Rev.1.10 Sep 2010

Notice

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
7. Renesas Electronics products are classified according to the following three quality grades: "Standard", "High Quality", and "Specific". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as "Specific" without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as "Specific" or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is "Standard" unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.

   "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.

   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.

   "Specific": Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.
8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

General Precautions in the Handling of MPU/MCU Products

The following usage notes are applicable to all MPU/MCU products from Renesas. For detailed usage notes on the products covered by this manual, refer to the relevant sections of the manual. If the descriptions under General Precautions in the Handling of MPU/MCU Products and in the body of the manual differ from each other, the description in the body of the manual takes precedence.

1. Handling of Unused Pins

   Handle unused pins in accord with the directions given under Handling of Unused Pins in the manual.

   — The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

2. Processing at Power-on

   The state of the product is undefined at the moment when power is supplied.

   — The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.

   In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed.

   In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

3. Prohibition of Access to Reserved Addresses

   Access to reserved addresses is prohibited.

   — The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

4. Clock Signals

   After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

   — When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

5. Differences between Products

   Before changing from one product to another, i.e. to one with a different part number, confirm that the change will not lead to problems.

   — The characteristics of MPU/MCU in the same group but having different part numbers may differ because of the differences in internal memory capacity and layout pattern. When changing to products of different part numbers, implement a system-evaluation test for each of the products.

About This Manual

1. Purpose and Target User

This manual is designed to be read primarily by application developers who have an understanding of this microcomputer (MCU) including its hardware functions and electrical characteristics. The user should have a basic understanding of electric circuits, logic circuits and, MCUs.
This manual consists of 29 chapters covering six main categories: Overview, CPU, System Control, Peripherals, Electrical Characteristics, and Usage Notes.

Carefully read all notes in this document prior to use. Notes are found throughout each chapter, at the end of each chapter, and in the dedicated Usage Notes chapter.

The Revision History at the end of this manual summarizes primary modifications and additions to the previous versions. For details, please refer to the relative chapters or sections of this manual.

The R32C/117 Group includes the documents listed below. Verify this manual is the latest version by visiting the Renesas Electronics website.

Type of Document	Contents	Document Name	Document Number
Datasheet	Overview of Hardware and Electrical Characteristics	R32C/117 Group Datasheet	REJ03B0254-0110
User's Manual: Hardware	Specifications and detailed descriptions of: -pin layout -memory map -peripherals -electrical characteristics -timing characteristics Refer to the Application Manual for peripheral usage.	R32C/117 Group User's Manual: Hardware	This publication
User's Manual: Software/Software Manual	Descriptions of instruction set	R32C/100 Series Software Manual	REJ09B0267-0100
Application Note	-Usages -Applications -Sample programs -Programing technics using Assembly language or C programming language	Available on the Renesas Electronics website.	
Renesas Technical Update	Bulletins on product specifications, documents, etc.		

2. Numbers and Symbols

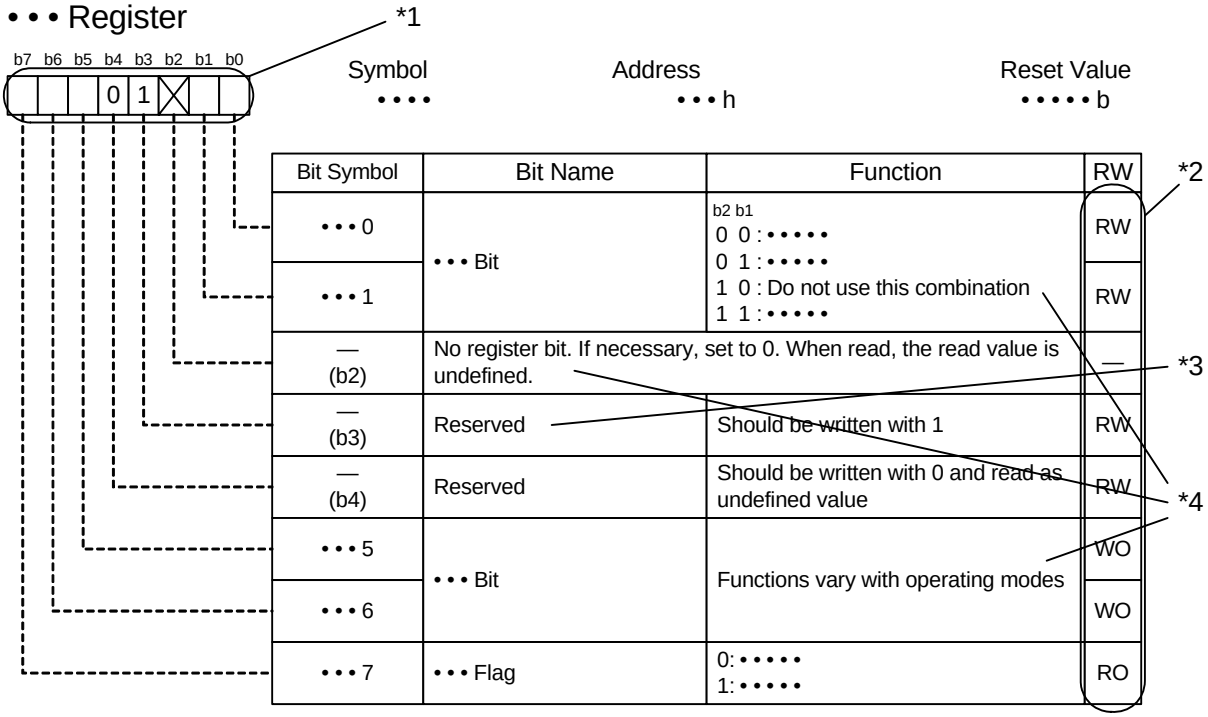
The following explains the denotations used in this manual for registers, bits, pins and various numbers.

(1) Registers, bits, and pins
Registers, bits, and pins are indicated by symbols. Each symbol has a register/bit/pin identifier after the symbol.
Example: PM03 bit in the PM0 register
P3_5 pin, VCC pin

(2) Numbers
A binary number has the suffix “b” except for a 1-bit value.
A hexadecimal number has the suffix “h”.
A decimal number has no suffix.
Example: Binary notation: 11b
Hexadecimal notation: EFA0h
Decimal notation: 1234

3. Registers

The following illustration describes registers used throughout this manual.



*1
Blank box: Set this bit to 0 or 1 according to the function.
0: Set this bit to 0.
1: Set this bit to 1.
X: Nothing is assigned to this bit.

*2
RW: Read and write
RO: Read only
WO: Write only (the read value is undefined)
—: Not applicable

*3
- Reserved bit: This bit field is reserved. Set this bit to a specified value. For RW bits, the written value is read unless otherwise noted.

*4
- No register bit(s): No register bit(s) is/are assigned to this field. If necessary, set to 0 for possible future implementation.
- Do not use this combination: Proper operation is not guaranteed when this value is set.
- Functions vary with operating modes: Functions vary with peripheral operating modes. Refer to register illustrations of the respective mode.

4. Abbreviations and Acronyms

The following acronyms and terms are used throughout this manual.

Abbreviation/Acronym	Meaning
ACIA	Asynchronous Communication Interface Adapter
bps	bits per second
CRC	Cyclic Redundancy Check
DMA	Direct Memory Access
DMAC	Direct Memory Access Controller
GSM	Global System for Mobile Communications
Hi-Z	High Impedance
IEBus	Inter Equipment Bus
I/O	Input/Output
IrDA	Infrared Data Association
LSB	Least Significant Bit
MSB	Most Significant Bit
NC	Non-Connection
PLL	Phase Locked Loop
PWM	Pulse Width Modulation
SIM	Subscriber Identity Module
UART	Universal Asynchronous Receiver/Transmitter
VCO	Voltage Controlled Oscillator

TABLE OF CONTENTS

1. Overview

1.1 Features

The M16C Family offers a robust platform of 32-/16-bit CISC microcomputers (MCUs) featuring high ROM code efficiency, extensive EMI/EMS noise immunity, ultra-low power consumption, high-speed processing in actual applications, and numerous and varied integrated peripherals. Extensive device scalability from low- to high-end, featuring a single architecture as well as compatible pin assignments and peripheral functions, provides support for a vast range of application fields.

The R32C/100 Series is a high-end microcontroller series in the M16C Family. With a 4-Gbyte memory space, it achieves maximum code efficiency and high-speed processing with 32-bit CISC architecture, multiplier, multiply-accumulate unit, and floating point unit. The selection from the broadest choice of on-chip peripheral devices — UART, CRC, DMAC, A/D and D/A converters, timers, I^2C, and watchdog timer enables to minimize external components.

The R32C/117 Group is the standard MCU within the R32C/100 Series. This product, provided as 100-pin and 144-pin plastic molded LQFP packages, configures nine channels of serial interface, one channel of multi-master I^2C-bus interface, and one channel of CAN module.

1.1.1 Applications

Car audio, audio, printer, office/industrial equipment, etc.

1.1.2 Performance Overview

Table 1.1 to Table 1.4 list the performance overview of the R32C/117 Group.

Table 1.1 Performance Overview for the 144 pin-Package (1/2)

Unit	Function	Explanation
CPU	Central processing unit	R32C/100 Series CPU Core • Basic instructions: 108 • Minimum instruction execution time: 15.625 ns (f(CPU) = 64 MHz) • Multiplier: 32-bit × 32-bit → 64-bit • Multiply-accumulate unit: 32-bit × 32-bit + 64-bit → 64-bit • IEEE-754 floating point standard: Single precision • 32-bit barrel shifter • Operating mode: Single-chip mode, memory expansion mode, microprocessor mode (optional (1))
Memory		Flash memory: 384 Kbytes to 1 Mbyte RAM: 40 K/48 K/63 Kbytes Data flash: 4 Kbytes × 2 blocks Refer to Table 1.5 for each product's memory size
Voltage Detector	Low voltage detector	Optional (1) Low voltage detection interrupt
Clock	Clock generator	• 4 circuits (main clock, sub clock, PLL, on-chip oscillator) • Oscillation stop detector: Main clock oscillator stop/restart detection • Frequency divide circuit: Divide-by-2 to divide-by-24 selectable • Low power modes: Wait mode, stop mode
External Bus Expansion	Bus and memory expansion	• Address space: 4 Gbytes (of which up to 64 Mbytes is user accessible) • External bus Interface: Support for wait-state insertion, 4 chip select outputs • Bus format: Separate bus/Multiplexed bus selectable, data bus width selectable (8/16/32 bits)
Interrupts		Interrupt vectors: 261 External interrupt inputs: $\overline{\text{NMI}}$, $\overline{\text{INT}}$ × 9, key input × 4 Interrupt priority levels: 7
Watchdog Timer		15 bits × 1 (selectable input frequency from prescaler output)
DMA	DMAC	4 channels • Cycle-steal transfer mode • Request sources: 57 • 2 transfer modes: Single transfer, repeat transfer
	DMAC II	• Can be activated by any peripheral interrupt source • 3 transfer functions: Immediate data transfer, calculation transfer, chained transfer
I/O Ports	Programmable I/O ports	• 2 input-only ports • 120 CMOS I/O ports (of which 32 are 5 V tolerant) • A pull-up resistor is selectable for every 4 input ports (except 5 V tolerant inputs)

Note:
1. Contact a Renesas Electronics sales office to use the optional features.

Table 1.2 Performance Overview for the 144-pin Package (2/2)

Unit	Function	Explanation
Timer	Timer A	16-bit timer × 5 Timer mode, event counter mode, one-shot timer mode, pulse-width modulation (PWM) mode Two-phase pulse signal processing in event counter mode (two-phase encoder input) × 3
	Timer B	16-bit timer × 6 Timer mode, event counter mode, pulse frequency measurement mode, pulse-width measurement mode
	Three-phase motor control timer	Three-phase motor control timer × 1 (timers A1, A2, A4, and B2 used) 8-bit programmable dead time timer
Serial Interface	UART0 to UART8	Asynchronous/synchronous serial interface × 9 channels • I^2C-bus (UART0 to UART6) • Special mode 2 (UART0 to UART6) • IEBus (optional (1)) (UART0 to UART6)
A/D Converter		10-bit resolution × 34 channels Sample and hold functionality integrated
D/A Converter		8-bit resolution × 2
CRC Calculator		CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$)
X-Y Converter		16 bits × 16 bits
Intelligent I/O		Time measurement (input capture): 16 bits × 16 Waveform generation (output compare): 16 bits × 24 Serial interface: Variable-length synchronous serial I/O mode, IEBus mode (optional (1))
Multi-master I^2C-bus Interface		1 channel
CAN Module		1 channel CAN functionality compliant with ISO11898-1 32 mailboxes
Flash Memory		Programming and erasure supply voltage: VCC = 3.0 to 5.5 V Minimum endurance: 1,000 program/erase cycles Security protection: ROM code protect, ID code protect Debugging: On-chip debug, on-board flash programming
Operating Frequency/Supply Voltage		64 MHz (high speed version)/VCC = 3.0 to 5.5 V 50 MHz (normal speed version)/VCC = 3.0 to 5.5 V
Operating Temperature		-20°C to 85°C (N version) -40°C to 85°C (D version) -40°C to 85°C (P version)
Current Consumption		45 mA (VCC = 5.0 V, f(CPU) = 64 MHz) 35 mA (VCC = 5.0 V, f(CPU) = 50 MHz) 8 µA (VCC = 3.3 V, f(XCIN) = 32.768 kHz, in wait mode)
Package		144-pin plastic molded LQFP (PLQP0144KA-A)

Note:
1. Contact a Renesas Electronics sales office to use the optional features.

Table 1.3 Performance Overview for the 100-pin Package (1/2)

Unit	Function	Explanation
CPU	Central processing unit	R32C/100 Series CPU Core • Basic instructions: 108 • Minimum instruction execution time: 15.625 ns (f(CPU) = 64 MHz) • Multiplier: 32-bit × 32-bit → 64-bit • Multiply-accumulate unit: 32-bit × 32-bit + 64-bit → 64-bit • IEEE-754 floating point standard: Single precision • 32-bit barrel shifter • Operating mode: Single-chip mode, memory expansion mode, microprocessor mode (optional (1))
Memory		Flash memory: 128 Kbytes to 1 Mbyte RAM: 20 K/40 K/48 K/63 Kbytes Data flash: 4 Kbytes × 2 blocks Refer to Table 1.5 for each product's memory size
Voltage Detector	Low voltage detector	Optional (1) Low voltage detection interrupt
Clock	Clock generator	• 4 circuits (main clock, sub clock, PLL, on-chip oscillator) • Oscillation stop detector: Main clock oscillator stop/restart detection • Frequency divide circuit: Divide-by-2 to divide-by-24 selectable • Low power modes: Wait mode, stop mode
External Bus Expansion	Bus and memory expansion	• Address space: 4 Gbytes (of which up to 64 Mbytes is user accessible) • External bus Interface: Support for wait-state insertion, 4 chip select outputs • Bus format: Separate bus/Multiplexed bus selectable, data bus width selectable (8/16 bits)
Interrupts		Interrupt vectors: 261 External interrupt inputs: $\overline{\text{NMI}}$, $\overline{\text{INT}}$ × 6, key input × 4 Interrupt priority levels: 7
Watchdog Timer		15 bits × 1 (selectable input frequency from prescaler output)
DMA	DMAC	4 channels • Cycle-steal transfer mode • Request sources: 51 • 2 transfer modes: Single transfer, repeat transfer
	DMAC II	• Can be activated by any peripheral interrupt source • 3 transfer functions: Immediate data transfer, calculation transfer, chained transfer
I/O Ports	Programmable I/O ports	• 2 input-only ports • 84 CMOS I/O ports (of which 32 are 5 V tolerant) • A pull-up resistor is selectable for every 4 input ports (except 5 V tolerant inputs)

Note:
1. Contact a Renesas Electronics sales office to use the optional features.

Table 1.4 Performance Overview for the 100-pin Package (2/2)

Unit	Function	Explanation
Timer	Timer A	16-bit timer × 5 Timer mode, event counter mode, one-shot timer mode, pulse-width modulation (PWM) mode Two-phase pulse signal processing in event counter mode (two-phase encoder input) × 3
	Timer B	16-bit timer × 6 Timer mode, event counter mode, pulse frequency measurement mode, pulse-width measurement mode
	Three-phase motor control timer	Three-phase motor control timer × 1 (timers A1, A2, A4, and B2 used) 8-bit programmable dead time timer
Serial Interface	UART0 to UART8	Asynchronous/synchronous serial interface × 9 channels • I^2C-bus (UART0 to UART6) • Special mode 2 (UART0 to UART6) • IEBus (optional (1)) (UART0 to UART6)
A/D Converter		10-bit resolution × 26 channels Sample and hold functionality integrated
D/A Converter		8-bit resolution × 2
CRC Calculator		CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$)
X-Y Converter		16 bits × 16 bits
Intelligent I/O		Time measurement (input capture): 16 bits × 16 Waveform generation (output compare): 16 bits × 19 Serial interface: Variable-length synchronous serial I/O mode, IEBus mode (optional (1))
Multi-master I^2C-bus Interface		1 channel
CAN Module		1 channel CAN functionality compliant with ISO11898-1 32 mailboxes
Flash Memory		Programming and erasure supply voltage: VCC = 3.0 to 5.5 V Minimum endurance: 1,000 program/erase cycles Security protection: ROM code protect, ID code protect Debugging: On-chip debug, on-board flash programming
Operating Frequency/Supply Voltage		64 MHz (high speed version)/VCC = 3.0 to 5.5 V 50 MHz (normal speed version)/VCC = 3.0 to 5.5 V
Operating Temperature		-20°C to 85°C (N version) -40°C to 85°C (D version) -40°C to 85°C (P version)

Package		100-pin plastic molded LQFP (PLQP0100KB-A)

Note:
1. Contact a Renesas Electronics sales office to use the optional features.

1.2 Product Information

Table 1.5 and Table 1.6 list the product information and Figure 1.1 shows the details of the part number.

Table 1.5 R32C/117 Group Product List for Normal Speed Version (1/2) As of September, 2010

Part Number	Package Code (1)	ROM Capacity (2)	RAM Capacity	Remarks
R5F6417BNFB (P)	PLQP0100KB-A	128 Kbytes + 8 Kbytes	20 Kbytes	-20°C to 85°C (N version)
R5F6417BDFB				-40°C to 85°C (D version)
R5F6417BPFB (P)				-40°C to 85°C (P version)
R5F6417ANFB (P)	PLQP0100KB-A	256 Kbytes + 8 Kbytes		-20°C to 85°C (N version)
R5F6417ADFB				-40°C to 85°C (D version)
R5F6417APFB (P)				-40°C to 85°C (P version)
R5F64175NFD (P)	PLQP0144KA-A	384 Kbytes + 8 Kbytes	40 Kbytes	-20°C to 85°C (N version)
R5F64175DFD				-40°C to 85°C (D version)
R5F64175PFD				-40°C to 85°C (P version)
R5F64175NFB (P)	PLQP0100KB-A			-20°C to 85°C (N version)
R5F64175DFB				-40°C to 85°C (D version)
R5F64175PFB				-40°C to 85°C (P version)
R5F64176NFD (P)	PLQP0144KA-A	512 Kbytes + 8 Kbytes		-20°C to 85°C (N version)
R5F64176DFD				-40°C to 85°C (D version)
R5F64176PFD				-40°C to 85°C (P version)
R5F64176NFB (P)	PLQP0100KB-A			-20°C to 85°C (N version)
R5F64176DFB				-40°C to 85°C (D version)
R5F64176PFB				-40°C to 85°C (P version)
R5F64177NFD (P)	PLQP0144KA-A	640 Kbytes + 8 Kbytes	48 Kbytes	-20°C to 85°C (N version)
R5F64177DFD				-40°C to 85°C (D version)
R5F64177PFD				-40°C to 85°C (P version)
R5F64177NFB (P)	PLQP0100KB-A			-20°C to 85°C (N version)
R5F64177DFB				-40°C to 85°C (D version)
R5F64177PFB				-40°C to 85°C (P version)
R5F64178NFD (P)	PLQP0144KA-A	768 Kbytes + 8 Kbytes	63 Kbytes	-20°C to 85°C (N version)
R5F64178DFD				-40°C to 85°C (D version)
R5F64178PFD				-40°C to 85°C (P version)
R5F64178NFB (P)	PLQP0100KB-A			-20°C to 85°C (N version)
R5F64178DFB				-40°C to 85°C (D version)
R5F64178PFB				-40°C to 85°C (P version)
R5F64179NFD (P)	PLQP0144KA-A	1 Mbyte + 8 Kbytes		-20°C to 85°C (N version)
R5F64179DFD				-40°C to 85°C (D version)
R5F64179PFD				-40°C to 85°C (P version)
R5F64179NFB (P)	PLQP0100KB-A			-20°C to 85°C (N version)
R5F64179DFB				-40°C to 85°C (D version)
R5F64179PFB				-40°C to 85°C (P version)

(D): Under development (P): On planning phase

Notes:
1. The old package codes are as follows:PLQP0100KB-A: 100P6Q-A; PLQP0144KA-A: 144P6Q-A
2. Data flash memory provides an additional 8 Kbytes of ROM.

Table 1.6 R32C/117 Group Product List for High Speed Version (2/2) As of September, 2010

Part Number	Package Code (1)	ROM Capacity (2)	RAM Capacity	Remarks
R5F6417BHNFB (P)	PLQP0100KB-A	128 Kbytes + 8 Kbytes	20 Kbytes	-20°C to 85°C (N version)

(D): Under development (P): On planning phase

Notes:
1. The old package codes are as follows:PLQP0100KB-A: 100P6Q-A; PLQP0144KA-A: 144P6Q-A
2. Data flash memory provides an additional 8 Kbytes of ROM.

