determined by the formula below.

$$M = \left(0.5 - \frac{1}{2 \times 372} \right) \times 100 [\%] = 49.866\%$$

Figure 14.28 Receive Data Sampling Timing in Smart Card Interface Mode (When Frequency is 372 Times the Bit Rate)

14.7.5 Initialization

Before starting transmitting and receiving data, initialize the SCI using the following procedure. Initialization is also necessary before switching from transmission to reception and vice versa.

1. Clear the TE and RE bits in SCR to 0.
2. Clear the error flags ORER, ERS, and PER in SSR to 0.
3. Set the GM, BLK, O/\bar{E} , BCP1, BCP0, CKS1, and CKS0 bits in SMR appropriately. Also set the PE bit to 1.
4. Set the SMIF, SDIR, and SINV bits in SCMR appropriately. When the SMIF bit is set, the TxD and RxD pins are changed from port pins to SCI pins, placing the pins into high impedance state.
5. Set the value corresponding to the bit rate in BRR.
6. Set the CKE1 and CKE0 bits in SCR appropriately. Clear the TIE, RIE, TE, RE, MPIE, and TEIE bits to 0 simultaneously. When the CKE0 bit is set to 1, the SCK pin is allowed to output clock pulses.
7. Set the TIE, RIE, TE, and RE bits in SCR appropriately after waiting for at least 1 bit time. Setting prohibited the TE and RE bits to 1 simultaneously except for self diagnosis.

To switch from reception to transmission, first verify that reception has completed, and initialize the SCI. At the end of initialization, RE and TE should be set to 0 and 1, respectively. Reception completion can be verified by reading the RDRF flag or PER and ORER flags. To switch from transmission to reception, first verify that transmission has completed, and initialize the SCI.

re-transferred from TDR to TSR allowing automatic data retransmission.

3. If no error signal is returned from the receiving end, the ERS bit in SSR is not set to case, one frame of data is determined to have been transmitted including re-transfer, TEND bit in SSR is set to 1. Here, a TXI interrupt request is generated if the TIE bit is set to 1. Writing transmit data to TDR starts transmission of the next data.

Figure 14.31 shows a sample flowchart for transmission. All the processing steps are automatically performed using a TXI interrupt request to activate the DTC. In transmission, TEND and TDRE flags in SSR are simultaneously set to 1, thus generating a TXI interrupt when TIE in SCR is set. This activates the DTC by a TXI request thus allowing transfer of transmit data if the TXI interrupt request is specified as a source of DTC activation before the TDRE and TEND flags are cleared. The TDRE and TEND flags are automatically cleared to 0 at data transfer by the DTC. If an error occurs, the SCI automatically re-transmits the same data. During re-transmission, TEND is set to 1 and TDR is set to the data to be re-transmitted. TEND is set to 0, thus not activating the DTC. Therefore, the SCI and DTC automatically transmit the specified number of bytes, including re-transmission in the case of error occurrence. However, the ERS flag is not automatically cleared; the ERS flag must be cleared by previously setting the ERS bit to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DTC, be sure to set and enable it prior to master/slave settings. For DTC settings, see section 7, Data Transfer Controller (DTC).

Note that the TEND flag is set in different timings depending on the GM bit setting in SM which is shown in figure 14.30.

Figure 14.30 TEND Flag Set Timings during Transmission

Figure 14.31 Sample Transmission Flowchart

Figure 14.33 shows a sample flowchart for reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DTC. In reception, setting the RDRF allows an RXI interrupt request to be generated when the RDRF flag is set to 1. This activates the DTC by an RXI request thus allowing transfer of receive data if the RXI interrupt request is specified as a source of DTC activate beforehand. The RDRF flag is automatically cleared after data transfer by DTC. If an error occurs during reception, i.e., either the ORER or PER flag is set to 1, a transmit/receive error interrupt (ERI) request is generated and the error flag must be cleared. If an error occurs, DTC is not activated and receive data is skipped, therefore, the number of bytes of receive data specified in DTC are transferred. Even if a parity error occurs and the PER flag is set to 1 in reception, receive data is transferred to RDR, thus allowing the data to be read.

Note: For operations in block transfer mode, see section 14.4, Operation in Asynchronous Mode

Figure 14.32 Data Re-transfer Operation in SCI Reception Mode

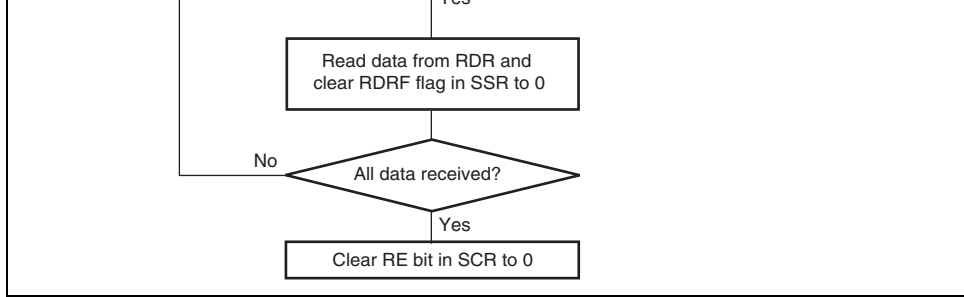

Figure 14.33 Sample Reception Flowchart

14.7.8 Clock Output Control

Clock output can be fixed using the CKE1 and CKE0 bits in SCR when the GM bit in SPCR is set to 1. Specifically, the minimum width of a clock pulse can be specified.

Figure 14.34 shows an example of clock output fixing timing when the CKE0 bit is controlled with GM = 1 and CKE1 = 0.

Figure 14.34 Clock Output Fixing Timing

At Transition from Smart Card Interface Mode to Software Standby Mode:

1. Set the port data register (DR) and data direction register (DDR) corresponding to the pins to the values for the output fixed state in software standby mode.
2. Write 0 to the TE and RE bits in SCR to stop transmission/reception. Simultaneously, CKE1 bit to the value for the output fixed state in software standby mode.
3. Write 0 to the CKE0 bit in SCR to stop the clock.
4. Wait for one cycle of the serial clock. In the mean time, the clock output is fixed to the specified level with the duty ratio retained.
5. Make the transition to software standby mode.

At Transition from Software Standby Mode to Smart Card Interface Mode:

1. Cancel software standby mode.
2. Write 1 to the CKE0 bit in SCR to start clock output. A clock signal with the appropriate ratio is then generated.

Figure 14.35 Clock Stop and Restart Procedure

Figure 14.36 IrDA Block Diagram

Transmission: During transmission, the output signals from the SCI (UART frames) are converted to IR frames using the IrDA interface (see figure 14.37).

For serial data of level 0, a high-level pulse having a width of $3/16$ of the bit rate (1-bit interval) is output (initial setting). The high-level pulse can be selected using the IrCKS2 to IrCKS0 bits in the SCICR.

The high-level pulse width is defined to be $1.41 \mu\text{s}$ at minimum and $(3/16 + 2.5\%) \times \text{bit interval}$ ($3/16 \times \text{bit rate}$) + $1.08 \mu\text{s}$ at maximum. For example, when the frequency of system clock is 10 MHz, a high-level pulse width of at least $1.41 \mu\text{s}$ to $1.6 \mu\text{s}$ can be specified.

For serial data of level 1, no pulses are output.

Figure 14.37 IrDA Transmission and Reception

Reception: During reception, IR frames are converted to UART frames using the IrDA interface before inputting to SCI_1.

Data of level 0 is output each time a high-level pulse is detected and data of level 1 is output if no pulse is detected in a bit cycle. If a pulse has a high-level width of less than 1.41 μs, the minimum width allowed, the pulse is recognized as level 0.

High-Level Pulse Width Selection: Table 14.13 shows possible settings for bits IrCKS2, IrCKS1, IrCKS0 (minimum pulse width), and this LSI's operating frequencies and bit rates, for a pulse width shorter than 3/16 times the bit rate in transmission.

10	100	100	100	100	100	100

20	101	101	101	101	101	101
25	110	110	110	110	110	110
33	110	110	110	110	110	110

When the RDRF flag in SSR is set to 1, an RXI interrupt request is generated. When the PER, or FER flag in SSR is set to 1, an ERI interrupt request is generated. An RXI interrupt activates the DTC to allow data transfer. The RDRF flag is automatically cleared to 0 at data transfer by the DTC.

A TEI interrupt is requested when the TEND flag is set to 1 while the TEIE bit is set to 1. If a TXI interrupt and a TEI interrupt are requested simultaneously, the TXI interrupt has priority acceptance. However, note that if the TDRE and TEND flags are cleared simultaneously in the TXI interrupt routine, the SCI cannot branch to the TEI interrupt routine later.

Table 14.14 SCI Interrupt Sources

Channel	Name	Interrupt Source	Interrupt Flag	DTC Activation
0	ERI0	Receive error	ORER, FER, PER	Not possible
	RX10	Receive data full	RDRF	Possible
	TX10	Transmit data empty	TDRE	Possible
	TE10	Transmit end	TEND	Not possible
1	ERI1	Receive error	ORER, FER, PER	Not possible
	RX11	Receive data full	RDRF	Possible
	TX11	Transmit data empty	TDRE	Possible
	TE11	Transmit end	TEND	Not possible
2	ERI2	Receive error	ORER, FER, PER	Not possible
	RX12	Receive data full	RDRF	Possible
	TX12	Transmit data empty	TDRE	Possible
	TE12	Transmit end	TEND	Not possible

1	ERI1	Receive error, error signal detection	ORER, PER, ERS	Not possible
	RX11	Receive data full	RDRF	Possible
	TX11	Transmit data empty	TEND	Possible
2	ERI2	Receive error, error signal detection	ORER, PER, ERS	Not possible
	RX12	Receive data full	RDRF	Possible
	TX12	Transmit data empty	TEND	Possible

Data transmission/reception using the DTC is also possible in smart card interface mode to in the normal SCI mode. In transmission, the TEND and TDRE flags in SSR are simultaneously set to 1, thus generating a TXI interrupt request. This activates the DTC by a TXI interrupt request thus allowing transfer of transmit data if the TXI interrupt request is specified as a source of DTC activation beforehand. The TDRE and TEND flags are automatically cleared to 0 at data transfer by the DTC. If an error occurs, the SCI automatically re-transmits the same data. During transmission, the TEND flag remains as 0, thus not activating the DTC. Therefore, the SCI does not activate the DTC automatically transmit the specified number of bytes, including re-transmission in the event of an error occurrence. However, the ERS flag in SSR, which is set at error occurrence, is not automatically cleared; the ERS flag must be cleared by previously setting the RIE bit in the SCI control register to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DTC, be sure to set and enable the DTC prior to making SCI settings. For DTC settings, see section 7, Data Transfer Controller (DTC).

In reception, an RXI interrupt request is generated when the RDRF flag in SSR is set to 1. This activates the DTC by an RXI interrupt request thus allowing transfer of receive data if the RXI interrupt request is specified as a source of DTC activation beforehand. The RDRF flag is automatically cleared to 0 at data transfer by the DTC. If an error occurs, the RDRF flag is cleared but the error flag is set. Therefore, the DTC is not activated and an ERI interrupt request is generated to the CPU instead; the error flag must be cleared.

Rev. 3.00, 03/04, page 10

and the FER flag may also be set. Note that, since the SCI continues the receive operation after receiving a break, even if the FER flag is cleared to 0, it will be set to 1 again.

14.10.3 Mark State and Break Sending

When the TE bit in SCR is 0, the TxD pin is used as an I/O port whose direction (input or output) and level are determined by DR and DDR of the port. This can be used to set the TxD pin state (high level) or send a break during serial data transmission. To maintain the communication line at mark state until TE is set to 1, set both DDR and DR to 1. Since the TE bit is cleared at this point, the TxD pin becomes an I/O port, and 1 is output from the TxD pin. To send a break during serial transmission, first set DDR to 1 and DR to 0, and then clear the TE bit to 0. When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission status. The TxD pin becomes an I/O port, and 0 is output from the TxD pin.

14.10.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode)

Transmission cannot be started when a receive error flag (ORER, FER, or RER) in SSR is set to 1, even if the TDRE flag in SSR is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be cleared to 0 even if the TE bit in SCR is cleared to 0.

14.10.5 Relation between Writing to TDR and TDRE Flag

Data can be written to TDR irrespective of the TDRE flag status in SSR. However, if the TDR is written to TDR when the TDRE flag is 0, that is, when the previous data has not been transferred to TSR yet, the previous data in TDR is lost. Be sure to write transmit data to TDR after verifying that the TDRE flag is set to 1.

Figure 14.38 Sample Transmission using DTC in Clock Synchronous Mode

14.10.7 SCI Operations during Mode Transitions

Transmission: Before making the transition to module stop, software standby, or sub-sleep mode, stop all transmit operations ($TE = TIE = TEIE = 0$). TSR, TDR, and SSR are reset. The output pins during each mode depend on the port settings, and the pins output a high signal after mode cancellation. If the transition is made during data transmission, the data transmitted will be undefined.

To transmit data in the same transmission mode after mode cancellation, set TE to 1, read and write to TDR, clear TDRE in this order, and then start transmission. To transmit data in a different transmission mode, initialize the SCI first.

Figure 14.39 shows a sample flowchart for mode transition during transmission. Figures 14.41 show the pin states during transmission.

Before making the transition from the transmission mode using DTC transfer to module stop, software standby, or sub-sleep mode, stop all transmit operations ($TE = TIE = TEIE = 0$). Setting TE and TIE to 1 after mode cancellation generates a TXI interrupt request to start transmission using the DTC.

Figure 14.45 shows a block diagram of the CRC operation circuit.

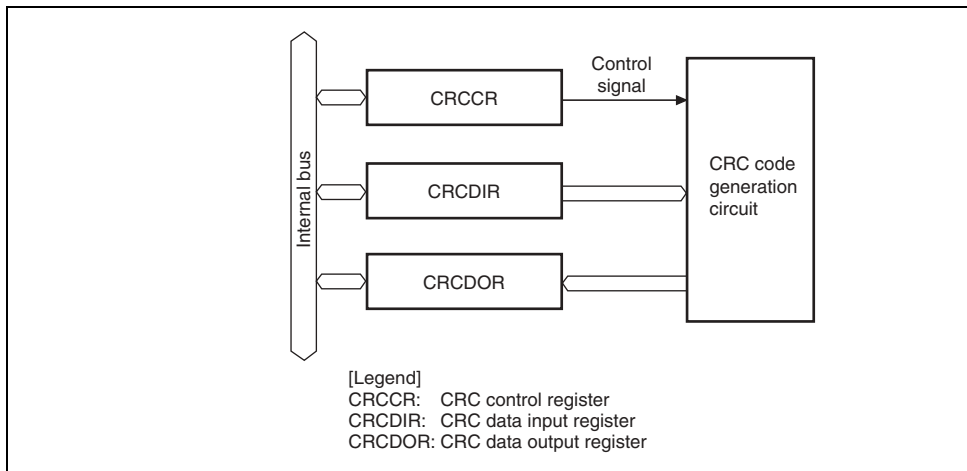

Figure 14.45 Block Diagram of CRC Operation Circuit

14.11.2 Register Descriptions

The CRC operation circuit has the following registers.

- CRC control register (CRCCR)
- CRC data input register (CRCDIR)
- CRC data output register (CRCDOR)

communication. The lower byte (bits 7 to 0) is transmitted when CRCDOR contents (bits 15 to 8) are divided into two bytes to be transmitted in two parts.

1: Performs CRC operation for MSB-first communication. The upper byte (bits 15 to 8) is first transmitted when CRCDOR contents (bits 15 to 8) are divided into two bytes to be transmitted in two parts.

1	G1	0	R/W	CRC Generating Polynomial Select
0	G0	0	R/W	These bits select the polynomial.
00: Reserved				
01: $X^8 + X^2 + X + 1$				
10: $X^{16} + X^{15} + X^2 + 1$				
11: $X^{16} + X^{12} + X^5 + 1$				

CRC Data Input Register (CRCDIR): CRCDIR is an 8-bit readable/writable register, the bytes to be CRC-operated are written. The result is obtained in CRCDOR.

CRC Data Output Register (CRCDOR): CRCDOR is a 16-bit readable/writable register that contains the result of CRC operation when the bytes to be CRC-operated are written to CRCDIR after CRCDOR is cleared. When the CRC operation result is additionally written to the CRCDOR, which CRC operation is to be performed, the CRC operation result will be H'0000 if the CRCDOR contains no CRC error. When bits 1 and 0 in CRCCR (G1 and G0 bits) are set to 0 and 1 respectively, the lower byte of this register contains the result.

- I²C bus status register (ICSR)
- I²C bus extended control register (ICXR)
- I²C SMBus control register (ICSMBCR)

15.3.1 I²C Bus Data Register (ICDR)

ICDR is an 8-bit readable/writable register that is used as a transmit data register when transmitting and a receive data register when receiving. ICDR is divided internally into transmit register (ICDRS), receive buffer (ICDRR), and transmit buffer (ICDRT). Data transfers to and from these three registers are performed automatically in accordance with changes in the bus state, and they affect the status of internal flags such as ICDRE and ICDRF.

In master transmit mode with the I²C bus format, writing transmit data to ICDR should be performed after start condition detection. When the start condition is detected, previous data in ICDR is ignored. In slave transmit mode, writing should be performed after the slave address is detected and the TRS bit is automatically changed to 1.

If IIC is in transmit mode (TRS=1) and the next data is in ICDRT (the ICDRE flag is 0), data is transferred automatically from ICDRT to ICDRS, following transmission of one frame of data using ICDRS. When the ICDRE flag is 1 and the next transmit data writing is waited, data is transferred automatically from ICDRT to ICDRS by writing to ICDR. If IIC is in receive mode (TRS=0), no data is transferred from ICDRT to ICDRS. Note that data should not be written to ICDR in receive mode.

Reading receive data from ICDR is performed after data is transferred from ICDRS to ICDR.

15.3.2 Slave Address Register (SAR)

SAR sets the slave address and selects the communication format. When the LSI is in slave mode with the I²C bus format selected, if the FS bit is set to 0 and the upper 7 bits of SAR match the upper 7 bits of the first frame received after a start condition, the LSI operates as the slave device specified by the master device. SAR can be accessed only when the ICE bit in ICCR is cleared to 0.

Bit	Bit Name	Initial Value	R/W	Description
7	SVA6	All 0	R/W	Slave Address Set a slave address.
6	SVA5			
5	SVA4			
4	SVA3			
3	SVA2			
2	SVA1			
1	SVA0			
0	FS	0	R/W	Format Select Selects the communication format together with the FS bit in SARX. Refer to table 15.2. This bit should be set to 0 when general call address recognition is performed.

5 SVAX4
 4 SVAX3
 3 SVAX2
 2 SVAX1
 1 SVAX0

Set the second slave address.

0	FSX	1	R/W	Format Select X
---	-----	---	-----	-----------------

Selects the communication format together with **FS** in SAR. Refer to table 15.2.

Table 15.2 Transfer Format

SAR	SARX	Operating Mode
FS	FSX	
0	0	I ² C bus format <ul style="list-style-type: none"> • SAR and SARX slave addresses recognized • General call address recognized
	1	I ² C bus format <ul style="list-style-type: none"> • SAR slave address recognized • SARX slave address ignored • General call address recognized
1	0	I ² C bus format <ul style="list-style-type: none"> • SAR slave address ignored • SARX slave address recognized • General call address ignored
	1	Clocked synchronous serial format <ul style="list-style-type: none"> • SAR and SARX slave addresses ignored • General call address ignored

0: MSB-first

1: LSB-first

Set this bit to 0 when the I²C bus format is used.

6	WAIT	0	R/W	Wait Insertion Bit
---	------	---	-----	--------------------

This bit is valid only in master mode with the I²C bus format.

0: Data and the acknowledge bit are transferred consecutively with no wait inserted.

1: After the fall of the clock for the final data bit (8th bit), the IRIC flag is set to 1 in ICCR, and a wait state is entered (with SCL at the low level). When the IRIC flag is cleared to 0 in ICCR, the wait ends and the acknowledge bit is transferred.

For details, refer to section 15.4.7, IRC Setting Timing Diagram, SCL Control.

5	CKS2	All 0	R/W	Transfer Clock Select
4	CKS1			
3	CKS0			

These bits are used only in master mode.

These bits select the required transfer rate, together with the IICX5 (channel 5), IICX4 (channel 4), and IICX3 (channel 3) bits in IICX3, and the IICX2 (channel 2), IICX1 (channel 1), and IICX0 (channel 0) bits in STCR. For details, refer to table 15.3.

B'001: 2 bits	B'001: 1 bits
B'010: 3 bits	B'010: 2 bits
B'011: 4 bits	B'011: 3 bits
B'100: 5 bits	B'100: 4 bits
B'101: 6 bits	B'101: 5 bits
B'110: 7 bits	B'110: 6 bits
B'111: 8 bits	B'111: 7 bits

15.3.5 I²C Bus Transfer Rate Select Register (IICX3)

IICX3 selects the IIC transfer rate clock and sets the transfer rate of IIC channels 3 to 5.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	—	—	Reserved These bits cannot be modified.
3	TCSS	0	R/W	Transfer Rate Clock Source Select This bit selects a clock rate to be applied to the IIC transfer rate. 0: $\phi/2$ 1: $\phi/4$
2 1 0	IICX5 IICX4 IICX3	All 0	R/W	IIC Transfer Rate Select These bits are used to control IIC operation. These bits select the transfer rate in master mode together with the CKS2 to CKS0 bits in ICMR. For transfer rate, see table 15.3. IICX5, IICX4, and IICX3 control IIC_5, IIC_4, and IIC_3, respectively

			1	$\phi/100$	50.0	80.0	100.0	160.0	200.0	250.0
		1	0	$\phi/112$	44.6	71.4	89.3	142.9	178.6	223.2
			1	$\phi/128$	39.1	62.5	78.1	125.0	156.3	195.3

(n = 0 to 5)

accessed.

6	IEIC	0	R/W	I ² C Bus Interface Interrupt Enable 0: Disables interrupts from the I ² C bus interface to 1: Enables interrupts from the I ² C bus interface to
5	MST	0	R/W	Master/Slave Select
4	TRS	0	R/W	Transmit/Receive Select 00: Slave receive mode 01: Slave transmit mode 10: Master receive mode 11: Master transmit mode Both these bits will be cleared by hardware when in a bus contention in master mode of the I ² C bus In slave receive mode with I ² C bus format, the R \bar{V} the first frame immediately after the start condition automatically sets these bits in receive mode or tra mode by hardware. Modification of the TRS bit during transfer is defer transfer is completed, and the changeover is made completion of the transfer.

- (1) When 0 is written by software (except for TRS setting condition 3)
- (2) When 0 is written in TRS after reading TRS = TRS setting condition 3)
- (3) When lost in bus contention in I²C bus format mode

[TRS setting conditions]

- (1) When 1 is written by software (except for TRS setting condition 3)
- (2) When 1 is written in TRS after reading TRS = TRS clearing condition 3)
- (3) When 1 is received as the R \overline{W} bit after the first address matching in I²C bus format slave mode

3	ACKE	0	R/W	<p>Acknowledge Bit Decision Selection</p> <p>0: The value of the acknowledge bit is ignored, and continuous transfer is performed. The value of the received acknowledge bit is not indicated by the bit in ICSR, which is always 0.</p> <p>1: If the acknowledge bit is 1, continuous transfer is halted.</p> <p>Depending on the receiving device, the acknowledge bit may be significant, in indicating completion of processing of the received data, for instance, or may be fixed to 0 and have no significance.</p>
---	------	---	-----	--

[BBSY setting condition]

- When the SDA level changes from high to low, the condition of SCL = high, assuming that the condition has been issued.

[BBSY clearing conditions]

- When the SDA level changes from low to high, the condition of SCL = high, assuming that the condition has been issued.

To issue a start/stop condition, use the MOV instruction.

The I²C bus interface must be set in master transmit mode before the issue of a start condition. Set MST to 1 and TRS to 1 before writing 1 in BBSY and 0 in SCP.

The BBSY flag can be read to check whether the bus (SCL, SDA) is busy or free.

after a start condition is issued (when the ICDR bit is set to 1 because of first frame transmission)

- When a wait is inserted between the data and acknowledge bit when the WAIT bit is 1 (fall of transmit/receive clock)
- At the end of data transfer (rise of the 9th transmit/receive clock)
- When a slave address is received after bus master address is lost
- If 1 is received as the acknowledge bit (when the ACKB bit in ICSR is set to 1) when the ACKE bit is 1
- When the AL flag is set to 1 after bus mastership is lost while the ALIE bit is 1

I²C bus format slave mode:

- When the slave address (SVA or SVAX) matches the AAS or AASX flag in ICSR is set to 1) and at the end of data transfer up to the subsequent retransmission start condition or stop condition (rise of the 9th clock)
- When the general call address is detected (when 1 is received for R \overline{W} bit, and ADZ flag in ICSR is set to 1) and at the end of data reception up to the subsequent retransmission start condition or stop condition (rise of the 9th receive clock)
- When 1 is received as an acknowledge bit when the ACKE bit is 1 (when the ACKB bit is set to 1)
- When a stop condition is detected while the STOP bit is 0 (when the STOP or ESTP flag in ICSR is set to 1)

(when data is transferred from ICDRT to ICDR, the ICDRE flag is set to 1, and the ICDRF flag is set to 1.)
is transferred from ICDRS to ICDRR in receive mode and the ICDRF flag is set to 1.)

[Clearing conditions]

- When 0 is written in IRIC after reading IRIC = 1.
- When ICDR is accessed by DTC *2 (This may be a clearing condition. For details, see the description of the DTC operation on the next page.)

-
- Notes:
1. Only 0 can be written to clear the flag to 0.
 2. The DTC does not support IIC_4 and IIC_5.
 3. If the BBSY bit is written to, the value of the flag is not changed.

ICDR and ICDR flags are not cleared at the end of the specified number of transfers in each transfer using the DTC. The ICDRE or ICDRF flag is cleared, however, since the specified number of ICDR reads or writes have been completed.

Tables 15.4 and 15.5 show the relationship between the flags and the transfer states.

1	ADZ	0	R/(W)*	<p>General Call Address Recognition Flag</p> <p>In I²C bus format slave receive mode, this flag is set to 1 when the first frame following a start condition is the general call address (H'00).</p> <p>[Setting condition]</p> <p>When the general call address (one frame including the slave address bit is H'00) is detected in slave receive mode and FS=1 or FSX = 0</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When ICDR is written to (transmit mode) or read (receive mode)• When 0 is written in ADZ after reading ADZ =• In master mode <p>If a general call address is detected while FS=1 and FSX=0, the ADZ flag is set to 1; however, the general call address is not recognized (AAS flag is not set to 1).</p>
---	-----	---	--------	--

Receive mode:

0: Returns 0 as acknowledge data after data reception

1: Returns 1 as acknowledge data after data reception

When this bit is read, the value loaded from the bus (returned by the receiving device) is read in transmission (when TRS = 1). In reception (when TRS = 0), the value set by internal software is read.

When this bit is written, acknowledge data that is read after receiving is rewritten regardless of the TRS value. If the ICSR register bit is written using bit-manipulation instructions, the acknowledge data should be rewritten by the acknowledge data setting is rewritten by the ACKB reading value.

Write the ACKE bit to 0 to clear the ACKB flag to 0 after transmission is ended and a stop condition is issued in master mode, or before transmission is ended and the device is released to issue a stop condition by a master device.

Note: * Only 0 can be written to clear the flag.

1: Disables IRIC flag setting and interrupt generation when the stop condition is detected.

6	HNDS	0	R/W	<p>Handshake Receive Operation Select</p> <p>Enables or disables continuous receive operation in receive mode.</p> <p>0: Enables continuous receive operation</p> <p>1: Disables continuous receive operation</p> <p>When the HNDS bit is cleared to 0, receive operation is performed continuously after data has been received successfully while ICDRF flag is 0.</p> <p>When the HNDS bit is set to 1, SCL is fixed to the high level after data has been received successfully while ICDRF flag is 0; thus disabling the next data to be transferred. The bus line is released and next receive operation is enabled by reading the receive data.</p>
---	------	---	-----	--

(1) When data is received successfully while ICDR is read (at the rise of the 9th clock pulse).

(2) When ICDR is read successfully in receive mode, data was received while ICDRF = 1.

[Clearing conditions]

- When ICDR (ICDRR) is read.
- When 0 is written to the ICE bit.

When ICDRF is set due to the condition (2) above, it is temporarily cleared to 0 when ICDR (ICDRR) is read. However, since data is transferred from ICDRS to ICDRR immediately, ICDRF is set to 1 again.

Note that ICDR cannot be read successfully in transmit mode (TRS = 1) because data is not transferred from ICDRS to ICDRR. Be sure to read data from ICDR in receive mode (TRS = 0).

- When data is transferred from ICDRT to ICDR
 1. When data is transmitted completely while $ICDRF = 0$ (at the rise of the 9th clock pulse).
 2. When data is written to ICDR completely in ICDR mode after data was transmitted while ICDRT mode.

[Clearing conditions]

- When data is written to ICDR (ICDRT).
- When the stop condition is detected in I²C bus format or serial format.
- When 0 is written to the ICE bit.

Note that if the ACKE bit is set to 1 in I²C bus format, enabling acknowledge bit decision, ICDRE is not cleared when data is transmitted completely while the acknowledge bit is 1.

When ICDRE is set due to the condition (2) above, ICDRE is temporarily cleared to 0 when data is written to ICDR (ICDRT); however, since data is transferred from ICDRT to ICDR immediately, ICDRF is set to 1 again. Do not transfer data to ICDR when TRS = 0 because the ICDRE value is invalid during the time.

1: If the SDA pin state disagrees with the data that the interface outputs at the rise of SCL and the SDA pin is driven low by another device in idle state or after a start condition instruction was executed.

1	FNC1	0	R/W	Function Bit
0	FNC0	0	R/W	These bits cancel some restrictions on usage. For more information, refer to section 15.6, Usage Notes.

00: Restrictions on operation remaining in effect
01: Setting prohibited
10: Setting prohibited
11: Restrictions on operation canceled

6	SMB4E			These bits enable/disable to support the SMBus, combining with bits FSEL1 and FSEL0. The SMB4E bit controls IIC_5, the SMB3E bit controls IIC_4, the SMB2E bit controls IIC_3, the SMB1E bit controls IIC_2, the SMB0E bit controls IIC_1.

0: Disables to support the SMBus				
1: Enables to support the SMBus				
1	FSEL1	0	R/W	Frequency Selection
0	FSEL0	0	R/W	These bits must be specified to match the system frequency in order to support the SMBus. For default setting, see table 15.7.

	Max.	2200*	1667*	1375*	1100*	827	688	550	440
1	Min.	2000*	1515*	1250*	1000*	752	625	500	400
	Max.	3800*	2879*	2375*	1900*	1429*	1188*	950	760

Notes: n = 0 to 5

* Since the value is outside the SMBus specification, it should not be set.

Table 15.7 ISCMBCR Setting

System Clock	SMBnE	FSEL1	FSEL0
5 to 6.6 MHz	0	0	0
6.6 to 10 MHz	1	0	0
10 to 13.3 MHz	1	0	1
13.3 to 20 MHz	1	1	0
20 to 33 MHz	1	1	1

n = 0 to 5

The symbols used in figures 15.3 to 15.5 are explained in table 15.8.

