Wideband, Low-Power, Ultra-High Dynamic Range Differential Amplifier

The ISL55210 is a very wide band, Fully Differential Amplifier (FDA) intended for high dynamic range ADC input interface applications. This voltage feedback FDA design includes an independent output common mode voltage control.

Intended for very high dynamic range ADC interface applications, at the lowest quiescent power ( 115 mW ), the ISL55210 offers a 4.0 GHz Gain Bandwidth Product with a very low input noise of $0.85 \mathrm{nV} / \sqrt{ }(\mathrm{Hz})$. In a balanced differential I/O configuration, with $2 \mathrm{~V}_{\text {P-P }}$ output into a $200 \Omega$ load configured for a gain of 15 dB , the IM3 terms are $<-100 \mathrm{dBc}$ through 110 MHz . With a minimum operating gain of $2 \mathrm{~V} / \mathrm{V}(6 \mathrm{~dB})$, the ISL55210 supports a wide range of higher gains with minimal BW or SFDR degradation. Its ultra high differential slew rate of $5,600 \mathrm{~V} / \mu \mathrm{s}$ ensures clean large signal SFDR performance or a fast settling step response.

The ISL55210 requires only a single 3.3V (max 4.2V) power supply with 35 mA typical quiescent current. This industry leading low current solution can be further reduced when needed using the optional power shutdown to $<0.4 \mathrm{~mA}$ supply current. External feedback and gain setting resistors give maximum flexibility and accuracy. A companion device, the ISL55211, includes on-chip feedback and 3 possible gain setting connections where an internally fixed gain solution is preferred. The ISL55210 is available in a leadless, 16 Ld TQFN package and is specified for operation over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ ambient temperature range.

## Features

- Gain Bandwidth Product . . . . . . . . . . . . . . . . . . . . . . . . 4.0GHz
- Input Voltage Noise . . . . . . . . . . . . . . . . . . . . . . . 0.85nV/ $\sqrt{ }(\mathrm{Hz})$
- Differential Slew Rate . . . . . . . . . . . . . . . . . . . . . . . 5,600V/ $\mu \mathrm{s}$
- 2V P-P, 2-tone IM3 (200』) 100MHz ................ -109dBc
- Supply Voltage Range . . . . . . . . . . . . . . . . . . . . . . 3. 3.0 V to 4.2 V
- Quiescent Power (3.3V Supply) . . . . . . . . . . . . . . . . . . . 115mW

## Applications

- Low Power, High Dynamic Range ADC Interface
- Differential Mixer Output Amplifier
- SAW Filter Pre/Post Driver
- Differential Comms-DAC Output Driver

## NOTES:

1. Please refer to $\underline{\mathrm{TB} 347}$ for details on reel specifications.
2. These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and $100 \%$ matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb -free soldering operations). Intersil Pb free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), please see device information page for ISL55210. For more information on MSL please see techbrief TB363.

## Recommended Operating Conditions

Ambient Operating Temperature

CAUTION: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

## NOTES:

4. $\theta_{\mathrm{JA}}$ is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379.
5. For $\theta_{\mathrm{JC}}$, the "case temp" location is the center of the exposed metal pad on the package underside.

## Applications

## Basic Operation

The ISL55210 is a very wideband, voltage feedback based, differential amplifier including an output common mode control loop and optional power shutdown feature. Intended for very low distortion differential signal driving, this non-unity gain stable device also delivers extremely low input noise terms of $0.85 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ and $5 \mathrm{pA} / \sqrt{\mathrm{Hz}}$. Most applications are intended for AC coupled I/O using a single 3.3 V supply. It will operate over a single supply range of 3.0 V to 4.2 V . Where DC coupled operation is desired, using split power supplies will allow the ISL55210 I/O common mode range limits to be observed while giving either a differential I/O or single to differential configuration.

Most applications behave as a differential inverting op amp design. There is, therefore, an input gain resistor on each side of the inputs that must be driven. To retain overall low output noise, these resistors are normally of low value. The device can be powered down to $<400 \mu \mathrm{~A}$ supply current using the optional disable pin. To operate normally, this pin should be asserted high using a simple logic gate to $+\mathrm{V}_{\mathrm{S}}$ or tied high through a $10 \mathrm{k} \Omega$ resistor to $+\mathrm{V}_{\mathrm{S}}$. When disabled, the power dissipation drops to $<1 \mathrm{~mW}$ but, due to the inverting op amp type architecture, the input signal will feed forward through the external resistors giving limited isolation.

