# Micro-power Single and Dual Precision Rail-to-Rail Input-Output (RRIO) Low Input Bias Current Op Amps 

The ISL28158 and ISL28258 are micro-power precision operational amplifiers optimized for single supply operation at 5.5 V and can operate down to 2.4 V .

These devices feature an Input Range Enhancement Circuit (IREC), which enables them to maintain CMRR performance for input voltages greater than the positive supply. The input signal is capable of swinging 0.25 V above the positive supply and to 100 mV below the negative supply with only a slight degradation of the CMRR performance. The output operation is rail-to-rail.

The ISL28158 and ISL28258 draw minimal supply current while meeting excellent DC-accuracy noise and output drive specifications. Competing devices seriously degrade these parameters to achieve micro-power supply current. Offset current, voltage and current noise, slew rate, and gain bandwidth product are all two to ten times better than on previous micro-power op amps.

The $1 / \mathrm{f}$ corner of the voltage noise spectrum is at 100 Hz . This results in low frequency noise performance, which can only be found on devices with an order of magnitude higher supply current.

ISL28158 and ISL28258 can be operated from one lithium cell or two Ni-Cd batteries. The input range includes both positive and negative rail. The output swings to both rails.

## Features

- $34 \mu \mathrm{~A}$ typical supply current (ISL28158)
- $68 \mu \mathrm{~A}$ typical supply current (ISL28258)
- $300 \mu \mathrm{~V}$ maximum offset voltage (8 Ld SOIC)
- 1pA typical input bias current
- 200 kHz gain bandwidth product
- 2.4 V to 5.5 V single supply voltage range
- Rail-to-rail input and output
- Enable pin (ISL28158 only)
- Pb-free (RoHS compliant)

## Applications

- Battery- or solar-powered systems
- 4 mA to 20 mA current loops
- Handheld consumer products
- Medical devices
- Sensor amplifiers
- ADC buffers
- DAC output amplifiers

NOTES:

1. Please refer to $\overline{T B 347}$ for details on reel specifications.
2. These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and $100 \%$ matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb -free soldering operations). Intersil Pb -free products are MSL classified at Pb -free peak reflow temperatures that meet or exceed the Pb -free requirements of IPC/JEDEC J STD-020.
3. The part marking is located on the bottom of the part.

## Applications Information

## Introduction

The ISL28158 is a single CMOS rail-to-rail input, output (RRIO) operational amplifier with an enable feature. The ISL28258 is a dual version without the enable feature. Both devices are designed to operate from single supply ( 2.4 V to 5.5 V ) or dual supplies ( $\pm 1.2 \mathrm{~V}$ to $\pm 2.75 \mathrm{~V}$ ).

## Rail-to-Rail Input/Output

These devices feature PMOS inputs with an input common mode range that extends up to 0.3 V beyond the $\mathrm{V}+$ rail, and to 0.1 V below the V - rail. The CMOS output features excellent drive capability, typically swinging to within 6 mV of either rail with a $100 \mathrm{k} \Omega$ load.

## Results of Over-Driving the Output

Caution should be used when over-driving the output for long periods of time. Over-driving the output can occur in two ways 1) The input voltage times the gain of the amplifier exceeds the supply voltage by a large value or, 2) the output current required is higher than the output stage can deliver. These conditions can result in a shift in the Input Offset Voltage ( $\mathrm{V}_{\mathrm{OS}}$ ) as much as $1 \mu \mathrm{~V} / \mathrm{hr}$. of exposure under these conditions.

## IN+ and IN- Input Protection

All input terminals have internal ESD protection diodes to both positive and negative supply rails, limiting the input voltage to within one diode beyond the supply rails. They also contain back-to-back diodes across the input terminals (see "Pin Descriptions" on page 14-Circuit 1). For applications where the input differential voltage is expected to exceed 0.5 V , an external series resistor must be used to ensure the input currents never exceed 5 mA (Figure 47).

## Enable/Disable Feature

The ISL28158 offers an $\overline{\mathrm{EN}}$ pin that disables the device when pulled up to at least 2.0 V . In the disabled state (output in a high impedance state), the part consumes typically $10 \mu \mathrm{~A}$ at room temperature. By disabling the part, multiple ISL28158 parts can be connected together as a MUX. In this configuration, the outputs are tied together in parallel and a channel can be selected by the $\overline{\mathrm{EN}} \mathrm{pin}$. The loading effects of the feedback resistors of the disabled amplifier must be considered when multiple amplifier outputs are connected together. Note that feed through from the $\mathrm{IN}+$ to IN - pins occurs on any Mux Amp disabled channel where the input differential voltage exceeds 0.5 V (e.g., active channel
$\mathrm{V}_{\text {OUT }}=1 \mathrm{~V}$, while disabled channel $\mathrm{V}_{I N}=G N D$ ), so the mux
implementation is best suited for small signal applications. If large signals are required, use series $\mathrm{IN}+$ resistors, or large value $R_{F}$, to keep the feed through current low enough to minimize the impact on the active channel. See "Limitations of the Differential Input Protection" on page 15 for more details. The $\overline{\mathrm{EN}}$ pin also has an internal pull-down. If left open, the $\overline{\mathrm{EN}}$ pin will pull to the negative rail and the device will be enabled by default. When not used, the $\overline{\mathrm{EN}}$ pin should either be left floating or connected directly to the -V pin.