Figure 15.3 I²C Bus Data Formats (I²C Bus Formats)

Figure 15.4 I²C Bus Data Formats (Serial Formats)

R/ \overline{W}	Indicates the direction of data transfer: from the slave device to the master device when R/ \overline{W} is 1, or from the master device to the slave device when R/W is 0.
A	Acknowledge. (The receiving device drives SDA low to acknowledge a transfer. The slave device returns acknowledge in master transmit mode, and the master device returns acknowledge in master receive mode.)
DATA	Transferred data. The bit length of transferred data is set with the BC2 to BC0 bits in ICMR. The MSB first or LSB first is switched with the MLS bit in ICMR.
P	Stop condition. The master device drives SDA from low to high while SCL is high.

Figure 15.6 Sample Flowchart for IIC Initialization

Note: Be sure to modify the ICMR register after transmit/receive operation has been completed. If the ICMR register is modified during transmit/receive operation, bit counter EBC0 will be modified erroneously, thus causing incorrect operation.

15.4.3 Master Transmit Operation

In I²C bus format master transmit mode, the master device outputs the transmit clock and data, and the slave device returns an acknowledge signal.

Figure 15.7 Sample Flowchart for Operations in Master Transmit Mode

The transmission procedure and operations by which data is sequentially transmitted in synchronization with ICDR (ICDRT) write operations, are described below.

clear IRIC continuously so no other interrupt handling routine is executed. If the transmission of one frame of data has passed before the IRIC clearing, the end of transmission cannot be determined. The master device sequentially sends the transmit clock and the data written to ICDR. The selected slave device (i.e. the slave device matching slave address) drives SDA low at the 9th transmit clock pulse and returns acknowledge signal.

- [7] When one frame of data has been transmitted, the IRIC flag is set to 1 at the rise of transmit clock pulse. After one frame has been transmitted, SCL is automatically forced into synchronization with the internal clock until the next transmit data is written.
- [8] Read the ACKB bit in ICSR to confirm that ACKB is cleared to 0. When the slave device has not acknowledged (ACKB bit is 1), operate step [12] to end transmission, and then start transmit operation.
- [9] Write the transmit data to ICDR.
As indicating the end of the transfer, the IRIC flag is cleared to 0. Perform the ICDR clearing and the IRIC flag clearing sequentially, just as in step [6]. Transmission of the next frame is performed in synchronization with the internal clock.
- [10] When one frame of data has been transmitted, the IRIC flag is set to 1 at the rise of transmit clock pulse. After one frame has been transmitted, SCL is automatically forced into synchronization with the internal clock until the next transmit data is written.
- [11] Read the ACKB bit in ICSR.
Confirm that the slave device has been acknowledged (ACKB bit is 0). When there is no data to be transmitted, go to step [9] to continue the next transmission operation. When the slave device has not acknowledged (ACKB bit is set to 1), operate step [12] to end transmission.
- [12] Clear the IRIC flag to 0.
Write 0 to ACKE in ICCR, to clear received ACKB contents to 0. Write 0 to BBSY in ICCR. This changes SDA from low to high when SCL is high, and generates the acknowledge condition.

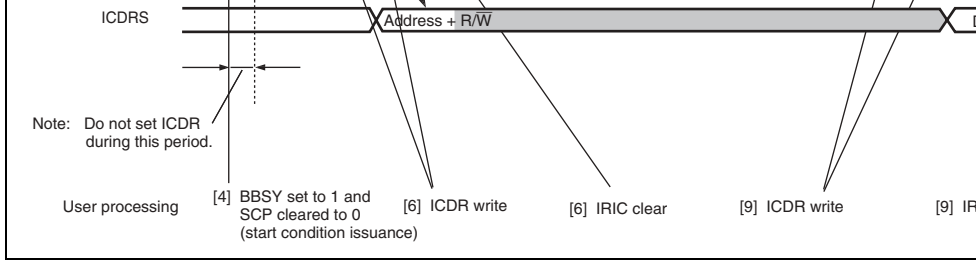

Figure 15.8 Operation Timing Example in Master Transmit Mode (MLS = WAIT)

Figure 15.9 Stop Condition Issuance Operation Timing Example in Master Transmit Mode (MLS = WAIT = 0)

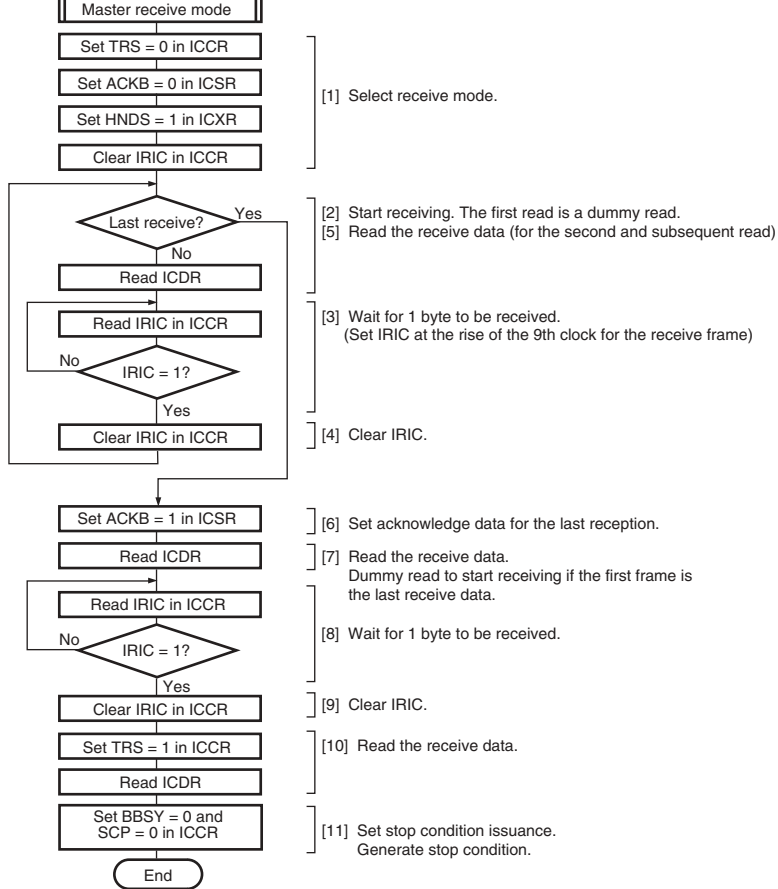

Figure 15.10 Sample Flowchart for Operations in Master Receive Mode (HND)

- [3] The master device drives SDA low to return the acknowledge data at the 9th receive clock pulse. The receive data is transferred to ICDRR from ICDRS at the rise of the 9th receive clock pulse, setting the ICDRF, IRIC, and IRTR flags to 1. If the IEIC bit has been set to 1, an interrupt request is sent to the CPU.
- The master device drives SCL low from the fall of the 9th receive clock pulse to the start of data reading.
- [4] Clear the IRIC flag to determine the next interrupt.
- Go to step [6] to halt reception operation if the next frame is the last receive data.
- [5] Read ICDR receive data. This clears the ICDRF flag to 0. The master device outputs the receive clock continuously to receive the next data.
- Data can be received continuously by repeating steps [3] to [5].
- [6] Set the ACKB bit to 1 so as to return the acknowledge data for the last reception.
- [7] Read ICDR receive data. This clears the ICDRF flag to 0. The master device outputs the receive clock to receive data.
- [8] When one frame of data has been received, the ICDRF, IRIC, and IRTR flags are set to 1 at the rise of the 9th receive clock pulse.
- [9] Clear the IRIC flag to 0.
- [10] Read ICDR receive data after setting the TRS bit. This clears the ICDRF flag to 0.
- [11] Clear the BBSY bit and SCP bit to 0 in ICCR. This changes SDA from low to high, SCL is high, and generates the stop condition.

**Figure 15.11 Master Receive Mode Operation Timing Example
(MLS = WAIT = 0, HNDS = 1)**

**Figure 15.12 Stop Condition Issuance Timing Example in Master Receive Mode
(MLS = WAIT = 0, HNDS = 1)**

Figure 15.13 Sample Flowchart for Operations in Master Receive Mode (receiving multiple bytes) (WAIT = 1)

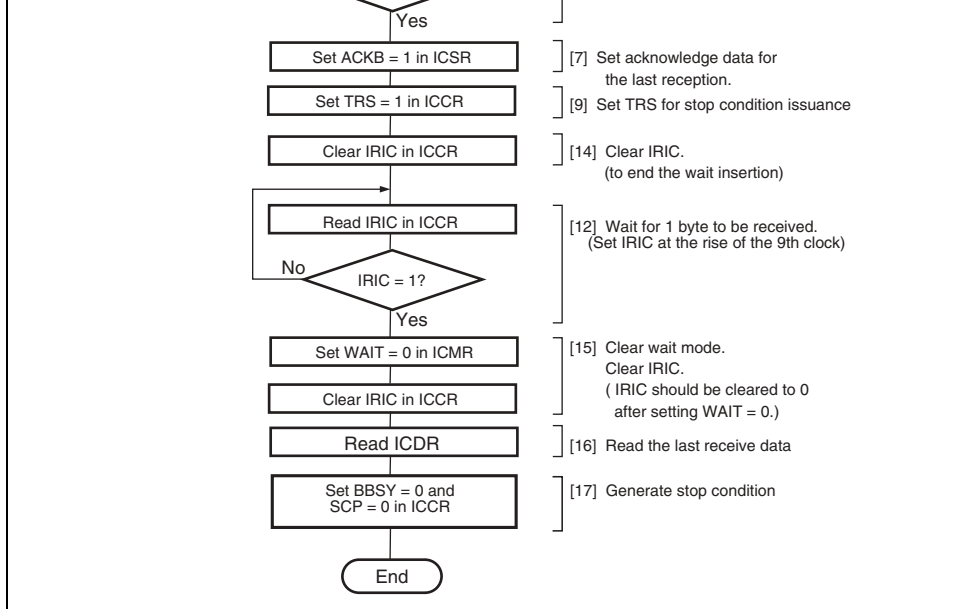

Figure 15.14 Sample Flowchart for Operations in Master Receive Mode (receiving a single byte) (WAIT = 1)

The reception procedure and operations using the wait function (WAIT bit), by which data is sequentially received in synchronization with ICDR (ICDRR) read operations, are described below.

The following describes the multiple-byte reception procedure. In single-byte reception, steps of the following procedure are omitted. At this time, follow the procedure shown in Figure 15.14

The IRTR and ICDRF flags are set to 1, indicating that one frame of data has been received. The master device outputs the receive clock continuously to receive data.

- [4] Read the IRTR flag in ICSR.
If the IRTR flag is 0, execute step [6] to clear the IRIC flag to 0 to release the wait.
If the IRTR flag is 1 and the next data is the last receive data, execute step [7] to halt reception.
- [5] If IRTR flag is 1, read ICDR receive data.
- [6] Clear the IRIC flag. When the flag is set as (1) in step [3], the master device outputs the receive clock and drives SDA low at the 9th receive clock pulse to return an acknowledge.

Data can be received continuously by repeating steps [3] to [6].

- [7] Set the ACKB bit in ICSR to 1 so as to return the acknowledge data for the last receive data.
- [8] After the IRIC flag is set to 1, wait for at least one clock pulse until the rise of the next receive clock pulse for the next receive data.
- [9] Set the TRS bit in ICCR to 1 to switch from receive mode to transmit mode. The TRS value becomes valid when the rising edge of the next 9th clock pulse is input.
- [10] Read the ICDR receive data.
- [11] Clear the IRIC flag to 0.
- [12] The IRIC flag is set to 1 in either of the following cases.
 - (1) At the fall of the 8th receive clock pulse for one frame
SCL is automatically fixed low in synchronization with the internal clock until the IRIC flag is cleared.
 - (2) At the rise of the 9th receive clock pulse for one frame
The IRTR and ICDRF flags are set to 1, indicating that one frame of data has been received.

SCL is high, and generates the stop condition.

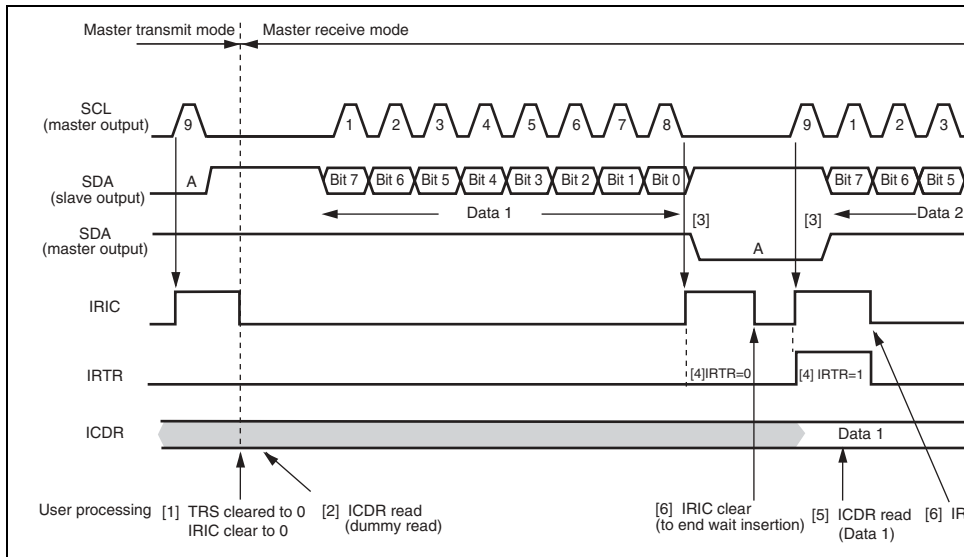

Figure 15.15 Master Receive Mode Operation Timing Example
(MLS = ACKB = 0, WAIT = 1)

Figure 15.16 Stop Condition Issuance Timing Example in Master Receive Mode
(MLS = ACKB = 0, WAIT = 1)

15.4.5 Slave Receive Operation

In I²C bus format slave receive mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal.

The slave device operates as the device specified by the master device when the slave address of the first frame following the start condition that is issued by the master device matches its own address.

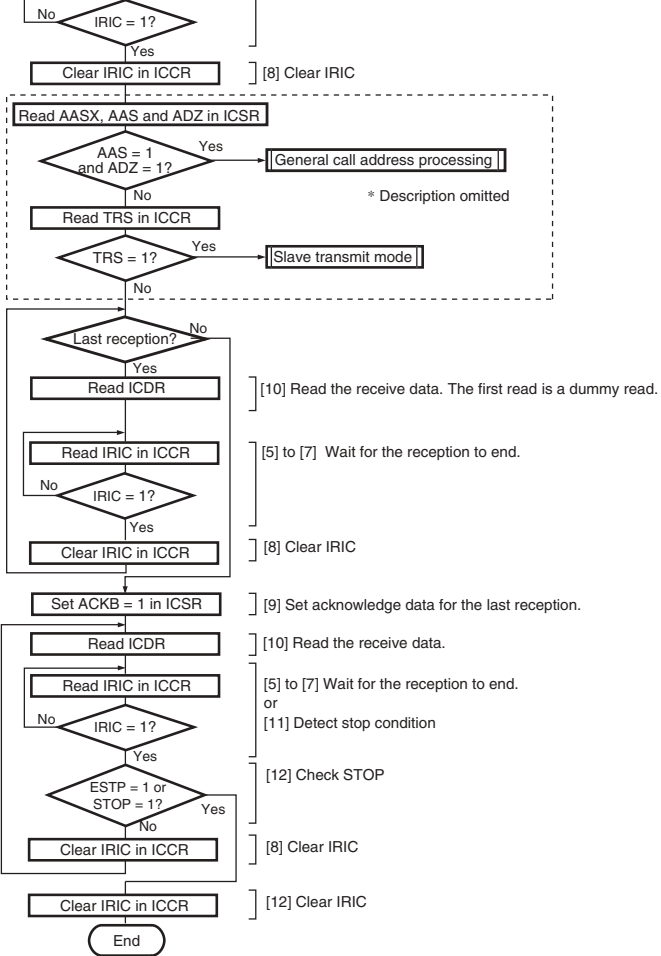

Figure 15.17 Sample Flowchart for Operations in Slave Receive Mode (HND)

- [4] When the slave address matches in the first frame following the start condition, the slave device operates as the slave device specified by the master device. If the 8th data bit ($\overline{R/W}$) TRS bit remains cleared to 0, and slave receive operation is performed. If the 8th data bit ($\overline{R/W}$) is 1, the TRS bit is set to 1, and slave transmit operation is performed. When the slave address does not match, receive operation is halted until the next start condition is detected.
- [5] At the 9th clock pulse of the receive frame, the slave device returns the data in the ADR register as the acknowledge data.
- [6] At the rise of the 9th clock pulse, the IRIC flag is set to 1. If the IEIC bit has been set to 1, an interrupt request is sent to the CPU.
If the AASX bit has been set to 1, IRTR flag is also set to 1.
- [7] At the rise of the 9th clock pulse, the receive data is transferred from ICDRS to ICDR, setting the ICDRF flag to 1. The slave device drives SCL low from the fall of the 9th clock pulse until data is read from ICDR.
- [8] Confirm that the STOP bit is cleared to 0, and clear the IRIC flag to 0.
- [9] If the next frame is the last receive frame, set the ACKB bit to 1.
- [10] If ICDR is read, the ICDRF flag is cleared to 0, releasing the SCL bus line. This enables the master device to transfer the next data.

Receive operations can be performed continuously by repeating steps [5] to [10].

- [11] When the stop condition is detected (SDA is changed from low to high when SCL is high), the BBSY flag is cleared to 0 and the STOP bit is set to 1. If the STOPI bit has been set to 1, the IRIC flag is set to 1.
- [12] Confirm that the STOP bit is set to 1, and clear the IRIC flag to 0.

Figure 15.18 Slave Receive Mode Operation Timing Example (1)
(MLS = 0, HNDS= 1)

Figure 15.19 Slave Receive Mode Operation Timing Example (2)
(MLS = 0, HNDS= 1)

Figure 15.20 Sample Flowchart for Operations in Slave Receive Mode (HNDS)

- TRIS bit remains cleared to 0, and slave receive operation is performed. If the start condition (R/ \bar{W}) is 1, the TRS bit is set to 1, and slave transmit operation is performed. When address does not match, receive operation is halted until the next start condition is detected.
- [5] At the 9th clock pulse of the receive frame, the slave device returns the data in the ICDR register as the acknowledge data.
 - [6] At the rise of the 9th clock pulse, the IRIC flag is set to 1. If the IEIC bit has been set to 1, an interrupt request is sent to the CPU.
If the AASX bit has been set to 1, the IRTR flag is also set to 1.
 - [7] At the rise of the 9th clock pulse, the receive data is transferred from ICDRS to ICDR, setting the ICDRF flag to 1.
 - [8] Confirm that the STOP bit is cleared to 0 and clear the IRIC flag to 0.
 - [9] If the next read data is the third last receive frame, wait for at least one frame time before setting the ACKB bit. Set the ACKB bit after the rise of the 9th clock pulse of the second last receive frame.
 - [10] Confirm that the ICDRF flag is set to 1 and read ICDR. This clears the ICDRF flag.
 - [11] At the rise of the 9th clock pulse or when the receive data is transferred from IRDR to ICDR due to ICDR read operation, The IRIC and ICDRF flags are set to 1.
 - [12] When the stop condition is detected (SDA is changed from low to high when SCL is high), the BBSY flag is cleared to 0 and the STOP or ESTP flag is set to 1. If the STOPIN bit has been cleared to 0, the IRIC flag is set to 1. In this case, execute step [14] to read the receive data.
 - [13] Clear the IRIC flag to 0.

Receive operations can be performed continuously by repeating steps [9] to [13].

- [14] Confirm that the ICDRF flag is set to 1, and read ICDR.
- [15] Clear the IRIC flag.

Figure 15.21 Slave Receive Mode Operation Timing Example (1)
 (MLS = ACKB = 0, HNDS = 0)

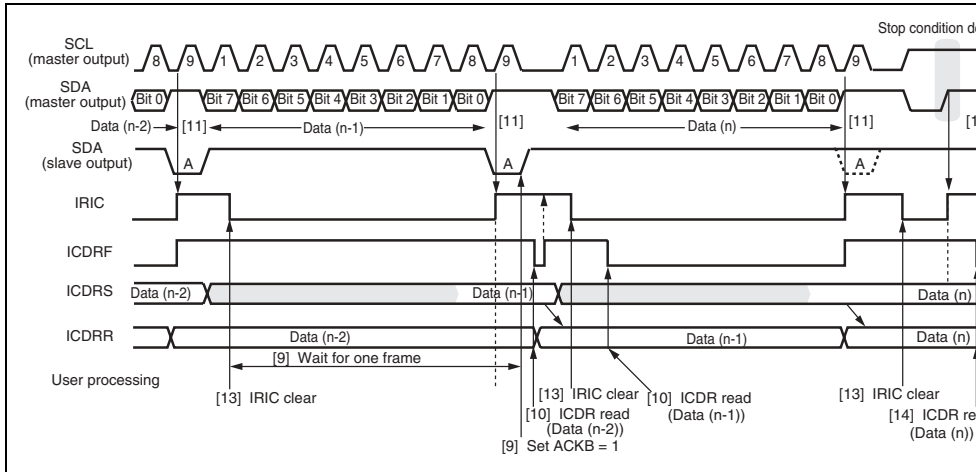

Figure 15.22 Slave Receive Mode Operation Timing Example (2)
 (MLS = ACKB = 0, HNDS = 0)

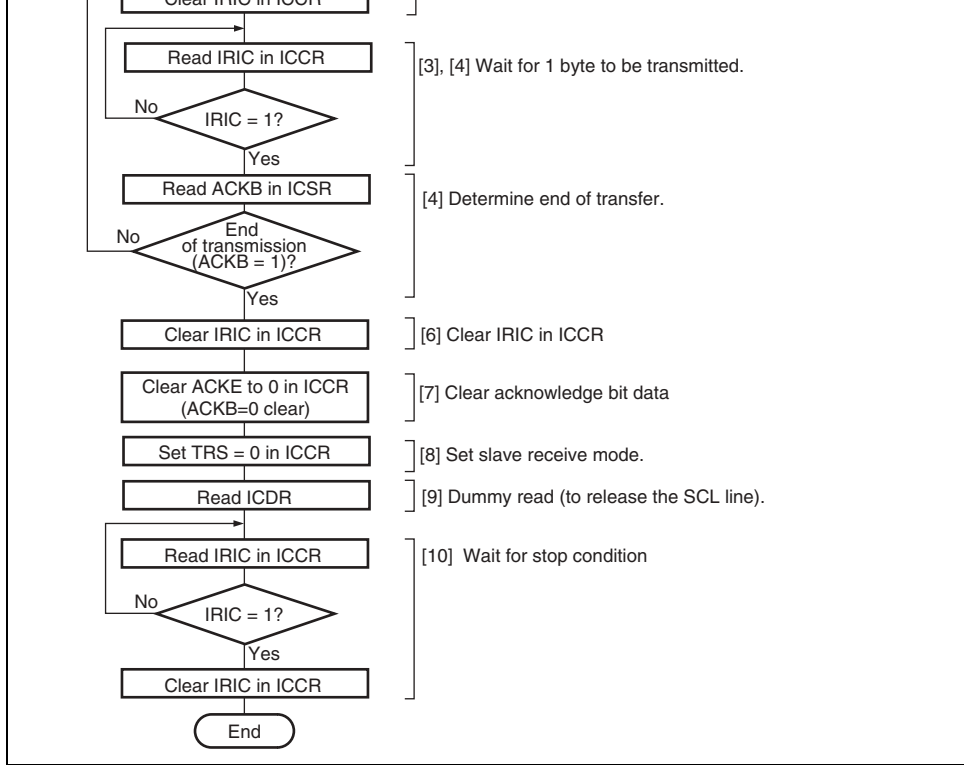

Figure 15.23 Sample Flowchart for Slave Transmit Mode

In slave transmit mode, the slave device outputs the transmit data, while the master device provides the receive clock and returns an acknowledge signal. The transmission procedure and operation of slave transmit mode are described below.

the clock output by the master device.

The IRIC flag is cleared to 0 to detect the end of transmission. Processing from the ICDR register writing to the IRIC flag clearing should be performed continuously. Prevent any other interrupt processing from being inserted.

- [4] The master device drives SDA low at the 9th clock pulse, and returns an acknowledge signal. As this acknowledge signal is stored in the ACKB bit in ICSR, this bit can be used to determine whether the transfer operation was performed successfully. When one frame of data has been transmitted, the IRIC flag in ICCR is set to 1 at the rise of the 9th transmit clock pulse. When the ICDRE flag is 0, the data written into ICDR is transferred to the slave device and the ICDRE and IRIC flags are set to 1 again. If the ICDRE flag has been set to 1, the slave device drives SCL low from the fall of the 9th transmit clock until data is written into ICDR.
- [5] To continue transmission, write the next data to be transmitted into ICDR. The ICDRE flag is cleared to 0. The IRIC flag is cleared to 0 to detect the end of transmission. Processing from the ICDR register writing to the IRIC flag clearing should be performed continuously. Prevent any other interrupt processing from being inserted.

Transmit operations can be performed continuously by repeating steps [4] and [5].

- [6] Clear the IRIC flag to 0.
- [7] To end transmission, clear the ACKE bit in the ICCR register to 0, to clear the acknowledge bit stored in the ACKB bit to 0.
- [8] Clear the TRS bit to 0 for the next address reception, to set slave receive mode.
- [9] Dummy-read ICDR to release SCL on the slave side.
- [10] When the stop condition is detected, that is, when SDA is changed from low to high while SCL is high, the BBSY flag in ICCR is cleared to 0 and the STOP flag in ICSR is set to 1. When the STOPIM bit in ICXR is 0, the IRIC flag is set to 1. If the IRIC flag has been set to 1, it is cleared to 0.

**Figure 15.24 Slave Transmit Mode Operation Timing Example
(MLS = 0)**

(a) Data transfer ends with ICDRE=0 at transmission, or ICDRF=0 at reception.

(b) Data transfer ends with ICDRE=1 at transmission, or ICDRF=1 at reception.

Figure 15.27 IRIC Setting Timing and SCL Control (3)

15.4.8 Operation Using the DTC

This LSI provides the DTC to allow continuous data transfer. IIC_4 and IIC_5 cannot use DTC. The DTC is initiated when the IRTR flag is set to 1, which is one of the two interrupt flags (IRTR and IRIC). When the ACKE bit is 0, the ICDRE, IRIC, and IRTR flags are set at the start of data transmission regardless of the acknowledge bit value. When the ACKE bit is 1, the ICDRE, IRIC, and IRTR flags are set if data transmission is completed with the acknowledge bit value of 0, and when the ACKE bit is 1, only the IRIC flag is set if data transmission is completed with the acknowledge bit value of 1.

When initiated, DTC transfers specified number of bytes, clears the ICDRE, IRIC, and IRTR flags to 0. Therefore, no interrupt is generated during continuous data transfer; however, if data transmission is completed with the acknowledge bit value of 1 when the ACKE bit is 1, DTC is not initiated, thus allowing an interrupt to be generated if enabled.

Item	Master Transmit Mode	Master Receive Mode	Slave Transmit Mode	Slave Receive Mode
Slave address + R/W bit transmission/reception	Transmission by DTC (ICDR write)	Transmission by CPU (ICDR write)	Reception by CPU (ICDR read)	Reception by CPU (ICDR read)
Dummy data read	—	Processing by CPU (ICDR read)	—	—
Actual data transmission/reception	Transmission by DTC (ICDR write)	Reception by DTC (ICDR read)	Transmission by DTC (ICDR write)	Reception by DTC (ICDR read)
Dummy data (H'FF) write	—	—	Processing by DTC (ICDR write)	—
Last frame processing	Not necessary	Reception by CPU (ICDR read)	Not necessary	Reception by CPU (ICDR read)
Transfer request processing after last frame processing	1st time: Clearing by CPU 2nd time: Stop condition issuance by CPU	Not necessary	Automatic clearing on detection of stop condition during transmission of dummy data (H'FF)	Not necessary
Setting of number of DTC transfer data frames	Transmission: Actual data count + 1 (+1 equivalent to slave address + R/W bits)	Reception: Actual data count	Transmission: Actual data count + 1 (+1 equivalent to dummy data (H'FF))	Reception: Actual data count

Figure 15.28 Block Diagram of Noise Canceler

15.4.10 Initialization of Internal State

The IIC has a function for forcible initialization of its internal state if a deadlock occurs during communication.

Initialization is executed in accordance with clearing ICE bit.

Scope of Initialization: The initialization executed by this function covers the following

- ICDRE and ICDRF internal flags
- Transmit/receive sequencer and internal operating clock counter
- Internal latches for retaining the output state of the SCL and SDA pins (wait, clock, data output, etc.)

The following items are not initialized:

- Actual register values (ICDR, SAR, SARX, ICMR, ICCR, ICSR, ICXR (other than ICDRE, ICDRF))
- Internal latches used to retain register read information for setting/clearing flags in the ICCR, and ICSR registers

Rev. 3.00, 03/04, page 492 of 830

RENESAS

The value of the BBSY bit cannot be modified directly by this module clear function, but when a stop condition pin waveform is generated according to the state and release timing of the SDA pins, the BBSY bit may be cleared as a result. Similarly, state switching of other bits and flags may also have an effect.

To prevent problems caused by these factors, the following procedure should be used when initializing the IIC state.

1. Execute initialization of the internal state according to the ICE bit clearing.
2. Execute a stop condition issuance instruction (write 0 to BBSY and SCP) to clear the BBSY bit to 0, and wait for two transfer rate clock cycles.
3. Re-execute initialization of the internal state according to the ICE bit clearing.
4. Initialize (re-set) the IIC registers.

3	IIC13	IEIC	I ² C bus interface interrupt request	IRIC	Possible
0	IIC10	IEIC	I ² C bus interface interrupt request	IRIC	Possible
1	IIC11	IEIC	I ² C bus interface interrupt request	IRIC	Possible
4	IIC14	IEIC	I ² C bus interface interrupt request	IRIC	Not possible
5	IIC15	IEIC	I ² C bus interface interrupt request	IRIC	Not possible

- Write to ICDR when ICE = 1 and TRS = 1 (including automatic transfer from ICDRS)
 - Read from ICDR when ICE = 1 and TRS = 0 (including automatic transfer from ICDRR)
3. Table 15.11 shows the timing of SCL and SDA outputs in synchronization with the i clock. Timings on the bus are determined by the rise and fall times of signals affected by bus load capacitance, series resistance, and parallel resistance.

Table 15.11 I²C Bus Timing (SCL and SDA Outputs)

Item	Symbol	Output Timing	Unit	Notes
SCL output cycle time	t_{SCLC}	$28t_{cyc}$ to $512t_{cyc}$	ns	S
SCL output high pulse width	t_{SCLH}	$0.5t_{SCLC}$	ns	25
SCL output low pulse width	t_{SCLL}	$0.5t_{SCLC}$	ns	(re
SDA output bus free time	t_{BUFO}	$0.5t_{SCLC} - 1t_{cyc}$	ns	
Start condition output hold time	t_{STAH}	$0.5t_{SCLC} - 1t_{cyc}$	ns	
Retransmission start condition output setup time	t_{STAS}	$1t_{SCLC}$	ns	
Stop condition output setup time	t_{STOS}	$0.5t_{SCLC} + 2t_{cyc}$	ns	
Data output setup time (master)	t_{SDAS}	$1t_{SCLC} - 3t_{cyc}$	ns	
Data output setup time (slave)		$1t_{SCLC} - (6t_{cyc} \text{ or } 12t_{cyc}^*)$		
Data output hold time	t_{SDAH}	$3t_{cyc}$	ns	

Note: * $6t_{cyc}$ when IICXn is 0, $12t_{cyc}$ when IICXn is 1 (n = 0 to 5).

