The EL5174 is a single high bandwidth amplifier with an output in differential form. It is primarily targeted for applications such as driving twisted-pair lines in component video applications. The inputs can be in either single-ended or differential form but the outputs are always in differential form.

On the EL5174, two feedback inputs provide you with the ability to set the gain of each device (stable at minimum gain of one). For a fixed gain of two, please see the EL5173 data sheet (FN7312).
The output common mode level is set by the associated REF pin, which has a -3dB bandwidth of over 110MHz. Generally, this pin is grounded but can be tied to any voltage reference.

All outputs are short circuit protected to withstand temporary overload condition.

The EL5174 is available in a 8 Ld SOIC package. It is specified for operation across the full $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

## Related Literature

For a full list of related documents, visit our website:

- EL5174 product page

## Features

- Fully differential inputs, outputs, and feedback
- Differential input range $\pm 2.3 \mathrm{~V}$
- 550MHz 3dB bandwidth
- $1100 \mathrm{~V} / \mathrm{\mu s}$ slew rate
- Low distortion at 5MHz
- Single 5 V or dual $\pm 5 \mathrm{~V}$ supplies
- 60mA maximum output current
- Low power - 12.5mA
- Pb-free (RoHS compliant)

## Applications

- Twisted-pair driver
- Differential line driver
- VGA over twisted-pair
- ADSL/HDSL driver
- Single-ended to differential amplification
- Transmission of analog signals in a noisy environment

## Description of Operation and Application Information

## Product Description

The EL5174 is a low-power, wideband, differential to singleended amplifier. Because the $\mathrm{I}_{\mathrm{N}^{-}}$pin and REF pin are tied together internally, the EL5174 can be used as a single-ended to differential converter. The EL5174 and is internally compensated for closed loop gain of +1 of greater. Connected in a gain of 1 and driving a $1 \mathrm{k} \Omega$ differential load, the EL5174 has a -3dB bandwidth of 550 MHz . Driving a $200 \Omega$ differential load at gain of 2 , the bandwidth is about 130 MHz .

## Input, Output and Supply Voltage Range

The EL5174 is designed to operate with a single supply voltage of 5 V to 10 V or split supplies with its total voltage from 5 V to 10 V . The amplifiers have an input common mode voltage range from -4.3 V to 3.4 V for $\pm 5 \mathrm{~V}$ supply. The differential mode input range (DMIR) between the two inputs is from -2.3 V to +2.3 V . The input voltage range at the REF pin is from -3.3 V to 3.7 V . If the input common mode or differential mode signal is outside the above-specified ranges, it will cause the output signal to become distorted.

The output of the EL5174 can swing from -3.8 V to +3.8 V at $1 \mathrm{k} \Omega$ differential load at $\pm 5 \mathrm{~V}$ supply. As the load resistance becomes lower, the output swing is reduced.

## Differential and Common Mode Gain Settings

Because the $\mathrm{I}_{\mathrm{N}}$ pin and REF pin are bound together as the REF pin in an 8 Ld package, the signal at the REF pin is part of the common mode signal and also part of the differential mode signal. For the true balance differential outputs, the REF pin must be tied to the same bias level as the $I_{N^{+}}$pin. For a $\pm 5 \mathrm{~V}$ supply, just tie the REF pin to GND if the $\mathrm{I}^{+}{ }^{+}$pin is biased at 0 V with a $50 \Omega$ or $75 \Omega$ termination resistor. For a single supply application, if the $\mathrm{I}_{\mathrm{N}}+$ is biased to half of the rail, the REF pin should be biased to half of the rail also.

The gain setting for EL5174 is expressed in Equation 1:

$$
\begin{align*}
& \mathrm{v}_{\mathrm{ODM}}=\mathrm{V}_{\mathrm{IN}^{+}} \times\left(1+\frac{\mathrm{R}_{\mathrm{F} 1}+\mathrm{R}_{\mathrm{F} 2}}{\mathrm{R}_{\mathrm{G}}}\right) \\
& \mathrm{v}_{\mathrm{ODM}}=\mathrm{V}_{\mathrm{IN}^{+}}=\left(1+\frac{2 \mathrm{R}_{\mathrm{F}}}{\mathrm{R}_{\mathrm{G}}}\right)  \tag{EQ.1}\\
& \mathrm{v}_{\mathrm{OCM}}=\mathrm{V}_{\mathrm{REF}}=0 \mathrm{~V}
\end{align*}
$$

where:
$V_{\text {REF }}=0 V$
$\mathrm{R}_{\mathrm{F} 1}=\mathrm{R}_{\mathrm{F} 2}=\mathrm{R}_{\mathrm{F}}$

## Choice of Feedback Resistor and Gain Bandwidth Product

For applications that require a gain of +1 , no feedback resistor is required. Just short the OUT+ pin to FBP pin and OUT- pin to FBN pin. For gains greater than +1 , the feedback resistor
forms a pole with the parasitic capacitance at the inverting input. As this pole becomes smaller, the amplifier's phase margin is reduced. This causes ringing in the time domain and peaking in the frequency domain. Therefore, $\mathrm{R}_{\mathrm{F}}$ has some maximum value that should not be exceeded for optimum performance. If a large value of $R_{F}$ must be used, a small capacitor in the few Pico farad range in parallel with $R_{F}$ can help to reduce the ringing and peaking at the expense of reducing the bandwidth.