## Limitations of the Differential Input Protection

If the input differential voltage is expected to exceed 0.5 V , an external current limiting resistor must be used to ensure the input current never exceeds 5 mA . For non-inverting unity gain applications, the current limiting can be via a series IN+ resistor, or via a feedback resistor of appropriate value. For other gain configurations, the series $\mathrm{IN}+$ resistor is the best choice, unless the feedback ( $R_{F}$ ) and gain setting ( $R_{G}$ ) resistors are both sufficiently large to limit the input current to 5 mA .
Large differential input voltages can arise from several sources:

1) During open loop (comparator) operation. Used this way, the $\mathrm{IN}+$ and IN - voltages don't track, so differentials arise.
2) When the amplifier is disabled but an input signal is still present. An $R_{L}$ or $R_{G}$ to $G N D$ keeps the $I N$ - at GND, while the varying $\mathrm{IN}+$ signal creates a differential voltage. Mux Amp applications are similar, except that the active channel $\mathrm{V}_{\text {OUT }}$ determines the voltage on the IN - terminal.
3) When the slew rate of the input pulse is considerably faster than the op amp's slew rate. If the $\mathrm{V}_{\text {OUT }}$ can't keep up with the IN+ signal, a differential voltage results, and visible distortion occurs on the input and output signals. To avoid this issue, keep the input slew rate below $0.1 \mathrm{~V} / \mu \mathrm{s}$, or use appropriate current limiting resistors.
Large ( $>2 \mathrm{~V}$ ) differential input voltages can also cause an increase in disabled $\mathrm{I}_{\mathrm{CC}}$.

## Using Only One Channel

The ISL28258 is a dual op amp. If the application only requires one channel, the user must configure the unused channel to prevent it from oscillating. The unused channel will oscillate if the input and output pins are floating. This will result in higher than expected supply currents and possible noise injection into the channel being used. The proper way to prevent this oscillation is to short the output to the negative input and ground the positive input (as shown in Figure 48).

## Current Limiting

These devices have no internal current-limiting circuitry. If the output is shorted, it is possible to exceed the Absolute Maximum Rating for output current or power dissipation, potentially resulting in the destruction of the device.

## Power Dissipation

It is possible to exceed the $+125^{\circ} \mathrm{C}$ maximum junction temperatures under certain load and power-supply conditions. It is therefore important to calculate the maximum junction
temperature ( $T_{J M A X}$ ) for all applications to determine if power supply voltages, load conditions, or package type need to be modified to remain in the safe operating area. These parameters are related in Equation 1:

$$
\begin{equation*}
\mathrm{T}_{\text {JMAX }}=\mathrm{T}_{\text {MAX }}+\left(\theta_{\text {JA }} \times \mathrm{PD}_{\text {MAXTOTAL }}\right) \tag{EQ.1}
\end{equation*}
$$

where:

- PDMAXTOTAL is the sum of the maximum power dissipation of each amplifier in the package ( $\mathrm{PD}_{\mathrm{MAX}}$ )
- $P D_{\text {MAX }}$ for each amplifier can be calculated using Equation 2:
$\mathrm{PD}_{\text {MAX }}=2^{*} \mathrm{~V}_{\mathrm{S}} \times \mathrm{I}_{\text {SMAX }}+\left(\mathrm{V}_{\mathrm{S}}-\mathrm{V}_{\text {OUTMAX }}\right) \times \frac{\mathrm{V}_{\text {OUTMAX }}}{R_{\mathrm{L}}}$
(EQ. 2)
where:
- $\mathrm{T}_{\mathrm{MAX}}=$ Maximum ambient temperature
- $\theta_{J A}=$ Thermal resistance of the package
- $P D_{\text {MAX }}=$ Maximum power dissipation of 1 amplifier
- $\mathrm{V}_{\mathrm{S}}=$ Supply voltage (Magnitude of $\mathrm{V}_{+}$and $\mathrm{V}_{-}$)
- $I_{\text {MAX }}=$ Maximum supply current of 1 amplifier
- $\mathrm{V}_{\text {OUTMAX }}=$ Maximum output voltage swing of the application
- $\mathrm{R}_{\mathrm{L}}=$ Load resistance