TCSS	IICXn	t_{cyc} Indi- cation		Time Indication [ns]						
				I ² C Bus Spe- cifica- tion (Max.)	$\phi = 5$ MHz	$\phi = 8$ MHz	$\phi = 10$ MHz	$\phi = 16$ MHz	$\phi = 20$ MHz	$\phi = 2$ MHz
0	0	7.5 t_{cyc}	Standard mode	1000	1000	937	750	468	375	300
			High-speed mode	300	300	300	300	300	300	300
1	0	17.5 t_{cyc}	Standard mode	1000	1000	1000	1000	1000	875	700
			High-speed mode	300	300	300	300	300	300	300
1	1	37.5 t_{cyc}	Standard mode	1000	1000	1000	1000	1000	1000	1000
			High-speed mode	300	300	300	300	300	300	300

Note: n = 0 to 5

6. The I²C bus interface specifications for the SCL and SDA rise and fall times are under 300 ns. The I²C bus interface SCL and SDA output timing is prescribed by t_{cyc} , as table 15.11. However, because of the rise and fall times, the I²C bus interface specifications may not be satisfied at the maximum transfer rate. Table 15.13 shows output timing calculations for different operating frequencies, including the worst-case influence of fall times.

		High-speed mode	-250	1300	2550	1500	1150* ¹	1000* ¹	1000* ¹	1000
t_{BUFO}	$0.5 t_{\text{SCLO}}$ $-1 t_{\text{cyc}}$ $(-t_{\text{Sr}})$	Standard mode	-1000	4700	3800* ¹	3875* ¹	3900* ¹	3938* ¹	3950* ¹	3960* ¹
		High-speed mode	-300	1300	2300	1325	1000* ¹	888* ¹	900* ¹	910* ¹
t_{STAH0}	$0.5 t_{\text{SCL0}}$ $-1 t_{\text{cyc}}$ $(-t_{\text{Sr}})$	Standard mode	-250	4000	4550	4625	4650	4688	4700	4710
		High-speed mode	-250	600	2350	1375	1050	938	950	960
t_{STAS0}	$1 t_{\text{SCL0}}$ $(-t_{\text{Sr}})$	Standard mode	-1000	4700	9000	9000	9000	9000	9000	9000
		High-speed mode	-300	600	5300	3200	2500	2200	2200	2200
t_{STOS0}	$0.5 t_{\text{SCL0}}$ $+ 2 t_{\text{cyc}}$ $(-t_{\text{Sr}})$	Standard mode	-1000	4000	4400	4250	4200	4125	4100	4080
		High-speed mode	-300	600	2900	1700	1300	1075	1050	1030
t_{SDAS0} (master)	$1 t_{\text{SCLLO}}^{*3}$ $-3 t_{\text{cyc}}$ $(-t_{\text{Sr}})$	Standard mode	-1000	250	3150	3375	3450	3563	3600	3630
		High-speed mode	-300	100	1650	825	550	513	550	580
t_{SDAS0} (slave)	$1 t_{\text{SCLL}}^{*3}$ $-12 t_{\text{cyc}}^{*2}$ $(-t_{\text{Sr}})$	Standard mode	-1000	250	1300	2200	2500	2950	3100	3220
		High-speed mode	-300	100	-1400* ¹	-500* ¹	-200* ¹	250	400	520

The values in the above table will vary depending on the settings of the bits IICX5 to IICX0 and CKS0 to CKS2. Depending on the frequency it may not be able to achieve the maximum transfer rate; therefore, whether or not the I²C bus interface specifications are met must be determined in accordance with the actual settings and conditions.

2. Value when the IICXn bit is set to 1. When the IICXn bit is cleared to 0, the value is $(-6t_{cyc})$ (n = 0 to 5).
3. Calculated using the I²C bus specification values (standard mode: 4700 ns max, speed mode: 1300 ns min.).

7. Notes on ICDR register read at end of master reception

To halt reception at the end of a receive operation in master receive mode, set the TRS bit in ICCR to 1 and write 0 to BBSY and SCP in ICCR. This changes SDA from low to high when SCL is high, and generates the stop condition. After this, receive data can be read by means of an ICDR read, but if data remains in the buffer the ICDRS receive data will not be transferred to the ICDR, and so it will not be possible to read the second byte of data.

If it is necessary to read the second byte of data, issue the stop condition in master receive mode (i.e. with the TRS bit cleared to 0). When reading the receive data, first confirm that the BBSY bit in the ICCR register is cleared to 0, the stop condition has been generated, and the bus has been released, then read the ICDR register with TRS cleared to 0.

Note that if the receive data (ICDR data) is read in the interval between execution of the ICDR read instruction for issuance of the stop condition (writing of 0 to BBSY and SCP in ICCR) and the actual generation of the stop condition, the clock may not be output correctly in subsequent master transmission.

Clearing of the MST bit after completion of master transmission/reception, or other modifications of IIC control bits to change the transmit/receive operating mode or settings must be carried out during interval (a) in figure 15.29 (after confirming that the BBSY bit has been cleared to 0 in the ICCR register).

Figure 15.29 Notes on Reading Master Receive Data

Note: This restriction on usage can be canceled by setting the FNC1 and FNC0 bits to F
ICXR.

8. Notes on start condition issuance for retransmission

Figure 15.30 shows the timing of start condition issuance for retransmission, and the t
subsequently writing data to ICDR, together with the corresponding flowchart. Write
transmit data to ICDR after the start condition for retransmission is issued and then th
condition is actually generated.

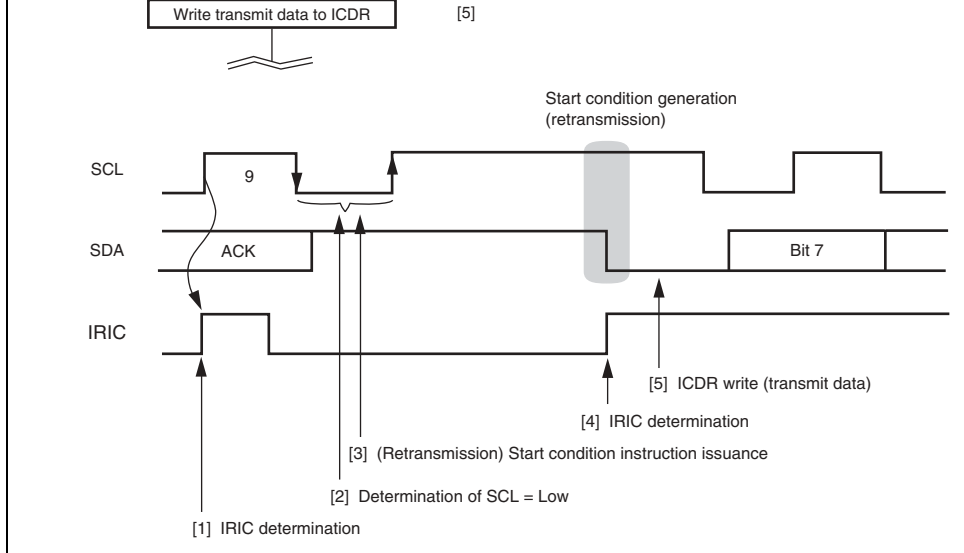

Figure 15.30 Flowchart for Start Condition Issuance Instruction for Retransmission Timing

Note: This restriction on usage can be canceled by setting the FNC1 and FNC0 bits to ICXR.

Figure 15.31 Stop Condition Issuance Timing

Note: This restriction on usage can be canceled by setting the FNC1 and FNC0 bits to 0 in the ICXR.

10. Note on IRIC flag clear when the wait function is used

When the wait function is used in I²C bus interface master mode and in a situation where the rise time of SCL exceeds the stipulated value or where a slave device in which a wait function is inserted by driving the SCL pin low is used, the IRIC flag should be cleared after detecting that the SCL is low.

If the IRIC flag is cleared to 0 when WAIT = 1 while the SCL is extending the high level, the SDA level may change before the SCL goes low, which may generate a start or stop condition erroneously.

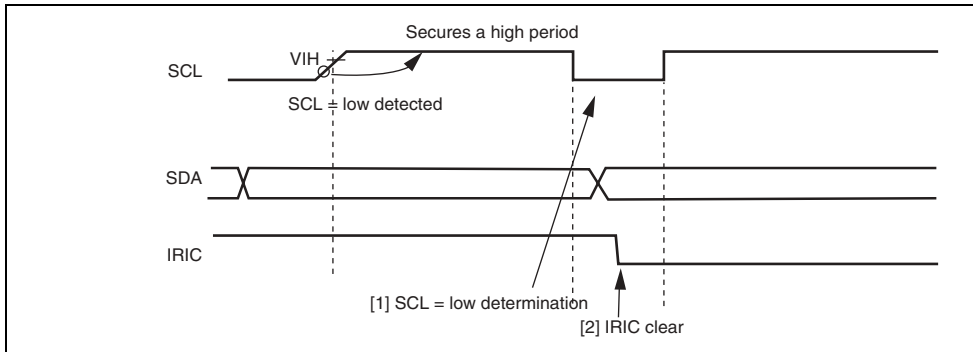

Figure 15.32 IRIC Flag Clearing Timing When WAIT = 1

Monitor the DC2 to DC6 counter in ICMR, when the count is 0000 (start of 7th clock pulse), wait for at least two transfer clock times in order to read ICDR or read/write ICCR during the time other than the shaded time.

Figure 15.33 ICDR Register Read and ICCR Register Access Timing in Slave Mode

Note: This restriction on usage can be canceled by setting the FNC1 and FNC0 bits to 1 in the ICXR.

mode, clear the TRS bit to and then dummy read ICDR.

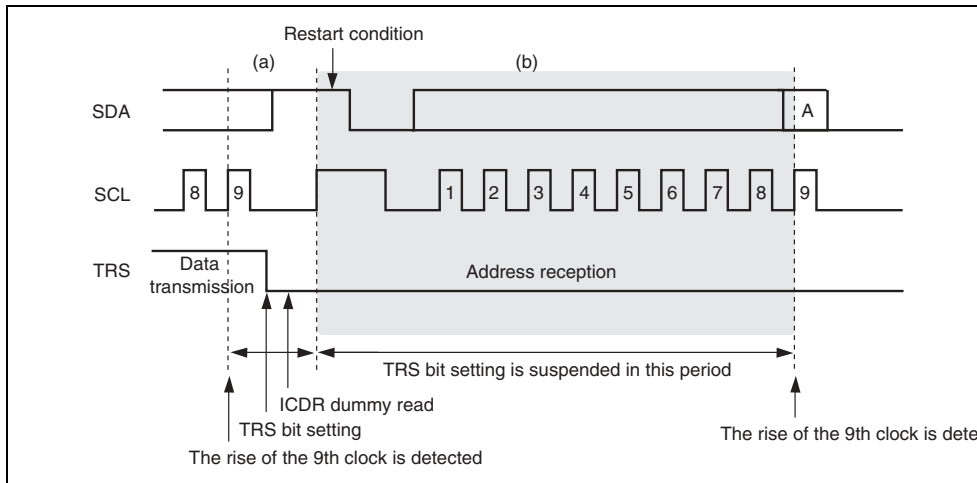

Figure 15.34 TRS Bit Set Timing in Slave Mode

Note: This restriction on usage can be canceled by setting the FNC1 and FNC0 bits to 1 in the ICXR.

13. Note on ICDR read in transmit mode and ICDR write in receive mode

When ICDR is read in transmit mode (TRS = 1) or ICDR is written to in receive mode (TRS = 0), the SCL pin may not be held low in some cases after transmit/receive operation has completed, thus inconveniently allowing clock pulses to be output on the SCL bus line. To access ICDR correctly, read the ICDR after setting receive mode or write to the ICDR after setting transmit mode.

- Set receive mode ($IRS = 0$) before the next start condition is input in slave mode. Complete transmit operation by the procedure shown in figure 15.23, in order to transition from slave transmit mode to slave receive mode.

15. Notes on Arbitration Lost in Master Mode Operation

The I²C bus interface recognizes the data in transmit/receive frame as an address when arbitration is lost in master mode and a transition to slave receive mode is automatically carried out.

When arbitration is lost not in the first frame but in the second frame or subsequent frame, transmit/receive data that is not an address is compared with the value set in the SAR register as an address. If the receive data matches with the address in the SAR or SAR2 register, the I²C bus interface erroneously recognizes that the address call has occurred (figure 15.35.)

In multi-master mode, a bus conflict could happen. When the I²C bus interface is operating in master mode, check the state of the AL bit in the ICSR register every time after one frame of data has been transmitted or received.

When arbitration is lost during transmitting the second frame or subsequent frame, take avoidance measures.

Figure 15.35 Diagram of Erroneous Operation when Arbitration Lost

Though it is prohibited in the normal I²C protocol, the same problem may occur when the MST bit is erroneously set to 1 and a transition to master mode is occurred during data transmission or reception in slave mode.

When the MST bit is set to 1 during data transmission or reception in slave mode, the arbitration decision circuit is enabled and arbitration is lost if conditions are satisfied. In this case, the transmit/receive data which is not an address may be erroneously recognized as an address.

In multi-master mode, pay attention to the setting of the MST bit when a bus conflict occurs. In this case, the MST bit in the ICCR register should be set to 1 according to the procedure below.

- A. Make sure that the BBSY flag in the ICCR register is 0 and the bus is free before setting the MST bit.
- B. Set the MST bit to 1.
- C. To confirm that the bus was not entered to the busy state while the MST bit is being set, check that the BBSY flag in the ICCR register is 0 immediately after the MST bit is set.

Note: Above restrictions can be released by setting the bits FNC1 and FNC2 in ICXR to 1.

- Supports LPC interface I/O read cycles and I/O write cycles
Uses four signal lines (LAD3 to LAD0) to transfer the cycle type, address, and data.
Uses three control signals: clock ($\overline{\text{LCLK}}$), reset ($\overline{\text{LRESET}}$), and frame ($\overline{\text{LFRAME}}$).
- Has three register sets comprising data and status registers
The basic register set comprises three bytes: an input register (IDR), output register (ODR), and status register (STR).
Channels 1 to 3 have fixed I/O addresses of H'0000 to H'FFFF, respectively.
A fast A20 gate function is also provided.
Sixteen bidirectional data register bytes can be manipulated in addition to the basic registers.
- Supports SERIRQ
Host interrupt requests are transferred serially on a single signal line (SERIRQ).
On channel 1, HIRQ1 and HIRQ12 can be generated.
On channels 2 and 3, SMI, HIRQ6, and HIRQ9 to HIRQ11 can be generated.
Operation can be switched between quiet mode and continuous mode.
The $\overline{\text{CLKRUN}}$ signal can be manipulated to restart the PCI clock (LCLK).
- Power-down functions, interrupts, etc.
The LPC module can be shut down by inputting the $\overline{\text{LPCPD}}$ signal.
Three pins, $\overline{\text{PME}}$, $\overline{\text{LSMI}}$, and LSCI, are provided for general input/output.
- Supports version 1.5 of the Intelligent Platform Management Interface (IPMI)
Channel 3 supports the SMIC interface, KCS interface, and BT interface.

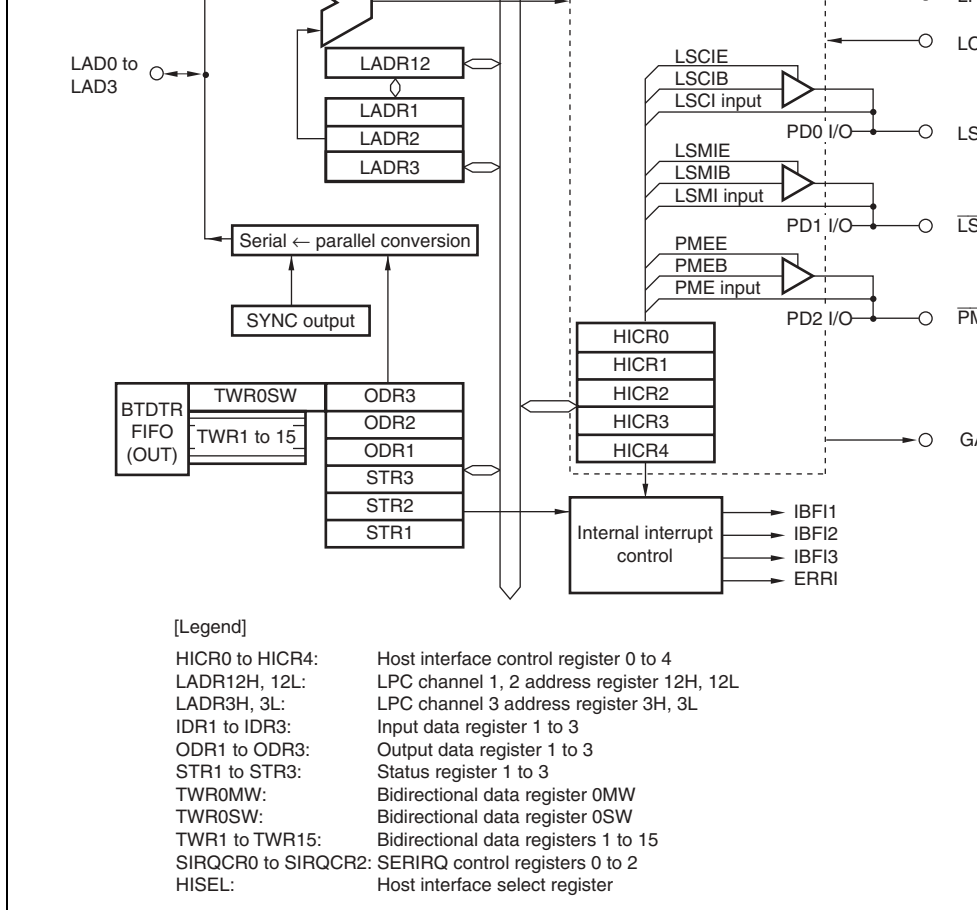

Figure 16.1 Block Diagram of LPC

LPC clock	LCLK	PE6	Input	33 MHz PCI clock signal
Serialized interrupt request	SERIRQ	PE7	I/O* ¹	Serialized host interrupt request signal, synchronized with (SMI, HIRQ1, HIRQ6, HIRQ12)
LSCI general output	LSCI	PD0	Output* ^{1, *2}	General output
LSMI general output	LSMI	PD1	Output* ^{1, *2}	General output
PME general output	PME	PD2	Output* ^{1, *2}	General output
GATE A20	GA20	PD3	Output* ^{1, *2}	A20 gate control signal output
LPC clock run	CLKRUN	PD4	I/O* ^{1, *2}	LCLK restart request signal of serial host interrupt request
LPC power-down	LPCPD	PD5	Input* ¹	LPC module shutdown signal

- Notes:
1. Pin state monitoring input is possible in addition to the LPC interface control input/output function.
 2. Only 0 can be output. If 1 is output, the pin goes to the high-impedance state, external resistor is necessary to pull the signal up to VCC.

- Input data register 1 (IDR1)
- Input data register 2 (IDR2)
- Input data register 3 (IDR3)
- Output data register 1 (ODR1)
- Output data register 2 (ODR2)
- Output data register 3 (ODR3)
- Bidirectional data registers 0 to 15 (TWR0 to TWR15)
- Status register 1 (STR1)
- Status register 2 (STR2)
- Status register 3 (STR3)
- SERIRQ control register 0 (SIRQCR0)
- SERIRQ control register 1 (SIRQCR1)
- SERIRQ control register 2 (SIRQCR2)
- Host interface select register (HISEL)

SMIC mode:

The following registers are required when SMIC mode is used.

- SMIC flag register (SMICFLG)
- SMIC control status register (SMICCSR)
- SMIC data register (SMICDTR)
- SMIC interrupt register 0 (SMICIR0)
- SMIC interrupt register 1 (SMICIR1)

address match determination. Table 16.4 shows the slave selection internal registers in slave LSI access.

Table 16.2 LADR1, LADR2 Initial Values

Register Name	Initial Value	Description
LADR1	H'0060	I/O address of channel 1
LADR2	H'0062	I/O address of channel 2

Table 16.3 Host Register Selection

Bits 15 to 3	I/O Address			Transfer Cycle	Host Register Selection
	Bit 2	Bit 1	Bit 0		
LADR1 (bits 15 to 3)	0	LADR1 (bit 1)	LADR1 (bit 0)	I/O write	IDR1 write (data, $C/\bar{D}1 \leftarrow 0$)
LADR1 (bits 15 to 3)	1	LADR1 (bit 1)	LADR1 (bit 0)	I/O write	IDR1 write (command, $C/\bar{D}1 \leftarrow 1$)
LADR1 (bits 15 to 3)	0	LADR1 (bit 1)	LADR1 (bit 0)	I/O read	ORD1 read
LADR1 (bits 15 to 3)	1	LADR1 (bit 1)	LADR1 (bit 0)	I/O read	STR1 read
LADR2 (bits 15 to 3)	0	LADR2 (bit 1)	LADR2 (bit 0)	I/O write	IDR2 write (data, $C/\bar{D}2 \leftarrow 0$)
LADR2 (bits 15 to 3)	1	LADR2 (bit 1)	LADR2 (bit 0)	I/O write	IDR2 write (command, $C/\bar{D}2 \leftarrow 1$)
LADR2 (bits 15 to 3)	0	LADR2 (bit 1)	LADR2 (bit 0)	I/O read	ODR2 read
LADR2 (bits 15 to 3)	1	LADR2 (bit 1)	LADR2 (bit 0)	I/O read	STR2 read

The IDR registers are 8-bit read-only registers to the slave processor (this LSI), and 8-bit read-only registers to the host processor. The registers selected from the host according to the address are described in the following sections: for information on IDR1 and IDR2 selection, see section 16.3.5, LPC Channel 1, 2 Address Register H, L (LADR12H, LADR12L), and for information on IDR3 selection, see section 16.3.4, LPC Channel 3 Address Register H, L (LADR3H, LADR3L). Data transferred in an LPC I/O write cycle is written to the selected register. The state of bit 2 of the I/O address is latched into the C/\overline{D} bit in STR, to indicate whether the written information is a command or data.

The initial values of the IDR registers are undefined.

16.3.7 Output Data Registers 0 to 3 (ODR1 to ODR3)

The ODR registers are 8-bit readable/writable registers to the slave processor (this LSI), and read-only registers to the host processor. The registers selected from the host according to the address are described in the following sections: for information on ODR1 and ODR2 selection, see section 16.3.5, LPC Channel 1, 2 Address Register H, L (LADR12H, LADR12L), and for information on ODR3 selection, see section 16.3.4, LPC Channel 3 Address Register H, L (LADR3H, LADR3L). In an LPC I/O read cycle, the data in the selected register is transferred to the host.

The initial values of the ODR registers are undefined.

cycle, the data in the selected register is transferred to the host.

The initial values of TWR0 to TWR15 are undefined.

the data in the selected register is transferred to the host processor.

The STR registers are initialized to H'00 by a reset or in hardware standby mode.

- STR1

Bit	Bit Name	Initial Value	R/W		Description
			Slave	Host	
7	DBU17	All 0	R/W	R	Defined by User
6	DBU16				The user can use these bits as necessary.
5	DBU15				
4	DBU14				
3	C/D $\bar{1}$	0	R	R	Command/Data When the host processor writes to an IDR1, bit 2 of the I/O address is written into this bit to indicate whether IDR1 contains data or a command. 0: Content of input data register (IDR1) is data 1: Content of input data register (IDR1) is a command
2	DBU12	0	R/W	R	Defined by User The user can use this bit as necessary.

				When there is receive data in IDR1. [Setting condition] When the host processor writes to IDR using write cycle
0	OBF1	0	R/(W)* R	Output Data Register Full Indicates whether or not there is transmit data in ODR1. 0: There is not transmit data in ODR1 [Clearing condition] When the host processor reads ODR1 using read cycle, or the slave processor writes 0 to OBF1 bit 1: There is transmit data in ODR1 [Setting condition] When the slave processor writes to ODR1

Note: * Only 0 can be written to clear the flag.

2	DBU22	0	R/W	R	Defined by User The user can use this bit as necessary.
1	IBF2	0	R	R	Input Data Register Full Indicates whether or not there is receive data. This bit is an internal interrupt source to the processor (this LSI). 0: There is not receive data in IDR2 [Clearing condition] When the slave processor reads IDR2 1: There is receive data in IDR2 [Setting condition] When the host processor writes to IDR2 using write cycle
0	OBF2	0	R/(W) *	R	Output Data Register Full Indicates whether or not there is transmit data in ODR2. 0: There is not transmit data in ODR2 [Clearing condition] When the host processor reads ODR2 using read cycle, or the slave processor writes 0 to the ODR2 1: There is transmit data in ODR2 [Setting condition] When the slave processor writes to ODR2

Note: * Only 0 can be written to clear the flag.

					[Setting condition] When the host processor writes to TWR15 u write cycle
6	OBF3B	0	R/(W)*	R	<p>Bidirectional Data Register Output Data Full</p> <p>Indicates whether or not there is transmit da TWR0 to TWR15.</p> <p>0: There is not transmit data in TWR15</p> <p>[Clearing condition]</p> <p>When the host processor reads TWR15 usin read cycle, or the slave processor writes 0 to OBF3B bit</p> <p>1: There is transmit data in TWR0 to TWR15</p> <p>[Setting condition]</p> <p>When the slave processor writes to TWR15</p>
5	MWMF	0	R	R	<p>Master Write Mode Flag</p> <p>Indicates that master write mode is entered writing to TWR0 from the host processor.</p> <p>0: [Clearing condition]</p> <p>When the slave processor reads TWR15</p> <p>1: [Setting condition]</p> <p>When the host processor writes to TWR0 us write cycle while SWMF = 0</p>

when the slave processor writes to 1W
MWMF = 0

3	C/D3	0	R	R	Command/Data When the host processor writes to an IDR3, bit 2 of the I/O address is written into this bit to indicate whether IDR3 contains data or a command. 0: Content of input data register (IDR3) is data 1: Content of input data register (IDR3) is a command
2	DBU32	0	R/W	R	Defined by User The user can use this bit as necessary.
1	IBF3A	0	R	R	Input Data Register Full Indicates whether or not there is receive data in IDR3. This is an internal interrupt source to the slave processor (this LSI). 0: There is not receive data in IDR3 [Clearing condition] When the slave processor reads IDR3 1: There is receive data in IDR3 [Setting condition] When the host processor writes to IDR3 using a write cycle

Note: * Only 0 can be written to clear the flag.

- STR3

(When TWRE = 0 and SELSTR3 = 1)

Bit	Bit Name	Initial Value	R/W		Description
			Slave	Host	
7	DBU37	All 0	R/W	R	Defined by User
6	DBU36				The user can use these bits as necessary.
5	DBU35				
4	DBU34				
3	C/ \bar{D} 3	0	R	R	Command/Data When the host processor writes to an IDR3 register, bit 2 of the I/O address is written into this bit to indicate whether IDR3 contains data or a command. 0: Content of input data register (IDR3) is data. 1: Content of input data register (IDR3) is a command.
2	DBU32	0	R/W	R	Defined by User The user can use this bit as necessary.

			write cycle
0	OBF3A	0	R/(W)* R
Output Data Register Full			
Indicates whether or not there is transmit data in ODR3.			
0: There is not receive data in ODR3

When the host processor reads ODR3 using a read cycle, or the slave processor writes 0 to the OBF3A bit			
1: There is receive data in ODR3			
[Setting condition]			
When the slave processor writes to ODR3			

Note: * Only 0 can be written to clear the flag.

0: Continuous mode

[Clearing conditions]

- LPC hardware reset, LPC software reset
- Specification by the stop frame of the SERIRQ transfer cycle

1: Quiet mode

[Setting condition]

- Specification by the stop frame of the SERIRQ transfer cycle

6	SELREQ	0	R/W	—	Start Frame Initiation Request Select
Specifies the condition of start frame activation when the host interrupt request is cleared in quiet mode.					
0: When all host interrupt requests are cleared in quiet mode, start frame initiation is requested					
1: When at least one host interrupt request is cleared in quiet mode, start frame initiation is requested					

5	IEDIR	0	R/W	—	Interrupt Enable Direct Mode
Specifies whether LPC channel 2 SERIRQ is requested when host interrupt source (SMI, HIRQ6, HIRQ9 to HIRQ11) generation is conditional upon OBF, or is controlled only by the host interrupt enable bit.					
0: Host interrupt is requested when host interrupt enable bit and corresponding OBF are both set to 1					
1: Host interrupt is requested when host interrupt enable bit is set to 1					

					<p>[Setting condition]</p> <p>Host SMI interrupt request by setting OBF3A and SMIE3B is enabled</p> <p>[When IEDIR3 = 1]</p> <p>Host SMI interrupt is requested</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> • Writing 1 after reading SMIE3B = 0

OBF2 is set by an ODR2 write.</p> <p>0: HIRQ6 interrupt request by OBF2 and IEDIR disabled</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • Writing 0 to IRQ6E2 • LPC hardware reset, LPC software reset • Clearing OBF2 to 0 (when IEDIR = 0) <p>1: [When IEDIR = 0]</p> <p>HIRQ6 interrupt request by setting OBF2 enabled</p> <p>[When IEDIR = 1]</p> <p>HIRQ6 interrupt is requested.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> • Writing 1 after reading IRQ6E2 = 0

0: The host interrupt is requested when both host interrupt enable bit and corresponding interrupt enable bit are set to 1

1: The host interrupt is requested when the interrupt enable bit is set to 1

6 to 0	—	All 0	R/W	—	Reserved
--------	---	-------	-----	---	----------

The initial value should not be changed.

0: Bits 7 to 4 in STR3 is the LPC interface.
 1: [When TWRE = 0]
 Bits 7 to 4 in STR3 are defined by user.
 [When TWRE = 1]
 Bits 7 to 4 in STR3 are the LPC interface bits.

6	SELIRQ11	All 0	R/W	—	Selects the SERIRQ Output
5	SELIRQ10				These bits select the output status for LPC
4	SELIRQ9				interrupt request (HIRQ11, HIRQ10, HIRQ
3	SELIRQ6				SMI, HIRQ12, and HIRQ1).
2	SELSMI				0: [When host interrupt request has been c
1	SELIRQ12				The SERIRQ output is high impedance.
0	SELIRQ1				[When host interrupt request has been s The SERIRQ output is 0 level. 1: [When host interrupt request has been c The SERIRQ output is 0 level. [When host interrupt request has been s The SERIRQ output is high impedance.