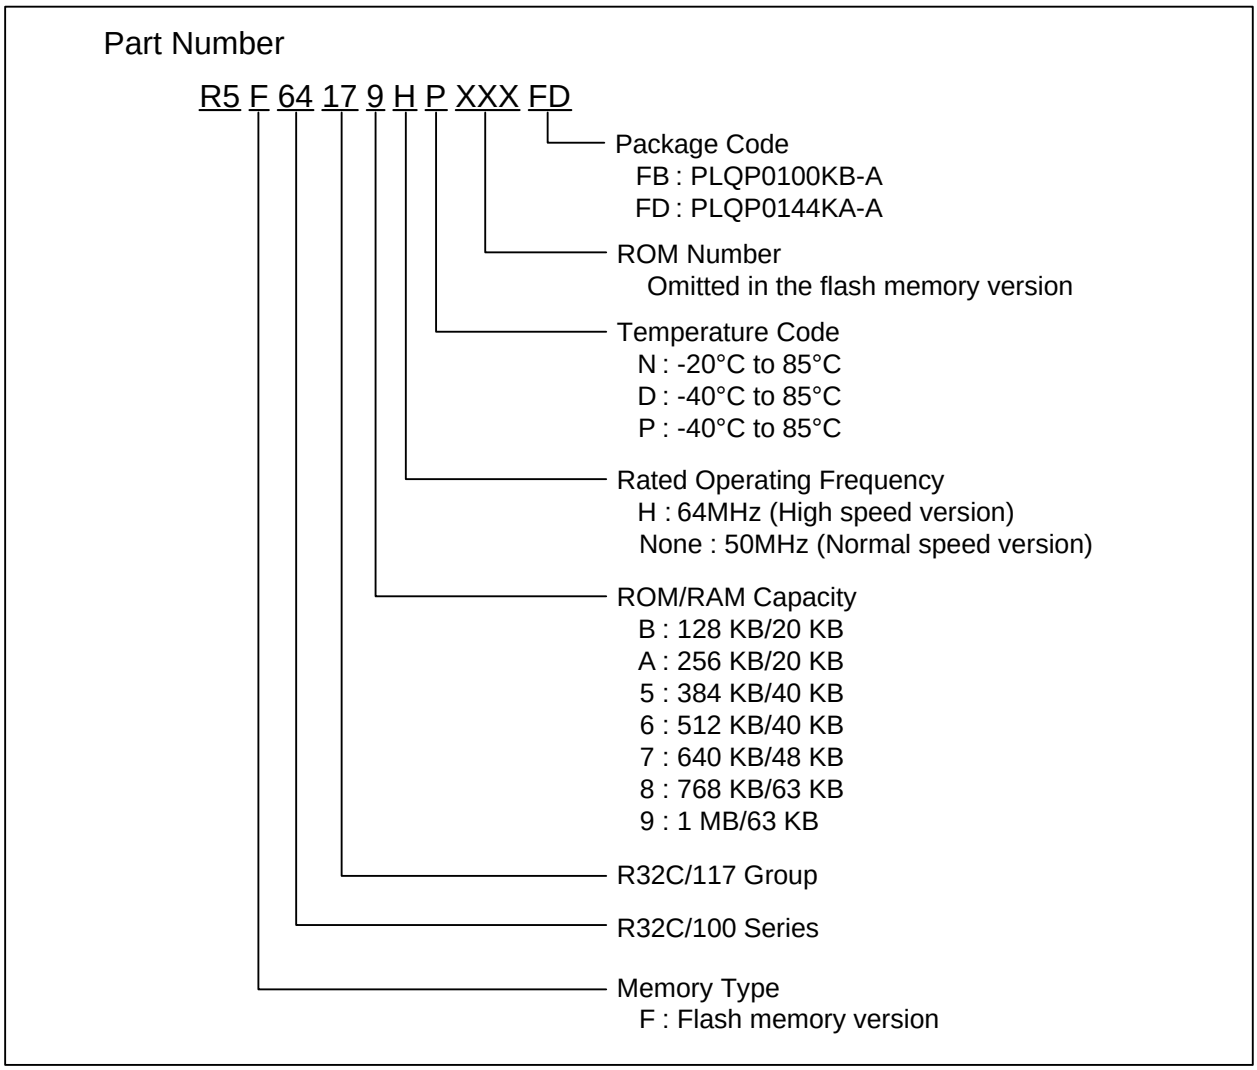

Figure 1.1 Part Numbering

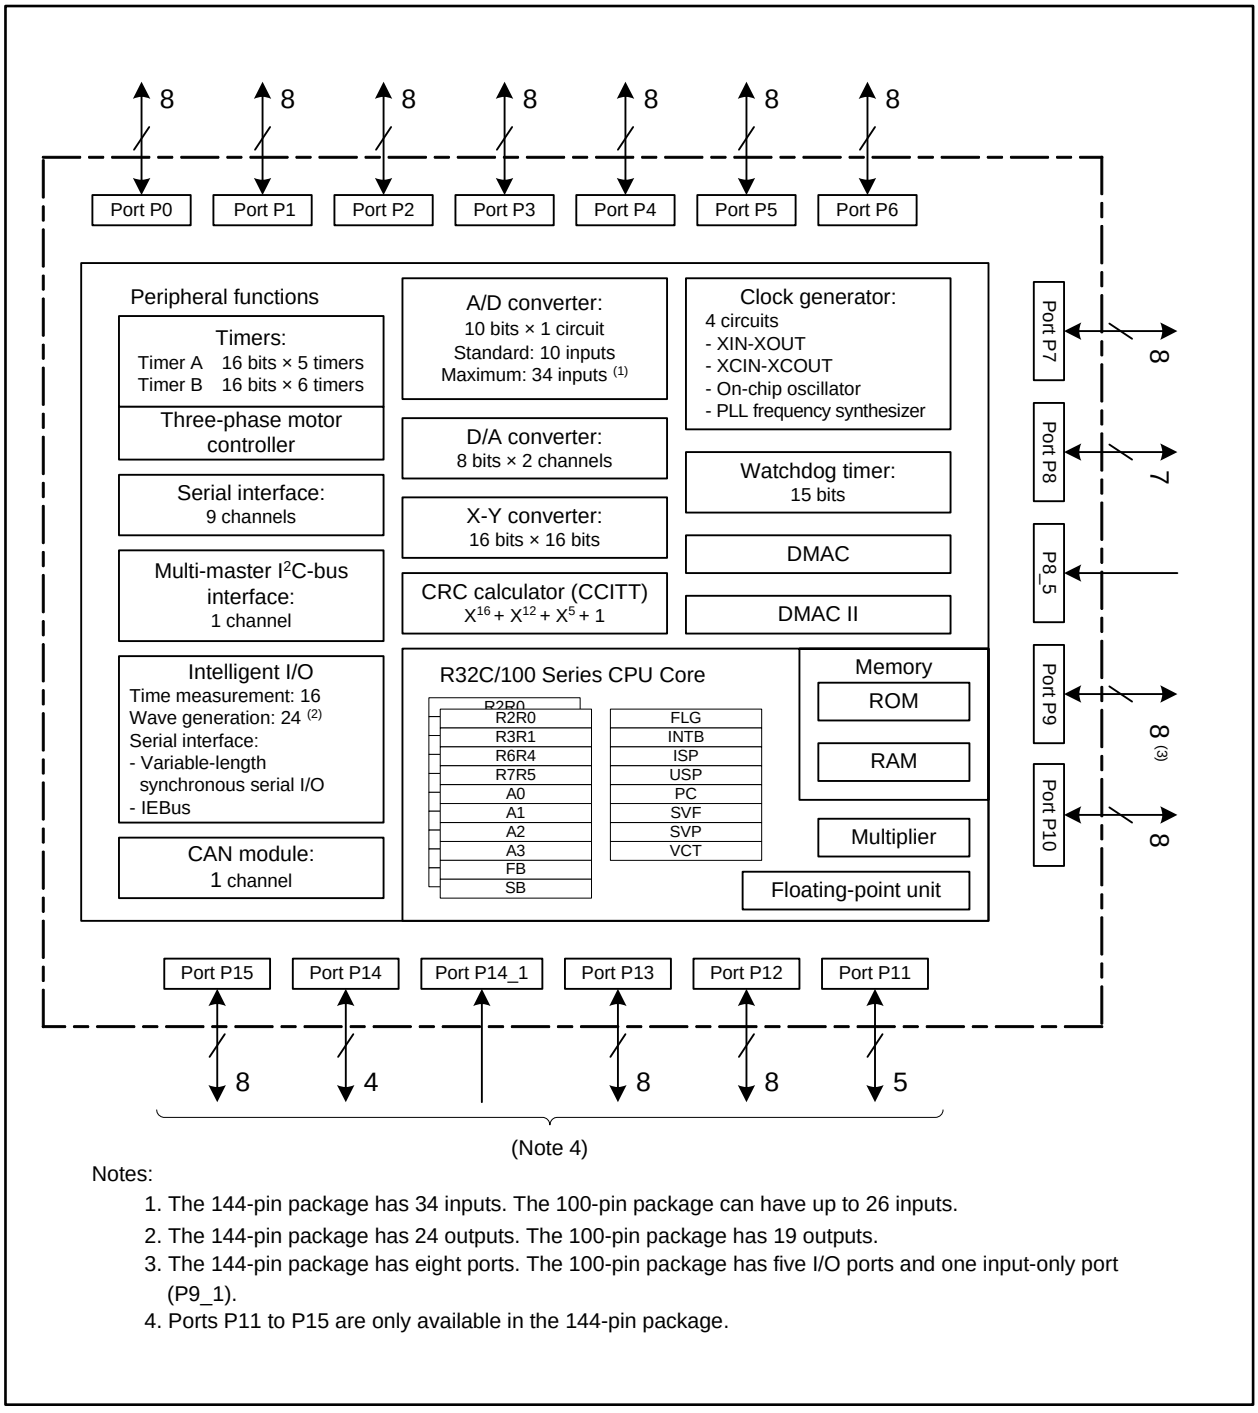
1.3 Block Diagram

Figure 1.2 shows the block diagram for the R32C/117 Group.

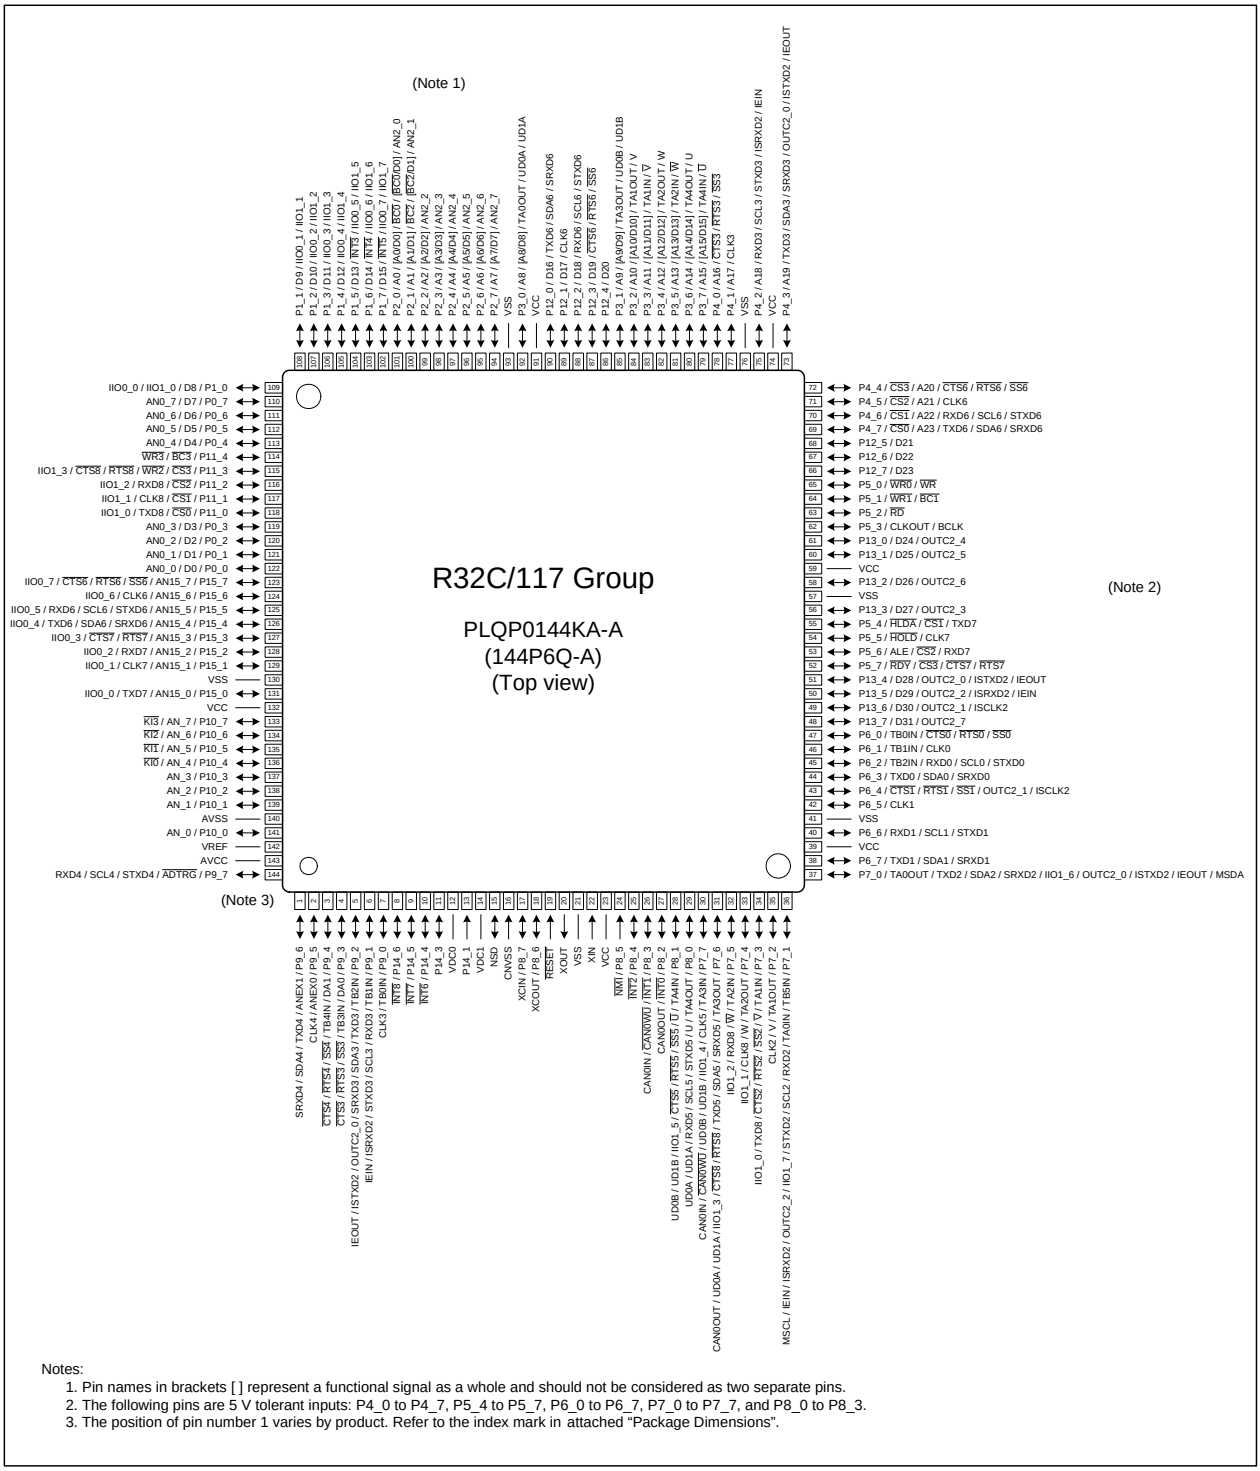


Notes:
1. The 144-pin package has 34 inputs. The 100-pin package can have up to 26 inputs.
2. The 144-pin package has 24 outputs. The 100-pin package has 19 outputs.
3. The 144-pin package has eight ports. The 100-pin package has five I/O ports and one input-only port (P9_1).
4. Ports P11 to P15 are only available in the 144-pin package.

Figure 1.2 R32C/117 Group Block Diagram

1.4 Pin Assignments

Figure 1.3 and Figure 1.4 show the pin assignments (top view) and Table 1.7 to Table 1.13 list the pin characteristics.



Notes:
1. Pin names in brackets [ ] represent a functional signal as a whole and should not be considered as two separate pins.
2. The following pins are 5 V tolerant inputs: P4_0 to P4_7, P5_4 to P5_7, P6_0 to P6_7, P7_0 to P7_7, and P8_0 to P8_3.
3. The position of pin number 1 varies by product. Refer to the index mark in attached “Package Dimensions”.

1.5 Pin Definitions and Functions

Table 1.14 to Table 1.18 list the pin definitions and functions.

Table 1.14 Pin Definitions and Functions (1/4)

Function	Symbol	I/O	Description
Power supply	VCC, VSS	I	Applicable as follows: VCC = 3.0 to 5.5 V, VSS = 0 V
Connecting pins for decoupling capacitor	VDC0, VDC1	—	A decoupling capacitor for internal voltage should be connected between VDC0 and VDC1
Analog power supply	AVCC, AVSS	I	Power supply for the A/D converter. AVCC and AVSS should be connected to VCC and VSS, respectively
Reset input	$\overline{\text{RESET}}$	I	The MCU is reset when this pin is driven low
CNVSS	CNVSS	I	This pin should be connected to VSS via a resistor
Debug port	NSD	I/O	This pin is to communicate with a debugger. It should be connected to VCC via a resistor of 1 to 4.7 kΩ
Main clock input	XIN	I	Input/output for the main clock oscillator. A crystal, or a ceramic resonator should be connected between pins XIN and XOUT. An external clock should be input at the XIN while leaving the XOUT open
Main clock output	XOUT	O	
Sub clock input	XCIN	I	Input/output for the sub clock oscillator. A crystal oscillator should be connected between pins XCIN and XCOUT. An external clock should be input at the XCIN while leaving the XCOUT open
Sub clock output	XCOUT	O	
BCLK output	BCLK	O	BCLK output
Clock output	CLKOUT	O	Output of the clock with the same frequency as low speed clocks, f8, or f32
External interrupt input	$\overline{\text{INT0}}$ to $\overline{\text{INT8}}$ (1)	I	Input for external interrupts
NMI input	P8_5/$\overline{\text{NMI}}$	I	Input for NMI
Key input interrupt	$\overline{\text{KI0}}$ to $\overline{\text{KI3}}$	I	Input for the key input interrupt
Bus control pins	D0 to D7	I/O	Input/output of data (D0 to D7) while accessing an external memory space with a separate bus
	D8 to D15	I/O	Input/output of data (D8 to D15) while accessing an external memory space with 16-bit or 32-bit separate bus
	D16 to D31 (2)	I/O	Input/output of data (D16 to D31) while accessing an external memory space with 32-bit separate bus
	A0 to A23	O	Output of address bits A0 to A23
	A0/D0 to A7/D7	I/O	Output of address bits (A0 to A7) and input/output of data (D0 to D7) by time-division while accessing an external memory space with multiplexed bus
	A8/D8 to A15/D15	I/O	Output of address bits (A8 to A15) and input/output of data (D8 to D15) by time-division while accessing an external memory space with 16-bit or 32-bit multiplexed bus

Notes:
1. Pins $\overline{\text{INT6}}$ to $\overline{\text{INT8}}$ are available in the 144-pin package only.
2. Pins D16 to D31 are available in the 144-pin package only.

Table 1.15 Pin Definitions and Functions (2/4)

Function	Symbol	I/O	Description
Bus control pins	$\overline{BC0}$/D0, $\overline{BC2}$/D1 (1)	I/O	Output of byte control ($\overline{BC0}$ and $\overline{BC2}$) and input/output of data (D0 and D1) by time-division while accessing an external memory space with multiplexed bus
	$\overline{CS0}$ to $\overline{CS3}$	O	Chip select output
	$\overline{WR0}$/$\overline{WR1}$/$\overline{WR2}$/$\overline{WR3}$, $\overline{WR}$/$\overline{BC0}$/$\overline{BC1}$/$\overline{BC2}$/$\overline{BC3}$, $\overline{RD}$ (1)	O	Output of write, byte control, and read signals. Either $\overline{WRx}$ or $\overline{WR}$ and $\overline{BCx}$ can be selected by a program. Data is read when $\overline{RD}$ is low. • When $\overline{WR0}$, $\overline{WR1}$, $\overline{WR2}$, $\overline{WR3}$, and $\overline{RD}$ are selected, data is written to the following address: 4n+0, when $\overline{WR0}$ is low 4n+1, when $\overline{WR1}$ is low 4n+2, when $\overline{WR2}$ is low 4n+3, when $\overline{WR3}$ is low on 32-bit external data bus or an even address, when $\overline{WR0}$ is low an odd address, when $\overline{WR1}$ is low on 16-bit external data bus • When $\overline{WR}$, $\overline{BC0}$, $\overline{BC1}$, $\overline{BC2}$, $\overline{BC3}$, and $\overline{RD}$ are selected, data is written, when $\overline{WR}$ is low and the following address is accessed: 4n+0, when $\overline{BC0}$ is low 4n+1, when $\overline{BC1}$ is low 4n+2, when $\overline{BC2}$ is low 4n+3, when $\overline{BC3}$ is low on 32-bit external data bus or an even address, when $\overline{BC0}$ is low an odd address, when $\overline{BC1}$ is low on 16-bit external data bus
	ALE	O	Latch enable signal in multiplexed bus format
	$\overline{HOLD}$	I	The MCU is in a hold state while this pin is held low
	$\overline{HLDA}$	O	This pin is driven low while the MCU is held in a hold state
	$\overline{RDY}$	I	Bus cycle is extended by the CPU if this pin is low on the falling edge of BCLK

Note:
1. Pins $\overline{BC2}$/D1, $\overline{WR2}$, $\overline{WR3}$, $\overline{BC2}$, and $\overline{BC3}$ are available in the 144-pin package only.

Table 1.16 Pin Definitions and Functions (3/4)

Function	Symbol	I/O	Description
I/O port (1, 2)	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7	I/O	I/O ports in CMOS. Each port can be programmed to input or output under the control of the direction register. Some ports are 5 V tolerant inputs. Pull-up resistors and N-channel open drain setting can be enabled on some ports. Refer to Table 1.18 “Pin Specifications” for details
Input port (2)	P9_1 (for 100-pin package) P14_1 (for 144-pin package)	I	Input port in CMOS Pull-up resistor is selectable. Refer to Table 1.18 “Pin Specifications” for details
Timer A	TA0OUT to TA4OUT	I/O	Timers A0 to A4 input/output
	TA0IN to TA4IN	I	Timers A0 to A4 input
Timer B	TB0IN to TB5IN	I	Timers B0 to B5 input
Three-phase motor control timer output	U,$\overline{U}$,V,$\overline{V}$,W,$\overline{W}$	O	Three-phase motor control timer output
Serial interface	$\overline{CTS0}$ to $\overline{CTS8}$	I	Handshake input
	$\overline{RTS0}$ to $\overline{RTS8}$	O	Handshake output
	CLK0 to CLK8	I/O	Transmit/receive clock input/output
	RXD0 to RXD8	I	Serial data input
	TXD0 to TXD8	O	Serial data output
I^2C-bus (simplified)	SDA0 to SDA6	I/O	Serial data input/output
	SCL0 to SCL6	I/O	Transmit/receive clock input/output
Serial interface special functions	STXD0 to STXD6	O	Serial data output in slave mode
	SRXD0 to SRXD6	I	Serial data input in slave mode
	$\overline{SS0}$ to $\overline{SS6}$	I	Input to control serial interface special functions

Notes:
1. Port P9_1 in the 100-pin package is an input-only port.
2. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only.

Table 1.17 Pin Definitions and Functions (4/4)

Function	Symbol	I/O	Description
A/D converter	AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7 (1)	I	Analog input for the A/D converter
	$\overline{\text{ADTRG}}$	I	External trigger input for the A/D converter
	ANEX0	I/O	Expanded analog input for the A/D converter and output in external op-amp connection mode
	ANEX1	I	Expanded analog input for the A/D converter
D/A converter	DA0, DA1	O	Output for the D/A converter
Reference voltage input	VREF	I	Reference voltage input for the A/D converter and D/A converter
Intelligent I/O	IIO0_0 to IIO0_7	I/O	Input/output for the Intelligent I/O group 0. Either input capture or output compare is selectable
	IIO1_0 to IIO1_7	I/O	Input/output for the Intelligent I/O group 1. Either input capture or output compare is selectable
	UD0A, UD0B, UD1A, UD1B	I	Input for the two-phase encoder
	OUTC2_0 to OUTC2_7 (2)	O	Output for OC (output compare) of the Intelligent I/O group 2
	ISCLK2	I/O	Clock input/output for the serial interface
	ISRXD2	I	Receive data input for the serial interface
	ISTXD2	O	Transmit data output for the serial interface
	IEIN	I	Receive data input for the serial interface
	IEOUT	O	Transmit data output for the serial interface
Multi-master I^2C-bus	MSDA	I/O	Serial data input/output
	MSCL	I/O	Transmit/receive clock input/output
CAN Module	CAN0IN	I	Receive data input for the CAN communications
	CAN0OUT	O	Transmit data output for the CAN communications
	$\overline{\text{CAN0WU}}$	I	Input for the CAN wake-up interrupt

Notes:
1. Pins AN15_0 to AN15_7 are available in the 144-pin package only.
2. Pins OUTC2_3 to OUTC2_7 are available in the 144-pin package only.

