## Offline High Brightness White LED Driver with High Power Factor for Universal Input

## Introduction

The ISL6745UEVAL2Z utilizes Intersil's double-ended voltage mode PWM controller for a SEPIC converter application requiring a constant output current. It consists of separate assemblies for the driver and for the LED board, which supports as many as 21 high brightness LEDs. The LED driver board converts a universal ( 85 V to 275VAC) AC input to a DC output rated at 300 mA . The design can be further optimized for applications that do not require universal AC input. ISL6745LEVAL2Z is for 80 V to 140 V applications.

Worldwide, on average, 19\% of the electric power goes for lighting [11]. In 2000, about 567BKWH of electric energy (or $16 \%$ of the nation's electric energy in the United States) is for residential, commercial or industrial lighting [22], [3]33. The commonly used lighting technologies include incandescent and halogen bulbs, fluorescent and compact fluorescent lamps (CFL), and high intensity discharge (HID) lamps. Generally, the efficiency of the lighting sources is indexed by efficacy, or lumen per watt weighted to the sensitivity of the human eye. The efficacy of typical energy saving CFL lamps is around $7 \% \sim 8 \%$, compared with $2 \%$ for the conventional the incandescent bulbs [4]. With the advancement of new materials and manufacturing processes, the economics and performance of high brightness LEDs are now attracting the attention of academia and industry. For instance, in 2006, Cree Inc. demonstrated a prototype with a record white LED luminous efficacy of $131 \mathrm{~lm} / \mathrm{W}$ [5]. Compared with commonly used lighting sources, white LEDs provide equivalent or superior efficacy, and improvements are announced frequently. Unlike the CFLs, LEDs contains no mercury, and are less susceptible to breakage. They have a very long expected life ( 100,000 hours, more than $10 x$ as much as CFLs), and high on/off repetition capability. Of particular interest, they are easy to power when compared to many traditional sources. The practical application of LED lighting for commercial and residential applications has become a reality. The typical operating current of the high brightness LED is about $300 \mathrm{~mA} \sim 1000 \mathrm{~mA}$. The typical drive voltage for high brightness white LED is about 2.5 V to 4 V .

The ISL6745UEVAL2Z evaluation board is a reference design for powering high brightness white LEDs. It utilizes the ISL6745 voltage mode PWM controller in the single-ended primary inductance converter (SEPIC) topology to convert a universal ac input to a variable 300 mA DC output. See Figure 1.

This application note describes the circuit operation design constraints, description of the evaluation board, and its performance.

FIGURE 1. TOP VIEW OF DRIVE AND LED BOARDS

## Key Features

- Universal AC Input
- Dimmable LED Brightness
- High Power Factor
- Overvoltage Protection
- Overcurrent Protection
- Transformerless

Specifications for ISL6745UEVAL2Z

- Input AC Voltage . . . . . . . . 85 V to $275 \mathrm{VAC}(50 \mathrm{~Hz} \sim 60 \mathrm{~Hz})$
- Outputs DC . . . . . . . . . . . . . . . . . . . . . . . . . Up to 300 mA
- Output DC Voltage Ripple . . . . . . . . . . . . . . . . . . . . . . 5\%
- Typical Efficiency . . . . . . . . . . . . . . . . . . . . . . . . . . . 75\%
- Typical Power Factor . . . . . . . . . . . . . . . . . . . . . . . . >0. 95

## Operation Mechanism and Design Constraints

A simplified offline SEPIC converter for LED lighting applications is shown in Figure 3, where the voltage across $\mathrm{C}_{1}$ is the rectified AC voltage. A current sense resistor is placed in series with the switch $S_{1}$. A second resistor is placed in series with the LED string to sense the load current. The control signals include the load current and switch current. The output voltage is sensed for the purpose of output overvoltage protection (OVP). Since the input capacitor $\mathrm{C}_{1}$ is very small, the voltage waveform is the rectified input voltage, and the voltage applied to the SEPIC converter is approximately a rectified sinusoidal. To achieve high power factor, the envelope of the converter input current must track the rectified input voltage waveform. This is accomplished when the converter is operated at a constant switching frequency, a constant duty ratio, and while operating in the discontinuous conduction mode (DCM). Assuming the impedance of the power source is negligible, the voltage across $\mathrm{C}_{1}$ is given in Equation 1, where subscript I denotes input AC line, and $V_{l}$ is the amplitude of the input AC voltage with frequency $\omega_{1}$.