6	TX_DATA_0 RDY	0	R/W	R	Write Transfer Ready Indicates whether or not the slave is ready for the host next write transfer. 0: The slave waits for ready status 1: The slave is ready for the host write transfer
5	—	0	R/W	R	Reserved The initial value should not be changed.
4	SMI	0	R/W	R	SMI Flag This bit indicates that the SMI is asserted. 0: Indicates waiting for SMI assertion 1: Indicates SMI assertion

1	—	0	R/W	R	Reserved The initial value should not be changed.
0	BUSY	0	R/(W)*	W	SMIC Busy This bit indicates that the slave is now transferring data. This bit can be cleared only by the slave and set only by the host. The rising edge of this bit is a source of interrupt to the slave. 0: Transfer cycle wait state [Clearing conditions] After the slave reads BUSY = 1, writes 0 to this bit. 1: Transfer cycle in progress [Setting condition] When the host writes 1 to this bit.

Note: Only 0 can be written to clear the flag.

SMICDIR is one of the registers used to implement SMIC mode. This is an 8-bit register accessible (readable/writable) from both the slave processor (this LSI) and host processor used for data transfer between the host and slave.

16.3.17 SMIC Interrupt Register 0 (SMICIR0)

SMICIR0 is one of the registers used to implement SMIC mode. This register includes the bits to indicate the source of interrupt to the slave.

				1: Transfer data transmission end [Setting condition] The transfer cycle is write transfer and the writes the transfer data to SMICDTR.
3	HDTRI	0	R/(W)* —	Transfer Data Receive End Interrupt This is a status flag that indicates that the host has finished receiving the transfer data from SMICDTR. When the IBFIE3 bit and HDTRIE bit are set to 1, the IBFI3 interrupt is requested to the slave. 0: Transfer data receive wait state [Clearing condition] After the slave reads HDTRI = 1, writes 0 to HDTRI. 1: Transfer data receive end [Setting condition] The transfer cycle is read transfer and the slave reads the transfer data from SMICDTR.
2	STARI	0	R/(W)* —	Status Code Receive End Interrupt This is a status flag that indicates that the host has finished receiving the status code from SMICDTR. When the IBFIE3 bit and STARIE bit are set to 1, the IBFI3 interrupt is requested to the slave. 0: Status code receive wait state [Clearing condition] After the slave reads STARI = 1, writes 0 to STARI. 1: Status code receive end [Setting condition] When the host reads the status code of SMICDTR.

0	BUSYI	R/(W)* —	<p>Transfer Start Interrupt</p> <p>This is a status flag that indicates that the host is transferring. When the IBFIE3 bit and BUSYI are set to 1, the IBFI3 interrupt is requested to the slave.</p> <p>0: Transfer start wait state [Clearing condition]</p> <p>After the slave reads BUSYI = 1, writes 0 to clear the flag.</p> <p>1: Transfer start [Setting condition]</p> <p>When the rising edge of the BUSY bit in SMR is detected.</p>
---	-------	----------	---

Note: * Only 0 can be written to clear the flag.

					interrupt source to the slave. 0: Disables transfer data transmission end 1: Enables transfer data transmission end
3	HDTRIE	0	R/W	—	Transfer Data Receive End Interrupt Enable Enables or disables HDTRI interrupt that is interrupt source to the slave. 0: Disables transfer data receive end interr 1: Enables transfer data receive end interr
2	STARIE	0	R/W	—	Status Code Receive End Interrupt Enable Enables or disables STARI interrupt that is interrupt source to the slave. 0: Disables status code receive end interr 1: Enables status code receive end interr
1	CTLWIE	0	R/W	—	Control Code Transmission End Interrupt E Enables or disables CTLWI interrupt that is interrupt source to the slave. 0: Disables control code transmission end 1: Enables control code transmission end i
0	BUSYIE	0	R/W	—	Transfer Start Interrupt Enable Enables or disables BUSYI interrupt that is interrupt source to the slave. 0: Disables transfer start interrupt 1: Enables transfer start interrupt

transfer. When the IBFIE3 bit and FRDIE bit are set to 1, IBFI3 interrupt is requested to the slave. After the slave reads data from the FIFO, the slave must clear the flag after creating an unacknowledged area by reading the data in FIFO.

0: FIFO read is not requested

[Clearing condition]

After the slave reads FRDI = 1, writes 0 to the register.

1: FIFO read is requested

[Setting condition]

After the host processor transfers data, the slave writes the data with FIFO Full state.

3	HRDI	0	R/(W)* —	BT Host Read Interrupt
---	------	---	----------	------------------------

This status flag indicates that the host reads data from the BTDTR buffer. When the IBFIE3 bit and IBFIE2 bit are set to 1, IBFI3 interrupt is requested to the slave.

0: Host BTDTR read wait state

[Clearing condition]

After the slave reads HRDI = 1, writes 0 to the register.

1: The host reads from BTDTR

[Setting condition]

The host reads one byte from BTDTR.

				The host writes one byte to BTDTR.
1	HBTWI	0	R/(W)* —	<p>BTDTR Host Write Start Interrupt</p> <p>This status flag indicates that the host writes one byte of valid data to BTDTR buffer. When the BFIE3 bit and HBTWIE bit are set to 1, IBFI3 interrupt is requested to the slave.</p> <p>0: BTDTR host write start wait state</p> <p>[Clearing condition]</p> <p>After the slave reads HBTWI = 1 and writes the bit.</p> <p>1: BTDTR host write start</p> <p>[Setting condition]</p> <p>The host starts writing valid data to BTDTR.</p>
0	HBTRI	0	R/(W)* —	<p>BTDTR Host Read End Interrupt</p> <p>This status flag indicates that the host reads one byte of valid data from BTDTR buffer. When the BFIE3 bit and HBTRIE bit are set to 1, IBFI3 interrupt is requested to the slave.</p> <p>0: BTDTR host read end wait state</p> <p>[Clearing condition]</p> <p>After the slave reads HBTRI = 1 and writes the bit.</p> <p>1: BTDTR host read end</p> <p>[Setting condition]</p> <p>When the host finished reading the valid data from BTDTR.</p>

Note: * Only 0 can be written to clear the flag.

bit and HRSTIE bit are set to 1, IBFI3 interrupt requested to the slave.

0: [Clearing condition]

When the slave reads HRSTI = 1 and writes 0 to this bit.

1: [Setting condition]

When the slave detects the rising edge of BMC_HWRST.

5	IRQCRI	0	R/(W)*	—	B2H_IRQ Clear Interrupt
---	--------	---	--------	---	-------------------------

This status flag indicates that the B2H_IRQ BTIMSR is cleared by the host. When the IE and IRQCRIE bit are set to 1, IBFI3 interrupt requested to the slave.

0: [Clearing condition]

When the slave reads IRQCRI = 1 and writes 0 to this bit.

1: [Setting condition]

When the slave detects the falling edge of B2H_IRQ.

3	B2HI	0	R/(W)* —	<p>Read End Interrupt</p> <p>This status flag indicates that the host has finished reading all data from the BTDR buffer. When the IBFIE3 bit and B2HIE bit are set to 1, the interrupt is requested to the slave.</p> <p>0: [Clearing condition]</p> <p>When the slave reads B2HI = 1 and writes 0 to this bit.</p> <p>1: [Setting conditions]</p> <p>ATNSW = 0: When the slave detects the falling edge of B2H_ATN.</p> <p>ATNSW = 1: When the slave detects the falling edge of H_BUSY.</p>
2	H2BI	0	R/(W)* —	<p>Write End Interrupt</p> <p>This status flag indicates that the host has finished writing all data to the BTDR buffer. When the IBFIE3 bit and H2BIE bit are set to 1, the interrupt is requested to the slave.</p> <p>0: [Clearing condition]</p> <p>After the slave reads H2BI = 1, writes 0 to this bit.</p> <p>1: [Setting condition]</p> <p>When the slave detects the falling edge of H2B_ATN.</p>

0	CRWPI	0	R/(W)*	—	Write Pointer Clear Interrupt
					This status flag indicates that the CLR_WR_PTR in BTCR is set to 1 by the host. When the IBFI3 and CRWPIE bit are set to 1, the IBFI3 interrupt is requested to the slave.
					0: [Clearing condition]
					After the slave reads CRWPI = 1, writes 0 to CLR_WR_PTR bit.
					1: [Setting condition]
					When the slave detects the rising edge of CLR_WR_PTR.

Note: * Only 0 can be written to clear the flag.

0 * :FIFO disabled

1 * :FIFO enabled

The FIFO size: 64 bytes (for host write transfer)
additional 64 bytes (for host read transfer).

4	FRDIE	0	R/W	—	FIFO Read Request Interrupt Enable Enables or disables the FRDI interrupt which is added to the IBFI3 interrupt source to the slave. 0: FIFO read request interrupt is disabled. 1: FIFO read request interrupt is enabled.
3	HRDIE	0	R/W	—	BT Host Read Interrupt Enable Enables or disables the HRDI interrupt which is added to the IBFI3 interrupt source to the slave. When using FIFO, the HRDIE bit must not be set to 1. 0: BT host read interrupt is disabled. 1: BT host read interrupt is enabled.
2	HWRIE	0	R/W	—	BT Host Write Interrupt Enable Enables or disables the HWRI interrupt which is added to the IBFI3 interrupt source to the slave. When using FIFO, the HWRIE bit must not be set to 1. 0: BT host write interrupt is disabled. 1: BT host write interrupt is enabled.

Note: * Don't care.

16.3.22 BT Control Status Register 1 (BTCSR1)

BTCSR1 is one of the registers used to implement the BT mode. The BTCSR1 register contains the bits used to enable or disable interrupts to the slave (this LSI). The IBFI3 interrupt is enabled by setting the IBFIE3 bit in HICR2 to 1.

Bit	Bit Name	Initial Value	R/W		Description
			Slave	Host	
7	RSTRENBL	0	R/W	—	Slave Reset Read Enable The host reads 0 from the BMC_HWRST bit in BTIMSR. When this bit is set to 1, the host can read 1 from the BMC_HWRST bit. 0: Host always reads 0 from BMC_HWRST bit. 1: Host can read 0 from BMC_HWRST bit.
6	HRSTIE	0	R/W	—	BT Reset Interrupt Enable Enables or disables the HRSTI interrupt when the IBFI3 interrupt source to the slave. 0: BT reset interrupt is disabled. 1: BT reset interrupt is enabled.
5	IRQCRIE	0	R/W	—	B2H_IRQ Clear Interrupt Enable Enables or disables the IRQCRI interrupt when the IBFI3 interrupt source to the slave. 0: B2H_IRQ clear interrupt is disabled. 1: B2H_IRQ clear interrupt is enabled.

2	H2BIE	0	R/W	—	Write End Interrupt Enable Enables or disables the H2BI interrupt with IBFI3 interrupt source to the slave. 0: Write end interrupt is disabled. 1: Write end interrupt is enabled.
1	CRRPIE	0	R/W	—	Read Pointer Clear Interrupt Enable Enables or disables the CRRPI interrupt with IBFI3 interrupt source to the slave. 0: Read pointer clear interrupt is disabled. 1: Read pointer clear interrupt is enabled.
0	CRWPIE	0	R/W	—	Write Pointer Clear Interrupt Enable Enables or disables the CRWPI interrupt with IBFI3 interrupt source to the slave. 0: Write pointer clear interrupt is disabled. 1: Write pointer clear interrupt is enabled.

6	H_BUSY	0	R	(W)* ³	<p>BT Read Transfer Busy Flag</p> <p>1: Indicates that the BTDTR buffer is being used for BT read transfer (read transfer is in progress.)</p> <p>0: Indicates waiting for BT read transfer</p> <p>[Clearing condition]</p> <p>When the host writes a 1 while H_BUSY is 0.</p> <p>1: Indicates that the BTDTR buffer is being used for BT read transfer</p> <p>[Setting condition]</p> <p>When the host writes a 1 while H_BUSY is 0.</p>
5	OEM0	0	R/W	R/(W)* ⁴	<p>User defined bit</p> <p>This bit is defined by the user, and validates the read data when set to 1 by a 0 written from the host.</p> <p>0: [Clearing condition]</p> <p>When the slave writes a 0 after a 1 has been read from OEM0.</p> <p>1: [Setting condition]</p> <p>When the slave writes a 1, after a 0 has been read from OEM0, or when the host writes a 1.</p>

3	B2H_ATN	0	R/(W)* ¹	R/(W)* ⁵	<p>Slave Buffer Write End Indication Flag</p> <p>This status flag indicates that the slave has completed writing all data to the BTDR buffer. Setting the B2H_IRQ_EN bit in the BTIMSR register enables the B2H_ATN bit to be used as an interrupt signal to the host.</p> <p>0: Host has completed reading the BTDR buffer [Clearing condition] When the host writes a 1</p> <p>1: Slave has completed writing to the BTDR buffer [Setting condition] When the slave writes a 1 after a 0 has been written from B2N_ATN.</p>
<hr/>					
2	H2B_ATN	0	R/(W)* ²	R/(W)* ¹	<p>Host Buffer Write End Indication Flag</p> <p>This status flag indicates that the host has completed writing all data to the BTDR buffer.</p> <p>0: Slave has completed reading the BTDR buffer [Clearing condition] When the slave writes a 0 after a 1 has been written from H2B_ATN.</p> <p>1: Host has completed writing to the BTDR buffer [Setting condition] When the host writes a 1</p>

0	CLR_WR_0 PTR	R/(W)* ² (W)* ¹	<p>When the host writes a 1.</p> <p>Write Pointer Clear</p> <p>This bit is used by the host to clear the write pointer during write transfer. A host read operation always yields 0 on readout.</p> <p>0: Write pointer clear wait</p> <p>[Clearing condition]</p> <p>When the slave writes a 0 after a 1 has been read from CLR_WR_PTR.</p> <p>1: Write pointer clear</p> <p>[Setting condition]</p> <p>When the host writes a 1.</p>
---	-----------------	---------------------------------------	--

- Notes:
1. Only 1 can be written to set this flag.
 2. Only 0 can be written to clear this flag.
 3. Only 1 can be written to toggle this flag.
 4. Only 0 can be written to set this flag.
 5. Only 1 can be written to clear this flag.

read from the host.

0: The reset is cancelled

[Clearing condition]

When the slave writes a 0, after a 1 has been read from BMC_HWRST.

1: The reset is in progress.

[Setting condition]

When the host writes a 1.

6	—	0	R/W	R/W	Reserved
5	—	0	R/W	R/W	

4	OEM3	0	R/W	R/(W)* ⁴	User defined bit
3	OEM2	0	R/W	R/(W)* ⁴	These bits are defined by the user and are only when set to 1 by a 0 written from the host.
2	OEM1	0	R/W	R/(W)* ⁴	

0: [Clearing condition]
When the slave writes a 0, after a 1 has been read from OEM.

1: [Setting condition]
When the slave writes a 1, after a 0 has been read from OEM, or when the host writes a 1.

[Setting condition]
When the slave writes a 1, after a 0 has read from B2H_IRQ

0	B2H_IRQ_0 EN	R	R/W	BMC to HOST interrupt enable Enables or disables the B2H_IRQ interrupt as an the interrupt source from the slave host. 0: B2H_IRQ interrupt is disabled [Clearing condition] When a 0 is written by the host. 1: B2H_IRQ interrupt is enabled [Setting condition] When a 1 is written by the host.
---	-----------------	---	-----	---

- Notes:
1. Only 1 can be written to set this flag.
 2. Only 0 can be written to clear this flag.
 3. Only 1 can be written to clear this flag.
 4. Only 0 can be written to set this flag.

16.3.27 BT FIFO Valid Size Register 1 (BTFVSR1)

BTFVSR1 is one of the registers used to implement BT mode. BTFVSR1 indicates a valid size in the FIFO for host read transfer.

Bit	Bit Name	Initial Value	R/W		Description
			Slave	Host	
7 to 0	N7 to N0	All 0	R	—	These bits indicate the number of valid bytes in the BT FIFO (the number of bytes which the host can read) for host read transfer. When data is written to the BT slave, the value in BTFVSR1 is incremented by the number of bytes that have been written to. When data is read from the host, the value is decremented by only the number of bytes that have been read.

1. Read the signal line status and confirm that the LPC module can be connected. Also, the LPC module is initialized internally.
2. Set the I/O addresses of the channels to be used (LADR1 to LADR3) and whether or not bidirectional registers, KCS interface, SMIC interface, and BT interface are to be used.
3. Set the enable bit (LPC3E to LPC1E) for the channel to be used.
4. Set the enable bits (FGA20E, PMEE, LSMIE, and LSCIE) for the additional functions to be used.
5. Set the selection bits for other functions (SDWNE, IEDIR).
6. As a precaution, clear the interrupt flags (LRST, SDWN, ABRT, and OBF). Read IDWR15 to clear IBF.
7. Set interrupt enable bits (IBFIE3 to IBFIE1, ERRIE) as necessary.

16.4.2 LPC I/O Cycles

There are ten kinds of LPC transfer cycle: memory read, memory write, I/O read, I/O write, DMA read, DMA write, bus mastership memory read, bus mastership memory write, bus mastership I/O read, and bus mastership I/O write. Of these, the chip's LPC supports only I/O read and I/O write cycles.

An LPC transfer cycle is started when the $\overline{\text{LFRAME}}$ signal goes low in the bus idle state. When the $\overline{\text{LFRAME}}$ signal goes low when the bus is not idle, this means that a forced termination of the LPC transfer cycle has been requested.

In an I/O read cycle or I/O write cycle, transfer is carried out using LAD3 to LAD0 in the following order, in synchronization with LCLK. The host can be made to wait by sending a value other than B'0000 in the slave's synchronization return cycle. However, the LPC interface always returns a value of B'0000 if the BT interface is not used.

4	Address 2	Host	Bits 11 to 8	Address 2	Host	B

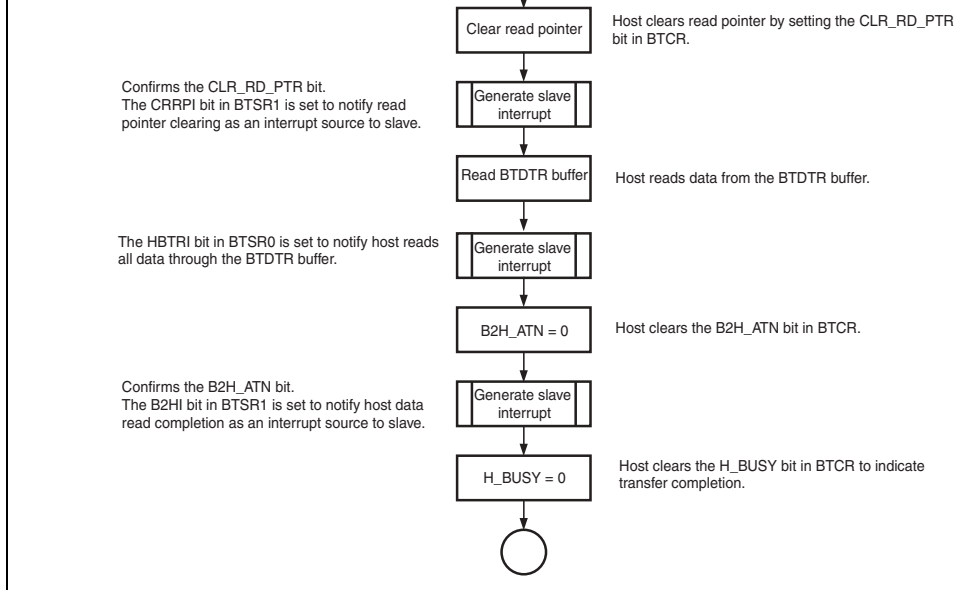

Figure 16.7 BT Read Transfer Flow

Fast A20 Gate Operation: The internal state of GA20 output is initialized to 1 when FGA20E bit is set to 1, PD3/GA20 is used for output of a fast A20 gate signal. The state of the PD3/GA20 pin can be monitored by reading the GA20 bit in HICR2.

The initial output from this pin will be a logic 1, which is the initial value. Afterward, the processor can manipulate the output from this pin by sending commands and data. This function is only available via the IDR1 register. The LPC interface decodes commands input from the host. When an H'D1 host command is detected, bit 1 of the data following the host command is output from the GA20 output pin. This operation does not depend on firmware or interrupts, and is faster than the regular processing using interrupts. Table 16.6 shows the conditions that set and clear the GA20 (PD3). Figure 16.8 shows the GA20 output in flowchart form. Table 16.7 indicates the GA20 output signal values.

Table 16.6 GA20 (PD3) Set/Clear Conditions

Pin Name	Setting Condition	Clearing Condition
GA20 (PD3)	When bit 1 of the data that follows an H'D1 host command is 1	When bit 1 of the data following the host command is 0

Figure 16.8 GA20 Output

0	1 data* ¹	0	1	(abbreviated for

1	H'D1 command	0	Q	
1	H'D1 command	0	Q	Consecutively e
0	Any data	0	1/0	sequences
1	H'D1 command	0	Q (1/0)	

Notes: 1. Arbitrary data with bit 1 set to 1.
2. Arbitrary data with bit 1 cleared to 0.

If the SDWNE bit has been set to 1 beforehand, the LPC hardware shutdown state is set at the same time as the $\overline{\text{LPCPD}}$ signal falls, and prior preparation is not possible. If the LPC software shutdown state is set by means of the SDWNB bit, on the other hand, the LPC software shutdown state cannot be cleared at the same time as the rise of the $\overline{\text{LPCPD}}$ signal. Taking these points into consideration, the following operating procedure uses a combination of LPC software shutdown and LPC hardware shutdown.

1. Clear the SDWNE bit to 0.
2. Set the ERRIE bit to 1 and wait for an interrupt by the SDWN flag.
3. When an ERRI interrupt is generated by the SDWN flag, check the LPC interface pin status flags and perform any necessary processing.
4. Set the SDWNB bit to 1 to set LPC software shutdown mode.
5. Set the SDWNE bit to 1 and make a transition to LPC hardware shutdown mode. The SDWNE bit is cleared automatically.
6. Check the state of the $\overline{\text{LPCPD}}$ signal to make sure that the $\overline{\text{LPCPD}}$ signal has not risen in steps 3 to 5. If the signal has risen, clear the SDWNE bit to 0 to return to the state in step 2.
7. Place the slave processor in sleep mode or software standby mode as necessary.
8. If software standby mode has been set, exit software standby mode by some means independent of the LPC.
9. When a rising edge is detected in the $\overline{\text{LPCPD}}$ signal, the SDWNE bit is automatically cleared to 0. If the slave processor has been placed in sleep mode, the mode is exited by means of the $\overline{\text{LRESET}}$ signal input, on completion of the LPC transfer cycle, or by some other means.

Table 16.8 shows the scope of LPC interface pin shutdown.

GA20	PD3	Δ	I/O	Hi-Z, only when FGA20E = 1
$\overline{\text{CLKRUN}}$	PD4	O	I/O	Hi-Z
$\overline{\text{LPCPD}}$	PD5	X	Input	Needed to clear shutdown state

Notes: O: Pins shut down by the shutdown function

Δ : Pins shut down only when the LPC function is selected by register setting

X: Pins not shut down

In the LPC shutdown state, the LPC's internal state and some register bits are initialized. The priority of LPC shutdown and reset states is as follows.

1. System reset (reset by $\overline{\text{STBY}}$ or $\overline{\text{RES}}$ pin input, or WDT0 overflow)
 - All register bits, including bits LPC3E to LPC1E, are initialized.
2. LPC hardware reset (reset by $\overline{\text{LRESET}}$ pin input)
 - LRSTB, SDWNE, and SDWNB bits are cleared to 0.
3. LPC software reset (reset by LRSTB)
 - SDWNE and SDWNB bits are cleared to 0.
4. LPC hardware shutdown
 - SDWNB bit is cleared to 0.
5. LPC software shutdown

The scope of the initialization in each mode is shown in table 16.9.

Host interrupt enable bits (IRQ1E1, IRQ12E1, SMIE2, IRQ6E2, IRQ9E2 to IRQ11E2, SMIE3B, SMIE3A, IRQ6E3, IRQ9E3 to IRQ11E3, SELREQ, IEDIR, IEDIR3, SMICIR1), Q/C flag	Initialized	Initialized	Ret

Figure 16.9 Power-Down State Termination Timing

Figure 16.10 SERIRQ Timing

The serialized interrupt transfer cycle frame configuration is as follows. Two of the states comprising each frame are the recover state in which the SERIRQ signal is returned to the idle state at the end of the frame, and the turnaround state in which the SERIRQ signal is not driven. The recover state must be driven by the host or slave processor that was driving the preceding

18	Stop	Host	Undefined	First, 1 or more idle states, then 2 or 3 states driven by host 2 states: Quiet mode next 3 states: Continuous mode next

There are two modes—continuous mode and quiet mode—for serialized interrupts. The mode for the next interrupt transfer cycle is selected by the stop frame of the serialized interrupt transfer cycle that ended before that cycle.

In continuous mode, the host initiates host interrupt transfer cycles at regular intervals. In quiet mode, the slave processor with interrupt sources requiring a request can also initiate an interrupt transfer cycle, in addition to the host. In quiet mode, since the host does not necessarily initiate interrupt transfer cycles, it is possible to suspend the clock (LCLK) supply and enter the power-down state. In order for a slave to transfer an interrupt request in this case, a request to re-

Figure 16.11 Clock Start or Speed-Up

Cases other than SERIRQ in quiet mode when clock restart is required must be handled different protocol, using the PME signal, etc.

Interrupt	Description
IBF11	Requested when IBFIE1 is set to 1 and IDR1 reception is completed
IBF12	Requested when IBFIE2 is set to 1 and IDR2 reception is completed
IBF13	Requested when IBFIE3 is set to 1 and IDR3 reception is completed, or TWRE and IBFIE3 are set to 1 and reception is completed up to TWR15 Interrupts by HDTWI, HDTRI, STARI, CTLWI, and BUSY1 of SMIC mode Interrupts by FRDI, HRDI, HWRI, HBTWI, HBTRI, HRSTI, IRQCRI, BEVH2BI, CRRPI, and CRWPI of BT mode
ERRI	Requested when ERRIE is set to 1 and LRST, SDWN, or ABRT is set to 1

16.5.2 SMI, HIRQ1, HIRQ6, HIRQ9, HIRQ10, HIRQ11, HIRQ12

The LPC interface can request seven kinds of host interrupt by means of SERIRQ. HIRQ1, HIRQ6, HIRQ9, HIRQ10, HIRQ11, and HIRQ12 are used on LPC channel 1 only, while SMI, HIRQ6, HIRQ9, HIRQ10, and HIRQ11 can be requested from LPC channel 2 or 3.

There are two ways of clearing a host interrupt request.

When the IEDIR bit in SIRQCR0 and the IEDIR3 bit in SIRQCR2 are cleared to 0s, host interrupt requests from all sources and LPC channels are all linked to the host interrupt request enable bits. When the IEDIR bit is cleared to 0 by a read by the host of ODR or TWR15 in the corresponding LPC channel, the corresponding host interrupt enable bit is automatically cleared to 0, and the host interrupt request is cleared.

When the IEDIR bit in SIRQCR0 and the IEDIR3 bit in SIRQCR2 are set to 1s, LPC channels 2 and 3 interrupt requests are dependent only upon the host interrupt enable bits. The host interrupt enable bit is not cleared when OBF for channel 2 or 3 is cleared. Therefore, SMIE2, SMIE3B, IRQ6E2 and IRQ6E3, IRQ9E2 and IRQ9E3, IRQ10E2 and IRQ10E3, and IRQ11E2 and IRQ11E3 lose their respective functional differences when both bits IEDIR and IEDIR3 are cleared.

contention. For example, if the host and slave processor both try to access IDR or ODR at the same time, the data will be corrupted. To prevent simultaneous accesses, IBF and OBF are used to allow access only to data for which writing has finished.

Unlike the IDR and ODR registers, the transfer direction is not fixed for the bidirectional registers (TWR). MWMF and SWMF are provided in STR to handle this situation. After access to TWR0, MWMF and SWMF must be used to confirm that the right to access TWR1 to TWR15 has been obtained.

Table 16.13 shows the host address example of registers LADR3, IDR3, ODR3, STR3, TWR0MW, TWR0SW, and TWR1 to TWR15.

output pins.

17.3.2 D/A Control Register (DACR)

DACR controls D/A converter operation.

Bit	Bit Name	Initial Value	R/W	Description
7	DAOE1	0	R/W	D/A Output Enable 1 Controls D/A conversion and analog output. 0: Analog output DA1 is disabled 1: D/A conversion for channel 1 and analog output are enabled
6	DAOE0	0	R/W	D/A Output Enable 0 Controls D/A conversion and analog output. 0: Analog output DA0 is disabled 1: D/A conversion for channel 0 and analog output are enabled
5	DAE	0	R/W	D/A Enable Controls D/A conversion in conjunction with the DAOE0 and DAOE1 bits. When the DAE bit is cleared, D/A conversion for channels 0 and 1 are controlled individually. When the DAE bit is set to 1, D/A conversion for channels 0 and 1 are controlled as one. Conversion result output is controlled by the DAOE0 and DAOE1 bits. For details, see table 17.2 below.
4 to 0	—	All 1	R	Reserved The initial value should not be changed.

[Legend]

*: Don't care

conversion results are output from the analog output pin DA0. The conversion results are output continuously until DADR0 is modified or the DAOE0 bit is cleared to 0. The value is calculated by the following formula:

$$\text{DADR contents} / 256 \times \text{AVref}$$

3. Conversion starts immediately after DADR0 is modified. After the interval of t_{bcnv} , conversion results are output.
4. When the DAOE0 bit is cleared to 0, analog output is disabled.

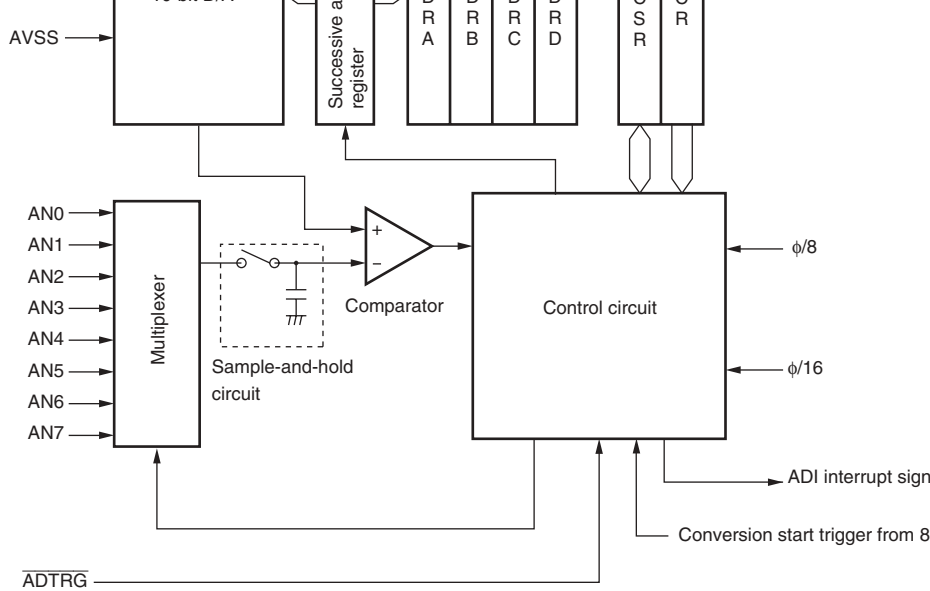

Figure 17.2 D/A Converter Operation Example

- Two kinds of operating modes
 - Single mode: Single-channel A/D conversion
 - Scan mode: Continuous A/D conversion on 1 to 4 channels
- Four data registers
 - Conversion results are held in a 16-bit data register for each channel
- Sample and hold function
- Three kinds of conversion start
 - Software, 8-bit timer (TMR) conversion start trigger, or external trigger signal.
- Interrupt request
 - A/D conversion end interrupt (ADI) request can be generated
- Module stop mode can be set

[Legend]

Analog input pin 6	AN6	Input	
Analog input pin 7	AN7	Input	
A/D external trigger input pin	$\overline{\text{ADTRG}}$	Input	External trigger input pin for starting A/D conversion

There are four 16-bit read-only ADDR registers, ADDRA to ADDRD, used to store the result of the A/D conversion. The ADDR registers, which store a conversion result for each channel, are listed in table 18.2.

