The EL9110 is a single channel differential receiver and equalizer. It contains a high speed differential receiver with 5 programmable poles. The outputs of these pole blocks are then summed into an output buffer. The equalization length is set with the voltage on a single pin. The EL9110 also contains a three-statable output, enabling multiple devices to be connected in parallel and used in a multiplexing application.

The gain can be adjusted up or down by 6 dB using the $\mathrm{V}_{\text {GAIN }}$ control signal. In addition, a further 6 dB of gain can be switched in to provide a matched drive into a cable.

The EL9110 has a bandwidth of 150 MHz and consumes just 33 mA on $\pm 5 \mathrm{~V}$ supply. A single input voltage is used to set the compensation levels for the required length of cable.

The EL9110 is available in the 16 Ld QSOP package and is specified for operation over the full $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

*Please refer to TB347 for details on reel specifications.
NOTE: These Intersil Pb-free plastic packaged products employ special Pb -free material sets; molding compounds/die attach materials and 100\% matte tin plate PLUS ANNEAL - e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb -free soldering operations. Intersil Pb -free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

## Features

- $150 \mathrm{MHz}-3 \mathrm{~dB}$ bandwidth
- CAT-5 compensation
- 75MHz @ 1000ft
- 125MHz @ 500ft
- 33mA supply current
- Differential input range 3.2 V
- Common mode input range $\pm 4.5 \mathrm{~V}$
- $\pm 5 \mathrm{~V}$ supply
- Output to within 1.5 V of supplies
- Available in 16 Ld QSOP package
- Pb-free available (RoHS compliant)

## Applications

- Twisted-pair receiving/equalizer
- KVM (Keyboard/Video/Mouse)
- VGA over twisted-pair
- Security video

## Applications Information

## Logic Control

The EL9110 has three logical input pins, Chip Enable (ENBL), Common Mode Extend (CMEXT), and Switch Gain (X2). The logic circuits all have a nominal threshold of 1.1 V above the potential of the logic reference pin. In most applications it is expected that this chip will run from a +5 V , $0 \mathrm{~V},-5 \mathrm{~V}$ supply system with logic being run between 0 V and +5 V . In this case the logic reference voltage should be tied to the 0 V supply. If the logic is referenced to the -5 V rail, then the logic reference should be connected to -5 V . The logic reference pin sources about $60 \mu \mathrm{~A}$ and this will rise to about $200 \mu \mathrm{~A}$ if all inputs are true (positive).

The logic inputs all source up to $10 \mu \mathrm{~A}$ when they are held at the logic reference level. When taken positive, the inputs sink a current dependent on the high level, up to $50 \mu \mathrm{~A}$ for a high level 5 V above the reference level.

The logic inputs, if not used, should be tied to the appropriate voltage in order to define their state.

## Control Reference and Signal Reference

Analog control voltages are required to set the equalizer and contrast levels. These signals are voltages in the range 0 V to 1 V , which are referenced to the control reference pin. It is expected that the control reference pin will be tied to 0 V and the control voltage will vary from 0 V to 1 V . It is; however, acceptable to connect the control reference to any potential between -5 V and 0 V to which the control voltages are referenced.

The control voltage pins themselves are high impedance. The control reference pin will source between $0 \mu \mathrm{~A}$ and $200 \mu \mathrm{~A}$ depending on the control voltages being applied.

The control reference and logic reference effectively remove the necessity for the 0 V rail and operation from $\pm 5 \mathrm{~V}$ (or 0 V and 10 V ) only is possible. However we still need a further reference to define the 0 V level of the single ended output signal. The reference for the output signal is provided by the OV pin. The output stage cannot pull fully up or down to either supply so it is important that the reference is positioned to allow full output swing. The 0 V reference should be tied to a 'quiet ground' as any noise on this pin is transferred directly to the output. The 0 V pin is a high impedance pin and draws dc bias currents of a few $\mu \mathrm{A}$ and similar levels of AC current.

## Common Mode Extension

The common mode extension circuitry extends the range of input common mode voltage before the input differential amplifier is overloaded. It does this by reducing the voltage equally at both inputs of the first differential amplifier as the common mode signal rises towards the supply. Similarly, when the common mode input signal goes low, the inputs to the first differential amplifier are raised whilst preserving the
differential signal and maintain the amplifier within its common mode operating range.