$$
\begin{equation*}
v_{C 1}(t)=V_{1}\left|\sin \left(\omega_{1} t\right)\right| \tag{EQ.1}
\end{equation*}
$$

If the switching frequency of the converter is much higher than the utility frequency, and $\mathrm{C}_{2}$ is properly sized, the voltage across $C_{2}$ will be equal to the voltage across $C_{1}$. A feedback voltage, $\mathrm{V}_{\mathrm{m}}$, is created by the error amplifier. $\mathrm{V}_{\mathrm{m}}$ is the amplified difference between the LED current, lo, and the reference voltage, Ir. Varying the reference voltage causes a proportional change in the LED brightness. The current signal from the current sense resistor, Rcs, which is connected in series with the boost switch S1, is compared with the overcurrent threshold for overcurrent protection. A sawtooth carrier signal is compared with the feedback signal Vm and generates the PWM signal to control the turn on/off of the switch. Typical waveforms of the inductor current, switch and diode currents are shown in Figure 2.

| $\mathrm{D}_{5}$ | Output Diode |

There are three stages of operations:

1. The switch turns on, Diode is off.
2. The switch turns off, the diode is on.
3. Both switch and diode are off.

During each switching period, the following circuit equations can be derived.

## SWITCH S1 TURNS ON

At the beginning of the cycle, when switch S 1 turns on, the free-wheeling current in $L_{1}$ is $\mathrm{L}_{\mathrm{L} 1}(0)$ and the voltage across the input inductor $L_{1}$ is $V_{C 1}$. The freewheeling current in $L_{1}$ is $\mathrm{L}_{\mathrm{L} 1}(0)$. The voltage applied to the input inductor $\mathrm{L}_{1}$ is $\mathrm{V}_{\mathrm{C} 1}$. Since the voltage across $\mathrm{C}_{2}$ equals $\mathrm{V}_{\mathrm{C} 1}$, the same voltage is applied to $L_{2}$. The inductor currents are given in Equation 2, where 0 denote the initial condition of the state variables. The switch current is the sum of the two inductor currents, and is given in Equation 3. This stage ends at $\mathrm{t}_{\mathrm{ON}}$.

$$
\begin{align*}
& \mathrm{i}_{\mathrm{L} 1}(\mathrm{t})=\mathrm{i}_{\mathrm{L} 1(0)}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{1}} \mathrm{t}  \tag{EQ.2}\\
& \mathrm{i}_{\mathrm{L} 2}(\mathrm{t})=-\mathrm{i}_{\mathrm{L} 1(0)}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{2}} \mathrm{t} \\
& \mathrm{i}_{\mathrm{Q}}(\mathrm{t})=\mathrm{i}_{\mathrm{L} 1(\mathrm{t})}+\mathrm{i}_{\mathrm{L} 2(\mathrm{t})}=\left(\frac{v_{\mathrm{C} 1}}{\mathrm{~L}_{1}}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{2}}\right) \mathrm{t}
\end{align*}
$$

## DIODE D5 CONDUCTS

The voltage applied to inductor $L_{1}$ is $-V_{0}$, the same as inductor $\mathrm{L}_{2}$. The current in $\mathrm{L}_{1}$ decays according to Equation 4. The current in $L_{2}$ decays and reverses. This stage ends when $\mathrm{i}_{\mathrm{L} 1}$ equals -it2. The diode current is the sum of both the inductor currents. The currents are given in Equation 5, where $\mathrm{t}_{\mathrm{ON}}$ is the interval when the switch is on.