## Application and Characterization Circuits

The circuit of Figure 28 forms a starting point for many of the characterization curves for the ISL55210. Since most lab sources and measurement devices are single-ended, this circuit converts to differential at the input through a wideband transformer and would also be a typical application circuit coming from a single ended source. Assuming the source is a $50 \Omega$ impedance, the $\mathrm{R}_{\mathrm{G}}$ resistors are set to provide both the input termination and the gain. Since the inverting summing nodes act as virtual ground points for AC signal analysis, the total termination impedance across the input transformer secondary will be $2 * \mathrm{R}_{\mathrm{G}}$. Setting this equal to $n^{2}{ }^{*} R_{S}$ will give a matched input impedance inside the bandwidth of the transformer (where " n " is the turns ratio). The amplifier gain is then set by adjusting the feedback resistors

FIGURE 27. SUPPLY CURRENT vs SUPPLY VOLTAGE
values. Since the ISL55210 is a VFA design, increasing the feedback resistor to get higher gain does not directly reduce the bandwidth as it would with a CFA based design. This gives increased flexibility in the input turns ratio and overall gain setting (while holding a matched input impedance) over alternate solutions.

FIGURE 28. TEST CIRCUIT \#1
Working with a transformer coupled input as shown in Figure 28, or with two DC blocking caps from a differential source, means the output common mode voltage set by either the default internal $\mathrm{V}_{\mathrm{CM}}$ setting, or a voltage applied to the $\mathrm{V}_{\mathrm{CM}}$ control pin, will also appear as the input common mode voltage. This provides a very easy way to control the ISL55210 I/O common mode operating voltages for an AC coupled signal path. The internal common mode loop holds the output pins to $\mathrm{V}_{\mathrm{CM}}$ and, since there is no DC path for an $\mathrm{I}_{\mathrm{CM}}$ current back towards the input in Figure 28, that $\mathrm{V}_{\mathrm{CM}}$ setting will also appear as the input common mode voltage. It is useful, for this reason, to leave any input transformer secondary centertap unconnected. The internally set $\mathrm{V}_{\mathrm{CM}}$ voltage is referenced from the negative supply pin. With a single 3.3 V supply, it is very close to 1.2 V but will change with total supply voltage across the device as shown in Figure 26.

Most of the characterization curves start with Figure 28 then get different gains by changing the feedback resistor, $R_{F}$, use different input transformers where then the $\mathrm{R}_{\mathrm{G}}$ is also adjusted to hold an input match, or vary the loading. For load tests below the $200 \Omega$ shown in Figure 28, a simple added shunt resistor is placed across the output pins. For loads $>200 \Omega$, the series and shunt load R's are adjusted to show that total load (including the $50 \Omega$ measurement load reflected through the 1:1 output measurement port transformer) and provide an apparent $50 \Omega$ differential source to that transformer. This output side transformer is for measurement purposes only and is not necessary for final applications circuits. There are output interface designs that do benefit from a transformer as part of the signal path, but the one shown at the right of Figure 28 is used only for characterization to get a doubly terminated $50 \Omega$ measurement path going differential to single ended.

Where just the amplifier is tested, a 4 port network analyzer is used and the very simple test circuit of Figure 29 is
implemented. This is used to extract the differential S21 curves and differential output impedance vs gain. Changing the gain is a simple matter of adjusting the two $\mathrm{R}_{\mathrm{F}}$ resistors of Figure 29. This circuit depends on the two AC coupled source $50 \Omega$ of the 4 port network analyzer and presents an AC coupled differential $100 \Omega$ load to the amplifier as the input impedance of the remaining two ports of the network analyzer.

FIGURE 29. TEST CIRCUIT \#2 4-PORT S-PARAMETER
MEASUREMENTS
Using this measurement allows the full small single bandwidth of the ISL55210 to be exposed. Many of the other measurements are using I/O transformers that are limiting the apparent bandwidth to reduced level. Figure 16 shows a series of normalized differential S 21 curves for gains of 12 dB to 30 dB in 6 dB steps. These are simply stepping two feedback resistor values ( $\mathrm{R}_{\mathrm{F}}$ ) up from $200 \Omega$ to $1600 \Omega$ in 2 X steps. The lowest gain of $12 \mathrm{~dB}(4 \mathrm{~V} / \mathrm{V})$ is showing a 2.2 GHz small signal bandwidth. This response gets some bandwidth extension due to phase margin <60degree effects, but by the gain of $24 \mathrm{~dB}(16 \mathrm{~V} / \mathrm{V})$, the bandwidth is following a Gain Bandwidth type characteristic showing 300MHz bandwidth or $>4 \mathrm{GHz}$ Gain Bandwidth Product (GBP).