This operation may not always be desirable. A problem occurs because the EL9110 sinks or sources a common mode current though its input pins to create the common mode offset voltage. Assuming the system has been set up so that the differential line has a well-balanced impedance, then a problem will only occur when the common mode impedance to ground is not low. This will occur in systems where the inputs to the EL9110 are AC coupled. In such systems it is recommended that the common mode extension be disabled. In systems where the differential input signal is directly coupled and has its common mode level defined by a low impedance line driver, the common mode extension circuitry can extend the total common mode range by 2 V to 3 V .

## Equalizing

When transmitting a signal across a twisted pair cable, it is found that the high frequency (above 1 MHz ) information is attenuated more significantly than the information at low frequencies. The attenuation is predominantly due to resistive skin effect losses and has a loss curve which depends on the resistivity of the conductor, surface condition of the wire and the wire diameter. For the range of high performance twisted pair cables based on 24awg copper wire (Cat 5 etc.) these parameters vary only a little between cable types, and in general cables exhibit the same frequency dependence of loss. (The lower loss cables can be compared with somewhat longer lengths of their more lossy brothers.) This enables a single equalizing law equation to be built into the EL9110.

With a control voltage applied between pins 2 and 1, the frequency dependence of the equalization is shown in Figure 8. The equalization matches the cable loss up to about 100 MHz . Above this, system gain is rolled off rapidly to reduce noise bandwidth. The roll-off occurs more rapidly for higher control voltages, thus the system (cable + equalizer) bandwidth reduces as the cable length increases. This is desirable, as noise becomes an increasing issue as the equalization increases.

The cable loss for $100 \mathrm{~m}, 200 \mathrm{~m}$, and 300 m of CAT 5 cable, based on manufacturer's loss curves is shown in Figure 14.

Thus:

- 100 m requires $\mathrm{V}_{\mathrm{C}}=0.2 \mathrm{~V}$
- 200 m requires $\mathrm{V}_{\mathrm{C}}=0.6 \mathrm{~V}$
and:
- 300 m requires $\mathrm{V}_{\mathrm{C}}=1.0 \mathrm{~V}$ approximately

## Contrast

By varying the voltage between pins 7 and 1, the gain of the signal path can be changed in the ratio 4:1. The gain change varies almost linearly with control voltage. For normal
operation it is anticipated the X 2 mode will be selected and the output load will be back matched. A unity gain to the output load will then be achieved with a gain control voltage of about 0.35 V . This allows the gain to be trimmed up or down by 6dB to compensate for any gain/loss errors that affect the contrast of the video signal. Figure 12 shows an example plot of the gain to the load with gain control voltage.

FIGURE 12. VARIATION OF GAIN WITH GAIN CONTROL VOLTAGE

FIGURE 13. CAT-5 CABLE ATTENUATION CHARACTERISTICS

## Circuit and Layout Recommendation

The interconnection cable is a transmission line therefore for proper function it should be treated like transmission line, a refection-free termination is necessary.

A reflection-free termination is a real "ohmic" resistor with as less as possible reactive parasitic.

The traces of the layout, up to the point where of the termination resistor placed, are part of the transmission line which also includes the cable's connector. A connector with a better controlled impedance is an obligation for good picture quality. The termination resistor should be placed close to the inputs of the device's pins (pin 3 and pin 4.) The small capacitance differential and common mode capacitance of the input pins of the device makes it possible to connect parallel to the termination resistor.

The cable will work as an antenna for all the RF spectrum which is "in the air" where the cable is used. The spectrum, particularly its common mode components, could and will contain high energy level of transients which are above the built-in protection level of the device and easily could damage its inputs. Using a transient protection circuit according to the given application is recommended.

Since the used signal's bandwidth is in the range of 100 MHz , for layout and power supply bypassing the roles of RF design should be applied.

The following picture is taken from the DB9110 demoboard's layout. For better visibility the ground plain is removed.

The ground plane is shown in Figure 14.