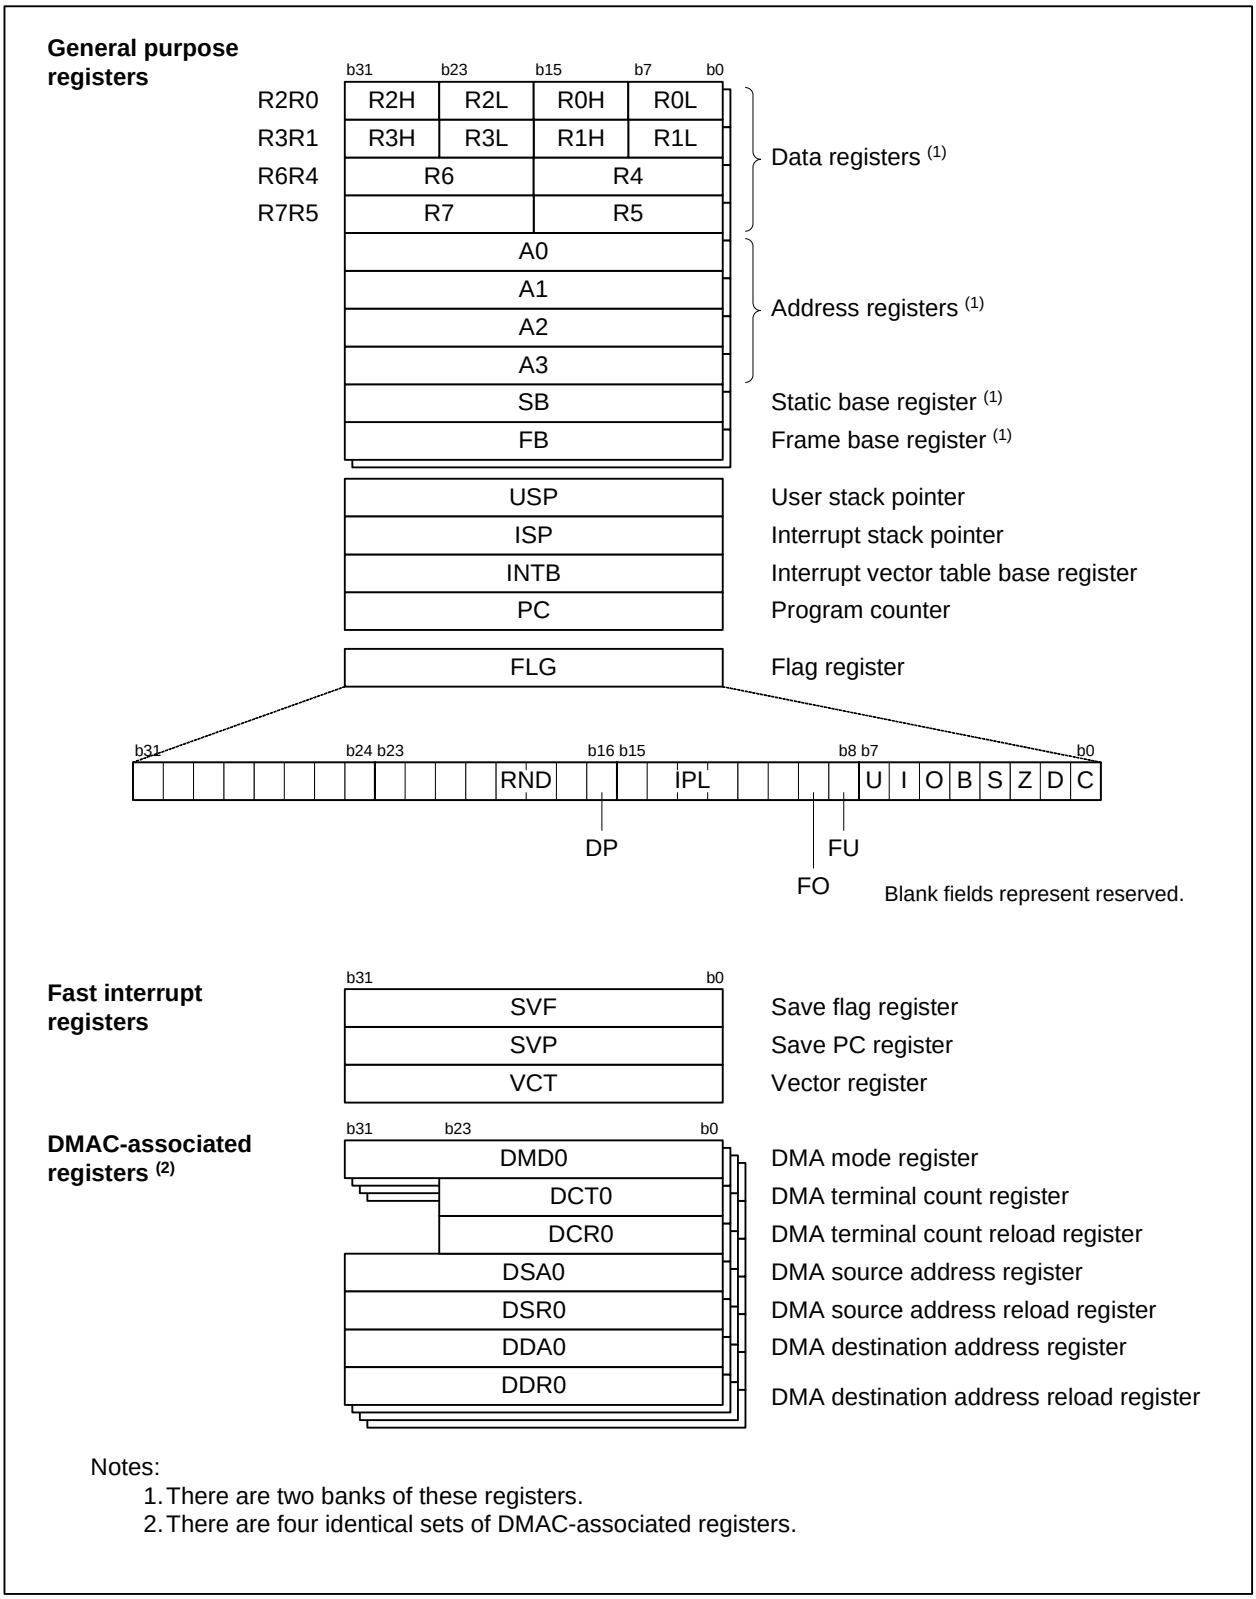
Table 1.18 Pin Specifications

Pin Names	Package		Selectable Functions		5 V Tolerant Input (3)
	144-pin	100-pin	Pull-up resistor (1)	N-channel open drain (2)	
P0_0 to P0_7	✓	✓	✓		
P1_0 to P1_7	✓	✓	✓		
P2_0 to P2_7	✓	✓	✓		
P3_0 to P3_7	✓	✓	✓		
P4_0 to P4_7	✓	✓		✓	✓
P5_0 to P5_3	✓	✓	✓		
P5_4 to P5_7	✓	✓		✓	✓
P6_0 to P6_7	✓	✓		✓	✓
P7_0 to P7_7	✓	✓		✓	✓
P8_0 to P8_3	✓	✓		✓	✓
P8_4, P8_6, P8_7	✓	✓	✓		
P9_0 to P9_3 (144-pin)	✓		✓	✓	
P9_1, P9_3 (100-pin)		✓	✓		
P9_4 to P9_7	✓	✓	✓	✓	
P10_0 to P10_7	✓	✓	✓		
P11_0 to P11_3	✓		✓	✓	
P11_4	✓		✓		
P12_0 to P12_3	✓		✓	✓	
P12_4 to P12_7	✓		✓		
P13_0 to P13_7	✓		✓		
P14_1, P14_3	✓		✓		
P14_4 to P14_6	✓		✓		
P15_0 to P15_7	✓		✓	✓	

Notes:
1. Pull-up resistors are selected in 4-pin units, but are only enabled for those pins set as input ports.
2. N-channel open drain output can be enabled on the applicable pins on a discrete pin basis.
3. 5 V tolerant input is enabled when an applicable pin is set as an input port. When it is set as an I/O port, to enable 5 V tolerant input, this pin should be set as N-channel open drain output.

2. Central Processing Unit (CPU)

The CPU contains registers as shown below. There are two register banks each consisting of registers R2R0, R3R1, R6R4, R7R5, A0 to A3, SB, and FB.



Notes:
1. There are two banks of these registers.
2. There are four identical sets of DMAC-associated registers.

Figure 2.1 CPU Registers

2.1 General Purpose Registers

2.1.1 Data Registers (R2R0, R3R1, R6R4, and R7R5)

These 32-bit registers are primarily used for transfers and arithmetic/logic operations.
Each of the registers can be divided into upper and lower 16-bit registers, e.g. R2R0 can be divided into R2 and R0, R3R0 can be divided into R3 and R1, etc.
Moreover, data registers R2R0 and R3R1 can be divided into four 8-bit data registers: upper (R2H and R3H), mid-upper (R2L and R3L), mid-lower (R0H and R1H), and lower (R0L and R1L).

2.1.2 Address Registers (A0, A1, A2, and A3)

These 32-bit registers have functions similar to data registers. They are also used for address register indirect addressing and address register relative addressing.

2.1.3 Static Base Register (SB)

This 32-bit register is used for SB relative addressing.

2.1.4 Frame Base Register (FB)

This 32-bit register is used for FB relative addressing.

2.1.5 Program Counter (PC)

This 32-bit counter indicates the address of the instruction to be executed next.

2.1.6 Interrupt Vector Table Base Register (INTB)

This 32-bit register indicates the start address of a relocatable vector table.

2.1.7 User Stack Pointer (USP) and Interrupt Stack Pointer (ISP)

Two types of 32-bit stack pointers (SPs) are provided: user stack pointer (USP) and interrupt stack pointer (ISP).
Use the stack pointer select flag (U flag) to select either the user stack pointer (USP) or the interrupt stack pointer (ISP). The U flag is bit 7 in the flag register (FLG). Refer to 2.1.8 “Flag Register (FLG)” for details.
To minimize the overhead of interrupt sequence due to less memory access, set the user stack pointer (USP) or the interrupt stack pointer (ISP) to a multiple of 4.

2.1.8 Flag Register (FLG)

This 32-bit register indicates the CPU status.

2.1.8.1 Carry Flag (C flag)

This flag becomes 1 when any of the carry, borrow, shifted-out bit, etc. is generated in the arithmetic logic unit (ALU).

2.1.8.2 Debug Flag (D flag)

This flag is only for debugging. Only set this bit to 0.

2.1.8.3 Zero Flag (Z flag)

This flag becomes 1 when the result of an operation is 0; otherwise it is 0.

2.1.8.4 Sign Flag (S flag)

This flag becomes 1 when the result of an operation is a negative value; otherwise it is 0.

2.1.8.5 Register Bank Select Flag (B flag)

This flag selects a register bank. It indicates 0 when the register bank 0 is selected, and 1 when the register bank 1 is selected.

2.1.8.6 Overflow Flag (O flag)

This flag becomes 1 if an overflow occurs in an operation; otherwise it is 0.

2.1.8.7 Interrupt Enable Flag (I flag)

This flag enables maskable interrupts. To disable maskable interrupts, set this flag to 0. To enable them, set this flag to 1. When an interrupt is accepted, the flag becomes 0.

2.1.8.8 Stack Pointer Select Flag (U flag)

To select the interrupt stack pointer (ISP), set this flag to 0. To select the user stack pointer (USP), set this flag to 1.
It becomes 0 when a hardware interrupts is accepted or when an INT instruction designated by a software interrupt number from 0 to 127 is executed.

2.1.8.9 Floating-point Underflow Flag (FU flag)

This flag becomes 1 when an underflow occurs in a floating-point operation; otherwise it is 0. It also becomes 1 when the operand has invalid numbers (subnormal numbers).

2.1.8.10 Floating-point Overflow Flag (FO flag)

This flag becomes 1 when an overflow occurs in a floating-point operation; otherwise it is 0. It also becomes 1 when the operand has invalid numbers (subnormal numbers).

2.1.8.11 Processor Interrupt Priority Level (IPL)

The processor interrupt priority level (IPL), consisting of three bits, selects a processor interrupt priority level from level 0 to 7. An interrupt is acceptable when the interrupt request level is higher than the selected IPL.
When the processor interrupt priority level (IPL) is set to 111b (level 7), all interrupts are disabled.

2.1.8.12 Fixed-point Radix Point Designation Bit (DP bit)

This bit designates the radix point. It also specifies which portion of the fixed-point multiplication result to take. It is used in the MULX instruction.

2.1.8.13 Floating-point Rounding Mode (RND)

The 2-bit floating-point rounding mode selects a rounding mode for floating-point calculation results.

2.1.8.14 Reserved

Only set this bit to 0. The read value is undefined.

2.2 Fast Interrupt Registers

The following three registers are provided to minimize the overhead of interrupt sequence. Refer to 11.4 “Fast Interrupt” for details.

2.2.1 Save Flag Register (SVF)

This 32-bit register is used to save the flag register when a fast interrupt is generated.

2.2.2 Save PC Register (SVP)

This 32-bit register is used to save the program counter when a fast interrupt is generated.

2.2.3 Vector Register (VCT)

This 32-bit register is used to indicate a jump address when a fast interrupt is generated.

2.3 DMAC-associated Registers

There are seven types of DMAC-associated registers. Refer to 13. “DMAC” for details.

2.3.1 DMA Mode Registers (DMD0, DMD1, DMD2, and DMD3)

These 32-bit registers are used to set DMA transfer mode, bit rate, etc.

2.3.2 DMA Terminal Count Registers (DCT0, DCT1, DCT2, and DCT3)

These 24-bit registers are used to set DMA transfer counting.

2.3.3 DMA Terminal Count Reload Registers (DCR0, DCR1, DCR2, and DCR3)

These 24-bit registers are used to set the reloaded values for DMA terminal count registers.

2.3.4 DMA Source Address Registers (DSA0, DSA1, DSA2, and DSA3)

These 32-bit registers are used to set DMA source addresses.

2.3.5 DMA Source Address Reload Registers (DSR0, DSR1, DSR2, and DSR3)

These 32-bit registers are used to set the reloaded value for DMA source address register.

2.3.6 DMA Destination Address Registers (DDA0, DDA1, DDA2, and DDA3)

These 32-bit registers are used to set DMA destination address.

2.3.7 DMA Destination Address Reload Registers (DDR0, DDR1, DDR2, and DDR3)

These 32-bit registers are used to set reloaded values for DMA destination address registers.

3. Memory

Figure 3.1 shows the memory map of the R32C/117 Group.
The R32C/117 Group provides a 4-Gbyte address space from 00000000h to FFFFFFFFh.

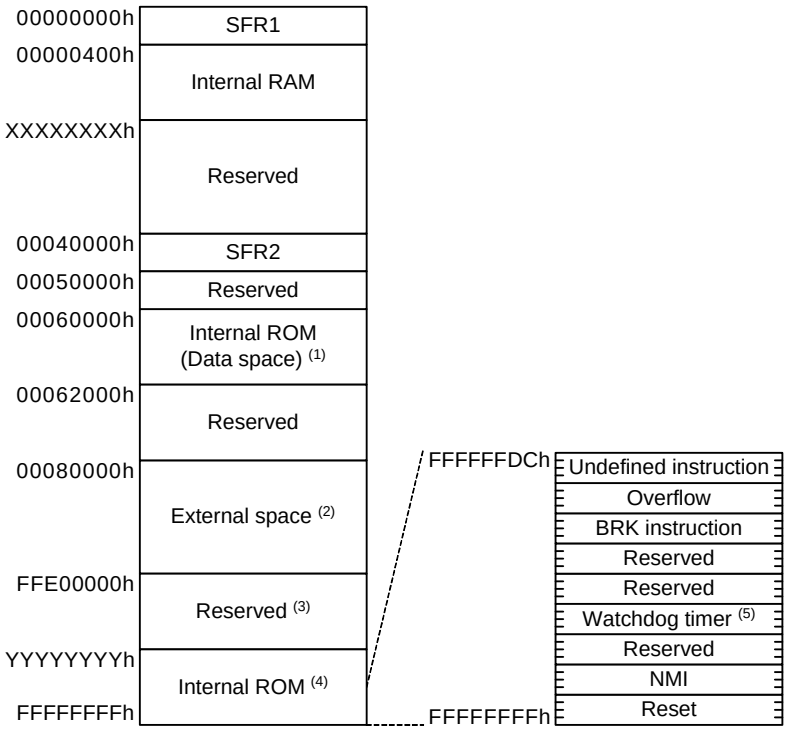
The internal ROM is mapped to the end of the memory map with the ending address fixed at FFFFFFFFh. Therefore, the 1-Mbyte internal ROM is mapped from FFF00000h to FFFFFFFFh.
The fixed interrupt vector table which contains each start address of interrupt handlers is mapped from FFFFFFDCh to FFFFFFFFh.
The internal RAM is mapped to the beginning of the memory map with the starting address fixed at 00000400h. Therefore, the 63-Kbyte internal RAM is mapped from 00000400h to 0000FFFFh. Besides being used for data storage, the internal RAM functions as a stack(s) for subroutines and/or interrupt handlers.

Special Function Registers (SFRs), which are control registers for peripheral functions, are mapped from 00000000h to 000003FFh, and from 00040000h to 0004FFFFh. Unoccupied SFR locations are reserved. No access is allowed.

In memory expansion mode or microprocessor mode, some spaces are reserved for internal use and should not be accessed.

Internal RAM	
Capacity	XXXXXXXXh
20 Kbytes	00005400h
40 Kbytes	0000A400h
48 Kbytes	0000C400h
63 Kbytes	00010000h

Internal ROM	
Capacity	YYYYYYYYh
128 Kbytes	FFFE0000h
256 Kbytes	FFFC0000h
384 Kbytes	FFFA0000h
512 Kbytes	FFF80000h
640 Kbytes	FFF60000h
768 Kbytes	FFF40000h
1 Mbyte	FFF00000h



Notes:
1. Additional two 4-Kbyte spaces (blocks A and B) for storing data are provided in the flash memory version.
2. This space can be used in memory expansion mode or microprocessor mode. Addresses from 02000000h to FDFFFFFFh are inaccessible.
3. This space is reserved in memory expansion mode. It can be external space in microprocessor mode.
4. This space can be used in single-chip mode or memory expansion mode. It can be external space in microprocessor mode.
5. The watchdog timer interrupt shares the vector table with the oscillator stop detection interrupt and low voltage detection interrupt.

Figure 3.1 Memory Map

4. Special Function Registers (SFRs)

SFRs are memory-mapped peripheral registers that control the operation of peripherals. Table 4.1 SFR List (1) to Table 4.39 SFR List (39) list the SFR details.

5. Resets

Three types of reset operations can be used to reset the MCU: hardware reset, software reset, and watchdog timer reset.

5.1 Hardware Reset

A hardware reset is generated when a low signal is applied to the $\overline{\text{RESET}}$ pin under the recommended operating conditions of supply voltage (refer to Table 5.1). When the $\overline{\text{RESET}}$ pin is driven low, all pins, and oscillators are initialized, and the main clock starts oscillating. The CPU and SFRs are initialized by a low-to-high transition on the $\overline{\text{RESET}}$ pin. Then, the CPU starts executing the program of the address indicated by the reset vector. The internal RAM is not affected by a hardware reset. However, if a hardware reset occurs during a write to the internal RAM, the content is undefined.
Figure 5.1 shows an example of the reset circuit. Figure 5.2 shows the reset sequence. Table 5.1 lists pin states while the $\overline{\text{RESET}}$ pin is held low. Figure 5.3 shows CPU register states after reset. For the SFR states after reset, refer to 4. “Special Function Registers (SFRs)”.

A. Reset on a stable supply voltage
(1) Drive the $\overline{\text{RESET}}$ pin low.
(2) Provide 20 or more clock cycle inputs into the XIN pin.
(3) Drive the $\overline{\text{RESET}}$ pin high.

B. Power-on reset
(1) Drive the $\overline{\text{RESET}}$ pin low.
(2) Raise the supply voltage to the recommended operating voltage.
(3) Insert td(P-R) ms as wait time to stabilize the internal voltage.
(4) Provide 20 or more clock cycle inputs into the XIN pin.
(5) Drive the $\overline{\text{RESET}}$ pin high.

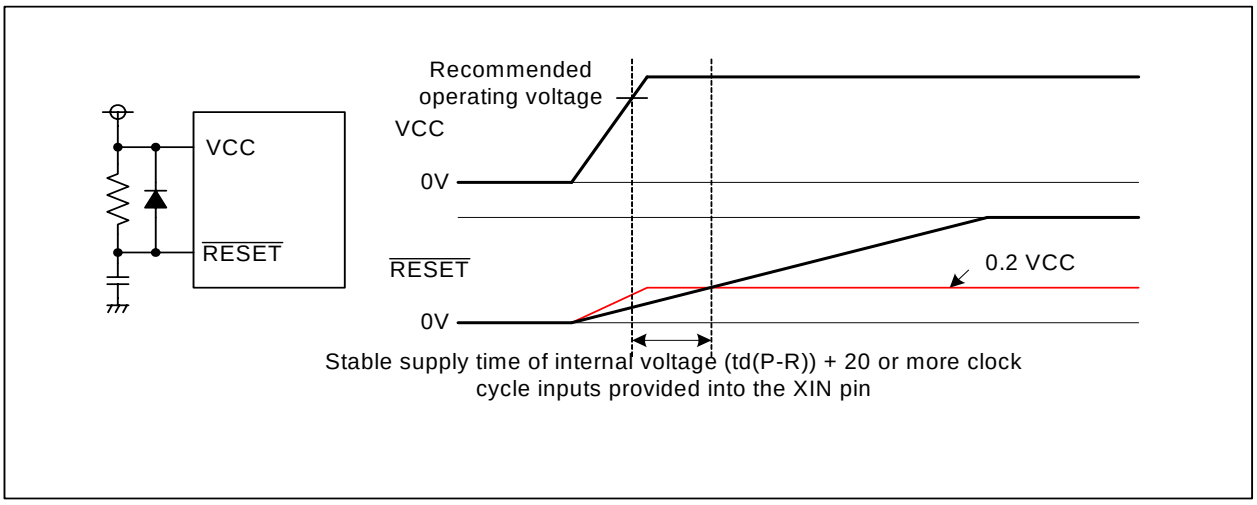

Figure 5.1 Reset Circuitry

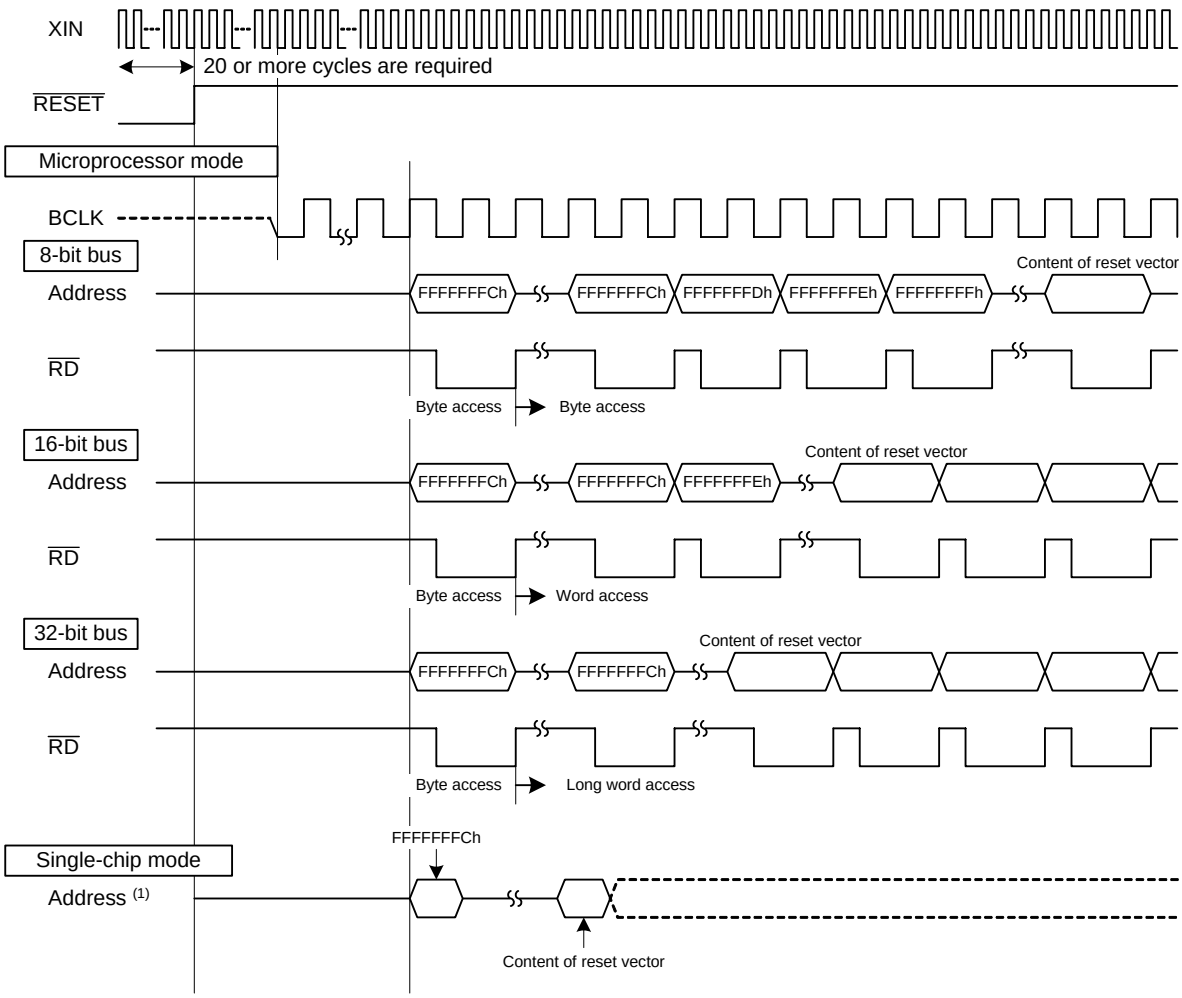

Note:
1. Address data is not output from pins in single-chip mode.