The closed loop differential output impedance of Figure 17 is simulated using Figure 29 in ADS. This shows a relatively low output impedance ( $<1 \Omega$ through 100 MHz ) constant with signal gain setting. Typical FDA outputs show a closed loop output
impedance that increases with signal gain setting. The ISL55210 holds a more constant response vs gain due to internal design elements unique to this device.

Common mode output measurements are made using the circuit Figure 30. Here, the outputs are summed together through two $100 \Omega$ resistors (still a $200 \Omega$ differential load) to a center point where the average, or common mode, output voltage may be sensed. This is coupled through a $1 \mu \mathrm{~F}$ DC blocking capacitor and measured using $50 \Omega$ test equipment. The common mode source impedance for this circuit is the parallel combination of the $2 \Omega-100 \Omega$ elements, or $50 \Omega$. Figure 18 uses this circuit to measure the small and large signal response from the $\mathrm{V}_{\mathrm{CM}}$ control pin to the output common mode. This pin includes an internal 50pF capacitor on the default bias network (to filter supply noise when there is no connection to this pin) which bandlimits the response to approximately 30 MHz . This is far lower than the actual bandwidth of the common mode loop. Figure 19 uses this output CM measurement circuit with a large signal ( $2 \mathrm{~V}_{\text {P-P }}$ ) differential output voltage (generated through the $V_{i}$ path of Figure 30) to measure the differential to common mode conversion.

FIGURE 30. TEST CIRCUIT \#3 COMMON MODE AC OUTPUT MEASUREMENTS

## Single Supply, Input Transformer Coupled, Design Considerations

The characterization circuit of Figure 28 shows one possible input stage interface that offers several advantages. The ISL55210 can also support a DC coupled differential to differential or single ended input to differential requirement if needed. Where AC coupling is adequate, the circuit of Figure 28 simplifies the input common mode voltage control. If the source coming into this stage is single ended, the input transformer provides a zero power conversion to differential. The two gain resistors ( $\mathrm{R}_{\mathrm{G}}$ in Figure 28 ) provide both the input termination impedance and the gain element for the amplifier. For minimum noise, only $\mathrm{R}_{\mathrm{G}}$ should be used and set to achieve the desired input impedance. Since the ISL55210 is a VFA device, these resistor values can be scaled up and down a bit more freely than a current feedback based FDA.

Page 11 of 19

For instance, if a minimum noise configuration is not required, but it is desirable to increase the feedback resistors to reduce the added loading they present to the output stage, the $R_{G}$ and $R_{F}$ resistors can be scaled up to achieve the same gain with an additional termination resistance added across the input transformer to adjust the termination impedance. Figure 31 shows an example using a 1:2 input turns ratio where the $R_{G}$ and $\mathrm{R}_{\mathrm{F}}$ elements have been scaled up and a shunt termination resistance added. This example provides a single to differential signal gain of 20dB and input impedance of $50 \Omega$ to the source. The 1:2 turn ratio transformer needs a $200 \Omega$ differential secondary impedance to provide an input side $50 \Omega$ match. This is provided here by the parallel combination of the $2 \Omega-200 \Omega R_{G}$ resistors and the $400 \Omega$ parallel impedance at the transformer secondary.

FIGURE 31. SINGLE TO DIFFERENTIAL WITH REDUCED FEEDBACK
LOADING

This circuit has scaled the feedback resistor up to $1 \mathrm{k} \Omega$ to still achieve the amplifier gain of $5 \mathrm{~V} / \mathrm{V}$ which gives the overall gain of $10 \mathrm{~V} / \mathrm{V}(20 \mathrm{~dB})$ when the 1:2 step up at the input is considered. The particular transformer shown is typical of 1:2 turns ratio broadband transformers, but there a many alternates with the similar or improved characteristics.