$$
\begin{align*}
& \mathrm{i}_{\mathrm{L} 1}(\mathrm{t})=\left(\mathrm{i}_{\mathrm{L} 1(0)}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{1}} \mathrm{t}_{\mathrm{ON}}-\left(\frac{\mathrm{v}_{\mathrm{O}}}{\mathrm{~L}_{1}}\right) \mathrm{t}\right)  \tag{EQ.4}\\
& \mathrm{i}_{\mathrm{L} 2}(\mathrm{t})=\left(\mathrm{i}_{\mathrm{L} 1(0)}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{1}} \mathrm{t}_{\mathrm{ON}}-\frac{\mathrm{v}_{\mathrm{O}}}{\mathrm{~L}_{1}} t\right) \\
& \mathrm{i}_{\mathrm{D}}(\mathrm{t})=\left(\mathrm{v}_{\mathrm{C} 1} \mathrm{t}_{\mathrm{ON}}-\mathrm{v}_{\mathrm{O}} \mathrm{t}\right)\left(\frac{1}{\mathrm{~L}_{1}}+\frac{1}{\mathrm{~L}_{2}}\right) \tag{EQ.5}
\end{align*}
$$

## DIODE D5 AND SWITCH S1 BLOCKING

This is the freewheeling period of both inductors $L_{1}$ and $L_{2}$. The freewheeling currents are given in Equation 6.

$$
\begin{align*}
& \mathrm{i}_{\mathrm{L} 1}(1)=\left(\mathrm{i}_{\mathrm{L} 1(0)}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{1}} \mathrm{t}_{\mathrm{ON}}-\frac{\mathrm{v}_{\mathrm{O}}}{\mathrm{~L}_{1}} \mathrm{t}_{\mathrm{d}}\right)  \tag{EQ.6}\\
& \mathrm{i}_{\mathrm{L} 2}(1)=\left(\mathrm{i}_{\mathrm{L} 1(0)}+\frac{\mathrm{v}_{\mathrm{C} 1}}{\mathrm{~L}_{2}} \mathrm{t}_{\mathrm{ON}}-\frac{\mathrm{v}_{\mathrm{O}}}{\mathrm{~L}_{1}} \mathrm{t}_{\mathrm{d}}\right)
\end{align*}
$$

where, the diode conducting time, $t_{d}$, is determined by the volt-second balance of the inductors, where $V_{l}$ is the amplitude of the AC line voltage.

$$
\begin{equation*}
\mathrm{t}_{\mathrm{d}}=\frac{\mathrm{t}_{\mathrm{ON}}}{\mathrm{~V}_{\mathrm{O}}} \mathrm{~V}_{\mathrm{I}}\left|\sin \omega_{1} \mathrm{t}\right| \tag{EQ.7}
\end{equation*}
$$

To ensure the converter operates in DCM, the freewheeling time should be greater than or equal to zero as expressed in Equation 8.

$$
\begin{equation*}
\mathrm{t}_{\mathrm{s}} \geq \mathrm{t}_{\mathrm{ON}}+\mathrm{t}_{\mathrm{d}} \tag{EQ.8}
\end{equation*}
$$

Therefore, the duty ratio of the PWM is expressed in Equation 9.

$$
\begin{equation*}
\mathrm{d}<\frac{\mathrm{V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{O}}+\mathrm{V}_{\mathrm{I}}} \tag{EQ.9}
\end{equation*}
$$

Averaging this diode current in one switching cycle gives the average output current $\mathrm{I}_{\mathrm{O}}(\mathrm{t})$ during that switching cycle.

$$
\begin{equation*}
i_{O}(t)=\frac{1}{t_{s}} t \int_{0}^{t_{s}} i_{D}(t) d t=\frac{1}{L_{1} \| L_{2}} \frac{\left(t_{O N} V_{1} \sin \left(\omega_{1} t\right)\right) 2}{2 t_{s} V_{O}} \tag{EQ.10}
\end{equation*}
$$

Averaging the $\mathrm{I}_{\mathrm{O}}(\mathrm{t})$ over one line period, yields the average current of the output, since the average output capacitor current is zero. Therefore, the output current equals the average diode current. The output current also equals the average current in inductor $L_{2}$, since the average current in $\mathrm{C}_{2}$ is zero. Therefore, the dominate ripple frequency is twice the line frequency as expressed in Equation 11.