Figure 5.2 Reset Sequence

Table 5.1 Pin States while $\overline{\text{RESET}}$ Pin is Held Low (1)

Pin Name	Pin States	
	CNVSS = VSS	CNVSS = VCC
P0	Input port (high-impedance)	Inputs data
P1	Input port (high-impedance)	Input port (high-impedance)
P2, P3	Input port (high-impedance)	Output addresses (undefined)
P4_0 to P4_6	Input port (high-impedance)	Output addresses (undefined)
P4_7	Input port (high-impedance)	Outputs the $\overline{\text{CS0}}$ signal (high)
P5_0	Input port (high-impedance)	Outputs the $\overline{\text{WR}}$ signal (high)
P5_1	Input port (high-impedance)	Outputs the $\overline{\text{BC1}}$ signal (undefined)
P5_2	Input port (high-impedance)	Outputs the $\overline{\text{RD}}$ signal (high)
P5_3	Input port (high-impedance)	Outputs the BCLK (2)
P5_4	Input port (high-impedance)	Outputs the $\overline{\text{HLDA}}$ signal (output signal depends on an input signal to the $\overline{\text{HOLD}}$ pin) (2)
P5_5	Input port (high-impedance)	Inputs the $\overline{\text{HOLD}}$ signal (high-impedance)
P5_6	Input port (high-impedance)	Outputs the $\overline{\text{CS2}}$ signal (high)
P5_7	Input port (high-impedance)	Inputs the $\overline{\text{RDY}}$ signal (high-impedance)
P6 to P10	Input port (high-impedance)	Input port (high-impedance)
P11 to P15 (3)	Input port (high-impedance)	Input port (high-impedance)

Notes:
1. Whether a pull-up resistor is enabled or not is undefined until the internal voltage has stabilized.
2. State after power is on and the internal voltage has stabilized. It is undefined until the internal voltage has stabilized
3. Ports P11 to P15 are available in the 144-pin package only.

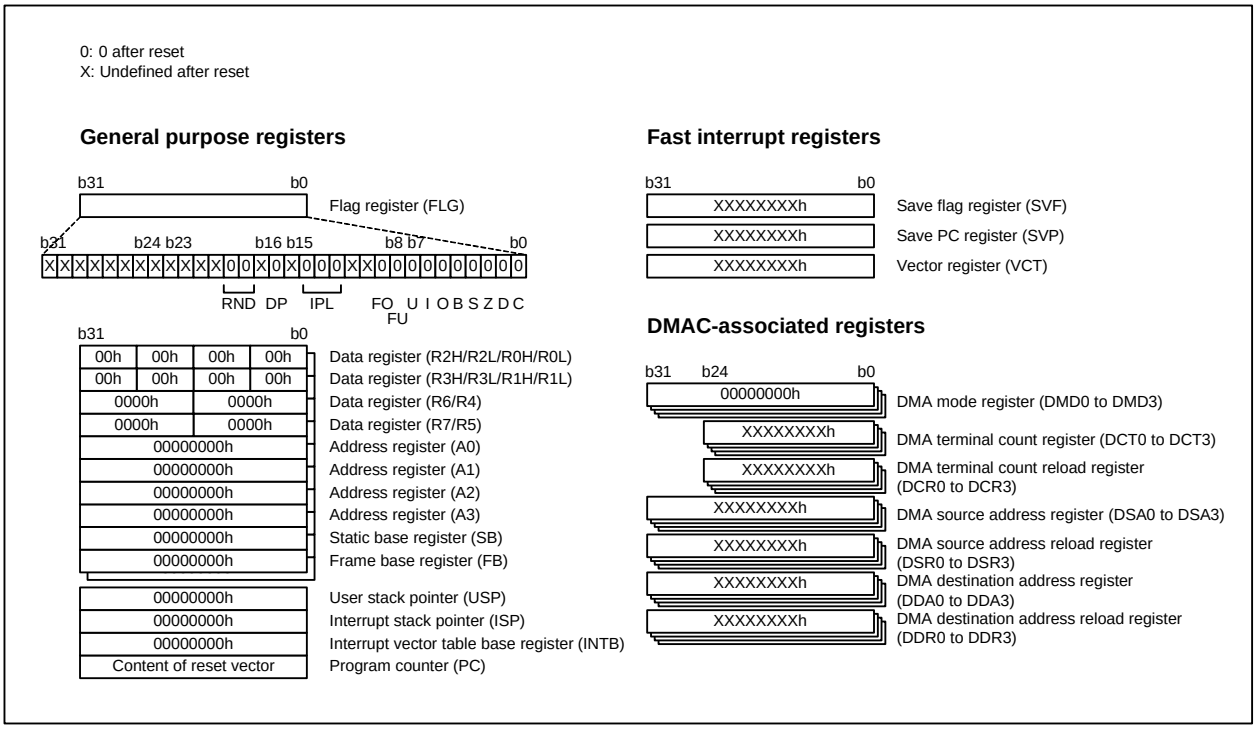

Figure 5.3 CPU Registers after Reset

5.2 Software Reset

A software reset is generated when the PM03 bit in the PM0 register is set to 1 (MCU is reset). When a software reset is released, the CPU, SFRs, and pins are initialized. Then, the CPU starts executing the program from the address indicated by the reset vector.

The PM03 bit should be set to 1 while the PLL clock is selected as the CPU clock source and the main clock oscillation is completely stable.

Processor mode remains unchanged since bits PM01 and PM00 in the PM0 register are not affected by a software reset.

5.3 Watchdog Timer Reset

A watchdog timer reset is generated when the watchdog timer underflows while the CM06 bit in the CM0 register is 1 (the MCU is reset if the watchdog timer underflows). When the watchdog timer reset is released, the CPU, SFRs, and pins are initialized. Then, the CPU starts executing the program from the address indicated by the reset vector.

Processor mode remains unchanged since bits PM01 and PM00 in the PM0 register are not affected by a watchdog timer reset.

5.4 Reset Vector

The reset vector in the R32C/100 Series is configured as shown in Figure 5.4.

The 32-bit start address of a program must be a multiple of 4. Because of this, the address always ends with two zero bits. The reset vector contains the upper 30 bits of the start address in bits 2 to 31. Bits 0 and 1 of the reset vector are used to select the external bus width in microprocessor mode.

In single-chip mode, these bits should be set to 00b.

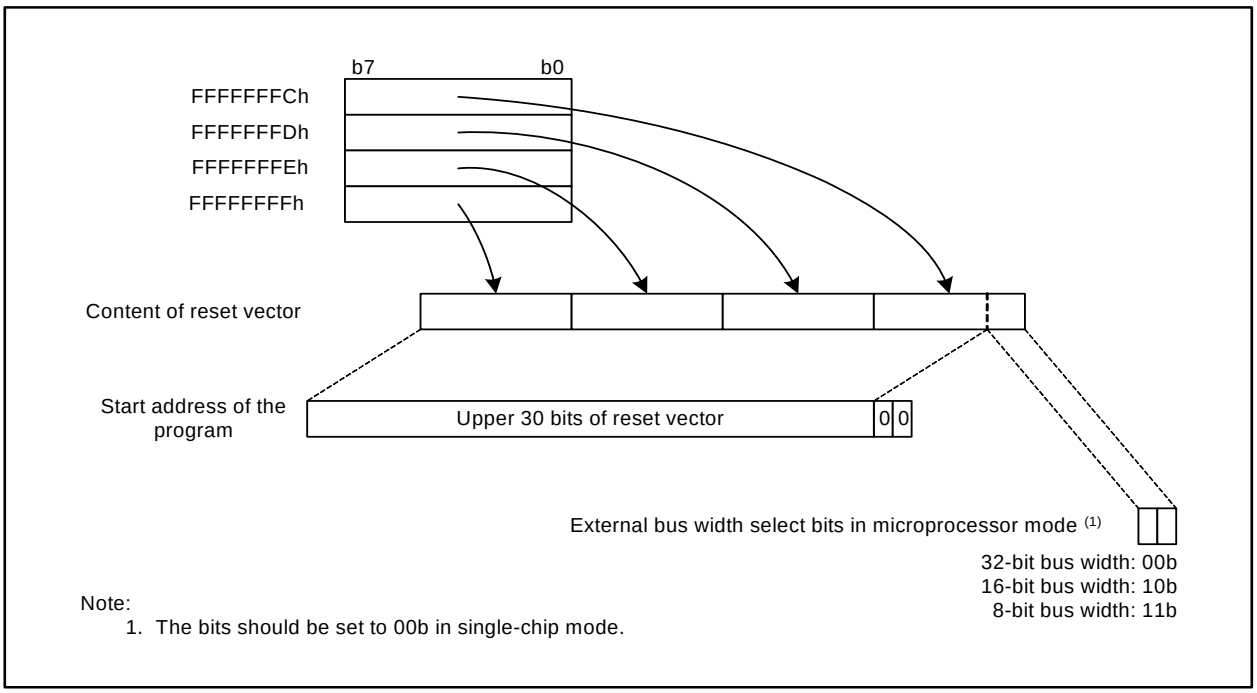

Figure 5.4 Reset Vector Configuration

6. Power Management

6.1 Voltage Regulators for Internal Logic

The supply voltage for internal logic is generated by reducing the input voltage from the VCC pin with the voltage regulators. Figure 6.1 shows a block diagram of the voltage regulators for internal logic, and Figure 6.2 shows the VRCR register.

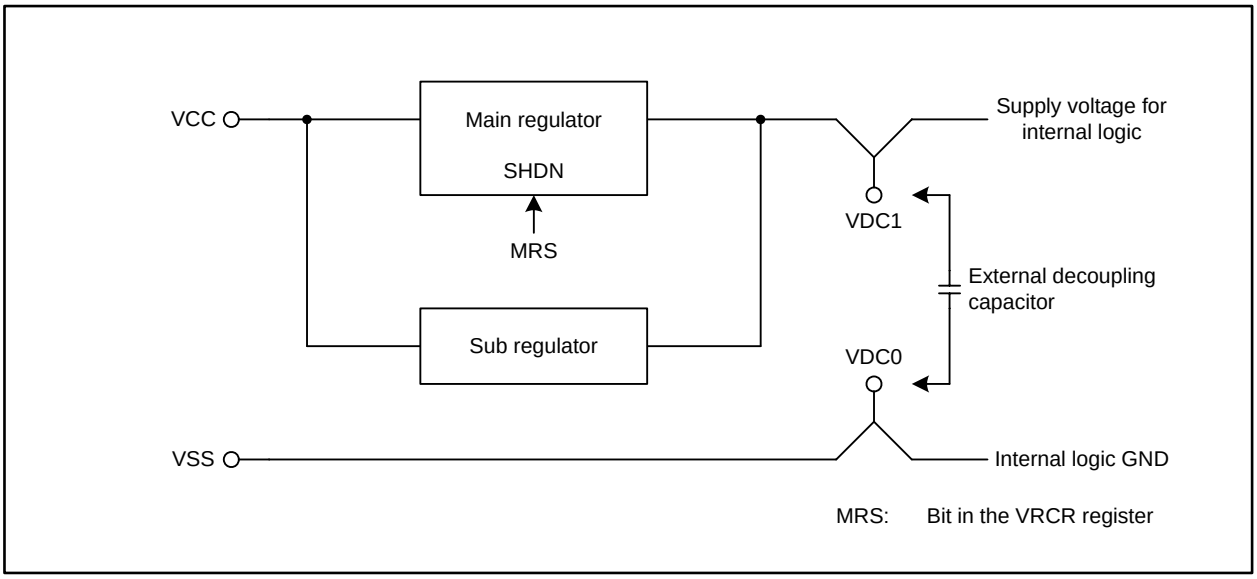

Figure 6.1 Block Diagram of Voltage Regulators for Internal Logic

Voltage Regulator Control Register (1)

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
VRCR	040060h	0000 0000b

Bit Symbol	Bit Name	Function	RW
MRS	Main Regulator Shut-down Bit (2)	0: Main regulator active 1: Main regulator stopped (3)	RW
— (b7-b1)	No register bits; should be written with 0 and read as 0		—

Notes:
1. Set the PRC31 bit in the PRCR3 register to 1 (write enabled) before rewriting this register.
2. This bit is fixed to 0 if the CM05 bit in the CM0 register is 0 (main clock oscillator enabled) or the CM10 bit in the CM1 register is 0 (PLL oscillator enabled) .
3. While the main regulator is stopped, do not rewrite the flash memory.

Figure 6.2 VRCR Register

6.1.1 Decoupling Capacitor

An external decoupling capacitor is required to stabilize internal voltage. The capacitor should be beneficially effective at higher frequencies and maintain more stable capacitance irrespective of temperature change. In general, ceramic capacitors are recommended. The capacitance varies by such conditions as operating temperature, DC bias, and aging. To select an appropriate capacitor, these conditions should be considered. Then refer to the recommended capacitor specifications listed in Table 6.1.

The traces for the capacitor and the VDC1/VDC0 pins should be as short and wide as physically possible.

Table 6.1 Recommended Capacitor Specifications

Temperature Characteristics				Rated Voltage (V)	Nominal Capacitance (µF)	Capacitance Tolerance (%)
Applicable standard		Operating temperature range (°C)	Capacitance change (%)			
B	JIS	-25 to 85	±10	6.3 or higher	4.7	±20 or better
R	JIS	-55 to 125	±15	6.3 or higher	4.7	±20 or better
X5R	EIA	-55 to 85	±15	6.3 or higher	4.7	±20 or better
X7R	EIA	-55 to 125	±15	6.3 or higher	4.7	±20 or better
X8R	EIA	-55 to 150	±15	6.3 or higher	4.7	±20 or better
X6S	EIA	-55 to 105	±22	6.3 or higher	4.7	±20 or better
X7S	EIA	-55 to 125	±22	6.3 or higher	4.7	±20 or better

6.2 Low Voltage Detector

The low voltage detector monitors the supply voltage of VCC pin.
This circuit is used to monitor the power supply upstream of the voltage regulators for internal logic and provide advanced warning that the power is about to fail. By providing a few milliseconds of advanced warning, the CPU can save any critical parameters to the flash memory and gracefully shut down.
Figure 6.3 shows a block diagram of the low voltage detector and Figure 6.4 and Figure 6.5 show registers associated with the circuit.

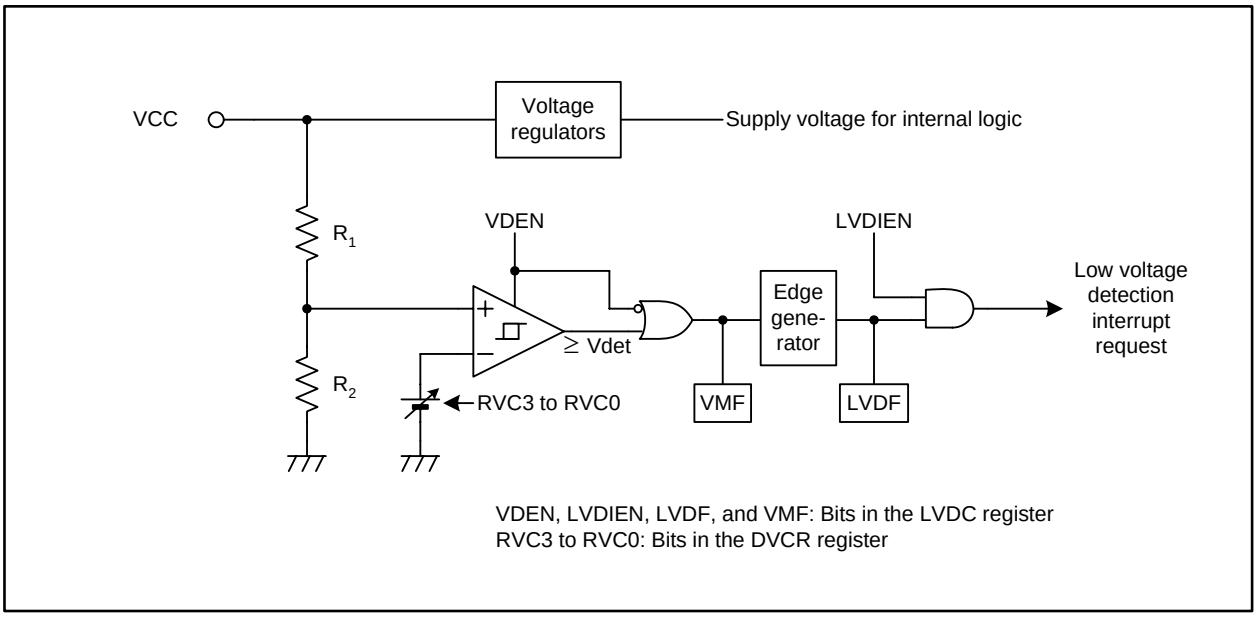

Figure 6.3 Low Voltage Detector Block Diagram

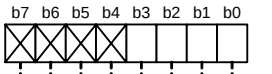
Low Voltage Detector Control Register (1)



Symbol	Address	Reset Value
LVDC	40062h	0000 XX00b

Bit Symbol	Bit Name	Function	RW
VDEN	Low Voltage Detection Enable Bit	0: Low voltage detection disabled 1: Low voltage detection enabled	RW
LVDIEN	Low Voltage Detection Interrupt Enable Bit (2)	0: Interrupt disabled 1: Interrupt enabled	RW
LVDF	Low Voltage Detection Flag (3, 4)	0: Low voltage undetected 1: Low voltage detected (Vdet passed)	RW
VMF	Voltage Monitor Flag (3)	0: VCC < Vdet 1: VCC ≥ Vdet or low voltage detection disabled	RO
— (b7-b4)	No register bits; should be written with 0 and read as 0		—

Notes:
1. Set the PRC31 bit in the PRCR3 register to 1 (write enabled) before rewriting this register.
2. Before setting this bit to 1, set the VDEN bit to 1 (low voltage detection enabled) first, and wait until the circuit has stabilized.
3. This bit is valid when the VDEN bit is set to 1 (low voltage detection enabled).
4. This bit becomes 0 if a 0 is written to (Writing a 1 to this bit has no effect).

Figure 6.4 LVDC Register

3.45 V	3.35 V	3.57 V
3.30 V	3.20 V	3.42 V

Figure 6.5 DVCR register

6.2.1 Operational State of Low Voltage Detector

The low voltage detector starts running after td(E-A) if the VDEN bit in the LVDC register is set to 1 (low voltage detection enabled).

When the input voltage to the VCC pin has dropped below Vdet(F), the VMF bit becomes 0 (VCC < Vdet) and the LVDF bit becomes 1 (low voltage detected (Vdet passed)). Then an interrupt request occurs if the LVDIEN bit is set to 1 (low voltage detection interrupt enabled). The LVDF bit should be set to 0 (low voltage undetected) by a program.

When the voltage has re-risen above Vdet(R), the VMF bit becomes to 1 (VCC ≥ Vdet) and the LVDF bit becomes 1 (low voltage detected (Vdet passed)). Then an interrupt request occurs if the LVDIEN bit is set to 1 (low voltage detection interrupt enabled).

Figure 6.6 shows the operational state of low voltage detector.

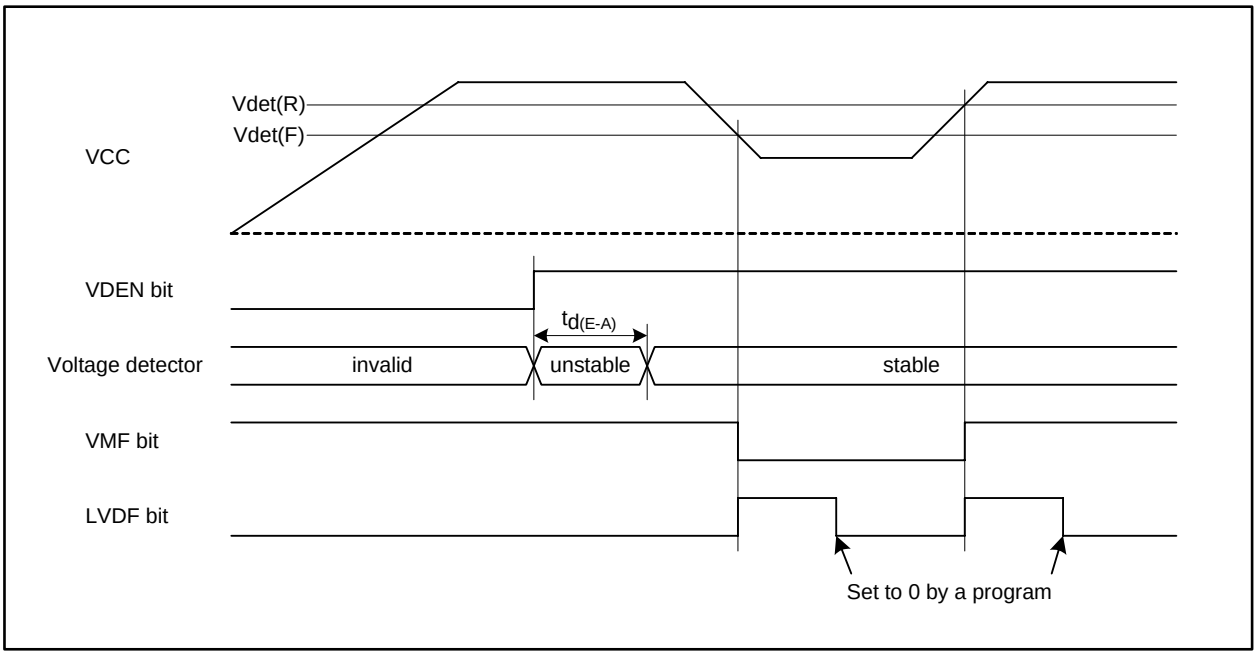

Figure 6.6 Operational State of Low Voltage Detector

6.2.2 Low Voltage Detection Interrupt

The low voltage detection interrupt occurs when the input voltage at the VCC pin rises to the Vdet(R) level and above, or falls below the Vdet(F) level if the LVDIEN bit in the LVDC register is set to 1 (low voltage detection interrupt enabled).

This interrupt shares the interrupt vector table with the watchdog timer interrupt and oscillator stop detection interrupt. In case of simultaneous use with other(s), it should be confirmed that the low voltage detection interrupt has occurred by reading the LVDF bit in the LVDC register in the interrupt handler.

The LVDF bit becomes 1 when the input voltage at the VCC pin has passed the Vdet(R) level or Vdet(F) level. When the LVDF bit changes from 0 to 1, a low voltage detection interrupt request occurs. This bit should be set to 0 (low voltage undetected) by a program.