This input interface also simplifies the input common mode control. The $\mathrm{V}_{\mathrm{CM}}$ pin controls the output common mode voltage. In most DC coupled FDA applications, the input common mode voltage is determined by both this output common mode and the source signal. In a configuration like Figure 31, there is no path for a common mode current to flow from output to input, so the input common mode voltage equals the output. A similar effect could be achieved with just two blocking caps on the two $R_{G}$ resistors. A DC coupled, single to differential, configuration will also have a common mode input that is moving with the input signal. Converting to just a differential signal at the amplifier, as in Figure 31, removes any input signal related artifacts from the input common mode making the ISL55210 behave as a differential only VFA amplifier. There is only a very small differential error signal at the inputs set by the loop gain, as in a normal single ended VFA application, but no common mode signal related terms.

The examples shown are using the transformer to convert from single to differential. However, if the source is already differential, these same transformer input circuits can drive the transformer differentially still providing impedance scaling if needed and common mode rejection for both DC and AC common mode issues. A good example would be differential mixer outputs or SAW filter outputs. Those differential sources could also be connected into the ISL55210 $\mathrm{R}_{\mathrm{G}}$ resistors through blocking caps as well eliminating the input transformer. The AC termination impedance for the differential source will then be the sum of the two $\mathrm{R}_{\mathrm{G}}$ resistors when simple blocking caps are used.

## Amplifier I/O Range Limits

The ISL55210 is intended principally to give the lowest IM3 performance on the lowest power for a differential I/O application. The amplifier will work DC coupled and over a relatively wide supply range of 3.0 V to 4.2 V supplies. The outputs have both a differential and common mode operating range while the input pins have a common operating range. For single supply operation, the ground pins are at ground as is the exposed metal pad on the underside of the package. The ISL55210 can operate split supply where then the ground pins will be a negative supply voltage and the exposed metal pad is either connected to this negative supply or left unconnected on an insulating board layer.

Briefly, the $I / O$ and $V_{C M}$ limits are:

1. Maximum $\mathrm{V}_{\mathrm{CM}}$ setting $=-\mathrm{V}_{\mathrm{S}}+2 \mathrm{~V}$
2. Input common mode operating range of $-\mathrm{V}_{\mathrm{S}}+1.1 \mathrm{~V}$ or the output $\mathrm{V}_{\mathrm{CM}}+0.5 \mathrm{~V}$
3. Output $\mathrm{V}_{\mathrm{O}}$ minimum (on each side) is either $-\mathrm{V}_{\mathrm{S}}+0.3 \mathrm{~V}$ or output $\mathrm{V}_{\mathrm{CM}}-0.9 \mathrm{~V}$
4. Output $\mathrm{V}_{\mathrm{O}}$ maximum (on each side) is $+\mathrm{V}_{\mathrm{S}}-1.5 \mathrm{~V}$

The output swing limits are often asymmetrical around the $\mathrm{V}_{\mathrm{CM}}$ voltage. The maximum single ended swings are set by these two limits:
$\mathrm{V}_{\text {OMIN }}$ is either $-\mathrm{V}_{\mathrm{S}}+0.3 \mathrm{~V}$ or $\mathrm{V}_{\mathrm{CM}}-0.9 \mathrm{~V}$ whichever is less. So for instance on a single 3.3 V supply with the default $\mathrm{V}_{\mathrm{CM}}$ voltage of 1.2 V , these two limits give the same result and the output pins can swing down to 0.3 V above $-\mathrm{V}_{\mathrm{S}}=0 \mathrm{~V}$. If, however, the $\mathrm{V}_{\mathrm{CM}}$ pin is raised to 1.5 V , then the minimum output voltage will become $1.5 \mathrm{~V}-0.9 \mathrm{~V}=0.6 \mathrm{~V}$.
$V_{\text {OMAX }}$ is set by a headroom limit to the positive supply to be:
$\mathrm{V}_{\text {OMAX }}=+\mathrm{V}_{\mathrm{S}}-1.5 \mathrm{~V}$. Again, on a 3.3 V single supply and the default 1.2V $\mathrm{V}_{\mathrm{CM}}$ setting, this mean the maximum referenced to ground output pin voltages can be $3.3 \mathrm{~V}-1.5 \mathrm{~V}=+1.8 \mathrm{~V}$ or 0.6 V above the default $V_{C M}$ voltage.