$$
\begin{equation*}
\mathrm{i}_{\mathrm{O}}=\frac{1}{\mathrm{t}_{1}} \int_{0}^{\mathrm{t}_{1}} \mathrm{I}_{\mathrm{O}}(\mathrm{t}) \mathrm{dt}=\frac{1}{\mathrm{~L}_{1} \| \mathrm{L}_{2}} \frac{\mathrm{~d}^{2} \mathrm{t}_{\mathrm{s}} \mathrm{~V}_{1}^{2}}{4 \mathrm{~V}_{\mathrm{O}}} \tag{EQ.11}
\end{equation*}
$$

The constraints for selecting the inductors are expressed in Equation 12:

$$
\begin{equation*}
\mathrm{L}_{1} \| \mathrm{L}_{2}<\left(\frac{\mathrm{V}_{1}}{\mathrm{~V}_{\mathrm{O}}+\mathrm{V}_{1}}\right)^{2} \frac{\mathrm{t}_{\mathrm{s}} \mathrm{~V}_{\mathrm{O}}}{4 \mathrm{I}_{\mathrm{O}}} \tag{EQ.12}
\end{equation*}
$$

As can be seen, the maximum ripple current in the input inductor $L_{1}$ occurs at the peaks of the input voltages as expressed in Equation 13.

$$
\begin{equation*}
\mathrm{I}_{1 \mathrm{rp}}=\frac{\mathrm{t}_{\mathrm{ON}} \mathrm{~V}_{1}}{\mathrm{~L}_{1}} \tag{EQ.13}
\end{equation*}
$$

Since, we assume unity power factor, and assume the power conversion efficiency is $\eta$ as shown in Equation 14.

$$
\begin{equation*}
\frac{1}{2} V_{1} I_{1} \eta=V_{O} l_{O} \tag{EQ.14}
\end{equation*}
$$

If we define the ripple factor $\mathrm{Krpi}=\mathrm{Irp} / \mathrm{II}$, where II is the peak of the input current, then the constraint for DCM operation of the converter is as expressed in Equation 15.

$$
\begin{align*}
& \mathrm{L}_{1}>\frac{\mathrm{t}_{\mathrm{ON}} \mathrm{~V}_{1}}{\mathrm{I}_{\mathrm{rp}}}=\frac{\mathrm{t}_{\mathrm{ON}} \mathrm{~V}_{1}}{\mathrm{~K}_{\mathrm{rp}} \mathrm{I}_{1}}=\frac{\mathrm{t}_{\mathrm{ON}}\left(\mathrm{~V}_{1}\right)^{2} \eta}{2 \mathrm{~K}_{\mathrm{rp}} \mathrm{~V}_{\mathrm{O}} \mathrm{I}_{\mathrm{O}}}  \tag{EQ.15}\\
& \mathrm{~L}_{2}<\left(\left[\frac{\mathrm{V}_{1}+\mathrm{V}_{\mathrm{O}}}{\mathrm{~V}_{1}}\right]^{2} \frac{4 \mathrm{I}_{\mathrm{O}}}{\mathrm{t}_{\mathrm{s}} \mathrm{~V}_{\mathrm{O}}}-\frac{2 \mathrm{~K}_{\mathrm{rp}} \mathrm{~V}_{\mathrm{O}} \mathrm{I}_{\mathrm{O}}}{\mathrm{t}_{\mathrm{ON}} \mathrm{~V}_{1}^{2}{ }^{2}}\right)^{-1}
\end{align*}
$$

In the above analysis, it is assumed that the voltage across the input capacitor $\mathrm{C}_{1}$ is independent of the circuit operation and follows the rectified input voltage closely. Furthermore, the voltage across $\mathrm{C}_{2}$ is identical to the voltage across $\mathrm{C}_{1}$. If the assumption is not correct, the current waveform will be distorted.

