## ISL55002

FN7497
Rev 4.00
July 27, 2006

The ISL55002 is a high speed, low power, low cost monolithic operational amplifier. The ISL55002 is unity-gain stable and features a $300 \mathrm{~V} / \mu$ s slew rate and 200 MHz bandwidth while requiring only 8.5 mA of supply current per amplifier.

The power supply operating range of the ISL55002 is from $\pm 15 \mathrm{~V}$ down to $\pm 2.5 \mathrm{~V}$. For single-supply operation, the ISL55002 operates from 30 V down to 5 V .

The ISL55002 also features an extremely wide output voltage swing of $-12.75 \mathrm{~V} /+13.4 \mathrm{~V}$ with $\mathrm{V}_{\mathrm{S}}= \pm 15 \mathrm{~V}$ and $R_{L}=1 \mathrm{k} \Omega$.

At a gain of +1 , the ISL55002 has a -3 dB bandwidth of 200 MHz with a phase margin of $55^{\circ}$. Because of its conventional voltage-feedback topology, the ISL55002 allow the use of reactive or non-linear elements in its feedback network. This versatility combined with low cost and 140 mA of output-current drive makes the ISL55002 an ideal choice for price-sensitive applications requiring low power and high speed.

The ISL55002 is available in an 8 Ld SO package and is specified for operation over the full $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100\% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb -free soldering operations. Intersil Pb -free products are MSL classified at Pb -free peak reflow temperatures that meet or exceed the Pb -free requirements of IPC/JEDEC J STD-020.

## Features

- 200MHz -3dB bandwidth
- Unity-gain stable
- Low supply current: 8.5 mA per amplifier
- Wide supply range: $\pm 2.5 \mathrm{~V}$ to $\pm 15 \mathrm{~V}$ dual-supply and 5 V to 30V single-supply
- High slew rate: $300 \mathrm{~V} / \mathrm{\mu s}$
- Fast settling: 75 ns to $0.1 \%$ for a 10 V step
- Wide output voltage swing: $-12.75 \mathrm{~V} /+13.4 \mathrm{~V}$ with
$\mathrm{V}_{\mathrm{S}}= \pm 15 \mathrm{~V}, \mathrm{R}_{\mathrm{L}}=1 \mathrm{k} \Omega$
- Enhanced replacement for EL2244
- Pb-free plus anneal available (RoHS compliant)

## Applications

- Video amplifiers
- Single-supply amplifiers
- Active filters/integrators
- High speed sample-and-hold
- High speed signal processing
- ADC/DAC buffers
- Pulse/RF amplifiers
- Pin diode receivers
- Log amplifiers
- Photo multiplier amplifiers
- Difference amplifiers

## Product Description

The ISL55002 is a wide bandwidth, low power, and low offset voltage feedback operational amplifier. This device is internally compensated for closed loop gain of +1 or greater. Connected in voltage follower mode and driving a $500 \Omega$ load, the -3 dB bandwidth is around a 200 MHz . Driving a $150 \Omega$ load and a gain of 2 , the bandwidth is about 90 MHz while maintaining a $300 \mathrm{~V} / \mu \mathrm{s}$ slew rate.

The ISL55002 is designed to operate with supply voltage from +15 V to -15 V . That means for single supply application, the supply voltage is from 0 V to 30 V . For split supplies application, the supply voltage is from $\pm 15 \mathrm{~V}$. The amplifier has an input common-mode voltage range from 1.5 V above the negative supply ( $V_{S^{-}}$pin) to 1.5 V below the positive supply $\left(V_{S^{+}}\right.$pin). If the input signal is outside the above specified range, it will cause the output signal to be distorted.

The outputs of the ISL55002 can swing from -12.75 V to +13.4 V for $\mathrm{V}_{\mathrm{S}}= \pm 15 \mathrm{~V}$. As the load resistance becomes lower, the output swing is lower.

## Choice of Feedback Resistor and Gain Bandwidth Product

For applications that require a gain of +1 , no feedback resistor is required. Just short the output pin to the inverting input pin. For gains greater than +1 , the feedback resistor forms a pole with the parasitic capacitance at the inverting input. As this pole becomes smaller, the amplifier's phase margin is reduced. This causes ringing in the time domain and peaking in the frequency domain. Therefore, $R_{F}$ can't be very big for optimum performance. If a large value of $R_{F}$ must be used, a small capacitor in the few Pico Farad range in parallel with $R_{F}$ can help to reduce the ringing and peaking at the expense of reducing the bandwidth. For gain of $+1, R_{F}=0$ is optimum. For the gains other than +1 , optimum response is obtained with $R_{F}$ with proper selection of $R_{F}$ and $R_{G}$ (see Figures 15 and 16 for selection).

## Video Performance

For good video performance, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This is especially difficult when driving a standard video load of $150 \Omega$, because of the change in output current with DC level. The dG and dP of this device is about $0.01 \%$ and $0.05^{\circ}$, while driving $150 \Omega$ at a gain of 2 . Driving high impedance loads would give a similar or better dG and dP performance.

## Driving Capacitive Loads and Cables

The ISL55002 can drive a 47 pF load in parallel with $500 \Omega$ with less than 3 dB of peaking at gain of +1 and as much as 100 pF at a gain of +2 with under 3 db of peaking. If less peaking is desired in applications, a small series resistor (usually between $5 \Omega$ to $50 \Omega$ ) can be placed in series with the output to eliminate most peaking. However, this will reduce the gain slightly. If the gain setting is greater than 1 , the gain resistor $R_{G}$ can then be
chosen to make up for any gain loss which may be created by the additional series resistor at the output.