Using these default conditions, and the maximum positive excursion of 0.6 V above the 1.2 V output $\mathrm{V}_{\mathrm{CM}}$ setting, the maximum differential $\mathrm{V}_{\mathrm{P}-\mathrm{P}}$ swing will be 4 X this 0.6 V single ended limit or $2.4 \mathrm{~V}_{\text {P-p }}$. Where $+\mathrm{V}_{\mathrm{S}}$ is increased the limit then becomes the 0.9 V below $\mathrm{V}_{\mathrm{CM}}$, but then the absolute maximum differential $\mathrm{V}_{\mathrm{P}-\mathrm{P}}$ is then 4 X 0.9 V to $3.6 \mathrm{~V}_{\mathrm{P}-\mathrm{P}}$ So, for instance, to get this maximum output swing, increase the supply voltage until $+V_{S}-1.5 \mathrm{~V}>\mathrm{V}_{\mathrm{CM}}+0.9 \mathrm{~V}$. If we assume a $\mathrm{V}_{\mathrm{CM}}$ voltage of 1.3 V for instance, then $1.3 \mathrm{~V}+0.9 \mathrm{~V}+1.5 \mathrm{~V}=3.7 \mathrm{~V}$ will give an unclipped
$3.6 \mathrm{~V}_{\text {P-P }}$ output capability. The $\mathrm{V}_{\mathrm{P}-\mathrm{P}}$ reported in Figure 26 is an asymmetrically clipped maximum swing. Going $10 \%$ above this 3.7 V target to 4.1 V will be within the recommended operating range and give some tolerancing headroom that would also suggest the $\mathrm{V}_{\mathrm{CM}}$ voltage be moved up to approximately 1.5 V . This coincides with the default output $\mathrm{V}_{\mathrm{CM}}$ from Figure 26. Operating at +4.1 V single supply in a Figure 28 type configuration will give the maximum linear available output swing of $3.6 \mathrm{~V}_{\text {P-P. }}$.

The differential inputs of the ISL55210 also have operating range limits relative to the supply voltages. Operating in an AC coupled circuit like Figure 28 will produce an input common mode voltage equal to the outputs. The inputs can operate with full linearity with this $\mathrm{V}_{\mathrm{CM}}$ voltage down to 1.1 V above the GND connection (or $-\mathrm{V}_{\mathrm{S}}$ supply). On the default 1.2 V output $\mathrm{V}_{\mathrm{CM}}$ on +3.3 V supplies this gives a 100 mV guardband on the input $\mathrm{V}_{\mathrm{CM}}$ voltages. Overriding the default $\mathrm{V}_{\mathrm{CM}}$ by applying a control voltage to the $\mathrm{V}_{\mathrm{CM}}$ pin should be done with care in going towards the negative supply due to this limit. On the + side, the maximum $\mathrm{V}_{\mathrm{CM}}$ above the $-\mathrm{V}_{\mathrm{S}}$ supply is 2 V so there is more room to move the output $\mathrm{V}_{\mathrm{CM}}$ up than down from the default value.

When operated as a DC coupled single to differential amplifier, the input common mode voltage will move with the input signal and will be different than the output common mode voltage when the external resistors are set for gain. When the input common mode can be different than the output, the additional constraint that must be observed is that the input common mode voltage cannot be $>$ output $\mathrm{V}_{\mathrm{CM}}+0.5 \mathrm{~V}$. This would only occur if the single source was coming from a higher voltage than the output $\mathrm{V}_{\mathrm{CM}}$ setting.

## Power Supply, Shutdown, and Thermal Considerations

The ISL55210 is intended for single supply operation from 3.0V to 4.2 V with an absolute maximum setting of 4.5 V . The 3.3 V supply current is trimmed to be nominally 35 mA at $+25^{\circ} \mathrm{C}$ ambient. Figure 27 shows the supply current for nominal $+25^{\circ} \mathrm{C}$ and $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ operation over the specified maximum supply range. The input stage is biased from an internal voltage referenced from the negative supply giving the exceptional 90dB low frequency PSRR shown in Figure 25.

Since the input stage bias is from a re-regulated internal supply, a simple approach to single +5 V operation can be supported as shown in Figure 32. Here, a simple IR drop from the +5 V supply will bring the operating supply voltage for the ISL55210 into its allowed range. Figure 32 shows example calculations for the voltage range at the ISL55210 $+\mathrm{V}_{\mathrm{S}}$ pin assuming a $\pm 5 \%$ tolerance on the +5 V supply and a 35 mA to 55 mA range on the total supply current. Considering the 34 mA to 44 mA quiescent current range from Figure 27 over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ ambient, and the 3.4 V to 4.4 V supply voltage range assumed here, this is designing for a 1 mA to 11 mA average load current which should be adequate for most intended application loads. Good supply decoupling at the device pins is required for this simple solution to still provide exceptional SFDR performance.