The converted 10-bit data is stored to bits 15 to 6. The lower 6-bit data is always read as 0.

The data bus between the CPU and the A/D converter is 8-bit width. The upper byte can be read directly from the CPU, but the lower byte should be read via a temporary register. The temporary register contents are transferred from the ADDR when the upper byte data is read. When reading the ADDR, read only the upper byte in byte units or read in word units.

Table 18.2 Analog Input Channels and Corresponding ADDR Registers

Analog Input Channel		A/D Data Register to Store A/D Conversion Results
Group 0	Group 1	
AN0	AN4	ADDRA
AN1	AN5	ADDRB
AN2	AN6	ADDRC
AN3	AN7	ADDRD

- When 0 is written after reading ADF = 1
- When DTC starts by an ADI interrupt and read

6	ADIE	0	R/W	A/D Interrupt Enable Enables ADI interrupt by ADF when this bit
5	ADST	0	R/W	A/D Start Setting this bit to 1 starts A/D conversion. In mode, this bit is cleared to 0 automatically w conversion on the specified channel ends. In mode, conversion continues sequentially on specified channels until this bit is cleared to software, a reset, or a transition to standby module stop mode.
4	SCAN	0	R/W	Scan Mode Selects the A/D conversion operating mode 0: Single mode 1: Scan mode
3	CKS	0	R/W	Clock Select Sets A/D conversion time. 0: Conversion time is 266 states (max) 1: Conversion time is 134 states (max) (when the system clock (ϕ) is 16 MHz or low Switch conversion time while ADST is 0.

Note: * Only 0 can be written for clearing the flag.

18.3.3 A/D Control Register (ADCR)

ADCR enables A/D conversion started by an external trigger signal.

Bit	Bit Name	Initial Value	R/W	Description
7	TRGS1	0	R/W	Timer Trigger Select 1 and 0
6	TRGS0	0	R/W	Enable the start of A/D conversion by a trigger. Only set bits TRGS1 and TRGS0 while A/D conversion is stopped (ADST = 0). 00: A/D conversion start by external trigger is selected. 01: A/D conversion start by external trigger is selected. 10: A/D conversion start by conversion trigger (TMR) is selected. 11: A/D conversion start by $\overline{\text{ADTRG}}$ pin is selected.
5 to 0	—	All 1	R/W	Reserved The initial values should not be changed.

1. A/D conversion on the specified channel is started when the ADST bit in ADCSR is set to 1 by software or an external trigger input.
2. When A/D conversion is completed, the result is transferred to the A/D data register corresponding to the channel.
3. On completion of A/D conversion, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
4. The ADST bit remains set to 1 during A/D conversion. When conversion ends, the ADST bit is automatically cleared to 0, and the A/D converter enters wait state.

18.4.2 Scan Mode

In scan mode, A/D conversion is to be performed sequentially on the specified channels (channels max.). Operations are as follows.

1. When the ADST bit in ADCSR is set to 1 by software or an external trigger input, A/D conversion starts on the first channel in the group (AN0 when the CH2 bit in ADCSR is 0, AN4 when the CH2 bit in ADCSR is 1).
2. When A/D conversion for each channel is completed, the result is sequentially transferred to the A/D data register corresponding to each channel.
3. When conversion of all the selected channels is completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt is requested after A/D conversion. Conversion of the first channel in the group starts again.
4. The ADST bit is not automatically cleared to 0 so steps [2] to [3] are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops.

(fixed) when CKS = 1.

Use the conversion time of 134 state only when the system clock (ϕ) is 16 MHz or lower.

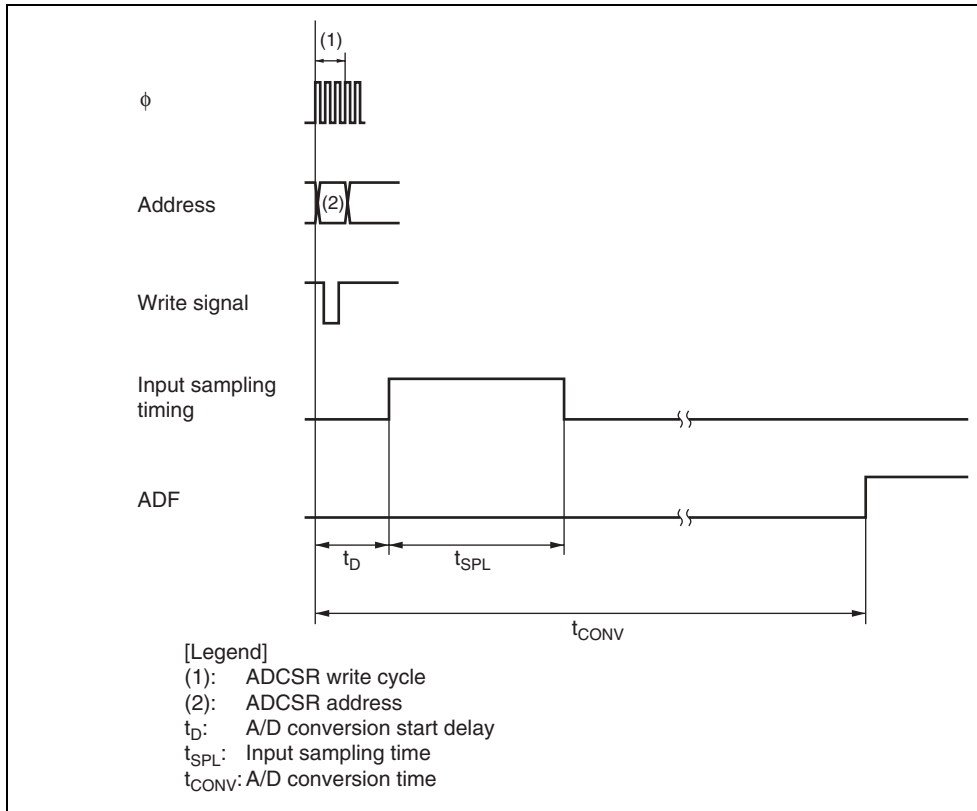

Figure 18.2 A/D Conversion Timing

A/D conversion can be externally triggered. When the TRGS1 and TRGS0 bits are set to 1 in ADCR, external trigger input is enabled at the ADTRG pin. A falling edge at the ADTRG pin sets the ADST bit to 1 in ADCSR, starting A/D conversion. Other operations, in both single and scan modes, are the same as when the ADST bit has been set to 1 by software. Figure 18.3 shows the timing.

Figure 18.3 External Trigger Input Timing

18.6 A/D Conversion Accuracy Definitions

This LSI's A/D conversion accuracy definitions are given below.

- Resolution
The number of A/D converter digital output codes
- Quantization error
The deviation inherent in the A/D converter, given by 1/2 LSB (see figure 18.4).
- Offset error
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from the minimum voltage value B'00 0000 0000 (H'0000) to B'00 0000 0001 (H'0001) (see figure 18.5).
- Full-scale error
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from B'11 1111 1110 (H'3FE) to B'11 1111 1111 (H'3FF) (see figure 18.5).
- Nonlinearity error
The error with respect to the ideal A/D conversion characteristics between the zero voltage and the full-scale voltage. Does not include the offset error, full-scale error, or quantization error (see figure 18.5).
- Absolute accuracy
The deviation between the digital value and the analog input value. Includes the offset error, full-scale error, quantization error, and nonlinearity error.

Figure 18.4 A/D Conversion Accuracy Definitions

Figure 18.5 A/D Conversion Accuracy Definitions

differential coefficient (e.g., voltage fluctuation rate of 5 mV/ μ s or greater) (see Figure 18.5). When converting a high-speed analog signal or converting in scan mode, a low-impedance load should be inserted.

18.7.2 Influences on Absolute Accuracy

Adding capacitance results in coupling with GND, and therefore noise in GND may adversely affect the absolute accuracy. Be sure to make the connection to an electrically stable GND (AVSS).

Care is also required to insure that filter circuits do not communicate with digital signals on the mounting board, so acting as antennas.

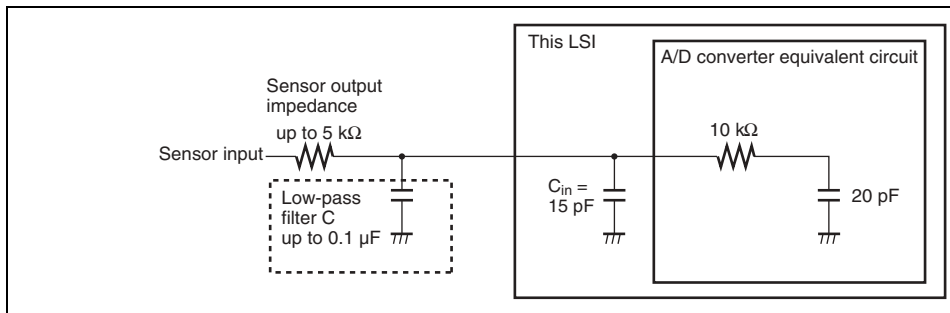

Figure 18.6 Example of Analog Input Circuit

The reference voltage of the AVref pin should be in the range $AVref \leq AVCC$.

18.7.4 Notes on Board Design

In board design, digital circuitry and analog circuitry should be as mutually isolated as possible, and layout in which digital circuit signal lines and analog circuit signal lines cross or are in close proximity should be avoided as far as possible. Failure to do so may result in incorrect operation of the analog circuitry due to inductance, adversely affecting A/D conversion values. Analog circuitry must be isolated from the analog input signals (AN0 to AN7), and analog power supply (AVCC) by the analog ground (AVSS). Also, the analog ground (AVSS) should be connected at one point to a stable digital ground (VSS) on the board.

18.7.5 Notes on Noise Countermeasures

A protection circuit connected to prevent damage due to an abnormal voltage such as an overvoltage surge at the analog input pins (AN0 to AN7) should be connected between AVCC and AVref, as shown in figure 18.7. Also, the bypass capacitors connected to AVCC and AVref, and the bypass capacitors connected to AN0 to AN7 must be connected to AVSS.

If a filter capacitor is connected, the input currents at the analog input pins (AN0 to AN7) are averaged, and so an error may arise. Also, when A/D conversion is performed frequently in scan mode, if the current charged and discharged by the capacitance of the sample-and-hold capacitor in the A/D converter exceeds the current input via the input impedance (R_{in}), an error will occur in the analog input pin voltage. Careful consideration is therefore required when deciding the values of the constants.

Figure 18.7 Example of Analog Input Protection Circuit

Note: Values are reference values.

Figure 18.8 Analog Input Pin Equivalent Circuit

- Two flash-memory MATs according to LSI initiation mode
The on-chip flash memory has two memory spaces in the same address space (hereafter referred to as memory MATs). The mode setting in the initiation determines which memory MAT is initiated first. The MAT can be switched by using the bank-switching method at initiation.
 - The user memory MAT is initiated at a power-on reset in user mode: 256 kbytes (H8S/2168), 384 kbytes (H8S/2167), 512 kbytes (H8S/2166)
 - The user boot memory MAT is initiated at a power-on reset in user boot mode: 8 kbytes (H8S/2168), 16 kbytes (H8S/2167), 32 kbytes (H8S/2166)
- Programming/erasing interface by the download of on-chip program
This LSI has a dedicated programming/erasing program. After downloading this program to the on-chip RAM, programming/erasing can be performed by setting the argument parameters.
- Programming/erasing time
The flash memory programming time is 3 ms (typ) in 128-byte simultaneous programming, and approximately 25 μ s per byte. The erasing time is 1000 ms (typ) per 64-kbyte block.
- Number of programming
The number of flash memory programming can be up to 100 times at the minimum. (The number of times ranged from 1 to 100 is guaranteed.)
- Three on-board programming modes
 - Boot mode
This mode is a program mode that uses an on-chip SCI interface. The user MAT and boot MAT can be programmed. This mode can automatically adjust the bit rate between the host and this LSI.
 - User program mode
The user MAT can be programmed by using the optional interface.

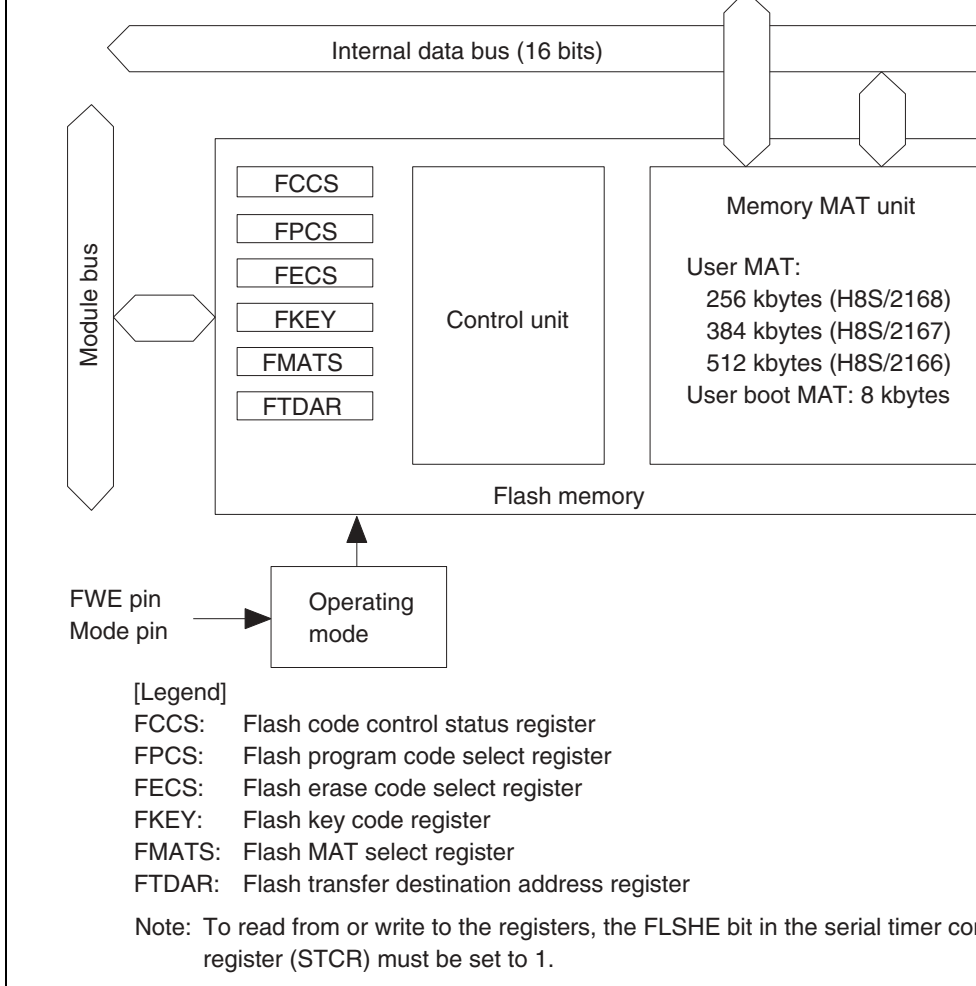

Figure 20.1 Block Diagram of Flash Memory

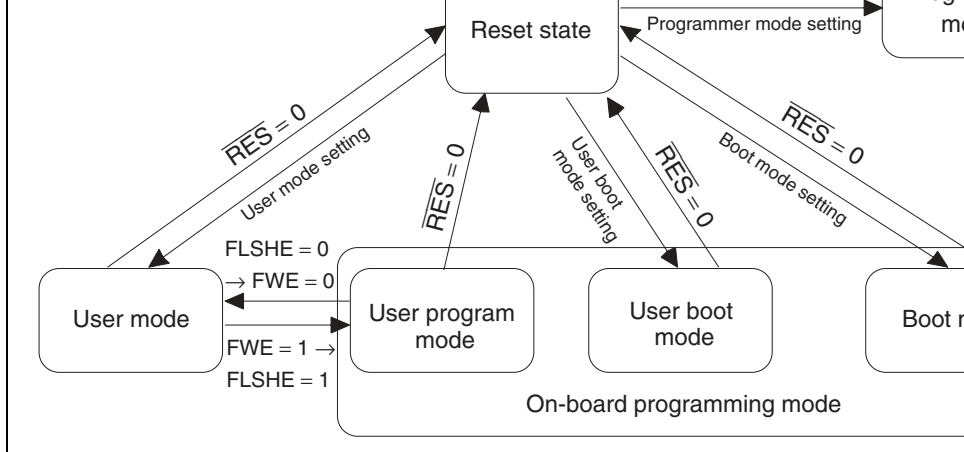

Figure 20.2 Mode Transition of Flash Memory

MAT				User boot
All erasure	○ (Automatic)	○	○	○ (Autom
Block division erasure	○ * ¹	○	○	×
Program data transfer	From host via SCI	Via optional device	Via optional device	Via program
Reset initiation MAT	Embedded program storage MAT	User MAT	User boot MAT* ²	—
Transition to user mode	Changing mode setting and reset	Changing FLSHE bit and FWE pin	Changing mode setting and reset	—

Notes: 1. All-erasure is performed. After that, the specified block can be erased.
 2. Firstly, the reset vector is fetched from the embedded program storage MAT. After that, the flash memory related registers are checked, the reset vector is fetched from the user boot MAT.

- The user boot MAT can be programmed or erased only in boot mode and programmed in user boot mode.
- The user MAT and user boot MAT are erased in boot mode. Then, the user MAT and user boot MAT can be programmed by means of the command method. However, the contents of the user boot MAT cannot be read until this state.
 Only user boot MAT is programmed and the user MAT is programmed in user boot mode. If only user MAT is programmed because user boot mode is not used.
- The boot operation of the optional interface can be performed by the mode pin setting from user program mode in user boot mode.

Figure 20.3 Flash Memory Configuration

The size of the user MAT is different from that of the user boot MAT. An address which the size of the 8-kbyte user boot MAT should not be accessed. If the attempt is made, data is as undefined value.

Notes: 1. EB12 to EB15 are not available in the H8S/2168.

2. EB14 and EB15 are not available in the H8S/2167.

Figure 20.4 Block Division of User MAT

Figure 20.5 Overview of User Procedure Program

1. Selection of on-chip program to be downloaded

For programming/erasing execution, the FLSHE bit in STCR must be set to 1 to transfer the user program mode.

This LSI has programming/erasing programs which can be downloaded to the on-chip program. The on-chip program to be downloaded is selected by setting the corresponding bits in the programming/erasing interface register. The address of the programming destination is specified by the flash transfer destination address register (FTDAR).

The operating frequency is set before execution of programming/erasing. This setting is performed by using the programming/erasing interface parameter.

4. Programming/erasing execution

For programming/erasing execution, the FLSHE bit in STCR and the FWE pin must be set to transition to user program mode.

The program data/programming destination address is specified in 128-byte units when programming.

The block to be erased is specified in erase-block units when erasing.

These specifications are set by using the programming/erasing interface parameter at the time a chip program is initiated. The on-chip program is executed by using the JSR or BSR instruction and performing the subroutine call of the specified address in the on-chip program.

The execution result is returned to the programming/erasing interface parameter.

The area to be programmed must be erased in advance when programming flash memory.

All interrupts are prohibited during programming and erasing. Interrupts must be masked before entering within the user system.

5. When programming/erasing is executed consecutively

When the processing is not ended by the 128-byte programming or one-block erasure, the program address/data and erase-block number must be updated and consecutive programming/erasing is required.

Since the downloaded on-chip program is left in the on-chip RAM after the processing, the program download and initialization are not required when the same processing is executed consecutively.

TxD1	Output	Serial transmit data output (used in boot mode)
RxD1	Input	Serial receive data input (used in boot mode)

20.3 Register Descriptions

The registers/parameters which control flash memory are shown in the following. To read/write to these registers/parameters, the FLSHE bit in the serial timer control register (STCR) must be set to 1. For details on STCR, see section 3.2.3, Serial Timer Control Register (STCR).

- Flash code control status register (FCCS)
- Flash program code select register (FPCS)
- Flash erase code select register (FECS)
- Flash key code register (FKEY)
- Flash MAT select register (FMATS)
- Flash transfer destination address register (FTDAR)
- Download pass/fail result (DPFR)
- Flash pass/fail result (FPFR)
- Flash multipurpose address area (FMPAR)
- Flash multipurpose data destination area (FMPDR)
- Flash erase Block select (FEBS)
- Flash programming/erasing frequency control (FPEFEQ)

There are several operating modes for accessing flash memory, for example, read mode/program mode.

There are two memory MATs: user MAT and user boot MAT. The dedicated registers/parameters are allocated for each operating mode and MAT selection. The correspondence of operating modes and registers/parameters for use is shown in table 20.3.

Parameter					
FPEFEQ	—	○	—	—	—
FMPAR	—	—	○	—	—
FMPDR	—	—	○	—	—
FEBS	—	—	—	○	—

- Notes:
1. The setting is required when programming or erasing user MAT in user boot mode.
 2. The setting may be required according to the combination of initiation mode and target MAT.

20.3.1 Programming/Erasing Interface Register

The programming/erasing interface registers are as described below. They are all 8-bit registers that can be accessed in byte. These registers are initialized at a reset or in hardware stand-by mode.

Indicates an error occurs during programming or erasing flash memory. When FLER is set to 1, flash memory enters the error protection state.

When FLER is set to 1, high voltage is applied to internal flash memory. To reduce the damage to memory, the reset must be released after the reset period of 100 μ s which is longer than normal.

0: Flash memory operates normally.

Programming/erasing protection for flash memory (error protection) is invalid.

[Clearing condition]

- At a reset or in hardware standby mode

1: An error occurs during programming/erasing flash memory.

Programming/erasing protection for flash memory (error protection) is valid.

[Setting conditions]

- When an interrupt, such as NMI, occurs during programming/erasing flash memory.
- When the flash memory is read during programming/erasing flash memory (including vector read or an instruction fetch).
- When the SLEEP instruction is executed during programming/erasing flash memory (including software-standby mode)
- When a bus master other than the CPU, such as DTC, gets bus mastership during programming/erasing flash memory.

- vector is not read, resulting in the CPU runaway.
- 0: The space for the interrupt vector table is not modified.
When interrupt vector data is not read successfully, the operation for the interrupt exception handling cannot be guaranteed. An occurrence of a interrupt should be masked.
 - 1: The space for the interrupt vector table is not modified.
Even when interrupt vector data is not read successfully, the interrupt exception handling operation with the interrupt vector number 31 is enabled.

2, 1	—	All 0	R/W	Reserved The initial value should not be changed.
0	SCO	0	(R)/W*	Source Program Copy Operation Requests the on-chip programming/erasing program to be downloaded to the on-chip RAM. When this bit is set to 1, the on-chip program vector selected by FPCS/FECS is automatically downloaded to the on-chip RAM specified by FTDAR. In order to set this bit to 1, H'A5 must be written and this operation must be executed in the on-chip RAM. Four NOP instructions must be executed immediately after setting this bit to 1. Since this bit is cleared to 0 when download is completed, this bit cannot be read as 1. All interrupts must be disabled. This should be done in the user system. 0: Download of the on-chip programming/erasing program to the on-chip RAM is not executed.

- Flash Program Code Select Register (FPCS)

FPCS selects the on-chip programming program to be downloaded.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R/W	Reserved The initial value should not be changed.
0	PPVS	0	R/W	Program Pulse Verify Selects the programming program. 0: On-chip programming program is not selected. [Clearing condition] When transfer is completed 1: On-chip programming program is selected.

- Flash Erase Code Select Register (FECS)

FECS selects download of the on-chip erasing program.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R/W	Reserved The initial value should not be changed.
0	EPVB	0	R/W	Erase Pulse Verify Block Selects the erasing program. 0: On-chip erasing program is not selected. [Clearing condition] When transfer is completed 1: On-chip erasing program is selected.

1	K1	0	R/W	Only when H'5A is written, programming/erasing is executed. Even if the on-chip programming/erasing program is executed, the flash memory cannot be programmed or erased when the value other than H'5A is written to FKEY.
0	K0	0	R/W	
H'A5: Writing to the SCO bit is enabled. (The SCO bit cannot be set by the value other than H'5A)				
H'5A: Programming/erasing is enabled. (The value other than H'5A is in software protection state)				
H'00: Initial value				

mode if user boot MAT is selected by FMATS. (user boot MAT must be programmed in boot mode or programmer mode.)

H'AA: The user boot MAT is selected (in user-MAT selection state when the value of these bits is other than H'AA)

Initial value when these bits are initiated in boot mode.

H'00: Initial value when these bits are initiated in boot mode except for user boot mode (in user-MAT selection state)

[Programmable condition]

These bits are in the execution state in the on-chip

Note: * Set to 1 when in user boot mode, otherwise set to 0.

to 1 and the value specified by TDA6 to TDA0 is the range of H'00 to H'03.

0: The value specified by bits TDA6 to TDA0 is the range.

1: The value specified by bits TDA6 to TDA0 is the range (H'04 to H'FF) and the download is stopped.

6	TDA6	0	R/W	Transfer Destination Address
5	TDA5	0	R/W	Specifies the start address to download an on-chip program. H'00 to H'03 can be specified as the start address in the on-chip RAM space.
4	TDA4	0	R/W	
3	TDA3	0	R/W	H'00: H'FFE080 is specified as a start address to download an on-chip program.
2	TDA2	0	R/W	
1	TDA1	0	R/W	H'01: H'FF0800 is specified as a start address to download an on-chip program.
0	TDA0	0	R/W	H'02: H'FF1800 is specified as a start address to download an on-chip program.
				H'03: H'FF8800 is specified as a start address to download an on-chip program.
				H'04 to H'FF: Setting prohibited. Specifying this value sets the TDER bit to 1 and stops the download.

The programming/erasing interface parameter is used in the following four items.

1. Download control
2. Initialization before programming or erasing
3. Programming
4. Erasing

These items use different parameters. The correspondence table is shown in table 20.4. The meaning of the bits in FPFR varies in each processing program: initialization, programming, erasure. For details, see descriptions of FPFR for each process.

Flash multipurpose data destination area FMPDR — — ○ — R/W Undefined

Flash erase block select FEBS — — — ○ R/W Undefined

Note: * A single byte of the start address to download an on-chip program, which is s
FTDAR

example, H'FF) before the download start (before setting the SCO bit to 1).

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	—	—	Unused Return 0
2	SS	—	R/W	Source Select Error Detect Only one type for the on-chip program which can be downloaded can be specified. When more than one type of the program are selected, the program is selected, or the program is selected without mapping, an error is occurred. 0: Download program can be selected normally 1: Download error is occurred (multi-selection of program which is not mapped is selected)
1	FK	—	R/W	Flash Key Register Error Detect Returns the check result whether the value of FKEY is set to H'A5. 0: KEY setting is normal (FKEY = H'A5) 1: Setting value of FKEY becomes error (FKEY other than H'A5)
0	SF	—	R/W	Success/Fail Returns the result whether download is ended normally or not. The determination result whether program is downloaded to the on-chip RAM is read back and the result of transferred to the on-chip RAM is returned. 0: Downloading on-chip program is ended normally (no error) 1: Downloading on-chip program is ended abnormally (error occurs)

frequency in this LSI is 5 to 33 MHz.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	—	—	Unused This bit should be cleared to 0.
15 to 0	F15 to F0	—	R/W	Frequency Set Set the operating frequency of the CPU. With the frequency multiplication function, set the frequency multiplication setting value must be calculated as the following methods. <ol style="list-style-type: none">1. The operating frequency which is shown in the specification must be rounded in a number to three decimal places and be shown in a number of two decimal places.2. The value multiplied by 100 is converted to a decimal digit and is written to the FPEFEQ parameter (general register ER0). For example, when the operating frequency of the CPU is 33.000 MHz, the value is as follows. <ol style="list-style-type: none">1. The number to three decimal places of 33.000 is rounded and the value is thus 33.00.2. The formula that $33.00 \times 100 = 3300$ is converted to the binary digit and B'0000,1100,1110,0100 (H'0CE4) is set to ER0.

				1: Setting of operating frequency is abnormal
0	SF	—	R/W	Success/Fail
				Indicates whether initialization is completed normally
				0: Initialization is ended normally (no error)
				1: Initialization is ended abnormally (error occurred)

(3) Programming Execution

When flash memory is programmed, the programming destination address on the user MAT must be passed to the programming program in which the program data is downloaded.

1. The start address of the programming destination on the user MAT must be stored in a general register ER1. This parameter is called as flash multipurpose address area parameter (FMPADR). Since the program data is always in units of 128 bytes, the lower eight bits (A7 to A0) must be set to H'00 or H'80 as the boundary of the programming start address on the user MAT.
2. The program data for the user MAT must be prepared in the consecutive area. The program data must be in the consecutive space which can be accessed by using the MOV.B instruction of the CPU and in other than the flash memory space.

When data to be programmed does not satisfy 128 bytes, the 128-byte program data must be prepared by filling with the dummy code H'FF.

The start address of the area in which the prepared program data is stored must be stored in a general register ER0. This parameter is called as flash multipurpose data destination area parameter (FMPDR).

For details on the program processing procedure, see section 20.4.2, User Program Mode.

programming is executed starting from the specified address of the user MAT. Therefore, the specified programming start address becomes a 128-byte boundary and MOA6 to MOA0 are always 0.

(b) Flash multipurpose data destination parameter (FMPDR: general register ER0 of CPU)

This parameter stores the start address in the area which stores the data to be programmed for the user MAT. When the storage destination of the program data is in flash memory, an error occurs. The error occurrence is indicated by the WD bit in FPFR.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MOD31 to MOD0	—	R/W	Store the start address of the area which stores program data for the user MAT. The consecutive byte data is programmed to the user MAT starting from the specified start address.

(c) Flash pass/fail parameter (FPFR: general register R0L of CPU)

This parameter indicates the return value of the program processing result.

Bit	Bit Name	Initial Value	R/W	Description
7	—	—	—	Unused Return 0.