The bandwidth of the EL5174 depends on the load and the feedback network. $R_{F}$ and $R_{G}$ appear in parallel with the load for gains other than +1. As this combination gets smaller, the bandwidth falls off. Consequently, $\mathrm{R}_{\mathrm{F}}$ also has a minimum value that should not be exceeded for optimum bandwidth performance. For gain of $+1, R_{F}=0$ is optimum. For the gains other than +1 , optimum response is obtained with $R_{F}$ between $500 \Omega$ to $1 \mathrm{k} \Omega$.

The EL5174 has a gain bandwidth product of 200 MHz for $R_{L D}=1 \mathrm{k} \Omega$. For gains $\geq 5$, its bandwidth can be predicted by Equation 2:
Gain $\times$ BW $=200 \mathrm{MHz}$

## Driving Capacitive Loads and Cables

The EL5174 can drive a 23pF differential capacitor in parallel with $1 \mathrm{k} \Omega$ differential load with less than 5 dB of peaking at gain of +1 . If less peaking is desired in applications, a small series resistor (usually between $5 \Omega$ to $50 \Omega$ ) can be placed in series with each output to eliminate most peaking. However, this will reduce the gain slightly. If the gain setting is greater than 1, the gain resistor $\mathrm{R}_{\mathrm{G}}$ can then be chosen to make up for any gain loss, which may be created by the additional series resistor at the output.

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, a back-termination series resistor at the amplifier's output will isolate the amplifier from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. Again, a small series resistor at the output can help to reduce peaking.

## Output Drive Capability

The EL5174 has an internal short-circuit protection. Its typical short circuit current is $\pm 60 \mathrm{~mA}$. If the output is shorted indefinitely, the power dissipation could easily increase such that the part will be destroyed. Maximum reliability is maintained if the output current never exceeds $\pm 60 \mathrm{~mA}$. This limit is set by the design of the internal metal interconnections.

## Power Dissipation

With the high output drive capability of the EL5174, it is possible to exceed the $+135^{\circ} \mathrm{C}$ absolute maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if the load conditions or package types need to be modified for the amplifier to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to Equation 3:

$$
\begin{equation*}
P D_{\text {MAX }}=\frac{T_{J M A X}-T_{A M A X}}{\Theta_{J A}} \tag{EQ.3}
\end{equation*}
$$

where:
$\mathrm{T}_{\mathrm{JMAX}}=$ Maximum junction temperature
$\mathrm{T}_{\text {AMAX }}=$ Maximum ambient temperature
$\theta_{\mathrm{JA}}=$ Thermal resistance of the package
The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or as expressed in Equation 4:

$$
\begin{equation*}
\mathrm{PD}=\left(\mathrm{V}_{\mathrm{STOT}} \times \mathrm{I}_{\mathrm{SMAX}}+\left(\mathrm{V}_{\mathrm{STOT}}-\Delta \mathrm{V}_{\mathrm{O}}\right) \times \frac{\Delta \mathrm{V}_{\mathrm{O}}}{\mathrm{R}_{\mathrm{LD}}}\right) \tag{EQ.4}
\end{equation*}
$$

where:
$\mathrm{V}_{\text {STOT }}=$ Total supply voltage $=\mathrm{V}_{\mathbf{S}^{+}}-\mathrm{V}_{\mathbf{S}^{-}}$
ISMAX $=$ Maximum quiescent supply current
$\Delta \mathrm{V}_{\mathrm{O}}=$ Maximum differential output voltage of the application
$\mathrm{R}_{\mathrm{LD}}=$ Differential load resistance
$l_{\text {LOAD }}=$ Load current
By setting the two $\mathrm{PD}_{\text {MAX }}$ equations equal to each other, we can solve the output current and $\mathrm{R}_{\text {LD }}$ to avoid the device overheat.

## Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, a good printed circuit board layout is necessary for optimum performance. Lead lengths should be as short as possible. The power supply pin must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the $\mathrm{V}_{\mathrm{S}^{-}}$pin is connected to the ground plane, a single $4.7 \mu \mathrm{~F}$ tantalum capacitor in parallel with a $0.1 \mu \mathrm{~F}$ ceramic capacitor from $\mathrm{V}_{\mathbf{S}}+$ to $G N D$ will suffice. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used. In this case, the $\mathrm{V}_{\mathrm{S}^{-}}$pin becomes the negative supply rail.

For good AC performance, parasitic capacitance should be kept to a minimum. Use of wire-wound resistors should be avoided because of their additional series inductance. Use of sockets should also be avoided if possible. Sockets add parasitic inductance and capacitance that can result in compromised performance. Minimizing parasitic capacitance at the amplifier's inverting input pin is very important. The feedback resistor should be placed very close to the inverting input pin. Strip line design techniques are recommended for the signal traces.

## Typical Applications

As the signal is transmitted through a cable, the high frequency signal will be attenuated. One way to compensate this loss is to boost the high frequency gain at the receiver side.