FIGURE 32. OPERATING FROM A SINGLE +5V SUPPLY

The ISL55210 includes a power shutdown feature that can be used to reduce system power dissipation when signal path operation is not required. This pin ( $\overline{\mathrm{PD}}$ ) is referenced to the ground pins and must be asserted low to activate the shutdown feature. When not used, a $10 \mathrm{k} \Omega$ external resistor to $+\mathrm{V}_{\mathrm{S}}$ should be used to assert a high level at this pin. Digital control on this pin can be either an open collector output (using that $10 \mathrm{k} \Omega$ pullup) or a CMOS logic line running off the same $+V_{S}$ as the amplifier. For split supply operation, the PD pins must be pulled to below $-\mathrm{V}_{\mathrm{S}}+0.54 \mathrm{~V}$ to disable.

Since the ISL55210 operates as a differential inverting op amp, there is only modest signal path isolation when disabled as shown in Figure 23. For small input signals, Figure 23 shows about 5 dB to 6 dB isolation while for large signals, back to back protection diodes across the inputs compress the signal to show actually an improved isolation. This is intended to protect any subsequent devices from large input signals during shutdown. Those diodes limit the maximum overdrive voltage across the input to approximately 0.5 V in each polarity. The $\mathrm{R}_{\mathrm{G}}$ resistors of Test Circuit \#1 limit the current into those diodes under this condition.

The supply current in shutdown does not reduce to zero as internal circuitry is still active to hold the output common mode voltage at the $\mathrm{V}_{\mathrm{CM}}$ control input voltage even during shutdown (or the default value). This is intended to hold the ISL55210 output near the desired common mode output level during shutdown. This improves turn on characteristic and keeps the output voltages in a safe range for downstream circuitry.

## DISABLED OPERATION WARNING IN DC COUPLED DESIGNS

When disabled, the output stage provides a nominal DC voltage at the Vcm control pin input or the default internal 1.2 V value. Being very low power, any external circuit condition that can cause the output pins to source or sink DC current can move the ISL55210 internal operating points into regions from which it may not recover when the device is enabled. If the external circuitry can force $>20 \mu \mathrm{~A}$ into the output pins or pull $>\mathbf{1 . 5 m A}$ out of the output pins correct operation is not guaranteed. For designs that might force current into the output stage during disable, adding a resistor to ground on the outputs might provide
an effective means of turning that into a low sourcing current condition with minimal impact to the desired signal path operation when enabled.

The very low internal power dissipation of the ISL55210, along with the excellent thermal conductivity of the QFN package when the exposed metal pad is tied to a conductive plate, reduces the $\mathrm{T}_{\mathrm{J}}$ rise above ambient to very modest levels. Assuming a nominal 115 mW dissipation and using the $+63^{\circ} \mathrm{C} / \mathrm{W}$ measured thermal impedance from Junction to ambient, gives a rise of only $0.12 * 63=+7.6^{\circ} \mathrm{C}$. Operation at elevated ambient temperatures is easily supported given this very low internal rise to junction.
The maximum internal junction temperatures would occur at maximum supply voltage, $+85^{\circ} \mathrm{C}$ maximum ambient operating, and where the QFN exposed pad is not tied to a conductive layer. Where the QFN must be mounted with an insulating layer to the exposed metal plate, such as in a split supply application, device measurements show an increased thermal impedance junction to ambient of $+120^{\circ} \mathrm{C} / \mathrm{W}$. Using this, and a maximum quiescent internal power on 4.5 V absolute maximum, which shows 45 mA for $+85^{\circ} \mathrm{C}$ maximum operating ambient from Figure 27, we get $4.5 \mathrm{~V} * 45 \mathrm{~mA} *+120^{\circ} \mathrm{C} / \mathrm{W}=+24^{\circ} \mathrm{C}$ rise above $+85^{\circ} \mathrm{C}$ or approximately $+109^{\circ} \mathrm{C}$ operating $\mathrm{T}_{\mathrm{J}}$ maximum - still well below the specified Absolute Maximum operating junction temperature of $+135^{\circ} \mathrm{C}$.

## Noise Analysis

The decompensated voltage feedback design of the ISL55210 provides very low input voltage and current noise. While a detailed noise model using arbitrary external resistors can be made, most applications will have a balanced feedback network with the two $R_{F}$ (feedback) resistors equal and the two $R_{G}$ (gain) resistors equal. Figure 33 shows the test circuit used to measure the output noise with the noise terms detailed. The aim here was to measure the output noise with two different resistor settings to extract out a model for the input referred En and In terms for just the amplifier itself.