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, a back-termination series resistor at the amplifier's output will isolate the amplifier from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. Again, a small series resistor at the output can help to reduce peaking.

## Output Drive Capability

The ISL55002 does not have internal short circuit protection circuitry. It has a typical short circuit current of 140 mA . If the output is shorted indefinitely, the power dissipation could easily overheat the die or the current could eventually compromise metal integrity. Maximum reliability is maintained if the output current never exceeds $\pm 60 \mathrm{~mA}$. This limit is set by the design of the internal metal interconnect. Note that in transient applications, the part is robust.

Short circuit protection can be provided externally with a back match resistor in series with the output placed close as possible to the output pin. In video applications this would be a $75 \Omega$ resistor and will provide adequate short circuit protection to the device. Care should still be taken not to stress the device with a short at the output.

## Power Dissipation

With the high output drive capability of the ISL55002, it is possible to exceed the $150^{\circ} \mathrm{C}$ absolute maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for an application to determine if load conditions or package types need to be modified to assure operation of the amplifier in a safe operating area.

The maximum power dissipation allowed in a package is determined according to:
$P D_{M A X}=\frac{T_{J M A X}-T_{A M A X}}{\Theta_{J A}}$
Where:

- TJMAX $=$ Maximum junction temperature
- TAMAX $=$ Maximum ambient temperature
- $\theta_{\mathrm{JA}}=$ Thermal resistance of the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or:

For sourcing:
$P D_{\text {MAX }}=V_{S} \times I_{\text {SMAX }}+\sum_{i=1}^{n}\left(V_{S}-V_{\text {OUTi }}\right) \times \frac{V_{\text {OUTi }}}{R_{\text {Li }}}$

Where:

- $\mathrm{V}_{\mathrm{S}}=$ Supply voltage
- ISMAX = Maximum quiescent supply current
- $\mathrm{V}_{\text {OUT }}=$ Maximum output voltage of the application
- $R_{\text {LOAD }}=$ Load resistance tied to ground
- ILOAD = Load current
- $\mathrm{N}=$ number of amplifiers (max = 2)

By setting the two $P D_{\text {MAX }}$ equations equal to each other, we can solve the output current and $\mathrm{R}_{\text {LOAD }}$ to avoid the device overheat.

## Power Supply Bypassing Printed Circuit Board Layout

As with any high frequency device, a good printed circuit board layout is necessary for optimum performance. Lead lengths should be as short as possible. The power supply pin must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the $\mathrm{V}_{\mathrm{S}}$ - pin is connected to the ground plane, a single $4.7 \mu \mathrm{~F}$ tantalum capacitor in parallel with a $0.1 \mu \mathrm{~F}$ ceramic capacitor from $\mathrm{V}_{\mathrm{S}^{+}}$to $G N D$ will suffice. This same capacitor combination should be placed at each supply

FIGURE 28. SALLEN-KEY LOW PASS FILTER
pin to ground if split supplies are to be used. In this case, the $\mathrm{V}_{\mathrm{S}^{-}}$pin becomes the negative supply rail.

## Printed Circuit Board Layout

For good AC performance, parasitic capacitance should be kept to minimum. Use of wire wound resistors should be avoided because of their additional series inductance. Use of sockets should also be avoided if possible. Sockets add parasitic inductance and capacitance that can result in compromised performance. Minimizing parasitic capacitance at the amplifier's inverting input pin is very important. The feedback resistor should be placed very close to the inverting input pin. Strip line design techniques are recommended for the signal traces.

## Application Circuits

## Sallen Key Low Pass Filter

A common and easy to implement filter taking advantage of the wide bandwidth, low offset and low power demands of the ISL55002. A derivation of the transfer function is provided for convenience (See Figure 28).

## Sallen Key High Pass Filter

Again this useful filter benefits from the characteristics of the ISL55002. The transfer function is very similar to the low pass so only the results are presented (See Figure 29).

## Differential Output Instrumentation Amplifier

The addition of a third amplifier to the conventional three amplifier instrumentation amplifier introduces the benefits of differential signal realization, specifically the advantage of using common-mode rejection to remove coupled noise and ground potential errors inherent in remote transmission. This configuration also provides enhanced bandwidth, wider output swing and faster slew rate than conventional three amplifier solutions with only the cost of an additional amplifier and few resistors.

\end{aligned}
$$

## Strain Gauge

The strain gauge is an ideal application to take advantage of the moderate bandwidth and high accuracy of the ISL55002. The operation of the circuit is very straightforward. As the strain variable component resistor in the balanced bridge is subjected to increasing strain, its resistance changes, resulting in an imbalance in the bridge. A voltage variation from the referenced high accuracy source is generated and translated to the difference amplifier through the buffer stage. This voltage difference as a function of the strain is converted into an output voltage.

NOTES:

1. Plastic or metal protrusions of 0.006 " maximum per side are not included.
2. Plastic interlead protrusions of $0.010^{\prime \prime}$ maximum per side are not included.
3. Dimensions "D" and "E1" are measured at Datum Plane "H".
4. Dimensioning and tolerancing per ASME Y14.5M-1994

## X-ON Electronics

Largest Supplier of Electrical and Electronic Components