6.2.3 An Application of Low Voltage Detector

Figure 6.7 shows an application of the low voltage detection interrupt.
The supply voltage for internal logic is generated by reducing the input voltage from the VCC pin with the voltage regulators. When the input voltage begins to fall, the internal voltage stays steady. Eventually, as the input voltage continues to fall, it begins to fall, which may affect the MCU operation. Consequently the system can be gracefully shut down from when the input voltage begins to fall until when the internal voltage begins to fall. The low voltage detection interrupt can be applied to detect the input voltage falling.

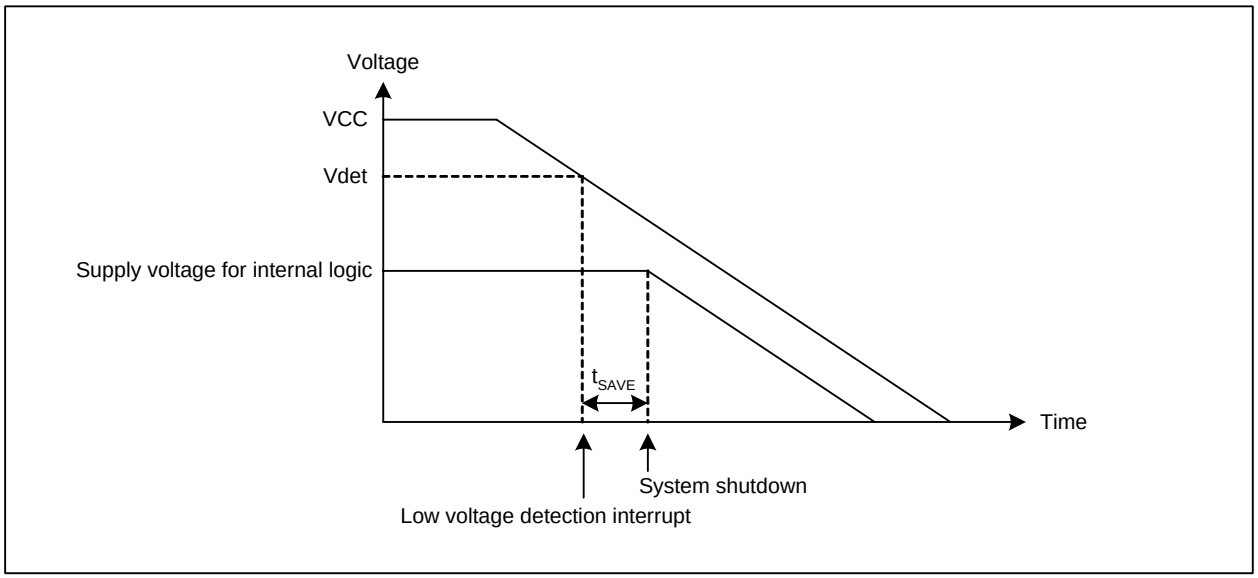

Figure 6.7 Low Voltage Detection Interrupt

7. Processor Mode

7.1 Types of Processor Modes

The R32C/100 Series supports three types of processor modes: single-chip mode, memory expansion mode, and microprocessor mode. Table 7.1 lists the characteristics of each processor mode.

Table 7.1 Processor Mode Characteristics

Processor Mode	Accessible Space	Pin State as I/O Ports
Single-chip mode	SFRs, internal RAM, internal ROM	All pins can be assigned to I/O ports or I/O pins for the peripheral functions
Memory expansion mode	SFRs, internal RAM, internal ROM, external space	Some pins are assigned to bus control pins (1)
Microprocessor mode	SFRs, internal RAM, external space	Some pins are assigned to bus control pins (1)

Note:
1. Refer to 9. “Bus” for details.

The R32C/117 Group supports two standard processor modes: single-chip mode and memory expansion mode. Microprocessor mode is optional. Contact a Renesas Electronics sales office to use this mode.

7.2 Processor Mode Setting

The processor mode to be used is selected by the CNVSS pin state and setting of bits PM01 and PM00 in the PM0 register. After a hardware reset, the operation starts in single-chip mode or microprocessor mode as shown in Table 7.2.

Table 7.2 Processor Mode after Hardware Reset

Input Level into the CNVSS Pin (1)	Processor Mode
Low	Single-chip mode
High	Microprocessor mode

Note:
1. The CNVSS pin should be connected to VCC or VSS via a resistor.

To change to memory expansion mode after starting an operation in single-chip mode, set bits PM01 and PM00 in the PM0 register to 01b (memory expansion mode). Note that the microprocessor mode, selected to start an operation, can be also changed to another mode by setting the bits mentioned above. In this case, however, the internal ROM is inaccessible in every changed mode.

The notes on changing processor mode are as follows:

1. When rewriting bits PM01 and PM00 to 01b (memory expansion mode) or 11b (microprocessor mode), do not rewrite bits PM07 to PM02 at the same time.
2. When rewriting bits PM07 to PM02, hold the setting of bits PM01 and PM00.
3. Do not change the current mode to microprocessor mode while a program in the internal ROM is being executed.
4. Do not change the current mode to single-chip mode while a program in the external space is being executed.
5. Do not change the current mode to memory expansion mode while a program in the same address as that assigned to the internal ROM is being executed.

Figure 7.1 shows the PM0 register and Figure 7.2 shows the memory map for each processor mode.

Processor Mode Register 0 (1)

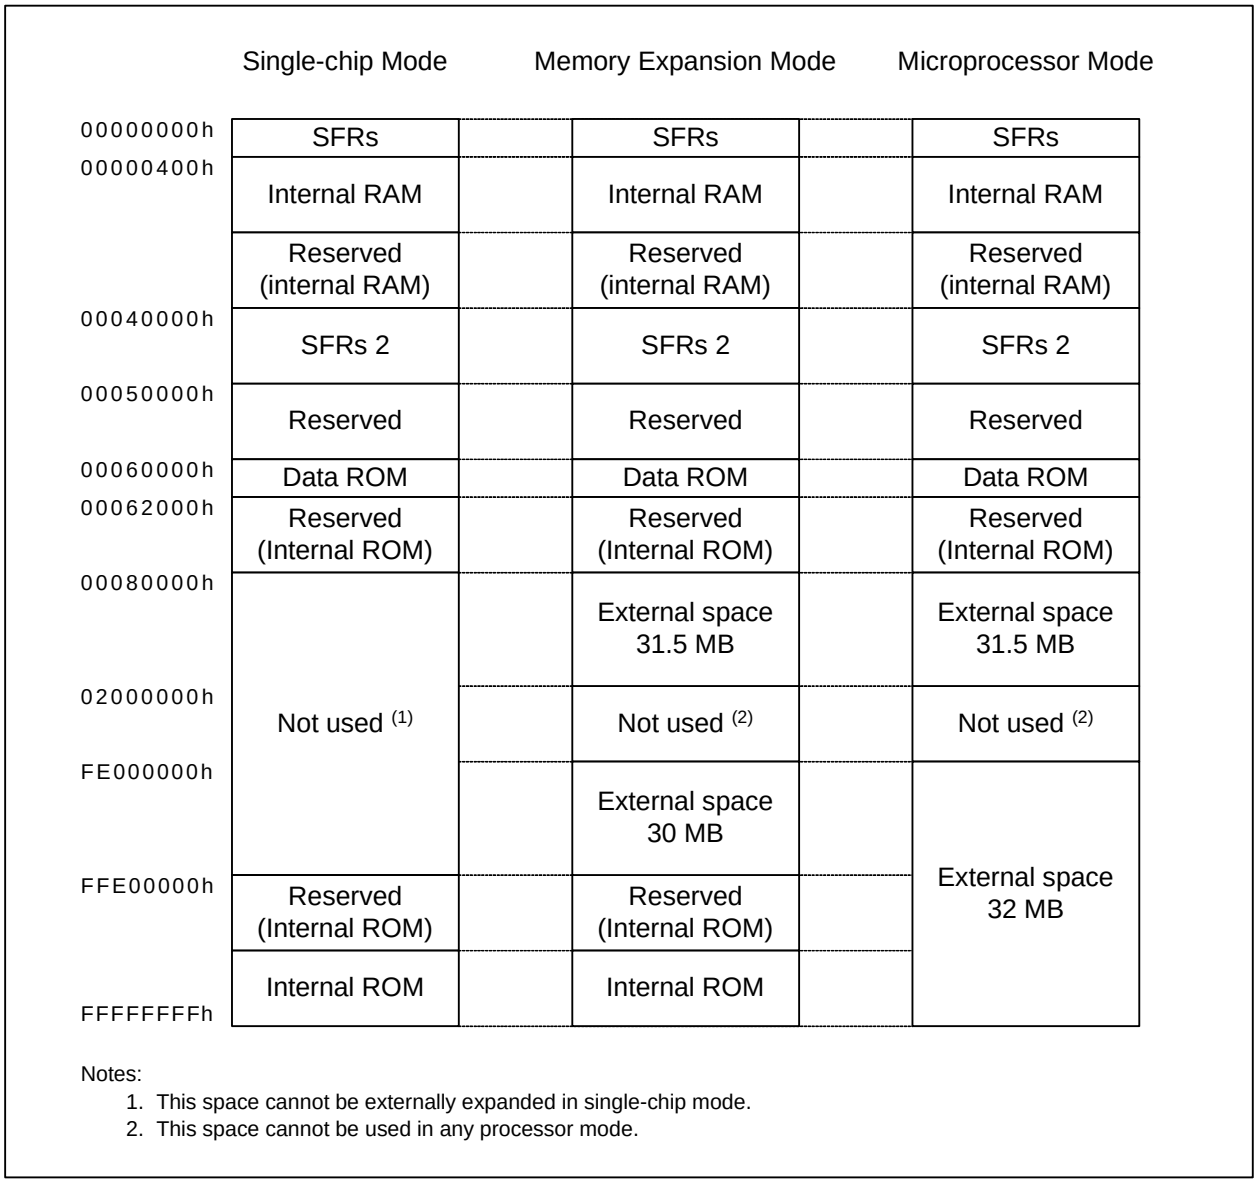
b7	b6	b5	b4	b3	b2	b1	b0
	0	0	0				

Symbol: PM0
Address: 40044h
Reset Value: 1000 0000b (CNVSS pin is held low)
0000 0011b (CNVSS pin is held high)

Bit Symbol	Bit Name	Function	RW
PM00	Processor Mode Bit (2, 3)	b1 b0 0 0 : Single-chip mode 0 1 : Memory expansion mode 1 0 : Do not use this combination 1 1 : Microprocessor mode	RW
PM01			RW
PM02	R/W Mode Select Bit	0: $\overline{RD}$ / $\overline{WR}$ / $\overline{BC0}$ / $\overline{BC1}$ / $\overline{BC2}$ / $\overline{BC3}$ 1: $\overline{RD}$ / $\overline{WR0}$ / $\overline{WR1}$ / $\overline{WR2}$ / $\overline{WR3}$	RW
PM03	Software Reset Bit	The MCU is reset when this bit is set to 1. The bit is read as 0	RW
— (b6-b4)	Reserved	Should be written with 0	RW
PM07	BCLK Output Function Select Bit (4)	0: Output BCLK (5) 1: Do not output BCLK. Select a function for the port P5_3 using bits CM01 and CM00 in the CM0 register	RW

Notes:
1. This register should be rewritten after the PRC1 bit in the PRCR register is set to 1 (write enabled).
2. The processor mode is not changed even when the PM03 bit is set to 1 (software reset).
3. Rewrite bits PM01 and PM00 with 01b or 11b after other bit(s) is/are rewritten. They should not be rewritten simultaneously.
4. In single-chip mode, the BCLK is not output even when the PM07 bit is set to 0.
   To stop clock output in memory expansion mode or microprocessor mode, the PM07 bit should be set to 1 and bits CM01 and CM00 in the CM0 register should be set to 00b (I/O port P5_3). The I/O port P5_3 outputs a low signal.
5. When the PM07 bit is set to 0 (output BCLK), bits CM01 and CM00 should be set to 00b.

Figure 7.1 PM0 Register



Notes:
1. This space cannot be externally expanded in single-chip mode.
2. This space cannot be used in any processor mode.

Figure 7.2 Memory Map of Each Processor Mode

8. Clock Generator

8.1 Clock Generator Types

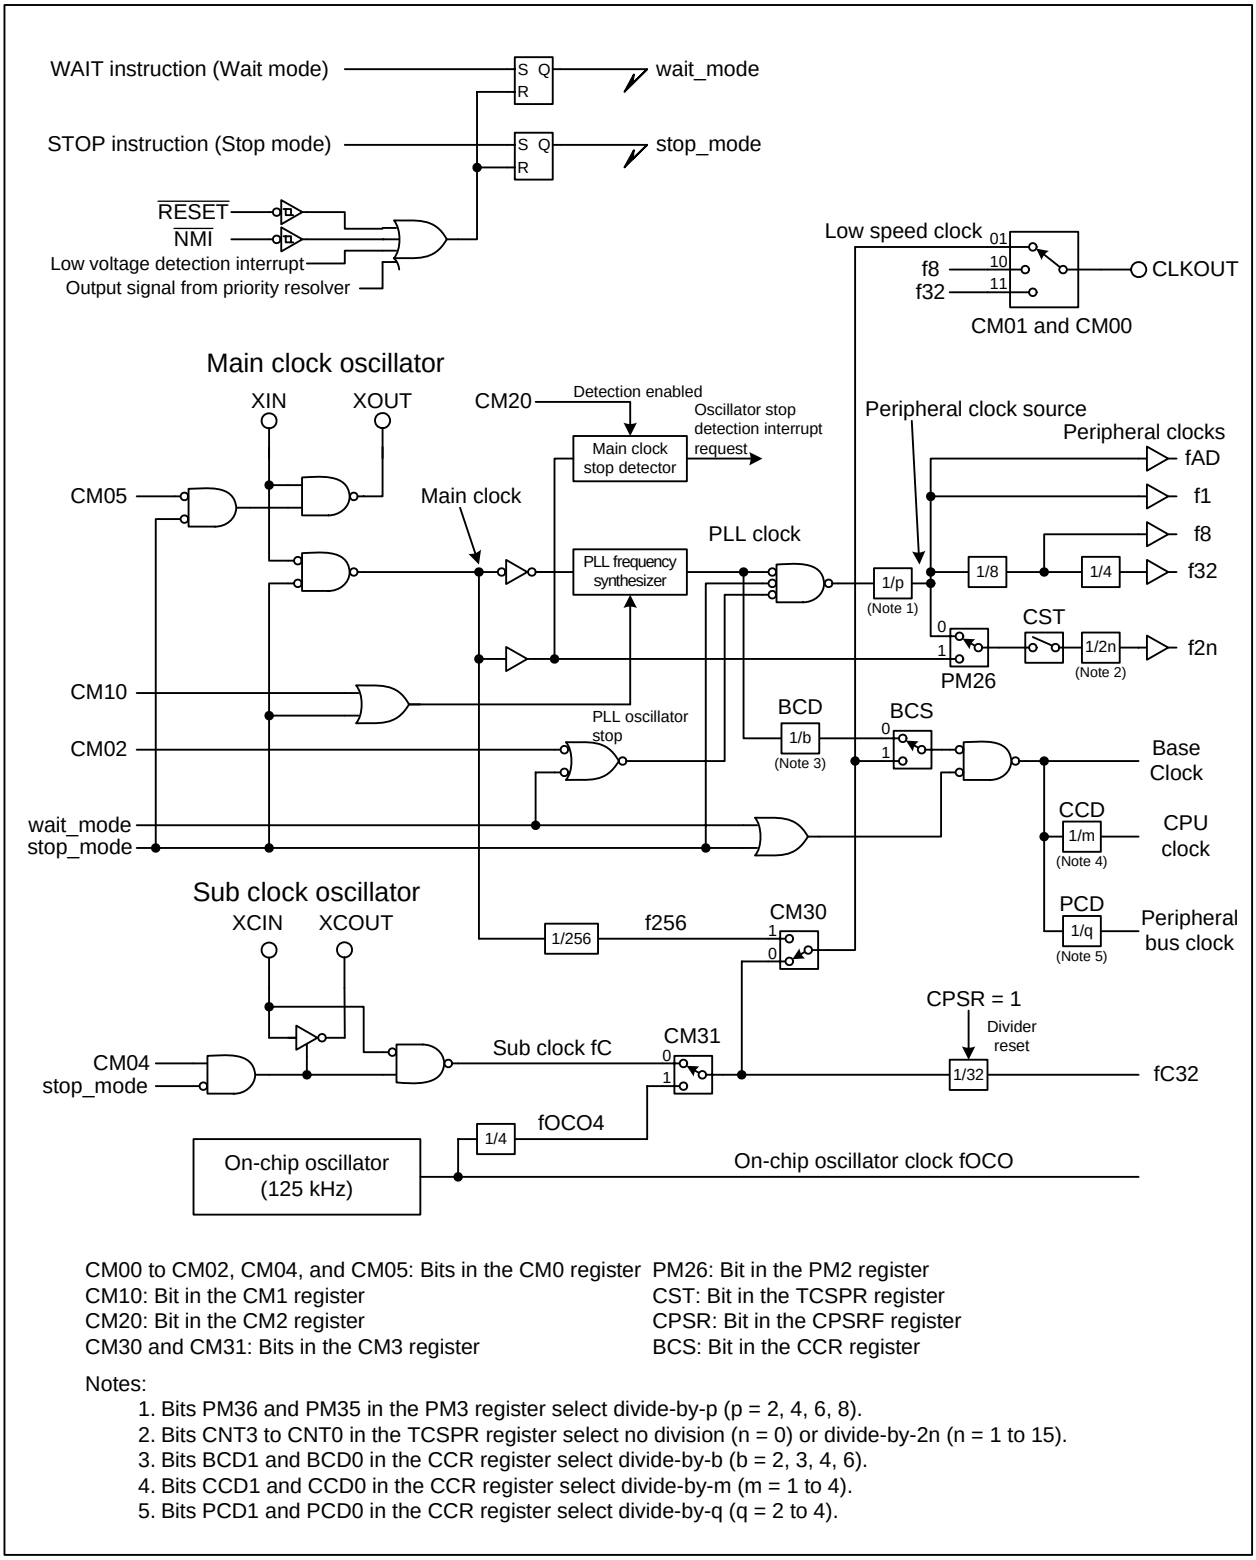
Four circuits are included to generate a system clock signal:

- Main clock oscillator
- Sub clock oscillator
- PLL frequency synthesizer
- On-chip oscillator

Table 8.1 lists specifications of clock generators. Figure 8.1 shows a block diagram of the clock generator and Figure 8.2 to Figure 8.10 show registers associated with clock control.

Table 8.1 Clock Generator Specifications

Item	Main Clock Oscillator	Sub Clock Oscillator	PLL Frequency Synthesizer	On-chip Oscillator
Used as	• PLL reference clock source • Peripheral clock source	• CPU clock source • Clock source for timers A and B	• CPU clock source • Peripheral clock source	• CPU clock source • Clock source for timers A and B
Clock frequency	4 to 16 MHz	32.768 kHz	$f_{SO(PLL)}$ or $f_{(PLL)}$	Approx. 125 kHz
Connectable oscillators or additional circuits	Ceramic resonator Crystal oscillator	Crystal oscillator	—	—
Pins for oscillators or additional circuits	XIN, XOUT	XCIN, XCOUT	—	—
Oscillator stop, Restart	Available	Available	Available	Available
Oscillator state after reset	Running	Stopped	Running	Stopped
Note	Externally generated clock can be input	Externally generated clock can be input	When the main clock oscillator stops running, the PLL frequency synthesizer oscillates at its own frequency, $f_{SO(PLL)}$	



CM00 to CM02, CM04, and CM05: Bits in the CM0 register
CM10: Bit in the CM1 register
CM20: Bit in the CM2 register
CM30 and CM31: Bits in the CM3 register
PM26: Bit in the PM2 register
CST: Bit in the TCSPR register
CPSR: Bit in the CPSRF register
BCS: Bit in the CCR register

Notes:
1. Bits PM36 and PM35 in the PM3 register select divide-by-p (p = 2, 4, 6, 8).
2. Bits CNT3 to CNT0 in the TCSPR register select no division (n = 0) or divide-by-2n (n = 1 to 15).
3. Bits BCD1 and BCD0 in the CCR register select divide-by-b (b = 2, 3, 4, 6).
4. Bits CCD1 and CCD0 in the CCR register select divide-by-m (m = 1 to 4).
5. Bits PCD1 and PCD0 in the CCR register select divide-by-q (q = 2 to 4).

Figure 8.1 Clock Generation Circuitry

Clock Control Register (1)

b7	b6	b5	b4	b3	b2	b1	b0
	0						

Symbol: CCR
Address: 0004h

Bit Symbol	Bit Name	Function	RW
BCD0	Base Clock Divide Ratio Select Bit (2)	b1 b0 0 0 : Divide-by-6 0 1 : Divide-by-4 1 0 : Divide-by-3 1 1 : Divide-by-2	RW
BCD1			RW
CCD0	CPU Clock Divide Ratio Select Bit (3)	b3 b2 0 0 : Divide-by-4 0 1 : Divide-by-3 1 0 : Divide-by-2 1 1 : No division	RW
CCD1			RW
PCD0	Peripheral Bus Clock Divide Ratio Select Bit (2, 3, 4)	b5 b4 0 0 : Do not use this combination 0 1 : Divide-by-2 1 0 : Divide-by-3 1 1 : Divide-by-4	RW
PCD1			RW
— (b6)	Reserved	Should be written with 0	RW
BCS	Base Clock Source Select Bit	0: PLL clock 1: fC, fOCO4, or f256 (5, 6)	RW

Notes:
1. Set the PRR register to AAh (write enabled) before rewriting this register.
2. The divide ratios of the base clock and peripheral bus clock should not be changed simultaneously. Otherwise, the peripheral bus clock frequency may be over the operational maximum.
3. The divide ratio of the CPU clock should be equal to or lower than that of peripheral bus clock.
4. This bit should be set only once after reset and the setting should not be changed. To rewrite this bit, the PBC register should be rewritten first.
5. To set this bit to 1, a 32-bit write access to addresses 0004h to 0007h should be performed.
6. To use these low speed clocks, select one of them by setting bits CM31 and CM30 in the CM3 register and then set the BCS bit to 1.

Figure 8.2 CCR Register

System Clock Control Register 0 (1)

b7	b6	b5	b4	b3	b2	b1	b0
0							

Symbol	Address	Reset Value
CM0	40046h	0000 1000b

Bit Symbol	Bit Name	Function	RW
CM00	Clock Output Function Select Bit (2)	b1 b0 0 0 : I/O port P5_3 0 1 : Output a low speed clock 1 0 : Output f8 1 1 : Output f32	RW
CM01			RW
CM02	Peripheral Clock Source Stop Bit (3)	0: Peripheral clock source not stopped in wait mode 1: Peripheral clock source stopped in wait mode (4)	RW
CM03	XCIN-XCOUT Drive Power Select Bit (5)	0: Low 1: High	RW
CM04	Port XC Switch Bit	0: I/O port 1: XCIN-XCOUT oscillator (6)	RW
CM05	Main Clock Oscillator (XIN-XOUT) Stop Bit (3, 7)	0: Main clock oscillator enabled 1: Main clock oscillator disabled	RW
CM06	Watchdog Timer Function Select Bit (8)	0: Watchdog timer interrupt 1: Reset (9)	RW
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. When the PM07 bit in the PM0 register is 0 (BCLK output), bits CM01 and CM00 should be set to 00b. In memory expansion mode, when the PM07 bit is 1 (the pin function is selected using bits CM01 and CM00) and bits CM01 and CM00 are set to 00b, a low is output from the P5_3 pin (This pin does not function as Port P5_3).
3. When the PM21 bit in the PM2 register is 1 (clock change disabled), neither the CM02 bit nor the CM05 bit changes, even if written to.
4. fC32 and f2n whose clock source is the main clock do not stop.
5. When entering stop mode, the CM03 bit becomes 1.
6. To set the CM04 bit to 1 (XCIN-XCOUT oscillator), bits PD8_7 and PD8_6 in the PD8 register should be set to 0 (input) and the PU25 bit in the PUR2 register should be set to 0 (pull-up resistor disabled).
7. This bit stops the main clock when entering low power mode. It cannot detect whether or not the main clock oscillator stops. When the CM05 bit is set to 1, the clock applied to the XOUT pin becomes high. Since the on-chip feedback resistor remains connected, the XIN pin is connected to the XOUT pin via the feedback resistor.
8. Set this bit before activating the watchdog timer.
9. Once this bit is set to 1, it cannot be set to 0 by a program.