FIGURE 33. NOISE MODEL AND TEST CIRCUIT

With equal feedback and gain resistors, the total output noise expression becomes very simple. This is:
$e_{0}=\sqrt{\left(e_{n i} \cdot N G\right)^{2}+2\left(i_{n} R_{f}\right)^{2}+2\left(4 k T R_{f} N G\right)}$
The NG term in Equation 1 is the Noise Gain $=1+R_{F} / R_{G}$. The last term in Equation 1 captures both the $R_{F}$ and $R_{G}$ resistor noise terms. If we assume a $50 \Omega$ source in Test Circuit \#1, the total $R_{G}$ resistor value will be $100 \Omega$ as that $50 \Omega$ will come through the transformer to look like a $50 \Omega$ source on each side. This gives a lower noise gain (3V/V) than signal gain (4V/V) for just the amplifier. The total gain in Test Circuit \#1 is still approximately $1.4 * 4=5.6 \mathrm{~V} / \mathrm{V}$ including the transformer step up.
Putting in $N G=3, R_{F}=200 \Omega, R_{G}=100 \Omega$ with the ISL55210 noise terms of $\mathrm{e}_{\mathrm{ni}}=0.85 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ and $\mathrm{In}=5 \mathrm{pA} / \sqrt{ } \mathrm{Hz}$ into Equation 1 ( $4 \mathrm{kT}=1.6 \mathrm{E}-20 \mathrm{~J}$ ) gives a total output differential noise voltage $=5.26 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$. Input referring this to the input side of the transformer of Test Circuit \#1 gives an input referred spot noise of only $0.88 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$. This extremely low input referred noise is a combination of low amplifier noise terms and the effect of the input transformer configuration.

## Driving Cap and Filter Loads

Most applications will drive a resistive or filter load. The ISL55210 is robust to direct capacitive load on the outputs up to approximately 10 pF . For frequency response flatness, it is best to avoid any output pin capacitance as much as possible - as that capacitance increases, the high frequency portion of the ISL55210 (>1GHz) response will start to show considerable peaking. No oscillations were observed up through 10pF load on each output.

For AC coupled applications, an output network that is a small series resistor ( $10 \Omega$ to $50 \Omega$ ) into a blocking cap is preferred. This series resistor will isolate parasitic capacitance to ground from the internally closed loop output stage of the amplifier and de-queue the self resonance of the blocking capacitors. Once the output stage sees this resistive element first, the remaining part of the filter design can be done without fear of amplifier instability.

## Driving ADCs

Many of the intended applications for the ISL55210 are as a low power, very high dynamic range, last stage interface to high performance ADCs. The lowest power ADCs, such as the ISLA112P50 shown on the front page, include an innovative "Femto-Charge" internal architecture that eliminates op amps from the ADC design and only passes signal charge from stage to stage. This greatly reduces the required quiescent power for these ADCs but then that signal charge has to be provided by the external circuit at the two input pins. This appears on an ADC like the ISLA112P50 as a clock rate dependent common mode input current that must be supplied by the interface circuit. At 500 MHz , this DC current is 1.3 mA on each input for the ISLA112P50.

Most interfaces will also include an interstage noise power bandlimiting filter between the amplifier and the ADC. This filter needs to be designed considering the loading of the amplifier,
any $\mathrm{V}_{\mathrm{CM}}$ level shifting that needs to take place, the filter shape, and this $\mathrm{I}_{\mathrm{CM}}$ issue into the ADC input pins. Here are 4 example topologies suitable for different situations.

1. AC coupled, broadband RLC interstage filter design. This approach lets the amplifier operate at its desired output common mode, then provides the ADC common mode voltage and current through a bias path as part of the filter design's last stage $R$ values. The $V_{B}$ is set to include the IR loss from that voltage to the ADC inputs due to the $I_{C M}$ current. This circuit is the one shown on the front page where we get a usable frequency range from about 500 kHz to 150 MHz .
2. AC coupled, higher frequency range interstage filter design. This design replaces the $R_{t}$ resistors in Figure 34 with large valued inductors and implements the filter just using shunt resistors at the end of the RLC filter (here, that is just the ADC internal differential Rin). In this case, the ADC $\mathrm{V}_{\mathrm{CM}}$ can be tied to the centerpoint of the bias path inductors (very much like a Bias-T) to provide the common mode voltage and current to