5	EE	—	R/W	<p>Programming Execution Error Detect</p> <p>1 is returned to this bit when the specified data cannot be written because the user MAT was not erased. If the bit is set to 1, there is a high possibility that the data is partially rewritten. In this case, after removing the error factor, erase the user MAT.</p> <p>If FMATS is set to H'AA and the user boot MAT is selected, an error occurs when programming is performed. In this case, both the user MAT and boot MAT are not rewritten. Programming of the user MAT should be performed in boot mode or program mode.</p> <p>0: Programming has ended normally 1: Programming has ended abnormally (programming result is not guaranteed)</p>
4	FK	—	R/W	<p>Flash Key Register Error Detect</p> <p>Returns the check result of the value of FKEY before the start of the programming processing.</p> <p>0: FKEY setting is normal (FKEY = H'5A) 1: FKEY setting is error (FKEY = value other than H'5A)</p>
3	—	—	—	<p>Unused</p> <p>Returns 0.</p>
2	WD	—	R/W	<p>Write Data Address Detect</p> <p>When the address in the flash memory area is set to the start address of the storage destination of program data, an error occurs.</p> <p>0: Setting of write data address is normal 1: Setting of write data address is abnormal</p>

				abnormal
0	SF	—	R/W	Success/Fail
				Indicates whether the program processing is ended normally or not.
				0: Programming is ended normally (no error)
				1: Programming is ended abnormally (error occurred)

Bit	Bit Name	Value	R/W	Description
31 to 8	—	—	—	Unused These bits should be cleared to H'0.
7	EB7	—	R/W	Erase Block
6	EB6	—	R/W	Set the erase-block number in the range from 0 to 15. 0 corresponds to the EB0 block and 15 corresponds to the EB15 block. The number other than 0 to 11, 0 to 15 should not be set in the H8S/2168, H8S/2166, and H8S/2166, respectively.
5	EB5	—	R/W	
4	EB4	—	R/W	
3	EB3	—	R/W	
2	EB2	—	R/W	
1	EB1	—	R/W	
0	EB0	—	R/W	

FLER bits in FCCS. For conditions to enter the protection state, see section 20.5.3, Error Protection

0: FWE and FLER settings are normal (FWE = 0, FLER = 0)

1: Programming cannot be performed (FWE = 1, FLER = 1)

5	EE	—	R/W	<p>Erase Execution Error Detect</p> <p>1 is returned to this bit when the user MAT could not be erased or when flash-memory related register settings are partially changed. If this bit is set to 1, there is a possibility that the user MAT is partially erased. In this case, after removing the error factor, erase the user MAT. If FMATS is set to H'AA and the user boot mode is selected, an error occurs when erasure is performed. In this case, both the user MAT and user boot MAT should be erased. Erasing of the user boot MAT should be performed in boot mode or programmer mode.</p> <p>0: Erasure has ended normally</p> <p>1: Erasure has ended abnormally (erasure result not guaranteed)</p>
4	FK	—	R/W	<p>Flash Key Register Error Detect</p> <p>Returns the check result of FKEY value before the erasing processing.</p> <p>0: FKEY setting is normal (FKEY = H'5A)</p> <p>1: FKEY setting is error (FKEY = value other than H'5A)</p>
3	EB	—	R/W	<p>Erase Block Select Error Detect</p> <p>Returns the check result whether the specified erase block number is in the block range of the user MAT.</p> <p>0: Setting of erase-block number is normal</p> <p>1: Setting of erase-block number is abnormal</p>

When the pin is set in on-board programming mode and the reset start is executed, the on-board programming state that can program/erase the on-chip flash memory is entered. On-board programming mode has three operating modes: boot mode, user program mode, and user boot mode.

For details of the pin setting for entering each mode, see table 20.5. For details of the state transition of each mode for flash memory, see figure 20.2.

Table 20.5 Setting On-Board Programming Mode

Mode Setting	FWE	$\overline{\text{MD2}}$	MD1	MD0	NR
Boot mode	1	0	0	0	1
User program mode	1*	1	1	0	0/1
User boot mode	1	0	0	0	0

Note: * Before downloading the programming/erasing programs, the FLSHE bit must be set to 1 to transition to user program mode.

20.4.1 Boot Mode

Boot mode executes programming/erasing user MAT and user boot MAT by means of the SCI command and program data transmitted from the host using the on-chip SCI. The tool for transmitting the control command and program data must be prepared in the host. The SCI communication mode is set to asynchronous mode. When reset start is executed after this pin is set in boot mode, the boot program in the microcomputer is initiated. After the SCI is automatically adjusted, the communication with the host is executed by means of the SCI command method.

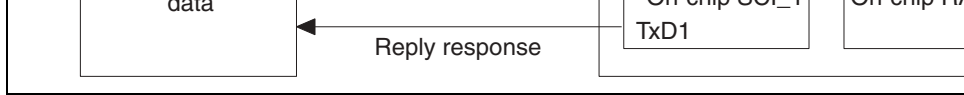

Figure 20.6 System Configuration in Boot Mode

(1) SCI Interface Setting by Host

When boot mode is initiated, this LSI measures the low period of asynchronous SCI communication data (H'00), which is transmitted consecutively by the host. The SCI transmit/receive is set to 8-bit data, 1 stop bit, and no parity. This LSI calculates the bit rate of transmission by the host by means of the measured low period and transmits the bit adjustment end sign (1 byte of H'00) to the host. The host must confirm that this bit adjustment end sign (H'00) has been received normally and transmits 1 byte of H'55 to this LSI. When reception is not executed normally, boot mode is initiated again (reset) and the operation described above must be executed. The timing between the host and this LSI is not matched by the bit rate of transmission by the host and the clock frequency of this LSI. To operate the SCI normally, the transfer bit rate of the host must be set to 4,800 bps, 9,600 bps, or 19,200 bps.

The system clock frequency, which can automatically adjust the transfer bit rate of the host to match the bit rate of this LSI, is shown in table 20.6. Boot mode must be initiated in the range of the system clock.

Figure 20.7 Automatic-Bit-Rate Adjustment Operation of SCI

2. Waiting for inquiry set command

After boot mode is initiated, the BR rate of the SPI interface is adjusted with that of the host. For inquiries about user-MAT size and configuration, MAT start address, and support required information is transmitted to the host.

3. Automatic erasure of all user MAT and user boot MAT

After inquiries have finished, all user MAT and user boot MAT are automatically erased.

4. Waiting for programming/erasing command

— When the program preparation notice is received, the state for waiting program data is entered. The programming start address and program data must be transmitted following the programming command. When programming is finished, the programming start address must be set to H'FFFFFFF and transmitted. Then the state for waiting program data is returned to the state of programming/erasing command wait.

— When the erasure preparation notice is received, the state for waiting erase-block data is entered. The erase-block number must be transmitted following the erasing command. When the erasure is finished, the erase-block number must be set to H'FF and transmitted. Then the state for waiting erase-block data is returned to the state for waiting programming/erasing command. The erasure must be used when the specified block is programmed without a reset start after programming is executed in boot mode. When programming can be executed by only one operation, all blocks are erased before the state for waiting programming/erasing/other command is entered. The erasing operation is required.

— There are many commands other than programming/erasing. Examples are sum check, blank check (erasure check), and memory read of the user MAT/user boot MAT and acquisition of current status information.

Note that memory read of the user MAT/user boot MAT can only read the programmed data. If all user MAT/user boot MAT has automatically been erased.

Figure 20.8 Overview of Boot Mode State Transition Diagram

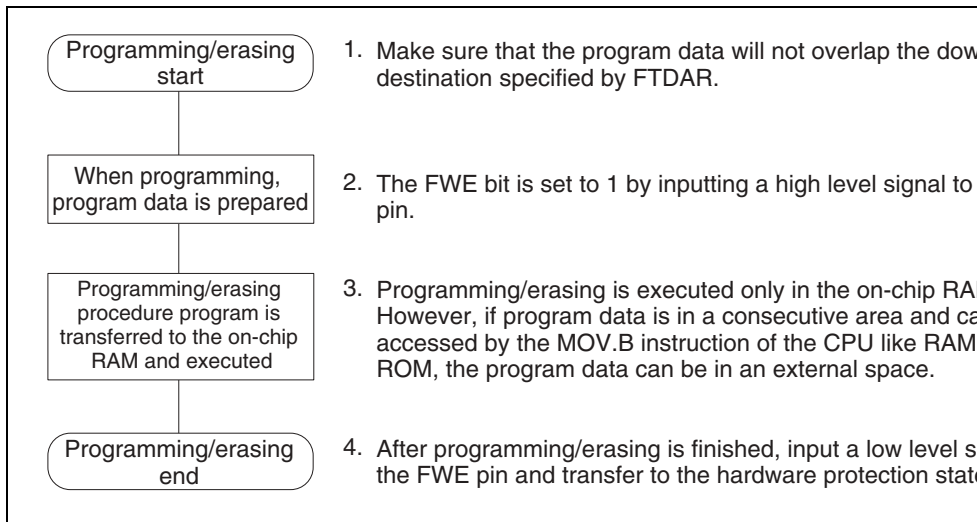

Figure 20.9 Programming/Erasing Overview Flow

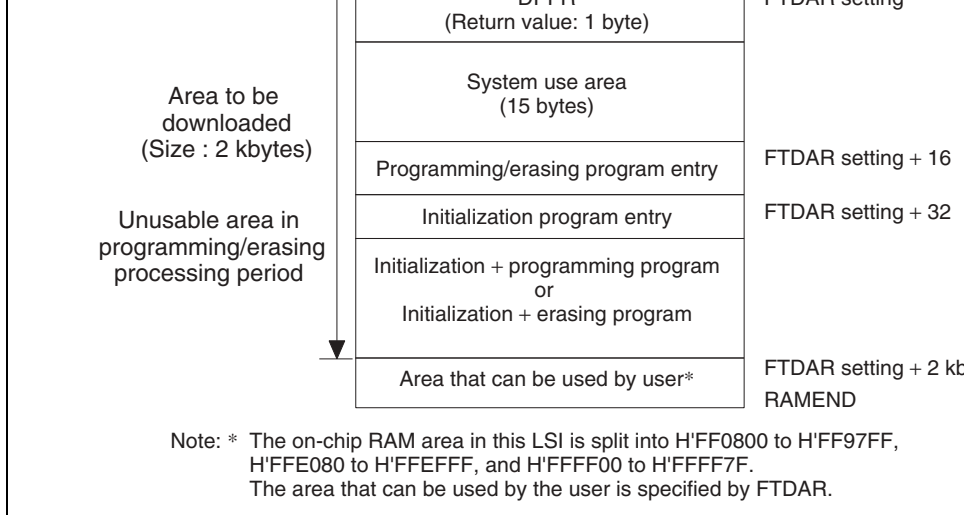

Figure 20.10 RAM Map When Programming/Erasing is Executed

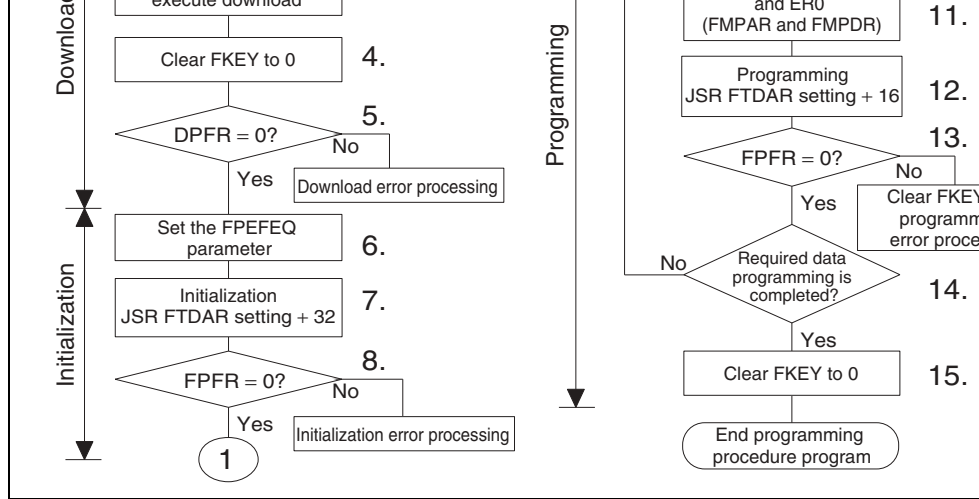

Figure 20.11 Programming Procedure

The procedure program must be executed in an area other than the flash memory to be programmed. Especially the part where the SCO bit in FCCS is set to 1 for downloading executed in the on-chip RAM.

The area that can be executed in the steps of the user procedure program (on-chip RAM, MAT, and external space) is shown in section 20.4.4, Procedure Program and Storable A Programming Data.

The following description assumes the area to be programmed on the user MAT is erased program data is prepared in the consecutive area. When erasing is not executed, erasing is executed before writing.

2. Program H'A5 in FKEY

If H'A5 is not written to FKEY for protection, 1 cannot be set to the SCO bit for download request.

3. 1 is set to the SCO bit of FCCS and then download is executed.

To set 1 to the SCO bit, the following conditions must be satisfied.

— H'A5 is written to FKEY.

— The SCO bit writing is executed in the on-chip RAM.

When the SCO bit is set to 1, download is started automatically. When the SCO bit is set to the user procedure program, the SCO is cleared to 0. Therefore, the SCO bit cannot be confirmed to be 1 in the user procedure program.

The download result can be confirmed only by the return value of DPFR. Before the SCO bit is set to 1, incorrect determination must be prevented by setting the one byte of the start address (to be used as DPFR) specified by FTDAR to a value other than the return value (e.g., 0).

When download is executed, particular interrupt processing, which is accompanied by the switch as described below, is performed as an internal microcomputer processing. For the instructions are executed immediately after the instructions that set the SCO bit to 1.

— The user-MAT space is switched to the on-chip program storage area.

— After the selection condition of the download program and the FTDAR setting are completed, the transfer processing to the on-chip RAM specified by FTDAR is executed.

— The SCO bit in FCCS is cleared to 0.

— The return value is set to the DPFR parameter.

— After the on-chip program storage area is returned to the user-MAT space, the user procedure program is returned.

— In the download processing, the values of general registers of the CPU are held.

4. FKEY is cleared to H'00 for protection.
5. The value of the DPFR parameter must be checked and the download result must be confirmed.
 - Check the value of the DPFR parameter (one byte of start address of the download destination specified by FTDAR). If the value is H'00, download has been performed normally. If the value is not H'00, the source that caused download to fail can be investigated by the description below.
 - If the value of the DPFR parameter is the same as before downloading (e.g. H'FF), address setting of the download destination in FTDAR may be abnormal. In this case, confirm the setting of the TDER bit (bit 7) in FTDAR.
 - If the value of the DPFR parameter is different from before downloading, check the TDER bit (bit 2) and the FK bit (bit 1) in the DPFR parameter to ensure that the download parameter selection and FKEY setting were normal, respectively.
6. The operating frequency are set to the FPEFEQ parameters for initialization.
 - The current frequency of the CPU clock is set to the FPEFEQ parameter (general purpose register ER0).

The settable range of the FPEFEQ parameter is 5 to 33 MHz. When the frequency is set out of this range, an error is returned to the FPFER parameter of the initialization program and initialization is not performed. For details on the frequency setting, see the description in 20.3.2 (2) (a), Flash programming/erasing frequency parameter (FPEFEQ).
7. Initialization

When a programming program is downloaded, the initialization program is also downloaded to the on-chip RAM. There is an entry point of the initialization program in the area from the address specified by FTDAR + 32 bytes of the on-chip RAM. The subroutine is called initialization and initialization is executed by using the following steps.

9. All interrupts and the use of a bus master other than the CPU are prohibited. The specified voltage is applied for the specified time when programming or erasing interrupts occur or the bus mastership is moved to other than the CPU during this time. If the voltage for more than the specified time will be applied and flash memory may be damaged. Therefore, interrupts and bus mastership to other than the CPU, such as to the DTC, are prohibited.

To disable interrupts, bit 7 (I) in the condition code register (CCR) of the CPU should be set to B'1 in interrupt control mode 0 or bits 7 and 6 (I and UI) should be set to B'11 in interrupt control mode 1. Interrupts other than NMI are held and not executed.

The NMI interrupts must be masked within the user system.

The interrupts that are held must be executed after all program processing.

When the bus mastership is moved to other than the CPU, such as to the DTC, the error protection state is entered. Therefore, taking bus mastership by the DTC is prohibited.

10. FKEY must be set to H'5A and the user MAT must be prepared for programming.

11. The parameter which is required for programming is set.

The start address of the programming destination of the user MAT (FMPAR) is set to register ER1. The start address of the program data area (FMPDR) is set to general register ERO.

— Example of the FMPAR setting

FMPAR specifies the programming destination address. When an address other than the user MAT area is specified, even if the programming program is executed, programming is not executed and an error is returned to the return value parameter. Since the unit is 128 bytes, the lower eight bits of the address must be H'00 or H'80, the boundary of 128 bytes.

- The general registers other than R0L are held in the programming program.
- R0L is a return value of the FPFR parameter.
- Since the stack area is used in the programming program, a stack area of 128 bytes maximum must be allocated in RAM.

13. The return value in the programming program, FPFR (general register R0L) is determined.

14. Determine whether programming of the necessary data has finished.

If more than 128 bytes of data are to be programmed, specify FMPAR and FMPDR in 128-byte units, and repeat steps 12 to 14. Increment the programming destination address by 128 bytes and update the programming data pointer correctly. If an address which has already been programmed is written to again, not only will a programming error occur, but also flash memory will be damaged.

15. After programming finishes, clear FKEY and specify software protection.

If this LSI is restarted by a reset immediately after user MAT programming has finished, secure the reset period (period of $\overline{RES} = 0$) of 100 μs which is longer than normal.

Figure 20.12 Erasing Procedure

The procedure program must be executed in an area other than the user MAT to be erased. Especially the part where the SCO bit in FCCS is set to 1 for downloading must be executed on-chip RAM.

The area that can be executed in the steps of the user procedure program (on-chip RAM, MAT, and external space) is shown in section 20.4.4, Procedure Program and Storable A Programming Data.

For the downloaded on-chip program area, refer to the RAM map for programming/erasing figure 20.10.

A single divided block is erased by one erasing processing. For block divisions, refer to 20.4. To erase two or more blocks, update the erase block number and perform the erasing processing for each block.

Set the erase block number of the user MAT in the flash erase block select parameter (general register ER0). If a value other than an erase block number of the user MAT is entered, the erase block is erased even though the erasing program is executed, and an error is returned. The return value parameter FPFR.

3. Erasure

Similar to as in programming, there is an entry point of the erasing program in the area of the start address of a download destination specified by FTDAR + 16 bytes of on-chip memory. The subroutine is called and erasing is executed by using the following steps.

MOV.L	#DLTOP+16, ER2	; Set entry address to ER2
JSR	@ER2	; Call erasing routine
NOB		

- The general registers other than R0L are held in the erasing program.
 - R0L is a return value of the FPFR parameter.
 - Since the stack area is used in the erasing program, a stack area of 128 bytes at the maximum must be allocated in RAM.
4. The return value in the erasing program, FPFR (general register R0L) is determined.
 5. Determine whether erasure of the necessary blocks has completed.
If more than one block is to be erased, update the FEBS parameter and repeat steps 2. Blocks that have already been erased can be erased again.
 6. After erasure completes, clear FKEY and specify software protection.
If this LSI is restarted by a reset immediately after user MAT erasure has completed, the reset period (period of $\overline{RES} = 0$) of 100 μ s which is longer than normal.

Figure 20.13 Repeating Procedure of Erasing and Programming

In the above procedure, download and initialization are performed only once at the beginning.

In this kind of operation, note the following:

- Be careful not to damage on-chip RAM with overlapped settings.

In addition to the erasing program area and programming program area, areas for the procedure programs, work area, and stack area are reserved in on-chip RAM. Do not make settings that will overwrite data in these areas.

- Be sure to initialize both the erasing program and programming program.

Initialization by setting the FPEFEQ parameter must be performed for both the erasing program and the programming program. Initialization must be executed for both entry addresses: (download start address for erasing program) + 32 bytes and (download start address for programming program) + 32 bytes.

and user boot MAT states are checked by this check routine.

While the check routine is running, NMI and all other interrupts cannot be accepted.

Next, processing starts from the execution start address of the reset vector in the user boot mode. At this point, H'AA is set to FMATS because the execution MAT is the user boot MAT.

(2) User MAT Programming in User Boot Mode

For programming the user MAT in user boot mode, additional processing made by setting H'AA to user-MAT selection state are required: switching from user-boot-MAT selection state to user-MAT selection state, switching back to user-boot-MAT selection state after programming completes.

Figure 20.14 shows the procedure for programming the user MAT in user boot mode.

Figure 20.14 Procedure for Programming User MAT in User Boot Mode

The difference between the programming procedures in user program mode and user boot mode is whether the MAT is switched or not as shown in figure 20.14.

In user boot mode, the user boot MAT can be seen in the flash memory space with the user MAT hidden in the background. The user MAT and user boot MAT are switched only while the user boot MAT is being programmed. Because the user boot MAT is hidden while the user MAT is being programmed, the procedure program must be located in an area other than flash memory. After programming completes, switch the MATs again to return to the first state.

MAT switching is enabled by writing a specific value to FMATS. However note that while the user boot MATs are being switched, the LSI is in an unstable state, e.g. access to a MAT is not allowed. After MAT switching is completed, and if an interrupt occurs, from which MAT the interrupt is read is undetermined. Perform MAT switching in accordance with the description in section 20.1. Switching between User MAT and User Boot MAT.

Figure 20.15 Procedure for Erasing User MAT in User Boot Mode

20.4.4 Procedure Program and Storable Area for Programming Data

In the descriptions in the previous section, the programming/erasing procedure program storable areas for program data are assumed to be in the on-chip RAM. However, the program data can be stored in and executed from other areas, such as part of flash memory which can be programmed or erased, or somewhere in the external address space.

(1) Conditions that Apply to Programming/Erasing

1. The on-chip programming/erasing program is downloaded from the address in the on-chip RAM specified by FTDAR, therefore, this area is not available for use.
2. The on-chip programming/erasing program will use 128 bytes at the maximum as a storable area, therefore, make sure that this area is secured.
3. Download by setting the SCO bit to 1 will lead to switching of the MAT. If, therefore, the programming/erasing operation is used, it should be executed from the on-chip RAM.
4. The flash memory is accessible until the start of programming or erasing, that is, until the result of downloading has been determined. When in a mode in which the external address space is not accessible, such as single-chip mode, the required procedure programs, interrupt handling vector and NMI handler should be transferred to the on-chip RAM before programming/erasing of the flash memory starts.
5. The flash memory is not accessible during programming/erasing operations, therefore, the programming/erasing operation program is downloaded to the on-chip RAM to be executed. The NMI-handling vector and programs such as that which activate the operation program, and NMI handler should thus be stored in on-chip memory other than flash memory or the external address space.
6. After programming/erasing, the flash memory should be inhibited until FKEY is cleared. The reset state ($\overline{\text{RES}} = 0$) must be in place for more than 100 μs when the LSI mode is set to reset on completion of a programming/erasing operation.

In consideration of these conditions, there are three factors; operating mode, the bank structure, and the user MAT, and operations.

The areas in which the programming data can be stored for execution are shown in tables.

Table 20.7 Hardware Protection

Item	Description	Function to be Protected	
		Download	Program
FWE pin protection	<ul style="list-style-type: none"> When a low level signal is input to the FWE pin, the FWE bit in FCCS is cleared and the program/erase-protected state is entered. 	—	○
Reset/standby protection	<ul style="list-style-type: none"> The program/erase interface registers are initialized in the reset state (including a reset by the WDT) and standby mode and the program/erase-protected state is entered. The reset state will not be entered by a reset using the $\overline{\text{RES}}$ pin unless the $\overline{\text{RES}}$ pin is held low until oscillation has stabilized after power is initially supplied. In the case of a reset during operation, hold the $\overline{\text{RES}}$ pin low for the RES pulse width that is specified in the section on AC characteristics section. If a reset is input during programming or erasure, data values in the flash memory are not guaranteed. In this case, execute erasure and then execute program again. 	○	○

Protection by the
FKEY register

- Downloading and programming/erasing are disabled unless the required key code is written in FKEY. Different key codes are used for downloading and for programming/erasing.

20.5.3 Error Protection

Error protection is a mechanism for aborting programming or erasure when an error occurs in the form of the microcomputer entering runaway during programming/erasing of the flash memory operations that are not according to the established procedures for programming/erasing. Programming or erasure in such cases prevents damage to the flash memory due to excessive programming or erasing.

If the microcomputer malfunctions during programming/erasing of the flash memory, the FERR bit in the FCCS register is set to 1 and the error-protection state is entered, and this aborts programming or erasure.

The FLER bit is set in the following conditions:

1. When an interrupt such as NMI occurs during programming/erasing.
2. When the flash memory is read during programming/erasing (including a vector read instruction fetch).
3. When a SLEEP instruction (including software-standby mode) is executed during programming/erasing.
4. When a bus master other than the CPU, such as the DTC, gets bus mastership during programming/erasing.

Figure 20.16 Transitions to Error-Protection State

being accessed. Always mask the maskable interrupts before switching between MATs. In addition, configure the system so that NMI interrupts do not occur during MAT switching.

4. After the MATs have been switched, take care because the interrupt vector table will have been switched. If interrupt processing is to be the same before and after MAT switching, transfer the interrupt-processing routines to the on-chip RAM and set the WEINTE bit in the FCCS to place the interrupt-vector table in the on-chip RAM.
5. Memory sizes of the user MAT and user boot MAT are different. When accessing the user boot MAT, do not access addresses above the top of its 8-kbyte memory space. If accessed beyond the 8-kbyte space, the values read are undefined.

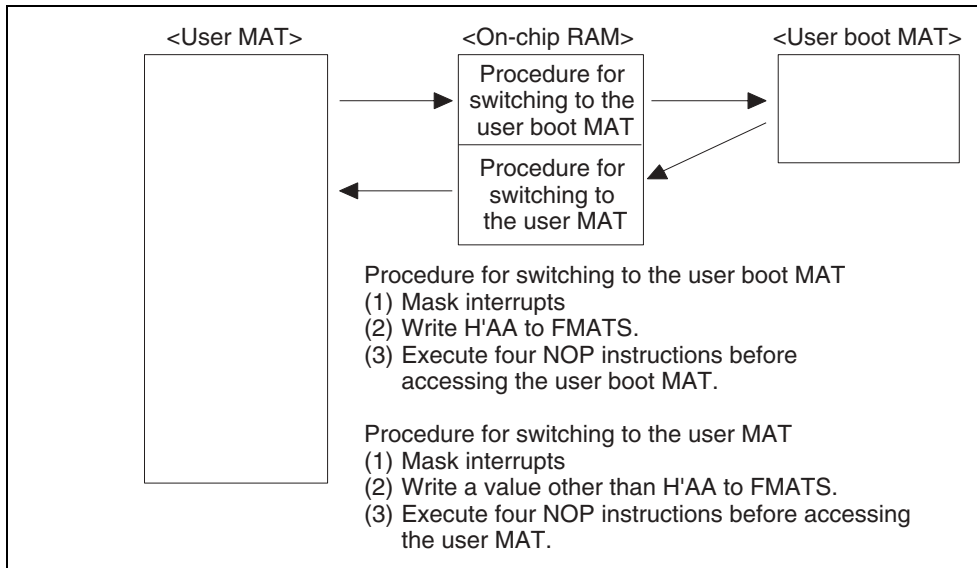

Figure 20.17 Switching between the User MAT and User Boot MAT

Notes: 1. For the PROM programmer and the version of its program, see the instructions for socket adapter.

2. In this LSI, set the programming voltage of the PROM programmer to 3.3 V.

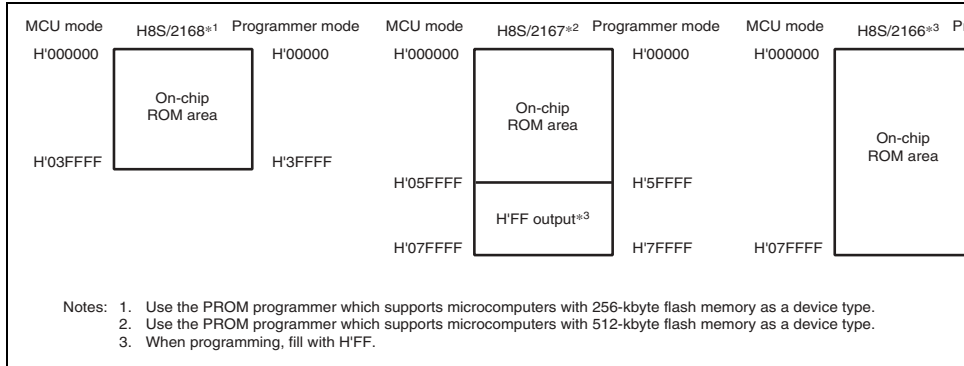

Figure 20.18 Memory Map in Programmer Mode

the program enters the inquiry/selection state.

2. Inquiry/Selection State

In this state, the boot program responds to inquiry commands from the host. The device ID, clock mode, and bit rate are selected. After selection of these settings, the program is ready to enter the programming/erasing state by the command for a transition to the programming/erasing state. The program transfers the libraries required for erasure to the chip RAM and erases the user MATs and user boot MATs before the transition.

3. Programming/erasing state

Programming and erasure by the boot program take place in this state. The boot program is made to transfer the programming/erasing programs to the RAM by commands from the host. Sum checks and blank checks are executed by sending these commands from the host.

These boot program states are shown in figure 20.19.

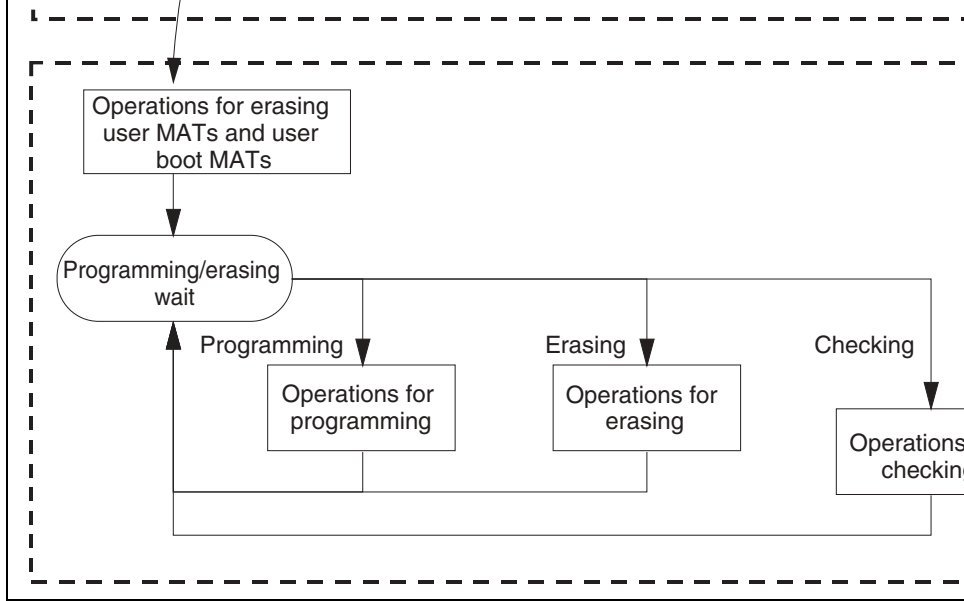

Figure 20.19 Boot Program States

Figure 20.20 Bit-Rate-Adjustment Sequence

(3) Communications Protocol

After adjustment of the bit rate, the protocol for communications between the host and the program is as shown below.