Figure 8.3 CM0 Register

Bit Symbol	Bit Name	Function	RW
CM20	Oscillator Stop Detection Enable Bit (2, 3)	0: Disabled 1: Enabled	RW
— (b1)	Reserved	Should be written with 0	RW
CM22	Oscillator Stop Detection Flag (4)	0: Main clock oscillator never stopped 1: Main clock oscillator stop detected	RW
CM23	Main Clock Monitor Flag (5)	0: Main clock oscillator active 1: Main clock oscillator stopped	RO
— (b7-b4)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. This bit should be set to 0 (oscillator stop detection disabled) when f256 is selected as base clock source in low speed mode.
3. When the PM21 bit in the PM2 register is 1 (clock change disabled), the CM02 bit is not changed by a write access.
4. When a main clock oscillator stop is detected, this bit becomes 1. It can be set to 0 but not to 1. If it is set to 0 while the main clock oscillator is stopped, it can be changed to 1 after the next main clock oscillator stop is detected.
5. The main clock state should be determined by several read accesses of this bit after an oscillator stop detection interrupt is generated.

— (b7)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register. Disable all the peripheral functions that use fAD, f1, f8, f32, or f2n (when the clock source is the peripheral clock source) to rewrite this register.
2. The divide ratio should be selected so that the peripheral clock source has a frequency specified in the electrical characteristics or below.

Figure 8.10 PM3 Register

The following sections illustrate clocks generated in clock generators.

8.1.1 Main Clock

The main clock is generated by the main clock oscillator. This clock can be a clock source for the PLL reference clock or the peripheral clock. It also functions as an operating clock for the CAN module.

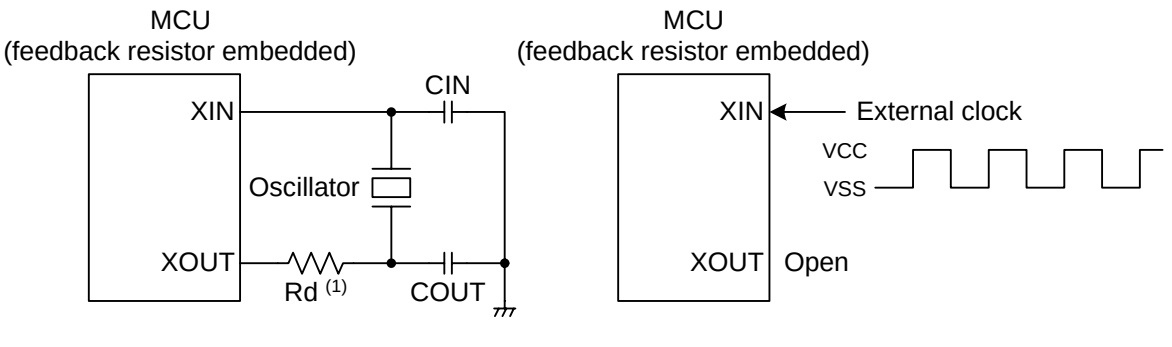
The main clock oscillator is configured with two pins, XIN and XOUT, connected by an oscillator or resonator. The circuit has an on-chip feedback resistor which is separated from the oscillator in stop mode to save power consumption. An external clock can be applied to the XIN pin in this circuit. Figure 8.11 shows an example of a main clock circuit connection.

Circuit constants may vary depending on each oscillator. They should be applied by each manufacturer's recommendations.

After a reset, the main clock oscillator is still active independently and disconnected from the PLL frequency synthesizer. A clock which the PLL frequency synthesizer self-oscillates, divided by 12, is provided to the CPU.

The setting of CM05 bit in the CM0 register to 1 (main clock oscillator disabled) enables power-saving. In this case, the clock applied to the XOUT pin becomes high. The XIN pin connected to the XOUT by an embedded feedback resistor is also driven high. When an external clock is applied to the XIN pin, the CM05 bit should not be set to 1.

All clocks, including the main clock, stop in stop mode. Refer to 8.7 "Power Control" for details.



Note:
1. A damping resistor should be placed if required. Resistance values may vary according to oscillator setting. Values recommended by the manufacturer should be set. A feedback resistor should be placed between XIN and XOUT if the manufacturer recommends placing a resistor externally.

Figure 8.11 Main Clock Circuit Connection

8.1.2 Sub Clock (fC)

The sub clock is generated by the sub clock oscillator. This clock can be a clock source for the CPU clock and a count source for timers A and B. It is output from the CLKOUT pin.

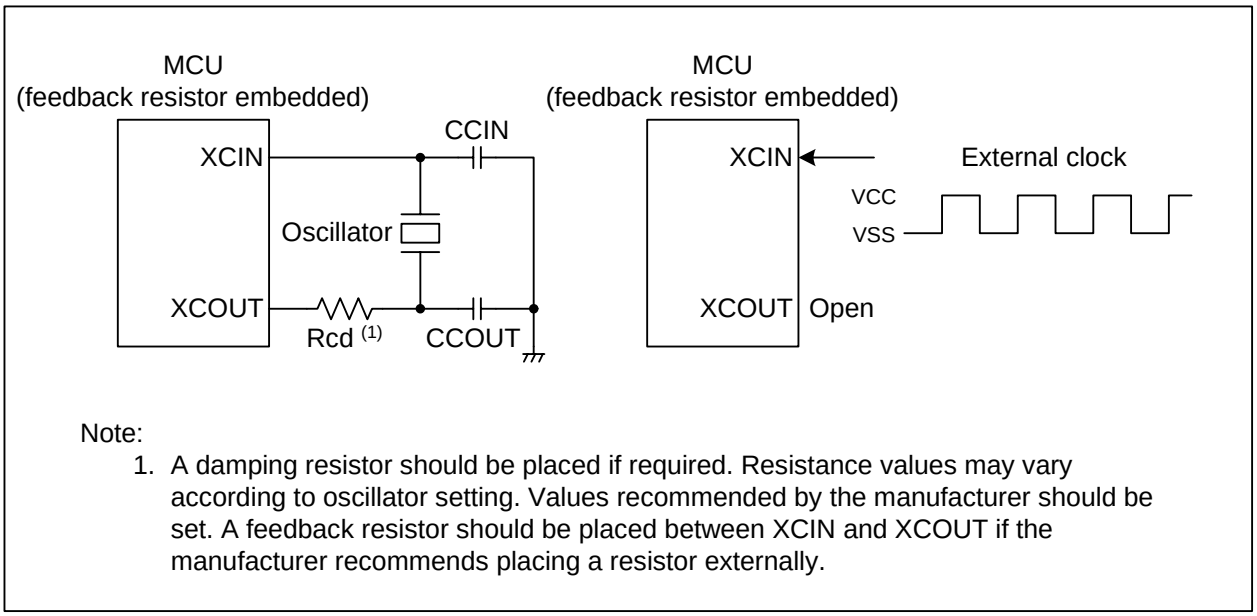
The sub clock oscillator is configured with pins XCIN and XCOUT connected by a crystal oscillator. The circuit has a on-chip feedback resistor which is separated from the oscillator in stop mode to save power consumption. An external clock can be applied to the XCIN pin. Figure 8.12 shows an example of a sub clock circuit connection. Circuit constants may vary depending on each oscillator. They should be applied by each manufacturer's recommendations.

After a reset, the sub clock oscillator is stopped. The feedback resistor is separated from the oscillator. To resume running, first set bits PD8_6 and PD8_7 in the PD8 register to 0 (input mode), and the PU25 bit in the PUR2 register to 0 (pull-up resistor unused). Then, set the CM04 bit in the CM0 register to 1 (XCIN-XCOUT oscillator).

To input an external clock to the XCIN pin, bits PD8_7 and PU25 should be set to 0, then the CM04 bit should be set to 1. The clock applied to the XCIN pin becomes a clock source for the sub clock.

When the CM3 register is set to 00h (fC selected) and the BCS bit in the CCR register is set to 1 (fC, fOCO4, or f256 is selected as base clock source) after the sub clock oscillation has stabilized, the sub clock becomes the base clock of the CPU clock and the peripheral bus clock.

All clocks, including the sub clock, stop in stop mode. Refer to 8.7 "Power Control" for details.



Note:
1. A damping resistor should be placed if required. Resistance values may vary according to oscillator setting. Values recommended by the manufacturer should be set. A feedback resistor should be placed between XCIN and XCOUT if the manufacturer recommends placing a resistor externally.

Figure 8.12 Sub Clock Circuit Connection

8.1.3 PLL Clock

The PLL clock is generated by the PLL frequency synthesizer based on the main clock. This clock can be a clock source for any clock including the CPU clock and the peripheral clock.
Figure 8.13 shows a block diagram of the PLL frequency synthesizer. Figure 8.14 and Figure 8.15 show registers PLC0 and PLC1, respectively.

Note:
1. Set the PRC2 bit in the PRCR register to 1 (write enabled) just before rewriting this register. Any interrupt or DMA transfer should not be generated between these two instructions.

Figure 8.15 PLC1 Register

In the PLL frequency synthesizer, the pulse-swallow operation is implemented. The divide ratio *m* is simply expressed by *n*×*p.* However, with the swallow counter, the divide ratio *p* is 6 in *a* out of *n*, or 5 in other cases, the actual *m* is therefore given by the formula below:

$$m = n \times p$$
$$= n \times \left(\frac{a}{n} \cdot 6 + \frac{n-a}{n} \cdot 5 \right)$$
$$= 5n + a$$

The setting range of *a* is $0 \le a < 5$, $0 \le a \le n$.

As *r* is the divide ratio of reference counter, the PLL clock has a *m/r* times the main clock (XIN) frequency.

$$\text{PLL clock frequency } f(PLL) = \frac{m}{r} \cdot \text{main clock frequency}$$
$$= \frac{5n + a}{r} \cdot \text{main clock frequency}$$

After a reset, the reference counter is divided by 16, the PLL frequency synthesizer is multiplied by 10. Since the main clock as reference clock is disconnected, the PLL frequency synthesizer may self-oscillate at its own frequency $f_{SO(PLL)}$.

Each register should be set to meet the following conditions:

-The reference clock, which is the main clock divided by *r*, should be within 2 to 4 MHz.

-The divide ratio *m* is $25 \le m \le 100$.

For the setting of registers PLC1 and PLC0, Table 8.2 below should be applied. The waiting time of $t_{LOCK(PLL)}$ is required after changing the setting until the PLL clock oscillation has stabilized while the main clock oscillation is stable.

Table 8.2 PLC1 and PLC0 Register Settings (1)

Main Clock	*r*	Reference Clock	*n*	*a*	*m*	PLC1 Register Setting	PLC0 Register Setting	*m/r*	PLL Clock

16 MHz	4	4 MHz	6	2	32	03h	45h	8	128 MHz

Note:
1. The setting of registers PLC1 and PLC0 should be done according to the list above.

8.1.4 On-chip Oscillator Clock

The on-chip oscillator clock is generated by the on-chip oscillator (OCO). This clock can be a clock source for the CPU clock and for a count source of timers A and B. This clock has a frequency of approximately 125 kHz. The clock divided by 4 can be used as base clock for the CPU clock and peripheral bus clock.

The on-chip oscillator clock is stopped after a reset. It starts running if the CM31 bit in the CM3 register is set to 1. The clock should be switched after the on-chip oscillator clock has stabilized.

8.2 Oscillator Stop Detection

This function is to detect the main clock is stopped when its oscillator stops running by external source.
When the CM20 bit in the CM2 register is set to 1 (oscillator stop detection enabled), an oscillator stop detection interrupt request is generated as soon as the main clock stops. Simultaneously, the PLL frequency synthesizer starts to self-oscillate at its own frequency. If the PLL frequency synthesizer is the clock source for CPU clock and peripheral clock, these clocks continue running.
When an oscillator stop is detected, the following bits in the CM2 register become 1:

- The CM22 bit: main clock oscillator stop detected
- The CM23 bit: main clock oscillator stopped
  (Refer to Figure 8.17 “State Transition (when the sub clock is used)”)

8.2.1 How to Use Oscillator Stop Detection

The oscillator stop detection interrupt shares vectors with the watchdog timer interrupt, and the low voltage detection interrupt. When using these interrupts simultaneously, read the CM22 bit with an interrupt handler to determine if an oscillator stop detection interrupt request has been generated.
When the main clock oscillator resumes running after an oscillator stop is detected, the PLL clock frequency may temporarily exceed the preset value before the PLL frequency synthesizer oscillation stabilizes. As soon as an oscillator stop is detected, the main clock oscillator should be stopped from resuming (set the CM05 bit in the CM0 register to 1) or the divide ratios of the base clock and peripheral clock source should be increased by a program. The respective divide ratio can be set by bits BCD1 and BCD0 in the CCR register and bits PM36 and PM35 in the PM3 register.
In low speed mode, when the main clock oscillator stops running, the oscillator stop detection interrupt request is generated, if the CM20 bit is set to 1 (oscillator stop detection enabled). The CPU clock remains running with a low speed clock source. Note that if the base clock is f256, which is the main clock divided by 256, the oscillator stop detection is disabled.
The oscillator stop detection is provided to handle main clock stop caused by external sources. To stop the main clock oscillator by a program, i.e., to enter stop mode or to set the CM05 bit to 1 (main clock oscillator disabled), the CM20 bit in the CM2 register should be set to 0 (oscillator stop detection disabled). To enter wait mode, this bit should be also set to 0.
The oscillator stop detection functions depending on the voltage of a capacitor which is being changed. More concrete terms, this function detects that the oscillator is stopped when the main clock goes lower than approximately 500 kHz. Note that if the CM22 bit is set to 0 by a program in an interrupt handler while the frequency is around 500 kHz, a stack overflow may occur caused by multiple interrupt requests.

8.3 Base Clock

Base clock is a reference clock for the CPU clock and peripheral bus clock. The base clock after a reset is the PLL clock divided by 6.
The base clock source is selected between the PLL clock and the low speed clocks which contains the sub clock (fC), on-chip oscillator clock divided by 4 (fOCO4), and main clock divided by 256 (f256).
If the PLL clock is selected, it is divided by a factor from 2, 3, 4, and 6 to become the base clock. If a low speed clock is selected, the clock itself can be the base clock.
The base clock source is set using the BCS bit in the CCR register and the divide ratio for the PLL clock is set using bits BCD1 and BCD0. Bits CM31 and CM30 in the CM3 register select a low speed clock.

8.4 CPU Clock and Peripheral Bus Clock

The CPU operating clock is referred to as the CPU clock. The CPU clock after a reset is the base clock divided by 2.

The CPU clock source is the base clock and the divide ratio is selected using bits CCD1 and CCD0 in the CCR register. The base clock divided by a factor from 2 to 4 becomes the peripheral bus clock. Its divide ratio is selected using bits PCD1 and PCD0 in the CCR register. The peripheral bus clock also functions as count source for the watchdog timer and operating clock for the CAN module.

In memory expansion mode or microprocessor mode, the peripheral bus clock as BCLK to be a reference clock for external timing generation is available as an output clock at the BCLK pin. Refer to 8.6 “Clock Output Function” for details.

When the CPU becomes out of control, to prevent the CPU clock whose clock source is the PLL clock from stopping, the CM05 bit in the CM0 register should be set to 0 (main clock oscillator enabled) and the BCS bit in the CCR register should be set to 0 (PLL clock selected as base clock source). Then the following procedures should be performed.

(1) Set the PRC1 bit in the PRCR register to 1 (write enabled to the PM2 register).
(2) Set the PM21 bit in the PM2 register to 1 (clock change disabled).

8.5 Peripheral Clock

The peripheral clock is an operating clock or a count source for peripheral functions excluding the watchdog timer and the CAN module. The source of this clock is generated by a clock, which has the same frequency as the PLL clock, divided by a factor from 2, 4, 6, and 8 according to the settings of bits PM36 and PM35 in the PM3 register. The peripheral clock is classified into three types of clock as shown below:

(1) f1, f8, f32, f2n

f1, f8, and f32 are the peripheral clock sources divided by 1, 8, and 32, respectively. The clock source for f2n is selected between the peripheral clock source and the main clock using the PM26 bit in the PM2 register. The f2n divide ratio can be set using bits CNT3 to CNT0 in the TCSPR register. (n = 1 to 15, not divided when n = 0)

f1, f8, f32, and f2n whose clock source is the peripheral clock source stop in low power mode or when the CM02 bit is set to 1 (peripheral clock source stopped in wait mode) to enter wait mode.

f1, f8, and f2n are used as a count source for timers A and B or an operating clock for the serial interface. f1 is used as an operating clock for the intelligent I/O as well.

f8 and f32 are available as output clocks at the CLKOUT pin. Refer to 8.6 “Clock Output Function” for details.

(2) fAD

fAD, which has the same frequency as peripheral clock source, is an operating clock for the A/D converter.

This clock stops in low power mode or when the CM02 bit is set to 1 (peripheral clock source stopped in wait mode) to enter wait mode.

(3) fC32

fC32, which is a sub clock divided by 32, or on-chip oscillator clock divided by 128, is used as count source for timers A and B. This clock is available when the sub clock or on-chip oscillator clock is active.

8.6 Clock Output Function

Low speed clocks, f8, and f32 are available to be output from the CLKOUT pin.
In memory expansion mode or microprocessor mode, the BCLK, that is, the peripheral bus clock which is the base clock divided by a factor from 2 to 4 is also available to be output from the BCLK pin.
Table 8.3 and Table 8.4 list the CLKOUT pin functions in single-chip mode and memory expansion mode or microprocessor mode, respectively.

Table 8.3 CLKOUT Pin Functions in Single-chip Mode

PM0 Register (1)	CM0 Register (2)		CLKOUT Pin Function
PM07	CM01	CM00	
0 or 1	0	0	I/O port P5_3
1	0	1	Output a low speed clock
1	1	0	Output f8
1	1	1	Output f32

Notes:
1. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.

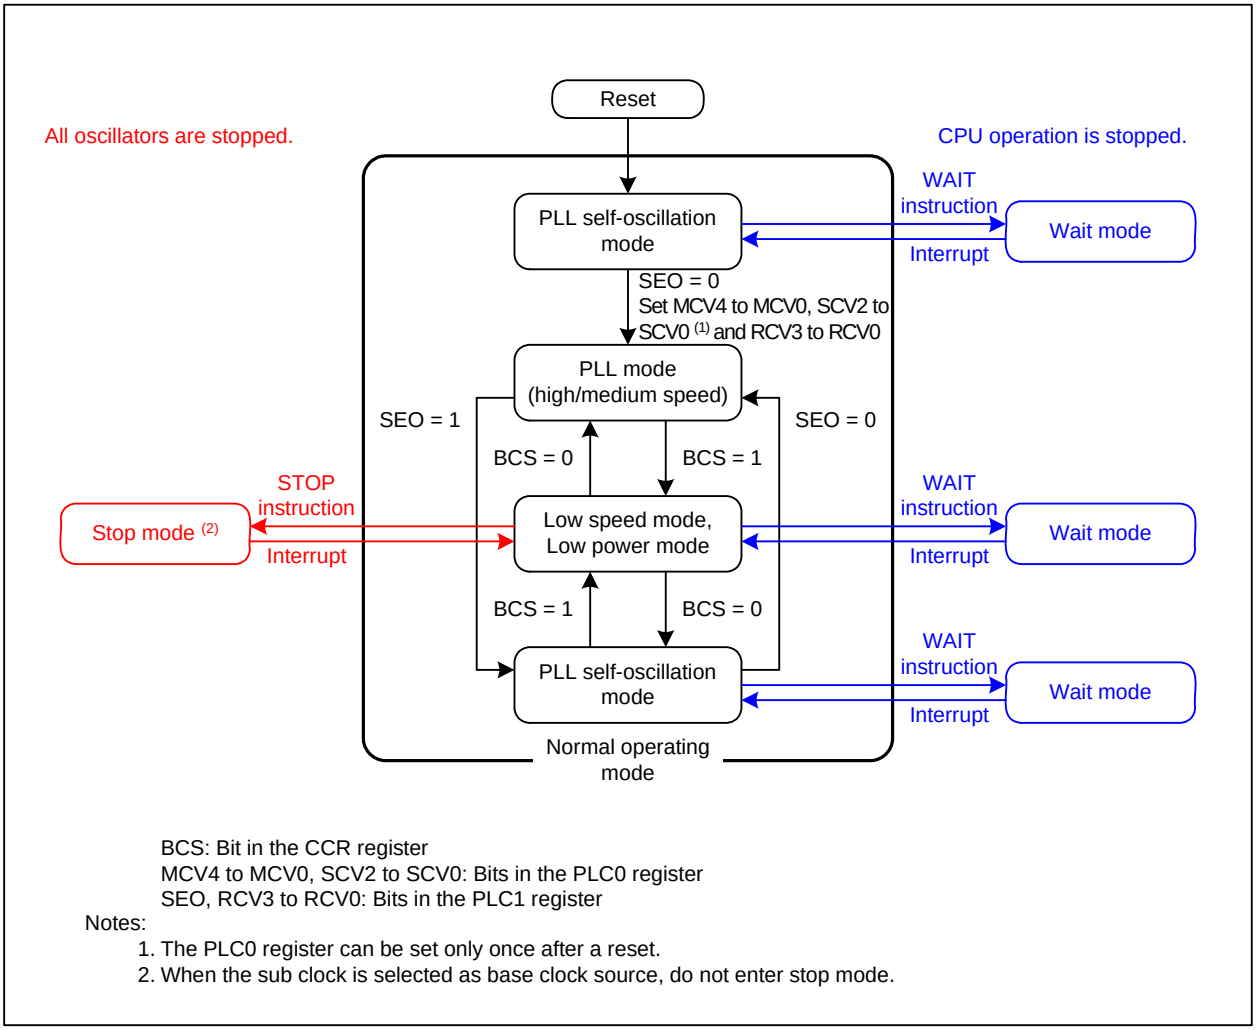
Table 8.4 CLKOUT Pin Functions in Memory Expansion Mode or Microprocessor Mode

PM0 Register (1)	CM0 Register (2)		CLKOUT Pin Function
PM07	CM01	CM00	
0	0 (3)	0 (3)	Output BCLK
1	0	0	Output low (no function as P5_3)
1	0	1	Output a low speed clock
1	1	0	Output f8
1	1	1	Output f32

Notes:
1. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.
3. When the PM07 bit is set to 0 (BCLK output), set bits CM01 and CM00 to 00b (I/O port P5_3).

8.7 Power Control

Power control contains three modes: wait mode, stop mode, and normal operating mode.
The name “normal operating mode” is used restrictively in this chapter, and it indicates all other modes except wait mode and stop mode. Figure 8.16 shows a block diagram of the state transition in normal operating mode, stop mode, and wait mode.



BCS: Bit in the CCR register
MCV4 to MCV0, SCV2 to SCV0: Bits in the PLC0 register
SEO, RCV3 to RCV0: Bits in the PLC1 register

Notes:
1. The PLC0 register can be set only once after a reset.
2. When the sub clock is selected as base clock source, do not enter stop mode.

Figure 8.16 State Transition in Stop Mode and Wait Mode

8.7.1 Normal Operating Mode

Normal operating mode is classified into the five modes shown below.
In normal operating mode, the CPU clock and peripheral clock are provided to operate the CPU and peripheral functions. Power consumption is controlled by the CPU clock frequency. The higher the CPU clock frequency is, the more processing power increases. The lower the CPU clock frequency is, the less power consumption is required. Power consumption can be reduced by stopping oscillators that are not being used.