FIGURE 34. AC COUPLED, BROADBAND RLC INTERSTAGE FILTER DE SIGN

FIGURE 36. AC COUPLED WITH OUTPUT SIDE TRANSFORMER
the ADC inputs. These bias inductors do limit the low frequency end of the operation where, with $1 \mu \mathrm{H}$ values, operation from 10 MHz to 200 MHz is supported using the approach of Figure 35.
3. AC coupled with output side transformer. This design includes an output side transformer, very similar to ADC characterization circuits. This approach allows a slightly lower amplifier output swing (if $N>1$ is used) and very easy 2 nd order low pass responses to be implemented. It also provides the $\mathrm{I}_{\mathrm{CM}}$ and $\mathrm{V}_{\mathrm{CM}}$ bias to the ADC through the transformer centertap. This approach would be attractive for higher ADC input swing targets and more aggressive noise power bandwidth control needs.
4. DC coupled with $A D C V_{C M}$ and $I_{C M}$ provided from the amplifier. Here, DC to very high frequency interstage low pass filters can be provided. Again, the $R_{S}$ element must be low to reduce the IR drop from the $\mathrm{V}_{\mathrm{CM}}$ of the converter, which now shows up on the output of the ISL55210, to the ADC input pins. In this case, split supplies are required to satisfy the amplifier output and input common mode range limits discussed earlier.

FIGURE 37. DC COUPLED WITH A COMMON $V_{\text {CM }}$ VOLTAGE FROM THE ADC

## Layout Considerations

The ISL55210 pinout is organized to isolate signal I/O along one axis of the package with ground, power and control pins on the other axis. Ground and power should be planes coming into the upper and lower sides of the package (see the Pin Configuration on page 1). The signal I/O should be laid out as tight as possible with parasitic $C$ to the ground and/or power planes reduced as much as possible by opening up those planes under the I/O elements.

The ground pins and package backside metal contact should be connected into a good ground plane. The power supply should have both a large value electrolytic cap to ground, then a high frequency ferrite beads, then $0.01 \mu \mathrm{~F}$ SMD ceramic caps at the supply pins. Some improvement in HD2 performance may be experienced by placing and X2Y cap between the two $\mathrm{V}_{\mathrm{S}+}$ pins and ground underneath the package on the board back side. This is 4 terminal device that is included in the EVM board layout.

## EVM Board (Rev. C)

Test circuit \#1 (Figure 28) is implemented on an Evaluation Module Board available from Intersil. This board includes a number of optional features that are not populated as the board is delivered. The full EVM board circuit is shown in Figure 38 where unloaded (optional) elements are shown in green.
The nominal supply voltage for the board and device is a single 3.3 V supply. From this, the ISL55210, ISL55211 generates an internal common mode voltage of approximately 1.2 V . That
voltage can be overridden by populating the two resistors and potentiometer shown as R19 to R21 above.

The primary test purpose for this board is to implement different interstage differential passive filters intended for the ADC interface along with the ADC input impedances. The board is delivered with only the output R's loaded to give a $200 \Omega$ differential load. This is done using the two $85 \Omega$ resistors as R9 and R10, then the 4 zero ohm elements (R10, R12, R24, and R25) and finally the two shunt elements R13 and R14 set to $35.5 \Omega$. Including the $50 \Omega$ measurement load on the output side of the 1:1 transformer reflecting in parallel with the two $35 \Omega$ resistors takes the nominal AC shunt impedance to $71 \Omega|\mid 50 \Omega=29.3 \Omega$. This adds to the two $85 \Omega$ series output elements to give a total load across the amplifier outputs of $170 \Omega+29.3 \Omega=199.3 \Omega$.

To test a particular ADC interface RLC filter and converter input impedance, replace R11 and R12 with RF chip inductors, load C10 and C11 with the specified ADC input capacitance and R26 with the specified ADC differential input R. With these loaded, the remaining resistive elements (R24, R25, R13, R14) are set to hit a desired total parallel impedance to implement the desired filter (must be < than the ADC input differential R since that sits in parallel with any "external" elements) and achieve a $25 \Omega$ source looking into each side of the tap point transformer.

This EVM board includes a user's manual showing a number of example circuits and tested results. Available on the Intersil web site in the ISL55210 Product Information Page.