1. 1-byte commands and 1-byte responses
 These commands and responses are comprised of a single byte. These are consists of inquiries and the ACK for successful completion.
2. n-byte commands or n-byte responses
 These commands and responses are comprised of n bytes of data. These are selections responses to inquiries.
 The amount of programming data is not included under this heading because it is determined in another command.
3. Error response
 The error response is a response to inquiries. It consists of an error response and an error code and comes two bytes.
4. Programming of 128 bytes
 The size is not specified in commands. The size of n is indicated in response to the programming unit inquiry.
5. Memory read response

Figure 20.21 Communication Protocol Format

- **Command (1 byte):** Commands including inquiries, selection, programming, erasing, and checking
- **Response (1 byte):** Response to an inquiry
- **Size (1 byte):** The amount of data for transmission excluding the command, amount of data, and checksum
- **Checksum (1 byte):** The checksum is calculated so that the total of all values from the command byte to the SUM byte becomes H'00.
- **Data (n bytes):** Detailed data of a command or response
- **Error response (1 byte):** Error response to a command
- **Error code (1 byte):** Type of the error
- **Address (4 bytes):** Address for programming
- **Data (n bytes):** Data to be programmed (the size is indicated in the response to the programming unit inquiry.)
- **Size (4 bytes):** 4-byte response to a memory read

H'21	Clock Mode Inquiry	Inquiry regarding numbers of clock modes and the values of each mode
H'11	Clock Mode Selection	Indication of the selected clock mode
H'22	Multiplication Ratio Inquiry	Inquiry regarding the number of frequency multiplied clock types, the number of multiplication ratios, and the values of multiple
H'23	Operating Clock Frequency Inquiry	Inquiry regarding the maximum and minimum values of the main clock and peripheral
H'24	User Boot MAT Information Inquiry	Inquiry regarding the number of user boot MATs and the start and last addresses of each MAT
H'25	User MAT Information Inquiry	Inquiry regarding the a number of user MATs and the start and last addresses of each
H'26	Block for Erasing Information Inquiry	Inquiry regarding the number of blocks and the start and last addresses of each block
H'27	Programming Unit Inquiry	Inquiry regarding the unit of programming
H'3F	New Bit Rate Selection	Selection of new bit rate
H'40	Transition to Programming/Erasing State	Erasing of user MAT and user boot MAT entry to programming/erasing state
H'4F	Boot Program Status Inquiry	Inquiry into the operated status of the boot program

The selection commands, which are device selection (H'10), clock mode selection (H'11), bit rate selection (H'3F), should be sent from the host in that order. These commands will be needed. When two or more selection commands are sent at once, the last command will be valid.

All of these commands, except for the boot program status inquiry command (H'4F), will be valid until the boot program receives the programming/erasing transition (H'40). The host can

Number of characters	Device code	Product name
...		
SUM		

- Response, H'30, (1 byte): Response to the supported device inquiry
- Size (1 byte): Number of bytes to be transmitted, excluding the command, size, and checksum, that is, the amount of data contributed by the number of devices, characters, device codes, and product names
- Number of devices (1 byte): The number of device types supported by the boot program
- Number of characters (1 byte): The number of characters in the device codes and boot program's name
- Device code (4 bytes): ASCII code of the supporting product
- Product name (n bytes): Type name of the boot program in ASCII-coded characters
- SUM (1 byte): Checksum
The checksum is calculated so that the total number of all values from the command and data, including the SUM byte becomes H'00.

(b) Device Selection

The boot program will set the supported device to the specified device code. The program will return the selected device code in response to the inquiry after this setting has been made.

Command	H'10	Size	Device code	SUM
---------	------	------	-------------	-----

- Command, H'10, (1 byte): Device selection
- Size (1 byte): Amount of device-code data
This is fixed at 2
- Device code (4 bytes): Device code (ASCII code) returned in response to the supported device inquiry
- SUM (1 byte): Checksum

Command

H'21

- Command, H'21, (1 byte): Inquiry regarding clock mode

Response

H'31	Size	Number of modes	Mode	...	SUM
------	------	-----------------	------	-----	-----

- Response, H'31, (1 byte): Response to the clock-mode inquiry
- Size (1 byte): Amount of data that represents the number of modes and modes
- Number of clock modes (1 byte): The number of supported clock modes
H'00 indicates no clock mode or the device allows to read the clock mode.
- Mode (1 byte): Values of the supported clock modes (i.e. H'01 means clock mode 1.)
- SUM (1 byte): Checksum

(d) Clock Mode Selection

The boot program will set the specified clock mode. The program will return the selected mode information after this setting has been made.

The clock-mode selection command should be sent after the device-selection commands.

Command

H'11	Size	Mode	SUM
------	------	------	-----

- Command, H'11, (1 byte): Selection of clock mode
- Size (1 byte): Amount of data that represents the modes
- Mode (1 byte): A clock mode returned in reply to the supported clock mode inquiry.
- SUM (1 byte): Checksum

Response

H'06

- Response, H'06, (1 byte): Response to the clock mode selection command
ACK will be returned when the clock mode matches.

Command H'22

- Command, H'22, (1 byte): Inquiry regarding multiplication ratio

Response	H'32	Size	Number of types				
	Number of multiplication ratios	Multiplication ratio	...				
	...						
	SUM						

- Response, H'32, (1 byte): Response to the multiplication ratio inquiry
- Size (1 byte): The amount of data that represents the number of clock sources and multiplication ratios and the multiplication ratios
- Number of types (1 byte): The number of supported multiplied clock types (e.g. when there are two multiplied clock types, which are the main and peripheral clock, the number of types will be H'02.)
- Number of multiplication ratios (1 byte): The number of multiplication ratios for each clock (e.g. the number of multiplication ratios to which the main clock can be set and the number of multiplication ratios to which the peripheral clock can be set.)
- Multiplication ratio (1 byte)
 - Multiplication ratio: The value of the multiplication ratio (e.g. when the clock-frequency multiplier is four, the value of multiplication ratio will be H'04.)
 - Division ratio: The inverse of the division ratio, i.e. a negative number (e.g. when the division ratio is two, the value of division ratio will be H'FE. $H'FE = D'-2$)

The number of multiplication ratios returned is the same as the number of multiplication ratios and as many groups of data are returned as there are types.
- SUM (1 byte): Checksum

- Response, H'33, (1 byte): Response to operating clock frequency inquiry
- Size (1 byte): The number of bytes that represents the minimum values, maximum values, and the number of frequencies.
- Number of operating clock frequencies (1 byte): The number of supported operating clock frequency types
(e.g. when there are two operating clock frequency types, which are the main and peripheral clocks, the number of types will be H'02.)
- Minimum value of operating clock frequency (2 bytes): The minimum value of the multiplied or divided clock frequency.
The minimum and maximum values represent the values in MHz, valid to the hundredths of MHz, and multiplied by 100. (e.g. when the value is 20.00 MHz, it will be 2000, with H'07D0.)
- Maximum value (2 bytes): Maximum value among the multiplied or divided clock frequencies.
There are as many pairs of minimum and maximum values as there are operating clock frequencies.
- SUM (1 byte): Checksum

- Size (1 byte): The number of bytes that represents the number of areas, area-start address and area-last address
- Number of Areas (1 byte): The number of consecutive user boot MAT areas
When user boot MAT areas are consecutive, the number of areas returned is H'01.
- Area-start address (4 byte): Start address of the area
- Area-last address (4 byte): Last address of the area
There are as many groups of data representing the start and last addresses as there are areas.
- SUM (1 byte): Checksum

(h) User MAT Information Inquiry

The boot program will return the number of user MATs and their addresses.

Command

H'25

- Command, H'25, (1 byte): Inquiry regarding user MAT information

Response

H'35	Size	Number of areas	
Start address area		Last address area	
...			
SUM			

- Response, H'35, (1 byte): Response to the user MAT information inquiry
- Size (1 byte): The number of bytes that represents the number of areas, area-start address and area-last address
- Number of areas (1 byte): The number of consecutive user MAT areas
When the user MAT areas are consecutive, the number of areas is H'01.
- Area-start address (4 bytes): Start address of the area
- Area-last address (4 bytes): Last address of the area
There are as many groups of data representing the start and last addresses as there are areas.
- SUM (1 byte): Checksum

- Size (three bytes): The number of bytes that represents the number of blocks, block-start addresses, and block-last addresses.
- Number of blocks (1 byte): The number of erased blocks
- Block start address (4 bytes): Start address of a block
- Block last Address (4 bytes): Last address of a block
There are as many groups of data representing the start and last addresses as there are
- SUM (1 byte): Checksum

(j) Programming Unit Inquiry

The boot program will return the programming unit used to program data.

Command

H'27

- Command, H'27, (1 byte): Inquiry regarding programming unit

Response

H'37	Size	Programming unit	SUM
------	------	------------------	-----

- Response, H'37, (1 byte): Response to programming unit inquiry
- Size (1 byte): The number of bytes that indicate the programming unit, which is fixed
- Programming unit (2 bytes): A unit for programming
This is the unit for reception of programming.
- SUM (1 byte): Checksum

- Bit rate (2 bytes): New bit rate
One hundredth of the value (e.g. when the value is 19200 bps, it will be 192, which is H'00C0.)
- Input frequency (2 bytes): Frequency of the clock input to the boot program
This is valid to the hundredths place and represents the value in MHz multiplied by 100 when the value is 20.00 MHz, it will be 2000, which is H'07D0.)
- Number of multiplication ratios (1 byte): The number of multiplication ratios to which the device can be set.
- Multiplication ratio 1 (1 byte) : The value of multiplication or division ratios for the operating frequency
Multiplication ratio (1 byte): The value of the multiplication ratio (e.g. when the clock frequency is multiplied by four, the multiplication ratio will be H'04.)
Division ratio: The inverse of the division ratio, as a negative number (e.g. when the frequency is divided by two, the value of division ratio will be H'FE. $H'FE = D'-2$)
- Multiplication ratio 2 (1 byte): The value of multiplication or division ratios for the operating frequency
Multiplication ratio (1 byte): The value of the multiplication ratio (e.g. when the clock frequency is multiplied by four, the multiplication ratio will be H'04.)
(Division ratio: The inverse of the division ratio, as a negative number (E.g. when the frequency is divided by two, the value of division ratio will be H'FE. $H'FE = D'-2$)
- SUM (1 byte): Checksum

Response

H'06

- Response, H'06, (1 byte): Response to selection of a new bit rate
When it is possible to set the bit rate, the response will be ACK.

Error Response

H'BF	ERROR
------	-------

- Error response, H'BF, (1 byte): Error response to selection of new bit rate

The methods for checking of received data are listed below.

1. Input frequency

The received value of the input frequency is checked to ensure that it is within the range of minimum to maximum frequencies which matches the clock modes of the specified device. When the value is out of this range, an input-frequency error is generated.

2. Multiplication ratio

The received value of the multiplication ratio or division ratio is checked to ensure that it matches the clock modes of the specified device. When the value is out of this range, a multiplication ratio error is generated.

3. Operating frequency

Operating frequency is calculated from the received value of the input frequency and the multiplication or division ratio. The input frequency is input to the LSI and the LSI is outputting the operating frequency. The expression is given below.

Operating frequency = Input frequency \times Multiplication ratio, or

Operating frequency = Input frequency \div Division ratio

The calculated operating frequency should be checked to ensure that it is within the range of minimum to maximum frequencies which are available with the clock modes of the specified device. When it is out of this range, an operating frequency error is generated.

4. Bit rate

To facilitate error checking, the value (n) of clock select (CKS) in the serial mode register and the value (N) in the bit rate register (BRR), which are found from the peripheral operating clock frequency (ϕ) and bit rate (B), are used to calculate the error rate to ensure that it is

Response H'06

- Response, H'06, (1 byte): Response to confirmation of a new bit rate

The sequence of new bit-rate selection is shown in figure 20.22.

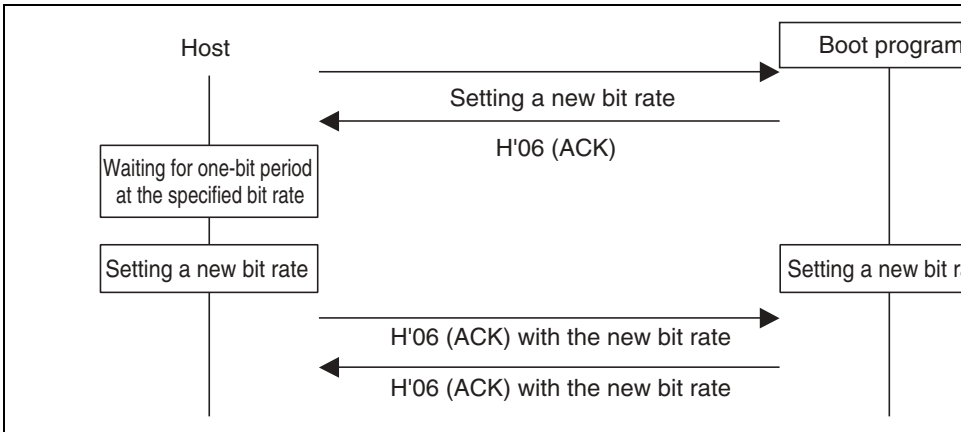

Figure 20.22 New Bit-Rate Selection Sequence

Response

H'06

- Response, H'06, (1 byte): Response to transition to programming/erasing state
The boot program will send ACK when the user MAT and user boot MAT have been by the transferred erasing program.

Error Response

H'C0

H'51

- Error response, H'C0, (1 byte): Error response for user boot MAT blank check
- Error code, H'51, (1 byte): Erasing error
An error occurred and erasure was not completed.

(7) Command Error

A command error will occur when a command is undefined, the order of commands is incorrect or a command is unacceptable. Issuing a clock-mode selection command before a device selection command or an inquiry command after the transition to programming/erasing state command, are examples.

Error Response

H'80

H'xx

- Error response, H'80, (1 byte): Command error
- Command, H'xx, (1 byte): Received command

(8) Command Order

The order for commands in the inquiry selection state is shown below.

1. A supported device inquiry (H'20) should be made to inquire about the supported devices.
2. The device should be selected from among those described by the returned information with a device-selection (H'10) command.
3. A clock-mode inquiry (H'21) should be made to inquire about the supported clock modes.
4. The clock mode should be selected from among those described by the returned information and set.

Rev. 3.00, 03/04, page 684 of 830

RENESAS

A programming selection command makes the boot program select the programming mode. A 128-byte programming command makes it program the memory with data, and an erasing selection command and block erasing command make it erase the block. The programming/erasing commands are listed below.

Table 20.12 Programming/Erasing Command

Command	Command Name	Description
H'42	User boot MAT programming selection	Transfers the user boot MAT programming
H'43	User MAT programming selection	Transfers the user MAT programming
H'50	128-byte programming	Programs 128 bytes of data
H'48	Erasing selection	Transfers the erasing program
H'58	Block erasing	Erases a block of data
H'52	Memory read	Reads the contents of memory
H'4A	User boot MAT sum check	Checks the checksum of the user boot MAT
H'4B	User MAT sum check	Checks the checksum of the user MAT
H'4C	User boot MAT blank check	Checks whether the contents of the user boot MAT are blank
H'4D	User MAT blank check	Checks whether the contents of the user MAT are blank
H'4F	Boot program status inquiry	Inquires into the boot program's status

command. When more than 128-byte data is programmed, 128-byte commands should repeatedly be executed. Sending a 128-byte programming command with H'FFFFFF address will stop the programming. On completion of programming, the boot program wait for selection of programming or erasing.

Where the sequence of programming operations that is executed includes programming another method or of another MAT, the procedure must be repeated from the programming selection command.

The sequence for programming-selection and 128-byte programming commands is shown in figure 20.23.

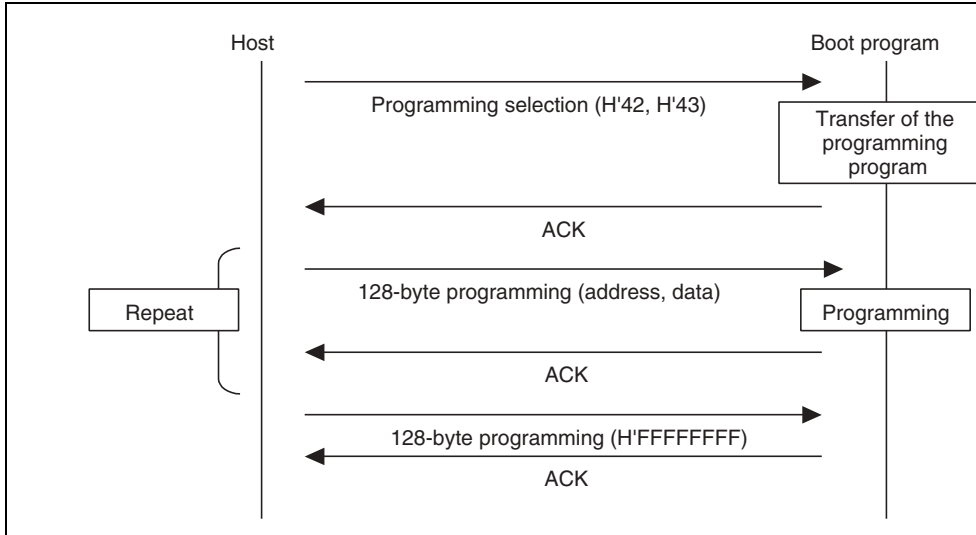

Figure 20.23 Programming Sequence

- ERROR : (1 byte): Error code
H'54: Selection processing error (transfer error occurs and processing is not complete)

- User MAT programming selection
The boot program will transfer a program for programming. The data is programmed to user MATs by the transferred program for programming.

Command

H'43

- Command, H'43, (1 byte): User MAT programming selection

Response

H'06

- Response, H'06, (1 byte): Response to user MAT programming selection
When the programming program has been transferred, the boot program will return a response.

Error Response

H'C3	ERROR
------	-------

- Error response : H'C3 (1 byte): Error response to user MAT programming selection
- ERROR : (1 byte): Error code
H'54: Selection processing error (transfer error occurs and processing is not complete)

(b) 128-byte programming

The boot program will use the programming program transferred by the programming software. In response to 128-byte programming, the user boot MATs or user MATs are programmed.

Command	H'50	Address						
	Data	...						
	...							
	SUM							

- Error response, H'D0, (1 byte): Error response for 128-byte programming
- ERROR: (1 byte): Error code
 - H'11: Checksum Error
 - H'2A: Address Error
 - H'53: Programming error

A programming error has occurred and programming cannot be continued.

The specified address should match the unit for programming of data. For example, when programming is in 128-byte units, the lower 8 bits of the address should be H'00 or H'80. When there are less than 128 bytes of data to be programmed, the host should fill the rest with H'FF.

Sending the 128-byte programming command with the address of H'FFFFFFFF will stop programming operation. The boot program will interpret this as the end of the programming and wait for selection of programming or erasing.

Command

H'50	Address	SUM
------	---------	-----

- Command, H'50, (1 byte): 128-byte programming
- Programming Address (4 bytes): End code is H'FF, H'FF, H'FF, H'FF.
- SUM (1 byte): Checksum

Response

H'06

- Response, H'06, (1 byte): Response to 128-byte programming
On completion of programming, the boot program will return ACK.

Error Response

H'D0	ERROR
------	-------

- Error Response, H'D0, (1 byte): Error response for 128-byte programming

erasure operating. On completion of erasing, the boot program will wait for selection of programming or erasing.

The sequences of issuing the erasure selection command and block-erasure command are shown in figure 20.24.

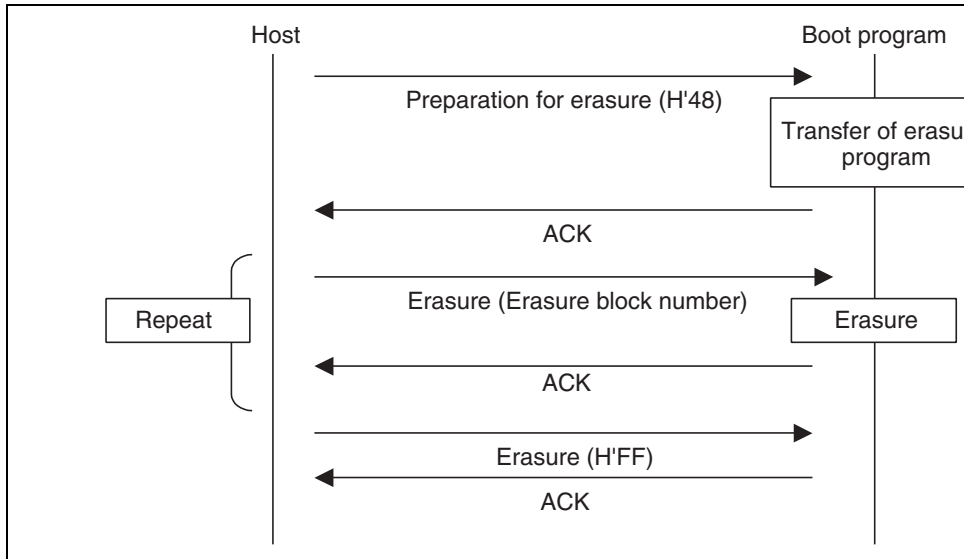

Figure 20.24 Erasure Sequence

- ERROR: (1 byte): Error code
H'54: Selection processing error (transfer error occurs and processing is not completed)

(b) Block Erasure

The boot program will erase the contents of the specified block.

Command	H'58	Size	Block number	SUM
---------	------	------	--------------	-----

- Command, H'58, (1 byte): Erasure
- Size (1 byte): The number of bytes that represents the erasure block number
This is fixed to 1.
- Block number (1 byte): Number of the block to be erased
- SUM (1 byte): Checksum

Response	H'06
----------	------

- Response, H'06, (1 byte): Response to Erasure
After erasure has been completed, the boot program will return ACK.

Error Response	H'D8	ERROR
----------------	------	-------

- Error Response, H'D8, (1 byte): Response to Erasure
- ERROR (1 byte): Error code
 - H'11: Sum check error
 - H'29: Block number error
Block number is incorrect.
 - H'51: Erasure error
An error has occurred during erasure.

On receiving block number H'FF, the boot program will stop erasure and wait for a selection command.

(11) Memory read

The boot program will return the data in the specified address.

Command	H'52	Size	Area	Read address			
	Read size			SUM			

- Command: H'52 (1 byte): Memory read
- Size (1 byte): Amount of data that represents the area, read address, and read size (fi
- Area (1 byte)
H'00: User boot MAT
H'01: User MAT

An address error occurs when the area setting is incorrect.

- Read address (4 bytes): Start address to be read from
- Read size (4 bytes): Size of data to be read
- SUM (1 byte): Checksum

Response	H'52	Read size					
	Data	...					
	SUM						

- Response: H'52 (1 byte): Response to memory read
- Read size (4 bytes): Size of data to be read
- Data (n bytes): Data for the read size from the read address
- SUM (1 byte): Checksum

Error Response	H'D2	ERROR
----------------	------	-------

- Error response: H'D2 (1 byte): Error response to memory read

- Command, H'4A, (1 byte): Sum check for user-boot MAT

Response	H'5A	Size	Checksum of user boot program	SUM
----------	------	------	-------------------------------	-----

- Response, H'5A, (1 byte): Response to the sum check of user-boot MAT
- Size (1 byte): The number of bytes that represents the checksum
This is fixed to 4.
- Checksum of user boot program (4 bytes): Checksum of user boot MATs
The total of the data is obtained in byte units.
- SUM (1 byte): Sum check for data being transmitted

(13) User MAT Sum Check

The boot program will return the byte-by-byte total of the contents of the bytes of the user MAT.

Command	H'4B
---------	------

- Command, H'4B, (1 byte): Sum check for user MAT

Response	H'5B	Size	Checksum of user program	SUM
----------	------	------	--------------------------	-----

- Response, H'5B, (1 byte): Response to the sum check of the user MAT
- Size (1 byte): The number of bytes that represents the checksum
This is fixed to 4.
- Checksum of user boot program (4 bytes): Checksum of user MATs
The total of the data is obtained in byte units.
- SUM (1 byte): Sum check for data being transmitted

(14) User Boot MAT Blank Check

The boot program will check whether or not all user boot MATs are blank and return the result.

The boot program will check whether or not all user MATs are blank and return the result.

Command

H'4D

- Command, H'4D, (1 byte): Blank check for user MATs

Response

H'06

- Response, H'06, (1 byte): Response to the blank check for user boot MATs
If the contents of all user MATs are blank (H'FF), the boot program will return ACK

Error Response

H'CD	H'52
------	------

- Error Response, H'CD, (1 byte): Error response to the blank check of user MATs.
- Error code, H'52, (1 byte): Erasure has not been completed.

(16) Boot Program State Inquiry

The boot program will return indications of its present state and error condition. This information can be made in the inquiry/selection state or the programming/erasing state.

Command

H'4F

- Command, H'4F, (1 byte): Inquiry regarding boot program's state

Response

H'5F	Size	Status	ERROR	SUM
------	------	--------	-------	-----

- Response, H'5F, (1 byte): Response to boot program state inquiry
- Size (1 byte): The number of bytes. This is fixed to 2.
- Status (1 byte): State of the boot program
- ERROR (1 byte): Error status

ERROR = 0 indicates normal operation.
ERROR = 1 indicates error has occurred.

- SUM (1 byte): Sum check

Table 20.14 Error Code

Code	Description
H'00	No Error
H'11	Sum Check Error
H'12	Program Size Error
H'21	Device Code Mismatch Error
H'22	Clock Mode Mismatch Error
H'24	Bit Rate Selection Error
H'25	Input Frequency Error
H'26	Multiplication Ratio Error
H'27	Operating Frequency Error
H'29	Block Number Error
H'2A	Address Error
H'2B	Data Length Error
H'51	Erase Error
H'52	Erase Incomplete Error
H'53	Programming Error
H'54	Selection Processing Error
H'80	Command Error
H'FF	Bit-Rate-Adjustment Confirmation Error

- only the specified socket adapter. If other adapters are used, the product may be damaged.
5. Do not remove the chip from the PROM programmer nor input a reset signal during programming/erasing. As a high voltage is applied to the flash memory during programming/erasing, doing so may damage or destroy flash memory permanently. If executed accidentally, reset must be released after the reset input period of 100 μ s will be longer than normal.
 6. The flash memory is not accessible until FKEY is cleared after programming/erasing completes. If this LSI is restarted by a reset immediately after programming/erasing finished, secure the reset period (period of $\overline{\text{RES}} = 0$) of more than 100 μ s. Though the reset state or hardware standby state during programming/erasing is prohibited, if executed accidentally, reset must be released after the reset input period of 100 μ s will be longer than normal.
 7. At powering on or off the Vcc power supply, fix the $\overline{\text{RES}}$ pin to low and set the flash memory to hardware protection state. This power on/off timing must also be satisfied at a power-on caused by a power failure and other factors.
 8. Program the area with 128-byte programming-unit blocks in on-board programming mode only once. Perform programming in the state where the programming-unit block is fully erased.
 9. When the chip is to be reprogrammed with the programmer after execution of programming/erasure in on-board programming mode, it is recommended that automatic programming be performed after execution of automatic erasure.
 10. To write data or programs to the flash memory, data or programs must be allocated to addresses higher than that of the external interrupt vector table (H'000040) and H'FF0000. Data is not written to the areas that are reserved for the system in the exception handling vector table.
 11. If data other than H'FFFFFFFF is written to the key code area (H'00003C to H'00003F) in the flash memory, only H'00 can be read in programmer mode. (In this case, data is read as H'00. Rewrite is possible after erasing the data.) For reading in programmer mode, make sure to write H'FFFFFFFF to the entire key code area. If data other than H'FF is to be written to the key code area, make sure to write H'FFFFFFFF to the entire key code area.

microcomputer which does not support download of the on-chip program by a SCO. This request cannot run in this LSI. Be sure to download the on-chip program to execute programming/erasing of flash memory in this LSI.

15. Unlike the conventional H8S F-ZTAT microcomputer, no countermeasures are available to prevent runaway by WDT during programming/erasing. Prepare countermeasures (e.g. use of periodic timer interrupts) for WDT with taking the programming/erasing time into consideration as required.

- Five test pins (ETCK, ETDI, ETDO, ETMS, and $\overline{\text{ETRST}}$)
 - TAP controller
 - Six instructions
 - BYPASS mode
 - EXTEST mode
 - SAMPLE/PRELOAD mode
 - CLAMP mode
 - HIGHZ mode
 - IDCODE mode
- (These instructions are test modes corresponding to IEEE 1149.1.)

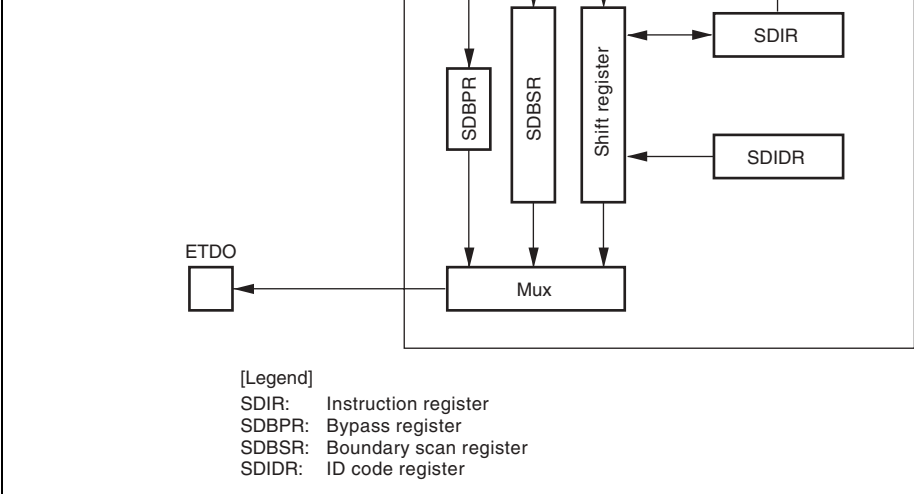

Figure 21.1 JTAG Block Diagram

			Characteristics: If there is no input, the pin is fixed to 1 by an internal pull-up.
Test mode select	ETMS	Input	<p>Test mode select input</p> <p>Sampled on the rise of the ETCK pin. The ETMS pin controls the internal state of the TAP controller. If there is no input, the ETMS pin is fixed to 1 by an internal pull-up.</p>
Test data input	ETDI	Input	<p>Serial data input</p> <p>Performs serial input of instructions and data to JTAG registers. ETDI is sampled on the rise of the ETCK pin. If there is no input, the ETDI pin is fixed to 1 by an internal pull-up.</p>
Test data output	ETDO	Output	<p>Serial data output</p> <p>Performs serial output of instructions and data from JTAG registers. Transfer is performed on the rise of the ETCK pin. If there is no output, the ETDO pin goes to the high-impedance state.</p>
Test reset	$\overline{\text{ETRST}}$	Input	<p>Test reset input signal</p> <p>Initializes the JTAG asynchronously. If there is no input, the $\overline{\text{ETRST}}$ pin is fixed to 1 by an internal pull-up.</p>

CEAMP, or HIGHZ mode. The boundary scan register (SDBSR) is a 32-bit register to which ETDI and ETDO pins are connected in SAMPLE/PRELOAD or EXTEST mode. The ID register (SDIDR) is a 32-bit register; a fixed code can be output via the ETDO pin in IDCODE mode. All registers cannot be accessed directly by the CPU.

Table 21.2 shows the kinds of serial transfer possible with each JTAG register.