The input capacitor can be estimated by using Equation 16.

$$
\begin{equation*}
\mathrm{C}_{1}=\frac{4 \mathrm{~K}_{\mathrm{rpi}}{ }^{2} \mathrm{t}_{\mathrm{s}} \mathrm{dp}}{\mathrm{~K}_{\mathrm{rpv}} \mathrm{~V}_{1}^{2} \mathrm{~L}_{2}} \tag{EQ.16}
\end{equation*}
$$

The AC source delivers power as a sine wave. Since the input is rectified, power is delivered to the load at twice the input line frequency. Therefore, the ripple frequency on the output voltage is also twice of the line frequency. To reduce the ripple, the output capacitor needs to be selected according to Equation 17.

$$
\begin{equation*}
\mathrm{C}_{\mathrm{O}}>\frac{\mathrm{V}_{1} \mathrm{l}_{\mathrm{l}}}{2 \mathrm{~V}_{\mathrm{rp}-\mathrm{p}} \mathrm{~V}_{\mathrm{O}} \omega_{1}} \tag{EQ.17}
\end{equation*}
$$

## Waveforms

FIGURE 4. INPUT VOLTAGE AND CURRENT (VAC = 80V, $\mathrm{I}_{\mathrm{O}}=30 \mathrm{~mA}$

The duty ratio is controlled by the difference between the reference signal $\mathrm{I}_{\mathrm{ADJ}}$ and the voltage across the current sense resistor $\mathrm{R}_{\mathrm{S}}$. By changing the current sense resistor, or the reference signal $I_{A D J}$, the brightness of the LED can be dimmed. A Type I Error Amplifier is used as shown in Figure 3, with the crossover frequency determined by the feedback capacitor $\mathrm{C}_{\mathrm{fb}}$ and the resistor R , given in Equation 18.

$$
\begin{equation*}
{ }^{\omega} \mathrm{C}=\frac{1}{R C_{f o}} \tag{EQ.18}
\end{equation*}
$$

The bandwidth should be less than the line frequency, so that the duty ratio of the converter does not disturb the sinusoidal power delivery from the source. Otherwise, harmonics appear in the input line current and degrade power factor. However, the bandwidth should be wide enough to allow adequate control of the load current. As a trade-off, the cut-off frequency can be around half of the line frequency.

Overvoltage protection is needed to protect the LED and converter from damage. Due to the nonlinear relationship between the diode current and voltage, a small increase in output voltage can cause a large increase in current. The overvoltage protection is implemented by comparing the output voltage with a constant reference voltage, and the comparator output is used to control a small FET in parallel with the softstart capacitor. Once the output voltage reaches the threshold, the FET is turned on, the soft-start capacitor discharged, and the duty cycle is reduced to zero. The PWM output is shutdown until the output voltage decays below the reset threshold. A new soft-start cycle begins at this time. This behavior repeats until the cause of the overvoltage is removed.

## Performance of ISL6745UEVAL2Z

The schematic of the ISL6745UEVAL2Z evaluation board is shown in page 12. The bill of material (BOM) for universal AC application is shown on page 8 . Figure 1 on page 1 shows photographs of the drive board and LED board. The configuration of the test bench is shown in Figure 12.

FIGURE 12. TEST BENCH CONFIGURATION

TABLE 2. TEST BENCH CONFIGURATION TEST

| PM | DMM | PAC |
| :---: | :---: | :---: |
| Power Meter | Digital Multimeter | Programmable AC <br> Power Supply |

To perform the bench testing, the following equipment is necessary:

- Programmable AC power supply, 275VAC minimum
- Fan to cool heatsinks
- Oscilloscope, 4 channels, 20 MHz minimum bandwidth
- DC electronic load, 1A minimum
- DC Multimeter
- Power meter with power factor calculation

When operating the evaluation board, certain precautions need to be followed.