(1) PLL Mode (high speed mode)

In this mode, the PLL clock is selected as the base clock source, and the main clock is provided as the reference clock source for the PLL frequency synthesizer. High speed mode enables the CPU to operate at the maximum operating frequency. The PLL clock divided by 2 becomes the base clock. The base clock frequency should be identical to that of the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

(2) PLL Mode (medium speed mode)

This mode indicates all modes in PLL mode except high speed mode. The PLL clock divided by 2, 3, 4, or 6 becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

(3) Low Speed Mode

In this mode, a low speed clock is used as the base clock source. The low speed clock becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

(4) Low Power Mode

This is a state where the main clock oscillator and the PLL frequency synthesizer are stopped after switching to low speed mode. The sub clock or the on-chip oscillator clock divided by 4 becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fC32, which is the only peripheral clock available, can be used as the count source for timers A and B. By setting the MRS bit in the VRCR register to 1 (main regulator stopped), this mode consumes even less power than the modes above.

(5) PLL Self-oscillation Mode

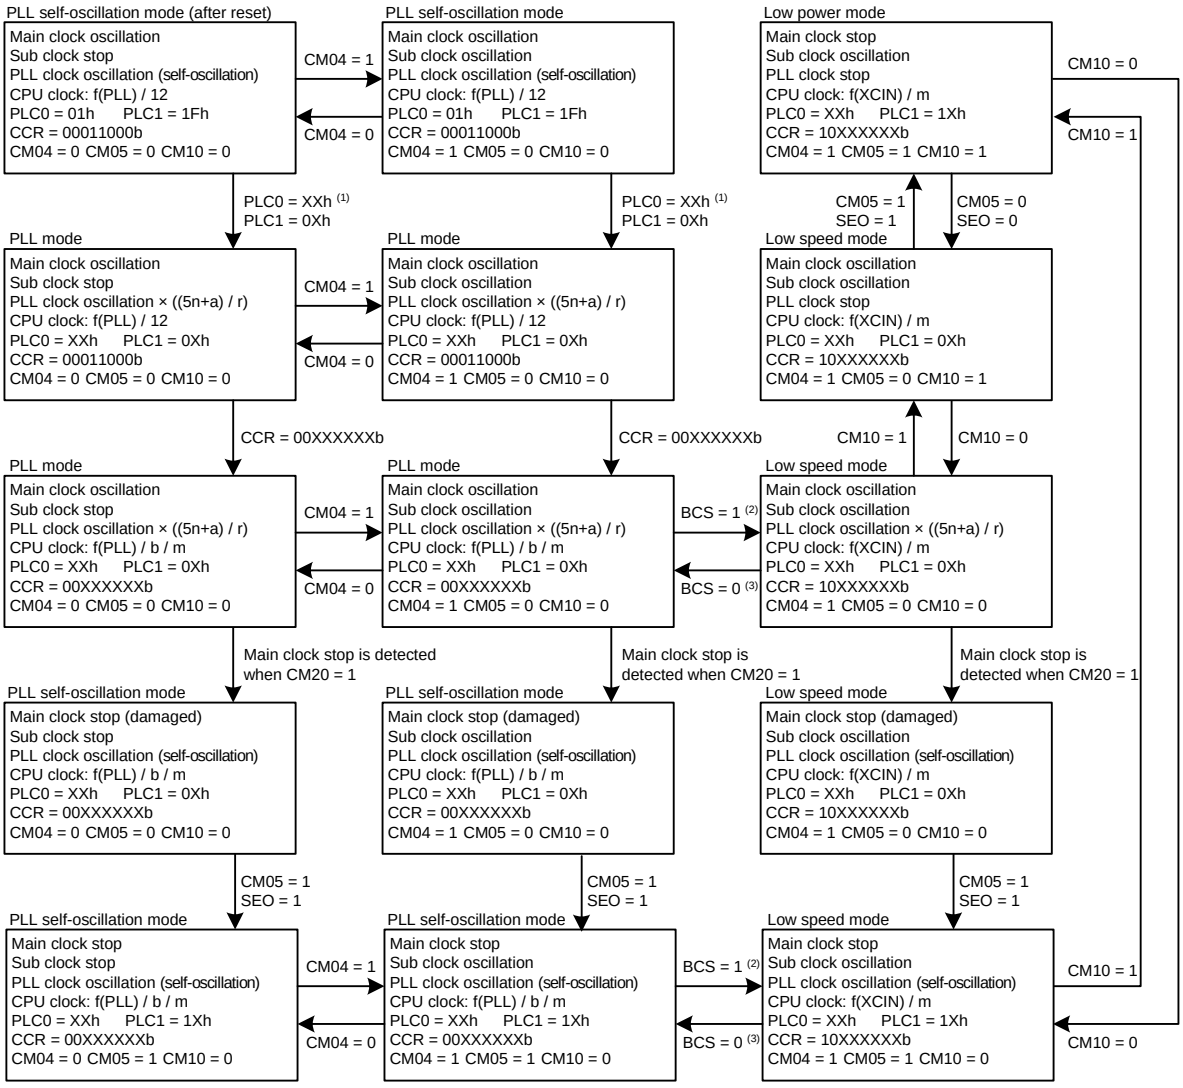
In this mode, the PLL clock is selected as the base clock source, and the main clock is not provided as the reference clock source for the PLL frequency synthesizer. The PLL frequency synthesizer self-oscillates at its own frequency. The PLL clock divided by 2, 3, 4, or 6 becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

The state transition within normal operating mode can be very complicated; therefore only the block diagrams of typical state transitions are shown. Figure 8.17 to Figure 8.19 show block diagrams of the respective state transition: state when the sub clock is used, state when the main clock divided by 256 is used, and state when the on-chip oscillator clock is used. As for the state transitions other than the above, setting of each register and the usage notes below can be used as references.

- PLL can be switched from PLL oscillating to self-oscillating by setting the SEO bit in the PLC1 register to 1. Set the SEO bit to 1 (self-oscillating) before setting the CM05 bit in the CM0 register to 0 (main clock oscillator disabled) to stop the main clock.
- The divide ratio of the clock should be increased and the frequency should be decreased by using bits BCD1 to BCD0 in the CCR register or bits PM36 to PM35 in the PM3 register before setting the SEO bit to 0 (PLL oscillating) in order to switch back PLL self-oscillation mode to PLL mode. Set back the settings of bits BCD1 to BCD0 and bits PM36 to PM35 once PLL oscillation is stabilized after setting the SEO bit to 0.
- Before switching the CPU clock to another, that clock should be stabilized. In particular, the sub clock oscillator may require more time to stabilize (1), therefore, certain waiting time to switch should be taken by a program immediately after turning the MCU ON or exiting stop mode.

Note:

1. Contact the oscillator manufacturer for oscillator stabilization time.



: An arrow indicates a one-way transition between modes. No transition should be made unless indicated.

Notes:
1. The PLC0 register can be set only once after a reset.
2. This clock should be switched after the PLL clock oscillation is fully stabilized.

Figure 8.19 State Transition (when the on-chip oscillator clock is used)

8.7.2 Wait Mode

In wait mode, due to the base clock stop, the CPU clock and peripheral bus clock stop running as well. The CPU and watchdog timer, operated by the CPU clock, also stop. Since the main clock, sub clock, PLL clock, and on-chip oscillator clock continue running, peripheral functions using these clocks also continue operating.

8.7.2.1 Peripheral Clock Source Stop Function

When the CM02 bit in the CM0 register is set to 1 (peripheral clock source stopped in wait mode), peripheral clocks f1, f8, f32, f2n (when the clock source is the peripheral clock source), and fAD stop running, which enables power saving. fC32 and f2n (when the clock source is the main clock) do not stop running.

8.7.2.2 Entering Wait Mode

To enter wait mode, the following procedures should be done before the WAIT instruction is executed.

- Initial setting
  Set the interrupt priority level to 7 for resuming (bits RLVL2 to RLVL0 in registers RIPL1 and RIPL2). Then set each interrupt request level.
- Steps before entering wait mode
  (1) Set the I flag to 0.
  (2) Set the interrupt request level for each interrupt source (interrupt number from 1 to 127) to 0, if its interrupt request level is not 0.
  (3) Perform a dummy read of any of the interrupt control registers.
  (4) Set the processor interrupt priority level (IPL) in the flag register to 0.
  (5) Enable interrupts temporarily by executing the following instructions:
  FSET I
  NOP
  NOP
  FCLR I
  (6) Set the interrupt request level for the interrupt to exit wait mode.
  Do not rewrite the interrupt control register after this step.
  (7) Set the IPL in the flag register.
  (8) Set the interrupt priority level for resuming to the same level as the IPL.
  Interrupt request level for the interrupt to exit wait mode > IPL = Interrupt priority level for resuming
  (9) Set the CM20 bit in the CM2 register to 0 (oscillator stop detection disabled) when the oscillator stop detection is used.
  (10) Enter either PLL self-oscillation mode, low speed mode, or low power mode.
  (11) Set the I flag to 1.
  (12) Execute the WAIT instruction.
- After exiting wait mode
  Set the interrupt priority level for resuming to 7 immediately after exiting wait mode.

8.7.2.3 Pin State in Wait Mode

Table 8.5 lists pin state in wait mode.

Table 8.5 Pin State in Wait Mode

Pin		Memory Expansion Mode/ Microprocessor Mode	Single-Chip Mode
Address bus, Data bus, $\overline{CS0}$ to $\overline{CS3}$, $\overline{BC0}$ to $\overline{BC3}$		The state immediately before entering wait mode is held	—
$\overline{RD}$, $\overline{WR}$, $\overline{WR0}$ to $\overline{WR3}$		High	—
$\overline{HLDA}$, BCLK		High	—
ALE		High	—
Ports		The state immediately before entering wait mode is held	
DA0, DA1		The state immediately before entering wait mode is held	
CLKOUT	When a low speed clock is selected	The clock is output	
	When f8 or f32 is selected	The clock is output when the CM02 bit in the CM0 register is set to 0 (no peripheral clock source stopped in wait mode). The state immediately before entering wait mode is held when the CM02 bit is set to 1 (peripheral clock source stopped in wait mode)	

8.7.2.4 Exiting Wait Mode

Wait mode is exited by the hardware reset, an NMI, or peripheral interrupts assigned to software interrupt numbers from 0 to 63.

To exit wait mode by either the hardware reset or an NMI, without using peripheral interrupts, bits ILVL2 to ILVL0 for the peripheral interrupts should be set to 000b (interrupt disabled) before executing the WAIT instruction.

The CM02 bit setting in the CM0 register affects the peripheral interrupts. When the CM02 bit is set to 0 (peripheral clock source not stopped in wait mode), peripheral interrupts for software interrupt numbers from 0 to 63 can be used to exit wait mode. When this bit is set to 1 (peripheral clock source stopped in wait mode), peripheral functions operated using clocks (f1, f8, f32, f2n whose clock source is the peripheral clock source, and fAD) generated by the peripheral clock source stop operating. Therefore, the peripheral interrupts cannot be used to exit wait mode. However, peripheral functions operated using clocks which are independent from the peripheral clock source (fC32, external clock, and f2n whose clock source is the main clock) do not stop operating. Thus, interrupts generated by peripheral functions and assigned to software interrupt numbers from 0 to 63 can be used to exit wait mode.

The CPU clock used when exiting wait mode by the peripheral interrupts or an NMI is the same clock used when the WAIT instruction is executed.

Table 8.6 lists interrupts to be used to exit wait mode and usage conditions.

Table 8.6 Interrupts to Exit Wait Mode and Usage Conditions

Interrupt	When the CM02 bit = 0	When the CM02 bit = 1
NMI	Available	Available
External interrupt (1)	Available	Available
Key input interrupt	Available	Available
Low voltage detection interrupt	Available	Available
Timer A interrupt Timer B interrupt	Available in any mode	Available in event counter mode, or when the count source is fC32 or f2n of which clock source is the main clock
Serial interface interrupt (2)	Available when the internal or external clock is used	Available when the external clock or f2n (when the clock source is the main clock) is used
A/D conversion interrupt	Available in single mode or single-sweep mode	Should not be used
Intelligent I/O interrupt	Available	Should not be used
I^2C-bus interface interrupt	Available	Should not be used
I^2C-bus line interrupt	Available	Available
CAN wake-up interrupt	Available	Available

Notes:
1. INT6 to INT8 are available in the intelligent I/O interrupt only.
2. UART7 and UART8 are excluded.

8.7.3 Stop Mode

In stop mode, all of the clocks, except for those that are protected, stop running. That is, the CPU and peripheral functions, operated by the CPU clock and peripheral clock, also stop. This is the most power-saving mode.

8.7.3.1 Entering Stop Mode

To enter stop mode, the following procedures should be done before the STOP instruction is executed.

- Initial setting
  Set the interrupt priority level for resuming (bits RLVL2 to RLVL0 in registers RIPL1 and RIPL2) to 7. Then set each interrupt request level.
- Steps before entering stop mode
  (1) Set the I flag to 0.
  (2) Set the interrupt request level for each interrupt source (interrupt number from 1 to 127) to 0, if the interrupt request level is not 0.
  (3) Perform a dummy read of any of the interrupt control registers.
  (4) Set the processor interrupt priority level (IPL) in the flag register to 0.
  (5) Enable interrupts temporarily by executing the following instructions:
  FSET I
  NOP
  NOP
  FCLR I
  (6) Set the interrupt request level for the interrupt to exit stop mode.
  Do not rewrite the interrupt control register after this step.
  (7) Set the IPL in the flag register.
  (8) Set the interrupt priority level for resuming to the same level as the IPL.
  Interrupt request level for the interrupt to exit stop mode > IPL = Interrupt priority level for resuming
  (9) Set the CM20 bit in the CM2 register to 0 (oscillator stop detection disabled) when the oscillator stop detection is used.
  (10) Change the base clock to either the main clock divided by 256 (f256) or the on-chip oscillator clock divided by 4 (fOCO4).
  (11) Set the I flag to 1.
  (12) Execute the STOP instruction.
- After exiting stop mode
  Set the interrupt priority level for resuming to 7 immediately after exiting stop mode.

8.7.3.2 Pin State in Stop Mode

Table 8.7 lists pin state in stop mode.

Table 8.7 Pin State in Stop Mode

Pin		Memory Expansion Mode/ Microprocessor Mode	Single-Chip Mode
Address bus, Data bus, $\overline{CS0}$ to $\overline{CS3}$, $\overline{BC0}$ to $\overline{BC3}$		The state immediately before entering stop mode is held	—
$\overline{RD}$, $\overline{WR}$, $\overline{WR0}$ to $\overline{WR3}$		High	—
$\overline{HLDA}$, BCLK		High	—
ALE		High	—
Ports		The state immediately before entering stop mode is held	
DA0, DA1		The state immediately before entering stop mode is held	
CLKOUT	When a low speed clock is selected	High	
	When f8 or f32 is selected	The state immediately before entering stop mode is held	
XIN		High-impedance	
XOUT		High	
XCIN, XCOUT		High-impedance	

8.7.3.3 Exiting Stop Mode

Stop mode is exited by the hardware reset, an NMI, low voltage detection interrupt, or peripheral interrupts assigned to software interrupt numbers from 0 to 63.

To exit stop mode by either the hardware reset or an NMI, without using peripheral interrupts, bits ILVL2 to ILVL0 for the peripheral interrupts should be set to 000b (interrupt disabled) before executing the STOP instruction.

The CPU clock used when exiting stop mode by the peripheral interrupts or an NMI is the same clock used when the STOP instruction is executed.

Table 8.8 lists interrupts to be used to exit stop mode and usage conditions.

Table 8.8 Interrupts to Exit Stop Mode and Usage Conditions

Interrupt	Usage Condition
NMI	
Low voltage detection interrupt	
External interrupt	INT6 to INT8 are available when intelligent I/O interrupt is used
Key input interrupt	
Timer A interrupt Timer B interrupt	Available when the timer counts external pulse, having its 100 Hz or less frequency, in event counter mode
Serial interface interrupt (1)	Available when external clock is used
I^2C-bus line interrupt	
CAN wake-up interrupt	

Note:

1. UART7 and UART8 are excluded.

8.8 System Clock Protection

The system clock protection is a function to disable clock change when the PLL clock is selected as base clock source. This prevents the CPU clock, which is out of control, from stopping.
When the PM21 bit in the PM2 register is set to 1 (clock change disabled), the following bits cannot be written to:

- Bits CM02 and CM05 in the CM0 register
- The CM10 bit in the CM1 register
- The CM20 bit in the CM2 register
- The PM27 bit in the PM2 register

To use the system clock protection, the CM05 bit in the CM0 register should be set to 0 (main clock oscillator enabled) and the BCS bit in the CCR register should be set to 0 (PLL clock selected as base clock source) before the following procedure is done:

(1) The PRC1 bit in the PRCR register should be set to 1 (write to the PM2 register enabled).
(2) The PM21 bit in the PM2 register should be set to 1 (clock change disabled).
(3) The PRC1 bit in the PRCR register should be set to 0 (write to the PM2 register disabled).

8.9 Notes on Clock Generator

8.9.1 Sub Clock

8.9.1.1 Oscillation Parameter Matching

The constant matching of sub clock oscillator should be evaluated in both cases when the drive power is high and low.
Contact your oscillator manufacturer for details on the oscillation circuit constant matching.

8.9.2 Power Control

Do not switch the base clock source until the oscillation of the clock to be used has stabilized. However, this does not apply to the on-chip oscillator since the on-chip oscillator starts running immediately after the CM31 bit in the CM3 register is set to 1.
To switch the base clock source from PLL clock to a low speed clock, that is, to set the BCS bit in the CCR register to 1, use either the MOV.L or OR.L instruction.

- Program example in assembly language

```
OR.L    #80h, 0004h
```

- Program example in C language

```
asm("OR.L  #80h, 0004h");
```

8.9.2.1 Stop Mode

- To exit stop mode by reset, apply a low signal to $\overline{\text{RESET}}$ pin until a main clock oscillation stabilizes.

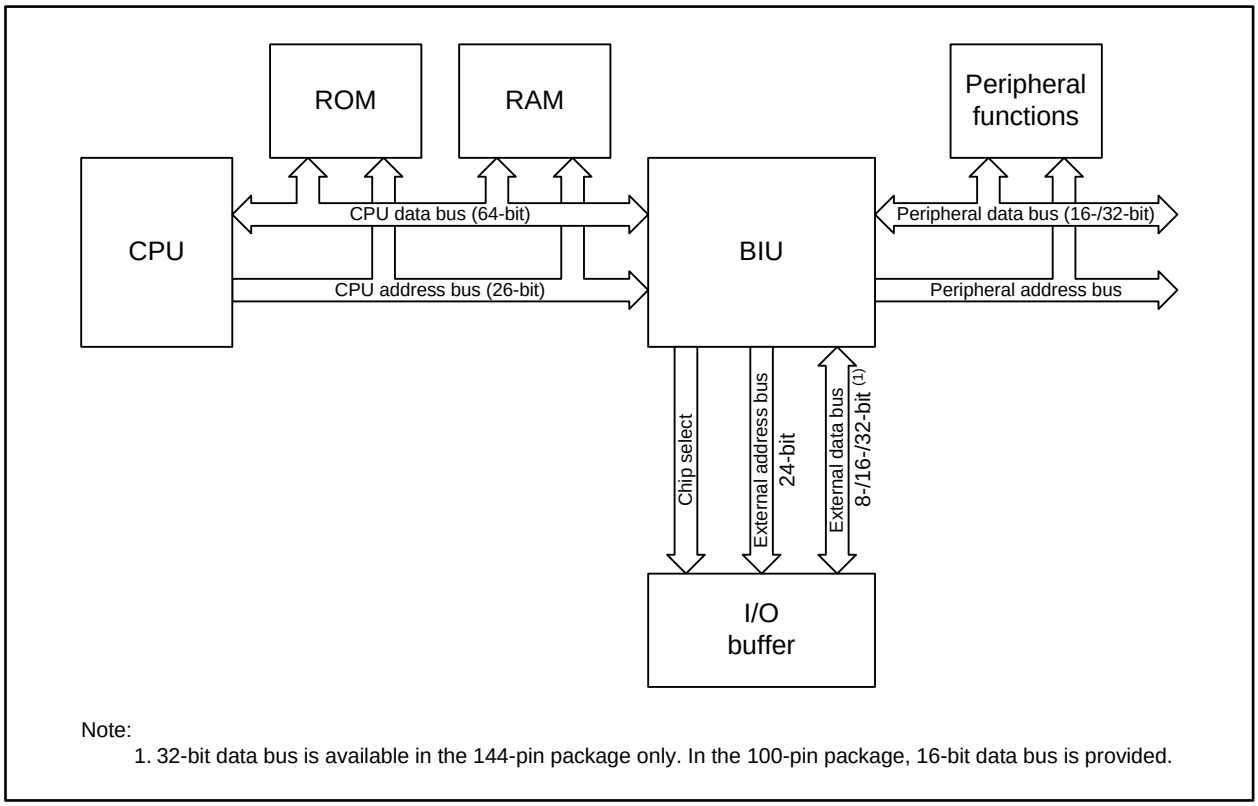
8.9.2.2 Suggestions to Power Saving

The followings are suggestions to reduce power consumption when programming or designing systems.

- I/O pins:
  If inputs are floating, both transistors may be conducting. Set unassigned pins to input mode and connect each of them to VSS via a resistor, or set them to output mode and leave them open.
- A/D converter:
  When the A/D conversion is not performed, set the VCUT bit in the AD0CON1 register to 0 (VREF disconnected). To perform the A/D conversion, set the VCUT bit to 1 (VREF connected) and wait 1 µs or more for the operation.
- D/A converter:
  When the D/A conversion is not performed, set the DAiE bit in the DACON register (i = 0, 1) to 0 (output disabled) and the DAi register to 00h.
- Peripheral clock stop:
  When entering wait mode, power consumption can be reduced by setting the CM02 bit in the CM0 register to 1 to stop peripheral clock source. However, the fC32 does not stop by the CM02 bit setting.

9. Bus

This MCU provides internal bus and external bus. The internal bus contains fast bus (CPU bus) and slow bus (peripheral bus). Figure 9.1 shows a block diagram of the bus.



Note:
1. 32-bit data bus is available in the 144-pin package only. In the 100-pin package, 16-bit data bus is provided.

Figure 9.1 Bus Block Diagram

In memory expansion mode or microprocessor mode, some pins function as bus control pin to control the address bus and the data bus. The bus control pins are as follows: A0 to A23, D0 to D31, $\overline{CS0}$ to $\overline{CS3}$, $\overline{WR0}$/$\overline{WR}$, $\overline{BC0}$, $\overline{WR1}$/$\overline{BC1}$, $\overline{WR2}$/$\overline{BC2}$, $\overline{WR3}$/$\overline{BC3}$, $\overline{RD}$, BCLK, $\overline{HLDA}$, $\overline{HOLD}$, ALE, and $\overline{RDY}$.

9.1 Bus Setting

The bus setting is controlled by the two lowest bits of reset vector, the PBC register, registers EBC0 to EBC3, and CSOP0 to CSOP2.
Table 9.1 lists bus settings and their sources.

Table 9.1 Bus Settings and Sources

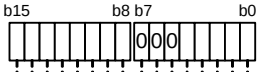
Bus Setting	Sources
Internal SFR bus timing	PBC register
External bus timing	Registers EBC0 to EBC3
External data bus width	PBC register, registers EBC0 to EBC3
External data bus width after reset	Two lowest bits of reset vector
Separate bus/Multiplexed bus selection	PBC register, registers EBC0 to EBC3
Pins to output chip select signals	Registers CSOP0 to CSOP2

9.2 Peripheral Bus Timing Setting

The peripheral bus of 16-/32-bit width operates at a frequency up to 32 MHz (the theoretical value and the maximum frequency of each product group are as defined by f(BCLK) in 28. “Electrical Characteristics”). The timing adjustment and bus-width conversion with the faster, 64-bit-wide CPU bus are controlled in the bus interface unit (BIU).

Figure 9.2 shows the PBC register which determines the peripheral bus timing.