Table 21.2 JTAG Register Serial Transfer

Register	Serial Input	Serial Output
SDIR	Possible	Possible
SDBPR	Possible	Possible
SDBSR	Possible	Possible
SDIDR	Impossible	Possible

Figure 21.2 TAP Controller State Transitions

21.5.1 Supported Instructions

This LSI supports the three essential instructions defined in the IEEE1149.1 standard (BYPASS, SAMPLE/PRELOAD, and EXTEST) and optional instructions (CLAMP, HIGHZ, and I/O)

BYPASS: Instruction code: B'1111

The BYPASS instruction is an instruction that operates the bypass register. This instruction shortens the shift path to speed up serial data transfer involving other chips on the printed circuit board. While this instruction is being executed, the test circuit has no effect on the system test circuits.

SAMPLE/PRELOAD: Instruction code: B'0100

The SAMPLE/PRELOAD instruction inputs values from this LSI internal circuitry to the boundary scan register, outputs values from the scan path, and loads data onto the scan path. When this instruction is being executed, this LSI's input pin signals are transmitted directly to the internal circuitry, and internal circuit values are directly output externally from the output pin. This LSI system circuits are not affected by execution of this instruction.

In a SAMPLE operation, a snapshot of a value to be transferred from an input pin to the internal circuitry, or a value to be transferred from the internal circuitry to an output pin, is latched into the boundary scan register and read from the scan path. Snapshot latching does not affect normal operation of this LSI.

In a PRELOAD operation, an initial value is set in the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. Without a PRELOAD operation, when the EXTEST instruction was executed an undefined value would be output from the output pin until completion of the initial scan sequence (transfer to the output latch) (with the EXTEST instruction, the parallel output latch value is constantly output to the output pin).

When the CLAMP instruction is enabled, the output pin outputs the value of the boundary scan register that has been previously set by the SAMPLE/PRELOAD instruction. While the CLAMP instruction is enabled, the state of the boundary scan register maintains the previous state regardless of the state of the TAP controller.

A bypass register is connected between the ETDI and ETDO pins. The related circuit operates the same way when the BYPASS instruction is enabled.

HIGHZ: Instruction code: B'0011

When the HIGHZ instruction is enabled, all output pins enter a high-impedance state. While the HIGHZ instruction is enabled, the state of the boundary scan register maintains the previous state regardless of the state of the TAP controller.

A bypass register is connected between the ETDI and ETDO pins. The related circuit operates the same way when the BYPASS instruction is enabled.

IDCODE: Instruction code: B'1110

When the IDCODE instruction is enabled, the value of the ID code register is output from the ETDO pin with LSB first when the TAP controller is in the Shift-DR state. While the IDCODE instruction is being executed, the test circuit does not affect the system circuit.

When the TAP controller is in the Test-Logic-Reset state, the instruction register is initialized with the IDCODE instruction.

— Alternatively, to prevent the $\overline{\text{ETRST}}$ pin of the board tester from being affected by system reset, circuits must be separated.

Figure 21.3 shows a design example of the reset signal circuit wherein no reset signal interference occurs.

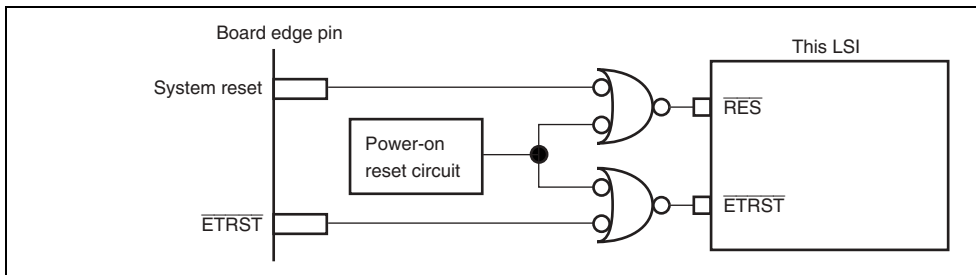

Figure 21.3 Reset Signal Circuit Without Reset Signal Interference

3. The registers are not initialized in standby mode. If the $\overline{\text{ETRST}}$ pin is set to 0 in standby mode, IDCODE mode will be entered.
4. The frequency of the ETCK pin must be lower than that of the system clock. For details, see section 25, Electrical Characteristics.
5. Data input/output in serial data transfer starts from the LSB. Figure 21.4 and 21.5 show examples of serial data input/output.
6. When data that exceeds the number of bits of the register connected between the ETDI and ETDO pins is serially transferred, the serial data that exceeds the number of register bits is output from the ETDO pin is the same as that input from the ETDI pin.
7. If the JTAG serial transfer sequence is disrupted, the $\overline{\text{ETRST}}$ pin must be reset. Transfer should then be retried, regardless of the transfer operation.
8. If a pin with a pull-up function is sampled while its pull-up function is enabled, 1 can be detected at the corresponding input scan register. In this case, the corresponding enable register should be cleared to 0.

Figure 21.4 Serial Data Input/Output (1)

Figure 21.5 Serial Data Input/Output (2)

Figure 22.1 Block Diagram of Clock Pulse Generator

The bus master clock is selected as either high-speed mode or medium-speed mode by software according to the settings of the SCK2 to SCK0 bits in the standby control register. Use of the medium-speed clock ($\phi/2$ to $\phi/32$) may be limited during CPU operation and when accessing internal memory of the CPU. The operation speed of the DTC and the external space access are thus stabilized regardless of the setting of medium-speed mode. For details on the standby control register, see section 23.1.1, Standby Control Register (SBYCR).

The subclock input is controlled by software according to the EXCLE bit setting in the low power control register. For details on the low power control register, see section 23.1.2, Low-Power Control Register (LPWRCR).

characteristics given in table 22.2 should be used.

When PFSEL is high, the system clock (ϕ) frequency should be no more than 25 MHz and a crystal resonator with frequency identical to that of the system clock (ϕ) should be used. When PFSEL is low, a crystal resonator with $\frac{1}{4}$ times the frequency of the system clock (ϕ) should be used.

Figure 22.2 Typical Connection to Crystal Resonator

Table 22.1 Damping Resistance Values

Frequency (MHz)	5	8	10	12	16	20	25
R_d (Ω)	300	200	0	0	0	0	0

Figure 22.3 Equivalent Circuit of Crystal Resonator

mode, subactive mode, subsleep mode, and watch mode. The frequency of the external clock should be the same as that of the system clock (ϕ) when PFSEL is high. When PFSEL is low, the external clock of 1/4 times the frequency of the system clock (ϕ) should be used.

Figure 22.4 Example of External Clock Input

When a specified clock signal is input to the EXTAL pin, internal clock signal output is determined after the external clock output stabilization delay time (t_{DEXT}) has passed. As signal output is not determined during the t_{DEXT} cycle, a reset signal should be set to low in reset state. For the external clock output stabilization delay time, refer to table 25.5 and 25.8.

22.3 Medium-Speed Clock Divider

The medium-speed clock divider divides the system clock (ϕ), and generates $\phi/2$, $\phi/4$, $\phi/8$, and $\phi/32$ clocks.

22.4 Bus Master Clock Select Circuit

The bus master clock select circuit selects a clock to supply the bus master with either the system clock (ϕ) or medium-speed clock ($\phi/2$, $\phi/4$, $\phi/8$, $\phi/16$, or $\phi/32$) by the SCK2 to SCK0 bits in SBYCR.

22.5 Subclock Input Circuit

The subclock input circuit controls subclock input from the EXCL pin. To use the subclock, a 32.768-kHz external clock should be input from the EXCL pin. At this time, the P96DDF and P9DDF registers should be cleared to 0, and the EXCLE bit in LPWRCCR should be set to 1.

When the subclock is not used, subclock input should not be enabled.

22.6 Subclock Waveform Forming Circuit

To remove noise from the subclock input at the EXCL pin, the subclock is sampled by a clock. The sampling frequency is set by the NESEL bit in LPWRCCR.

The subclock is not sampled in subactive mode, subsleep mode, or watch mode.

22.8 Usage Notes

22.8.1 Note on Resonator

Since all kinds of characteristics of the resonator are closely related to the board design, the user should use the example of resonator connection in this document for only reference; be sure to use an resonator that has been sufficiently evaluated by the user. Consult with the resonator manufacturer about the resonator circuit ratings which vary depending on the stray capacitance of the resonator and installation circuit. Make sure the voltage applied to the oscillation pins does not exceed the maximum rating.

22.8.2 Notes on Board Design

When using a crystal resonator, the crystal resonator and its load capacitors should be placed as close as possible to the EXTAL and XTAL pins. Other signal lines should be routed away from the oscillation circuit to prevent inductive interference with the correct oscillation as shown in figure 22.5.

Figure 22.5 Note on Board Design of Oscillation Circuit Section

- Sleep mode
The CPU stops but on-chip peripheral modules continue operating.
- Subsleep mode
The CPU and on-chip peripheral modules other than TMR_0, TMR_1, WDT_0, and stop operating.
- Watch mode
The CPU and on-chip peripheral modules other than WDT_1 stop operating.
- Software standby mode
Clock oscillation stops, and the CPU and on-chip peripheral modules stop operating.
- Hardware standby mode
Clock oscillation stops, and the CPU and on-chip peripheral modules enter reset state.
- Module stop mode
Independently of above operating modes, on-chip peripheral modules that are not used are stopped individually.

- Sub-chip module stop control register AH, AL (SUBMSTPAH, SUBMSTPAL)

23.1.1 Standby Control Register (SBYCR)

SBYCR controls power-down modes.

Bit	Bit Name	Initial Value	R/W	Description
7	SSBY	0	R/W	<p>Software Standby</p> <p>Specifies the operating mode to be entered after the SLEEP instruction.</p> <p>When the SLEEP instruction is executed in high-speed mode or medium-speed mode:</p> <p>0: Shifts to sleep mode 1: Shifts to software standby mode, subactive mode, watch mode</p> <p>When the SLEEP instruction is executed in subactive mode:</p> <p>0: Shifts to subsleep mode 1: Shifts to watch mode or high-speed mode</p> <p>Note that the SSBY bit is not changed even if a mode transition occurs by an interrupt.</p>

Specifies the operating clock for the bus masters other than the CPU in medium-speed mode.

0: All bus masters operate based on the medium-speed clock.

1: The DTC operates based on the system clock.

The operating clock is changed when a DTC transition is requested even if the CPU operates based on the medium-speed clock.

2	SCK2	0	R/W	System Clock Select 2 to 0
1	SCK1	0	R/W	Select a clock for the bus master in high-speed mode
0	SCK0	0	R/W	medium-speed mode.

When making a transition to subactive mode or wait mode, SCK2 to SCK0 must be cleared to 0.

000: High-speed mode (Initial value)

001: Medium-speed clock: $\phi/2$

010: Medium-speed clock: $\phi/4$

011: Medium-speed clock: $\phi/8$

100: Medium-speed clock: $\phi/16$

101: Medium-speed clock: $\phi/32$

11*: Must not be set.

[Legend]

*: Don't care

Recommended specification
Note: Setting prohibited.

23.1.2 Low-Power Control Register (LPWRCR)

LPWRCR controls power-down modes and signals in the multiplex bus extended mode.

Bit	Bit Name	Initial Value	R/W	Description
7	DTON	0	R/W	<p>Direct Transfer On Flag</p> <p>Specifies the operating mode to be entered after executing SLEEP instruction.</p> <p>When the SLEEP instruction is executed in high-speed or medium-speed mode:</p> <ul style="list-style-type: none">0: Shifts to sleep mode, software standby mode, or watch mode1: Shifts directly to subactive mode, or shifts to sleep mode or software standby mode <p>When the SLEEP instruction is executed in subactive mode:</p> <ul style="list-style-type: none">0: Shifts to subsleep mode or watch mode1: Shifts directly to high-speed mode, or shifts to subsleep mode

1: Shifts to subsleep mode or watch mode

When watch mode is cancelled:

0: Shifts to high-speed mode

1: Shifts to subactive mode

5	NESEL	0	R/W	Noise Elimination Sampling Frequency Select
				Selects the frequency by which the subclock (ϕ_{SUB}) input to the EXCL pin is sampled using the clock (ϕ) generated by the system clock pulse generator.
				0: Sampling using $\phi/32$ clock
				1: Sampling using $\phi/4$ clock
4	EXCLE	0	R/W	Subclock Input Enable
				Enables/disables subclock input from the EXCL pin.
				0: Disables subclock input from the EXCL pin
				1: Enables subclock input from the EXCL pin
3	—	0	R/W	Reserved
				The initial value should not be changed.
2	PNCCS	0	R/W	Address Multiplex Chip Select
				Controls the output polarity of chip select signals ($\overline{\text{CS256}}$, $\overline{\text{IOS}}$) in the address multiplex extended mode.
				0: Outputs $\overline{\text{CS256}}$, $\overline{\text{CPCS}}$, and $\overline{\text{IOS}}$
				1: Outputs CS256, CPCS, and IOS
1	PNCAH	0	R/W	Address Multiplex Address Hold
				Controls the output polarity of the address hold signal ($\overline{\text{AH}}$) in the address multiplex extended mode.
				0: Outputs $\overline{\text{AH}}$
				1: Outputs AH

7 to 0	SMSTPA15 to SMSTPA8	All 1	W	Reserved The initial values should not be changed.

- SUBMSTPAL

Bit	Bit Name	Initial Value	R/W	Corresponding Module
7 to 1	SMSTPA7 to SMSTPA1	All 1	W	Reserved The initial values should not be changed.
0	SMSTPA0	1	W	LPC interface (LPC)

- Notes:
- When a transition is made between modes by means of an interrupt, the transition cannot be made on interrupt source generation alone. Ensure that interrupt handling is performed after accepting interrupt request.
 - Always select high-speed mode before making a transition to watch mode or sub-active mode.
1. NMI, IRQ0 to IRQ15, KIN0 to KIN15, WUE8 to WUE15, and WDT_1 interrupts
 2. NMI, IRQ0 to IRQ15, KIN0 to KIN15, WUE8 to WUE15, WDT_0, WDT_1, TMR_0, and TMR_1 interrupts
 3. NMI, IRQ0 to IRQ15, KIN0 to KIN15, and WUE8 to WUE15 interrupts

	LPC						Halted (retained)	Halted (retained)	
	FRT								
	TMR_X, TMR_Y								
	IIC_0 to IIC_5								

Notes: Halted (retained) means that internal register values are retained. The internal state operation is suspended.

Halted (reset) means that internal register values and internal states are initialized.

In module stop mode, only modules for which a stop setting has been made are halted (reset or retained).

the bus master operating clock. For example, if $\phi/4$ is selected as the operating clock, on memory is accessed in 4 states, and internal I/O registers in 8 states.

By clearing all of bits SCK2 to SCK0 to 0, a transition is made to high-speed mode at the current bus cycle.

If a SLEEP instruction is executed when the SSBY bit in SBYCR is cleared to 0, and the bit in LPWRCR is cleared to 0, a transition is made to sleep mode. When sleep mode is an interrupt, medium-speed mode is restored. When the SLEEP instruction is executed with SSBY bit set to 1, the LSON bit cleared to 0, and the PSS bit in TCSR (WDT_1) cleared, operation shifts to software standby mode. When software standby mode is cleared by an interrupt, medium-speed mode is restored.

When the $\overline{\text{RES}}$ pin is set low, medium-speed mode is cancelled and operation shifts to the state. The same applies in the case of a reset caused by overflow of the watchdog timer.

When the $\overline{\text{STBY}}$ pin is driven low, a transition is made to hardware standby mode.

Figure 23.2 shows an example of medium-speed mode timing.

23.4 Sleep Mode

The CPU makes a transition to sleep mode if the SLEEP instruction is executed when the bit in SBYCR is cleared to 0 and the LSON bit in LPWRCR is cleared to 0. In sleep mode, operation stops but the peripheral modules do not stop. The contents of the CPU's internal registers are retained.

Sleep mode is exited by any interrupt, the $\overline{\text{RES}}$ pin, or the $\overline{\text{STBY}}$ pin.

When an interrupt occurs, sleep mode is exited and interrupt exception handling starts. Sleep mode is not exited if the interrupt is disabled, or interrupts other than NMI are masked by the C

Setting the $\overline{\text{RES}}$ pin level low cancels sleep mode and selects the reset state. After the oscillator settling time has passed, driving the $\overline{\text{RES}}$ pin high causes the CPU to start reset exception handling.

When the $\overline{\text{STBY}}$ pin level is driven low, a transition is made to hardware standby mode.

When an external interrupt request signal is input, system clock oscillation starts, and after the elapse of the time set in bits STS2 to STS0 in SBYCR, software standby mode is cleared and interrupt exception handling is started. When exiting software standby mode with an IRQ0 to IRQ15 interrupt, set the corresponding enable bit to 1. When exiting software standby mode with a KIN0 to KIN15 or WUE8 to WUE15 interrupt, enable the input. In these cases, ensure that the interrupt with a higher priority than interrupts IRQ0 to IRQ15 is generated. In the case of an IRQ0 to IRQ15 interrupt, software standby mode is not exited if the corresponding enable bit is set to 0 or if the interrupt has been masked by the CPU. In the case of a KIN0 to KIN15 or WUE8 to WUE15 interrupt, software standby mode is not exited if input is disabled or if the interrupt has been masked by the CPU.

When the $\overline{\text{RES}}$ pin is driven low, system clock oscillation is started. At the same time as clock oscillation starts, the system clock is supplied to the entire LSI. Note that the $\overline{\text{RES}}$ pin should be held low until clock oscillation settles. When the $\overline{\text{RES}}$ pin goes high after clock oscillation settles, the CPU begins reset exception handling.

When the $\overline{\text{STBY}}$ pin is driven low, software standby mode is cancelled and a transition is made to hardware standby mode.

Figure 23.3 shows an example in which a transition is made to software standby mode at the falling edge of the NMI pin, and software standby mode is cleared at the rising edge of the NMI pin.

In this example, an NMI interrupt is accepted with the NMIEG bit in SYSCR cleared to 0 (falling edge specification), then the NMIEG bit is set to 1 (rising edge specification), the SSBY bit is set to 1, and a SLEEP instruction is executed, causing a transition to software standby mode.

Software standby mode is then cleared at the rising edge of the NMI pin.

Figure 23.3 Software Standby Mode Application Example

When the $\overline{\text{STBY}}$ pin is driven high while the $\overline{\text{RES}}$ pin is low, clock oscillation is started. That the $\overline{\text{RES}}$ pin is held low until system clock oscillation settles. When the $\overline{\text{RES}}$ pin is subsequently driven high after the clock oscillation settling time has passed, reset exception handling starts.

Figure 23.4 shows an example of hardware standby mode timing.

Figure 23.4 Hardware Standby Mode Timing

When an interrupt occurs, watch mode is exited and a transition is made to high-speed mode or medium-speed mode when the LSON bit in LPWRCCR cleared to 0 or to subactive mode when the LSON bit is set to 1. When a transition is made to high-speed mode, a stable clock is supplied to the entire LSI and interrupt exception handling starts after the time set in the STS2 to STS7 and SBYCR has elapsed.

In the case of an IRQ0 to IRQ15 interrupt, watch mode is not exited if the corresponding interrupt enable bit has been cleared to 0 or the interrupt is masked by the CPU. In the case of a KIN0 to KIN7 or WUE8 to WUE15 interrupt, watch mode is not exited if input is disabled or the interrupt is masked by the CPU. In the case of an interrupt from the on-chip peripheral modules, watch mode is not exited if the interrupt enable register has been set to disable the reception of that interrupt or the interrupt is masked by the CPU.

When the $\overline{\text{RES}}$ pin is driven low, system clock oscillation starts. Simultaneously with the start of system clock oscillation, the system clock is supplied to the entire LSI. Note that the $\overline{\text{RES}}$ pin must be held low until clock oscillation is settled. If the $\overline{\text{RES}}$ pin is driven high after the clock oscillation settling time has passed, the CPU begins reset exception handling.

If the $\overline{\text{STBY}}$ pin is driven low, the LSI enters hardware standby mode.

When an interrupt occurs, subsleep mode is exited and interrupt exception handling starts.

In the case of an IRQ0 to IRQ15 interrupt, subsleep mode is not exited if the corresponding bit has been cleared to 0 or the interrupt is masked by the CPU. In the case of a KIN0 to KIN7 interrupt, subsleep mode is not exited if input is disabled or the interrupt is masked by the CPU. In the case of a WUE8 to WUE15 interrupt, subsleep mode is not exited if the interrupt enable register has been set to disable the reception of the interrupt or the interrupt is masked by the CPU.

When the $\overline{\text{RES}}$ pin is driven low, system clock oscillation starts. Simultaneously with the start of system clock oscillation, the system clock is supplied to the entire LSI. Note that the $\overline{\text{RES}}$ pin must be held low until clock oscillation is settled. If the $\overline{\text{RES}}$ pin is driven high after the oscillation settling time has passed, the CPU begins reset exception handling.

If the $\overline{\text{STBY}}$ pin is driven low, the LSI enters hardware standby mode.

0.

Subactive mode is exited by the SLEEP instruction, $\overline{\text{RES}}$ pin input, or $\overline{\text{STBY}}$ pin input.

When the SLEEP instruction is executed with the SSBY bit in SBYCR set to 1, the DTON bit in LPWRCR cleared to 0, and the PSS bit in TCSR (WDT_1) set to 1, the CPU exits subactive mode and a transition is made to watch mode. When the SLEEP instruction is executed with the SSBY bit in SBYCR cleared to 0, the LSON bit in LPWRCR set to 1, and the PSS bit in TCSR (WDT_1) set to 1, a transition is made to subsleep mode. When the SLEEP instruction is executed with the SSBY bit in SBYCR set to 1, the DTON bit and LSON bit in LPWRCR set to 10, and the PSS bit in TCSR (WDT_1) set to 1, a direct transition is made to high-speed mode.

For details of direct transitions, see section 23.11, Direct Transitions.

When the $\overline{\text{RES}}$ pin is driven low, system clock oscillation starts. Simultaneously with the system clock oscillation, the system clock is supplied to the entire LSI. Note that the $\overline{\text{RES}}$ pin must be held low until the clock oscillation is settled. If the $\overline{\text{RES}}$ pin is driven high after the clock oscillation settling time has passed, the CPU begins reset exception handling.

If the $\overline{\text{STBY}}$ pin is driven low, the LSI enters hardware standby mode.

disabled.

23.11 Direct Transitions

The CPU executes programs in three modes: high-speed, medium-speed, and subactive. When a direct transition is made from high-speed mode to subactive mode, there is no interruption of program execution. A direct transition is enabled by setting the DTON bit in LPWRCR to 01, and then executing the SLEEP instruction. After a transition, direct transition exception handling starts.

The CPU makes a transition to subactive mode when the SLEEP instruction is executed in high-speed mode with the SSBY bit in SBYCR set to 1, the LSON bit and DTON bit in LPWRCR set to 01, and the PSS bit in TCSR (WDT_1) set to 1.

To make a direct transition to high-speed mode after the time set in the STS2 to STS0 bits in SBYCR has elapsed, execute the SLEEP instruction in subactive mode with the SSBY bit in SBYCR set to 1, the LSON bit and DTON bit in LPWRCR set to 01, and the PSS bit in TCSR (WDT_1) set to 1.

23.12.3 DTC Module Stop Mode

If the DTC module stop mode specification and DTC bus request occur simultaneously, the bus is released to the DTC and the MSTP bit cannot be set to 1. After completing the DTC bus request, set the MSTP bit to 1 again.

23.12.4 Notes on Subclock Usage

When using the subclock, make a transition to power-down mode after setting the EXCLEN bit of the LPWRCR to 1 and loading the subclock two or more cycles. When not using the subclock, the EXCLEN bit should not be set to 1.

- Bit configurations of the registers are described in the same order as the Register Addresses (address order) above.
 - Reserved bits are indicated by — in the bit name column.
 - The bit number in the bit-name column indicates that the whole register is allocated counter or for holding data.
 - 16-bit registers are indicated from the bit on the MSB side.
3. Register States in Each Operating Mode
- Register states are described in the same order as the Register Addresses (address order) above.
 - The register states described here are for the basic operating modes. If there is a special mode for an on-chip peripheral module, refer to the section on that on-chip peripheral module.

24.1 Register Addresses (Address Order)

The data bus width indicates the numbers of bits by which the register is accessed.

The number of access states indicates the number of states based on the specified reference state.

Note: Access to undefined or reserved addresses is prohibited. Since operation or content of these registers is not guaranteed when these registers are accessed, do not attempt such operation.

				—	—	120		50 °C < T _a

RAM standby voltage	V _{RAM}	3.0	—	—	V
VCC start voltage	VCC _{START}	—	0	0.8	V
VCC rising edge	SVCC	—	—	20	ms/V

Notes: 1. Do not leave the AVCC, AVref, and AVSS pins open even if the A/D converter or D/A converter is not used.

Even if the A/D converter or D/A converter is not used, apply a value in the range from 3 V to the AVCC and AVref pins by connecting them to the power supply (VCC). The relationship between these two pins should be AVref ≤ AVCC.

2. When noise cancel has been enabled.
3. An external pull-up resistor is necessary to provide high-level output from SCL5 to SCL0 and SDA5 to SDA0 (ICE bit in ICCR is 1).
4. Port 8, C0 to C5, D6, and D7 are NMOS push-pull outputs.
Port 8, C0 to C5, D6, D7, and SCK0 to SCK2 (ICE bit in ICCR = 0) high levels are driven by NMOS. An external pull-up resistor is necessary to provide high-level output from these pins when they are used as an output.
5. Current consumption values are for V_{IH} min = VCC – 0.2 V and V_{IL} max = 0.2 V with all outputs unloaded and the on-chip pull-up MOSs in the off state.
6. When VCC = 3.0 V, V_{IH} min = VCC – 0.2 V, and V_{IL} max = 0.2 V.

current (per pin)

Permissible output high
current (total)

Total of all output pins

ΣI_{OH}

60

- Notes:
1. To protect LSI reliability, do not exceed the output current values in table 25.3.
 2. When driving a Darlington transistor or LED, always insert a current-limiting resistor in line, as show in figures 25.1 and 25.2.

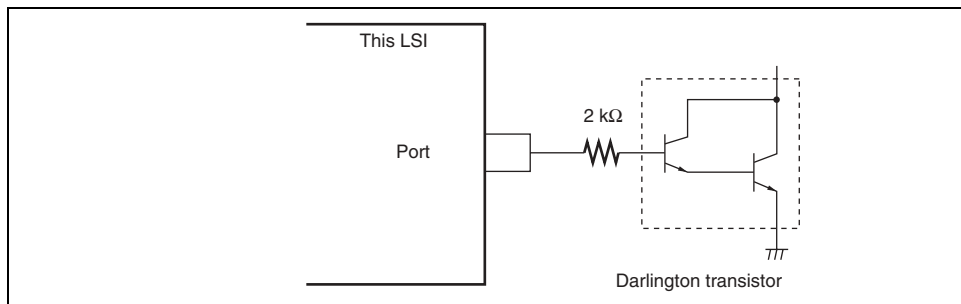

Figure 25.1 Darlington Transistor Drive Circuit (Example)

Figure 25.2 LED Drive Circuit (Example)

25.3.1 Clock Timing

Table 25.4 shows the clock timing. The clock timing specified here covers clock output (clock pulse generator (crystal) and external clock input (EXTAL pin) oscillation stabilization times. For details of external clock input (EXTAL pin and EXCL pin) timing, see table 25.6.

Table 25.4 Clock Timing

Condition: VCC = 3.0 V to 3.6 V, VSS = 0 V, ϕ = 5 MHz to 33 MHz

Item	Symbol	Min.	Max.	Unit	Ref

It is recommended that a bypass capacitor be connected to the VCC pin. (The values are reference values.)
When connecting, place a bypass capacitor near the pin.

Do not connect Vcc power supply to the VCC pin.
Always connect a capacitor for internal step-down voltage stabilization.
Use one or two ceramic multilayer capacitors (0.1 μ F / 0.47 μ F: connect in parallel when used) and place it (them) near the pin.

	(EXPE = 0)								
Port F	(EXPE = 1)	T	T	kept	kept	kept	kept	I/O port	
	(EXPE = 0)								

Legend

H: High level

L: Low level

T: High impedance

kept: Input ports are in the high-impedance state (when DDR = 0 and PCR = 1, the input MOS remains on).

Output ports maintain their previous state.

Depending on the pins, the on-chip peripheral modules may be initialized and the function determined by DDR and DR.

DDR: Data direction register

Note: * In the case of address output, the last address accessed is retained.

Figure C.1 Package Dimensions (TFP-144)

Section 12.3.4 Timer 312,
Control register (TCR) 313

Description amended.

Table 12.2 Clock Input to TCNT and Count Condition

Channel	TCR			Description
	CKS2	CKS1	CKS0	
TMR_Y	0	0	0	Disables clock input
	0	0	1	Increments at falling edge of internal clock ϕ
	0	1	0	Increments at falling edge of internal clock ϕ
	0	1	1	Increments at falling edge of internal clock ϕ
	1	0	0	Setting prohibited
TMR_X	0	0	0	Disables clock input
	0	0	1	Increments at falling edge of internal clock ϕ
	0	1	0	Increments at falling edge of internal clock ϕ
	0	1	1	Increments at falling edge of internal clock ϕ
	1	0	0	Setting prohibited

Note: * If the TMR_0 clock input is set as the TCNT overflow signal and the TMR_1 clock input is set as the TCNT_0 compare-match signal simultaneously, a count-up clock cannot be generated. See these conditions should therefore be avoided.

3, 2	—	All 0	R/W	Reserved The initial value should be changed.
------	---	-------	-----	--

14.3.11 Serial Enhanced Mode Register_0 and 2 (SEMR_0 and SEMR_2) 377

Description amended.

Bit	Bit Name	Initial Value	R/W	Description
4	ACS4	0	R/W	0011: Average transfer operation at 720 kHz when the system frequency is 32 MHz (operated using the basic clock with a frequency 16 times the transfer clock frequency)
2	ACS2	0	R/W	
1	ACS1	0	R/W	
0	ACS0	0	R/W	

14.8 IrDA Operation 417
Figure 14.36 IrDA Block Diagram

Figure amended

Section 24 List of Registers 766 Description amended.

24.2 Register Bits

Register							
Abbreviation	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1
SCICR	IrE	IrCKS2	IrCKS1	IrCKS0	—	—	—

Section 25 Electrical Characteristics 784 Amended

25.2 DC Characteristics

Table 25.2 DC Characteristics (1)

Item	Symbol	Min.	Typ.	Max.
Input low voltage	\overline{RES} , \overline{STBY} , (3) V_{IL}	-0.3	—	$VCC \times 0.1$
	NMI, FWE, $\overline{MD2}$, MD1, MD0			
	EXTAL	-0.3	—	$VCC \times 0.1$
		-0.3	—	$VCC \times 0.2$
	Port 7	-0.3	—	$AVCC \times 0.2$

25.3.3 Bus Timing

Table 25.8 Bus Timing

Item	Symbol	Min.	Max.
Write data hold time	t_{WDH}	$0.5 \times t_{cyc} - 5$	—

25.3.4 Multiplex Bus Timing

Table 25.9 Multiplex Bus Timing

25.6 Flash Memory Characteristics

813 to 815

Description amended and added.

Ta = 0°C to +75°C (operating temperature range for programming/erasing in regular specifications)

Table 25.16 Flash Memory Characteristics

Ta = 0°C to +85°C (operating temperature range for programming/erasing in wide-range specifications)

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Reprogramming count*5	N_{WEC}	100* ³	1000	—	Times	

Notes: 5. Reprogramming count in each erase block.