1. The power stage of the evaluation board has exposed high voltage and demands extra caution when operating. The voltage rating of the probes should meet the highest voltage present in the board. Isolation of the oscilloscope power source is needed when doing the measurement.
2. Power source considerations: It is important to choose the correct connector when attaching the source supply. An appropriate AC power supply is needed with adjustable output voltage (up to 300 V ) and current (up to 0.5 A ) with current limit capability.
3. Loading considerations: It is important to have a firm connection when attaching the load. In case an electronic load is used instead of the LED board, an appropriate electronic load with current up to 500 mA and voltage up to 80 V is desirable.
4. Air flow conditions: Full rated power should never be attempted without providing the specified 200 CFM of airflow over the LED board. This can be provided by a stand-alone fan.
5. When applying power the first time, it is suggested to apply light load, and set the current limit of the source supply to less than 1.5 x of the wattage of the load. Start the circuit with the minimum $A C$ voltage ( 80 V ). A quick efficiency check is the best way to confirm proper operation.
6. To measure the output voltage ripple more accurately, it is suggested to measure as closely as possible to the converter's output terminals. Since the AC signal being measured is small relative to the DC level, care must be exercised to minimize noise pick-up from external sources. The bandwidth of the oscilloscope can be set to 20 MHz . Use very short and direct connections to the oscilloscope probe such that the total loop area in the signal and ground connections is as small as possible.

Figure 10 is the drain-source voltage of the switch. In Figure 11, the D-S voltages of the MOSFET are shown with the corresponding gate signal at input peak and valley, respectively. Three distinct modes of operation can be observed.

1. As the FET is on, $\mathrm{V}_{\mathrm{Ds}}$ is zero. The input voltage is applied to the inductor $\mathrm{L}_{1}$, and the same voltage is applied to $\mathrm{L}_{2}$. During this interval, the output load is powered by the output capacitor.
2. When the FET gate signal is removed, the current in inductor $L_{1}$ begins to charge the capacitor $\mathrm{C}_{2}$ and the output capacitor $\mathrm{C}_{\mathrm{O}}$ through the output diode. At the same time, the inductor $\mathrm{L}_{2}$ also charges the output capacitor. Power transfers from input to output.
3. Oscillation begins as this period is ended indicating DCM operation.

FIGURE 13. OUTPUT VOLTAGE vs CURRENT

FIGURE 14. OUTPUT VOLTAGE RIPPLE (P-P)

FIGURE 15. INPUT POWER FACTORS
Figures 4,5 and 6 show the input current and the voltage across the input capacitor $\mathrm{C}_{1}$ for low line and high line operations. As can be seen from these waveforms, the power factor is comparatively high. Several possibilities can deteriorate the performance of the regulator:

1. $L_{1}$ and $L_{2}$ do not meet the design constraints causing the converter to operate in continuous conduction mode (CCM). Therefore, the energy stored in the inductors will be released to the $D C$ capacitor $C_{1}$, which will cause input current waveform distortion.
2. The control bandwidth exceeds.
3. The current sense signal reaches the peak current protection threshold. This may be caused by the saturation of the inductor, or improper setting of the current sense resistor, or OCP limit.
4. Improper choice of the output capacitor.
5. The intermediate capacitor $\mathrm{C}_{2}$ is too big so that the voltage across it does not track the input voltage. The input current can be more distorted for high line operation since the capacitor $\mathrm{C}_{2}$ can only be optimized for one input voltage.
6. The inductors get saturated. In this case, the peak current limit will be exceeded and the current waveform will contain large amount of third order harmonics.
The output voltage and LED current are shown in Figures 7, 8 and 9 for various load conditions. The voltage across the LED strings (of 21 LEDs in series) is shown in Figure 13. The output voltage increases almost linearly with the LED current as expected. The ripple of the output voltage is governed by Equation 16 and is in proportion to the output power. The relation of the ripple to the load current is shown in Figure 14. The power factor versus input voltage for different LED currents is shown in Figure 15. For most of the operational conditions, the power factor is above 0.9.
CAUTION: This evaluation unit should be used and operated only by persons experienced and knowledgeable in the design and operation of high voltage power conversion equipment. Use of this evaluation unit constitutes acceptance of all risk inherent in the operation of equipment having accessible hazardous voltage. Careless operation may result in serious injury or death. Use safety classes of other suitable eye protection. The maximum voltage of ISL6745LEVAL2Z is 140 V .

## Notice

Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others
You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.
"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.
"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc. Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.
. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products. (Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries. (Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.