Peripheral Bus Control Register (1, 2)



Symbol	Address	Reset Value
PBC	001Fh-001Eh	0504h

Bit Symbol	Bit Name	Function	RW
PRD0	Read Timing Setting Bit	Select from the three options below according to the peripheral bus clock setting (bits PCD1 and PCD0 in the CCR register). When bits PCD1 and PCD0 are set to: 1. 01b : 00100b 2. 10b : 01101b 3. 11b : 01111b	RW
PRD1			
PRD2			
PRD3			
PRD4			
— (b7-b5)	Reserved	Should be written with 0	RW
PWR0	Write Timing Setting Bit	Select from the three options below according to the peripheral bus clock setting (bits PCD1 and PCD0 in the CCR register). When bits PCD1 and PCD0 are set to: 1. 01b : 00101b 2. 10b : 01010b 3. 11b : 01111b	RW
PWR1			
PWR2			
PWR3			
PWR4			
EXMPX	External Bus Format Select Bit (3)	0: Separate bus in some spaces 1: Multiplexed bus in all spaces	RW
EXBW0	External Bus Maximum Width Setting Bit (4)	b15b14 0 0 : 8-bit width 0 1 : 16-bit width 1 0 : 32-bit width (5) 1 1 : Do not use this combination	RW
EXBW1			

Notes:
1. Set the PRR register to AAh (write enabled) before rewriting this register.
2. This register should be set only once after a reset. It should not be rewritten after the CCR register is set.
3. If this bit is set to 1 when the all MPX bits in registers EBC0 to EBC3 are set to 1, ports P0, P1, and P4_0 to P4_3 can be used as programmable I/O ports.
4. This bit should be the maximum bus width set in bits BW1 and BW0 in registers EBC0 to EBC3. The functions of ports P1, P12, and P13 vary with this bit setting.
5. This bit setting is applicable only in the 144-pin package.

Figure 9.2 PBC Register

9.3 External Bus Setting

External bus of 8-/16-/32-bit width operates at a frequency up to 32 MHz (the theoretical value and the maximum frequency of each product group are as defined by f(BCLK) in 28. “Electrical Characteristics”). The timing adjustment and bus-width conversion with the faster, 64-bit-wide CPU bus are controlled in the bus interface unit (BIU).

9.3.1 External Address Space Setting

In the R32C/100 Series, the CPU contains 26 address buses (A0 to A25) in the MCU. Since A26 to A31 are sign-extended of A25, it has 64 MB of accessible space in total in the addresses 00000000h to 01FFFFFFh and FE000000h to FFFFFFFFh.

As address bus for external output, up to 24 buses (A0 to A23) are available. Decoded A18 to A25 function as 4 chip select signals ($\overline{CS3}$ to $\overline{CS0}$). If 16 MB space is assigned to every chip select signal, up to 63.5 MB is available for external address space. When the processing mode is changed from single-chip mode to memory expansion mode, the address bus status is undefined until an external space is accessed.

Chip select signals $\overline{CS3}$ to $\overline{CS0}$ share pins with A20 to A23, respectively. Other combinations of signal and output port are also available as follows: signals $\overline{CS0}$ to $\overline{CS3}$ with ports P11_0 to P11_3 and signals $\overline{CS1}$ to $\overline{CS3}$ with ports P5_4, P5_6, and P5_7.

In microprocessor mode, the $\overline{CS0}$ signal is output from port P4_7 after a reset. The maximum space per chip select signal is 8 MB since A23 is not available. Signals $\overline{CS1}$ to $\overline{CS3}$ are output only when being set.

The $\overline{CSi}$ (i = 0 to 3) is held low while accessing an external space i. It shifts to high when accessing another external space. Figure 9.3 shows output examples of address bus and chip select signals.

A chip select signal to be used and an output pin are selected in registers CSOP0 to CSOP2. The space for each chip select signal is selected in registers CB01, CB12, and CB23.

Figure 9.4 to Figure 9.6 show registers CSOP0 to CSOP2. Figure 9.7, Figure 9.8, and Figure 9.9 show respectively registers CB01, CB12, and CB23. Figure 9.10 and Figure 9.11 show the chip select space.

A chip select signal should not be set for more than two output pins in registers CSOP0 to CSOP2.

Registers CB01, CB12, and CB23 should be set to meet the conditions below:

- In memory expansion mode

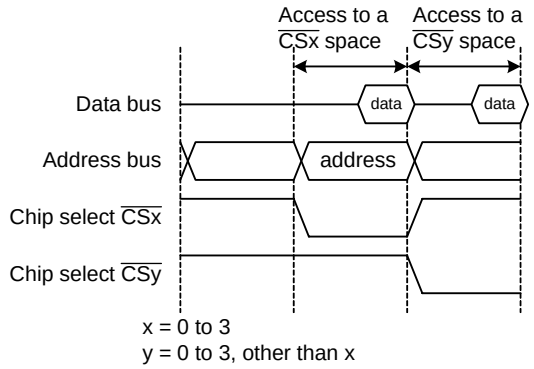
$$0080000h < (CB23 \times 2^{18}) < (CB12 \times 2^{18}) < (CB01 \times 2^{18}) \leq 3DC0000h$$

- In microprocessor mode

$$0080000h < (CB23 \times 2^{18}) < (CB12 \times 2^{18}) < (CB01 \times 2^{18}) \leq 3FC0000h$$

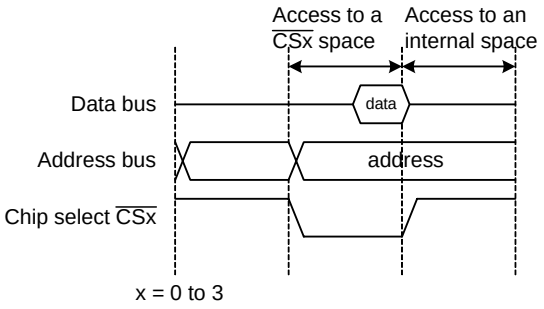
Pattern 1. Address bus: changed,
Chip select signal: changed,
at the first cycle after accessing an external space

When a $\overline{CSy}$ space is accessed in the first cycle after the access to a $\overline{CSx}$ space, both the address bus and the chip select signal are changed.



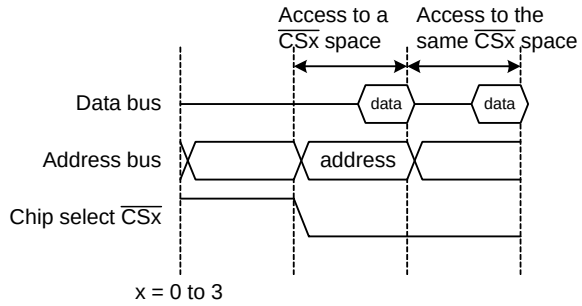
Pattern 2. Address bus: not changed,
Chip select signal: changed,
at the first cycle after accessing an external space

When an internal space is accessed in the first cycle after the access to a $\overline{CSx}$ space, only the chip select signal is changed.



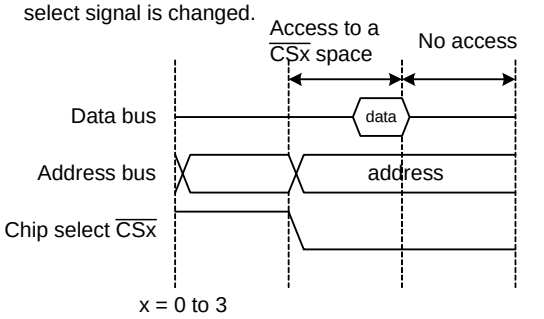
Pattern 3. Address bus: changed,
Chip select signal: not changed,
at the first cycle after accessing an external space

When the same $\overline{CSx}$ space is accessed in the first cycle after the access to a $\overline{CSx}$ space, only the address bus is changed.



Pattern 4. Address bus: not changed,
Chip select signal: not changed,
at the first cycle after accessing an external space

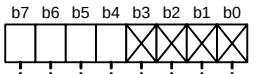
When no space is accessed in the first cycle after the access to a $\overline{CSx}$ space, (and no instruction prefetching is generated), neither the address bus nor the chip select signal is changed.



Note:
1. The patterns above show combinations of an address bus and a chip select signal in sequential two cycles. A chip select signal may be extended to two-bus cycles or more according to the combination.

Figure 9.3 Address Bus and Chip Select Signal Output Patterns (in Separate Bus Format)

Chip Select Output Pin Setting Register 0 (1)



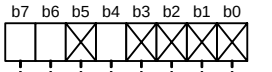
Symbol	Address	Reset Value
CSOP0	40054h	1000 XXXXb

Bit Symbol	Bit Name	Function	RW
— (b3-b0)	No register bits; should be written with 0 and read as undefined value		—
P4_4B	P4_4 Bus Function Setting Bit	0: Output A20 from P4_4 1: Output $\overline{CS3}$ from P4_4	RW
P4_5B	P4_5 Bus Function Setting Bit	0: Output A21 from P4_5 1: Output $\overline{CS2}$ from P4_5	RW
P4_6B	P4_6 Bus Function Setting Bit	0: Output A22 from P4_6 1: Output $\overline{CS1}$ from P4_6	RW
P4_7B	P4_7 Bus Function Setting Bit	0: Output A23 from P4_7 (2) 1: Output $\overline{CS0}$ from P4_7	RW

Notes:
1. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. The P4_7B bit should not be set to 0 when starting an operation in microprocessor mode.

Figure 9.4 CSOP0 Register

Chip Select Output Pin Setting Register 1 (1)



Symbol	Address	Reset Value
CSOP1	40055h	01X0 XXXXb

Bit Symbol	Bit Name	Function	RW
— (b3-b0)	No register bits; should be written with 0 and read as undefined value		—

Function	Setting Range	RW
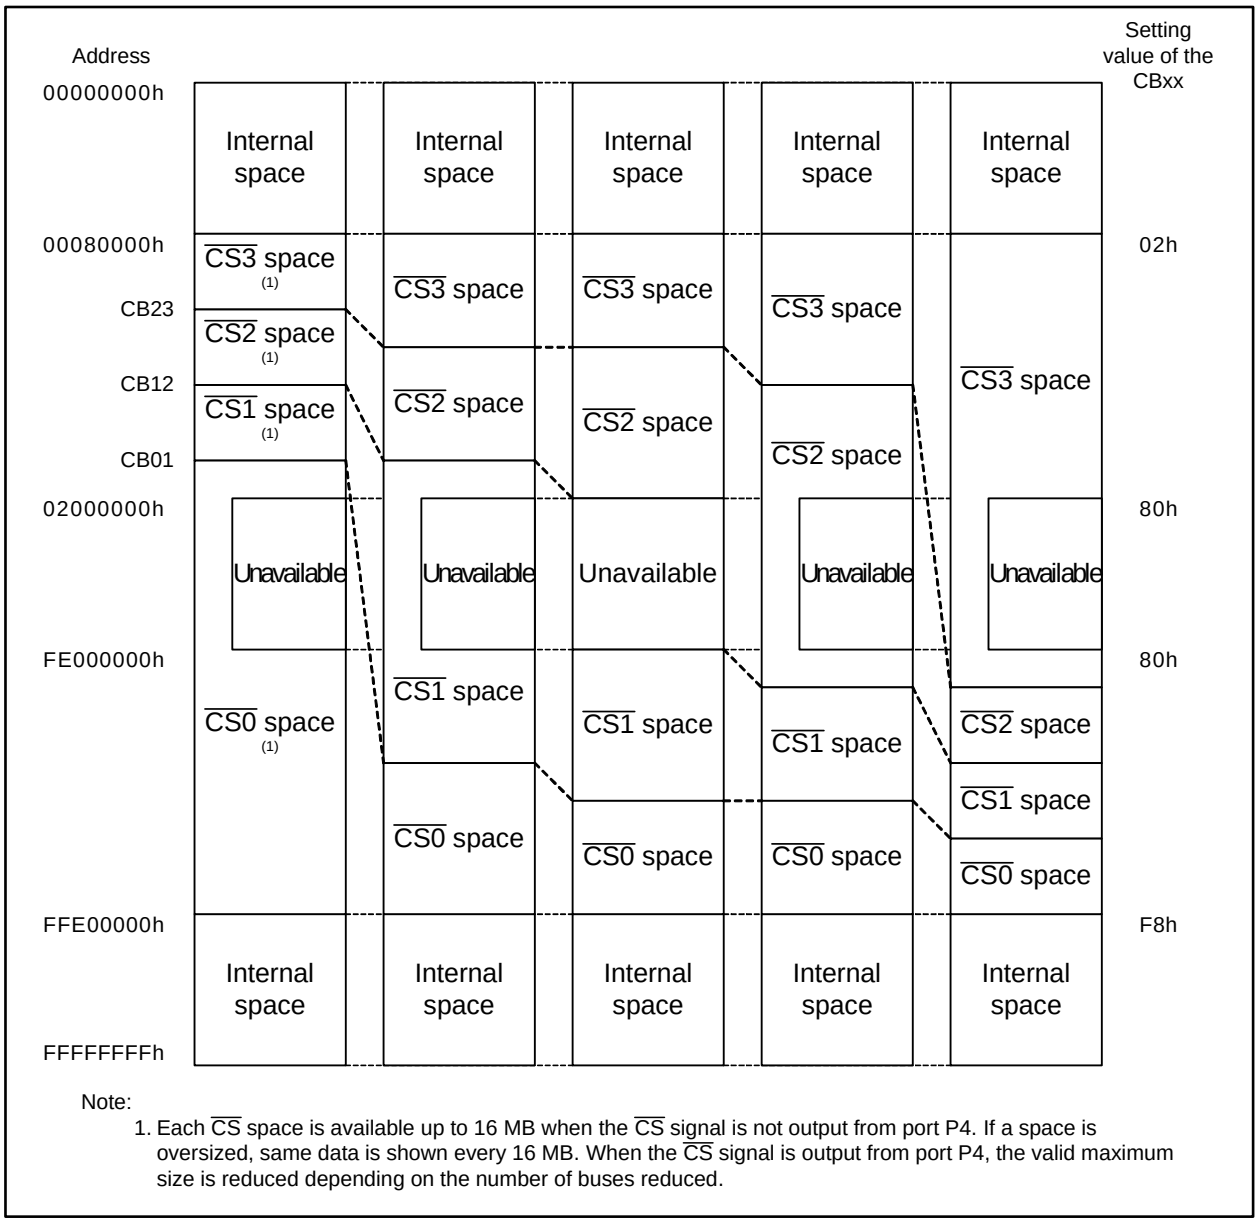
Set this register to the value from A25 to A18 of the start address of $\overline{CS2}$ space. The immediately preceding address mentioned above and lower is designated for $\overline{CS3}$ space	02h to F6h (2) in memory expansion mode, 02h to FDh (2) in microprocessor mode	RW

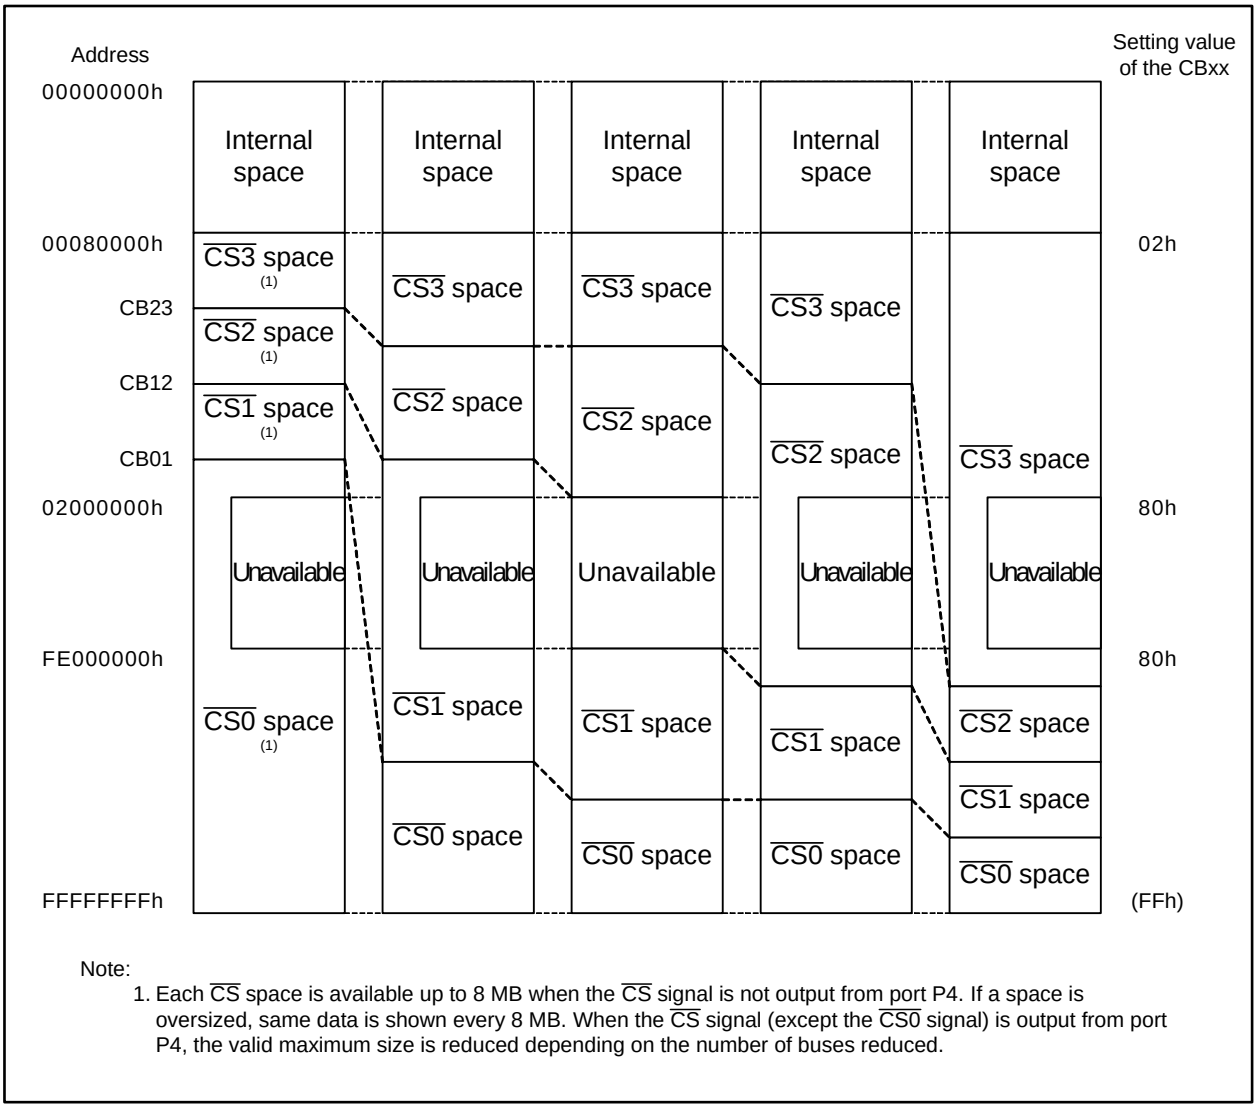
Notes:
1. Set the PRR register to AAh (write enabled) before rewriting this register.
2. The setting value should be lower than that for the CB12 register.

Figure 9.9 CB23 Register



Note:
1. Each $\overline{CS}$ space is available up to 16 MB when the $\overline{CS}$ signal is not output from port P4. If a space is oversized, same data is shown every 16 MB. When the $\overline{CS}$ signal is output from port P4, the valid maximum size is reduced depending on the number of buses reduced.

Figure 9.10 Chip Select Spaces in Memory Expansion Mode



Note:
1. Each $\overline{CS}$ space is available up to 8 MB when the $\overline{CS}$ signal is not output from port P4. If a space is oversized, same data is shown every 8 MB. When the $\overline{CS}$ signal (except the $\overline{CS0}$ signal) is output from port P4, the valid maximum size is reduced depending on the number of buses reduced.

Figure 9.11 Chip Select Spaces in Microprocessor Mode

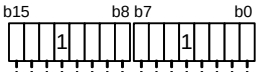
9.3.2 External Data Bus Width Setting

The external data bus width is selectable among 8 bits, 16 bits, and 32 bits. The bus width of each space is determined using bits BW1 and BW0 in registers EBC0 to EBC3. The maximum bus width for all spaces is set using bits EXBW1 and EXBW0 in the PBC register. The bus width specified in bits EXBW1 and EXBW0 should be equal to or greater than the value set using bits BW1 and BW0.

When an accessed space has a bus of less bit-width than that specified in bits EXBW1 and EXBW0, undefined value is output from the unused data output pins.

Figure 9.12 shows registers EBC0 to EBC3.

External Bus Control Register i (i = 0 to 3) (1)



Symbol	Address	Reset Value
EBC0, EBC1	001Dh-001Ch, 0019h-0018h	0000h

Notes:
1. Set the PRR register to AAh (write enabled) before rewriting this register.
2. Refer to 9.3.5. “External Bus Timing” for the relation between register settings and practical timing.
3. The maximum value set here should be applied to bits EXBW1 and EXBW0 in the PBC register.
4. This bit setting is applicable only in the 144-pin package.

Figure 9.12 Registers EBC0 to EBC3

9.3.3 Separate Bus/Multiplexed Bus Selection

The bus format is selectable between separate bus format and multiplexed bus format. The bus format for each space is set using the MPX bit in registers EBC0 to EBC3. To specify multiplexed bus format for all spaces, the EXPMX bit in the PBC register should be set to 1 (multiplexed bus in all spaces). The ports P0 and P1, and P4_0 to P4_3 can be used as programmable I/O ports.

(1) Separate Bus

In this bus format, data and address have their own I/O pins.
To specify separate bus mode, the MPX bit in registers EBC0 to EBC3 should be set to 0. The data bus width is selectable among 8 bits, 16 bits, and 32 bits using bits BW1 and BW0 in registers EBC0 to EBC3.
According to the specified data bus width, pin functions vary as follows:
In 8-bit data bus format (bits EXBW1 and EXBW0 in the PBC register are set to 00b),
Port P0: data bus,
Ports P1, P12, and P13: programmable I/O ports.
In 16-bit data bus format (bits EXBW1 and EXBW0 are set to 01b),
Ports P0 and P1: data buses,
Ports P12 and P13: programmable I/O ports.
Note that port P1 (D8 to D15) becomes undefined if the MCU accesses an space where bits BW1 and BW0 are set to 00b (8-bit data bus).
In 32-bit data bus format (bits EXBW1 and EXBW0 are set to 10b),
Ports P0, P1, P12, and P13: data buses.
Note that ports P1, P12, and P13 (D8 to D31) become undefined if the MCU accesses an space where bits BW1 and BW0 are set to 00b (8-bit width data bus). In case of an access to an space set to 01b (16-bit data bus), ports P12 and P13 (D16 to D31) become undefined.

(2) Multiplexed Bus

In this bus format, data and address are input/output to/from a time-shared identical pin.
To specify multiplexed bus mode, the MPX bit in registers EBC0 to EBC3 should be set to 1.
According to the specified data bus width, pins are multiplexed as follows:
In 8-bit data bus format (bits BW1 and BW0 in registers EBC0 to EBC3 are set to 00b),
D0 to D7 are multiplexed with A0 to A7.
In 16-bit or 32-bit data bus format (bits BW1 and BW0 are set to 01b or 10b),
D0 to D15 are multiplexed with $\overline{BC0}$, A1/$\overline{BC2}$, and A2 to A15.
In microprocessor mode, an operation is started in separate bus format after a reset. Therefore the multiplexed bus format is available only for spaces $\overline{CS1}$ to $\overline{CS3}$ and is not available for $\overline{CS0}$ space.

Table 9.2 shows pin functions for each processor mode and Table 9.3 shows pin functions for each bus format.

Table 9.2 Processor Mode and Pin Functions (1)

Process or Mode	Single-Chip Mode	Microprocessor Mode/Memory Expansion Mode						Memory Expansion Mode		
Bus format	—	Separate bus only (EXMPX = 0)			Separate bus and multiplexed bus (mixed) (EXMPX = 0)			Multiplexed bus only (EXMPX = 1)		
Data bus width	—	8 bits only	8/16 bits (mixed)	8/16/32 bits (mixed)	8 bits only	8/16 bits (mixed)	8/16/32 bits (mixed)	8 bits only	8/16 bits (mixed)	8/16/32 bits (mixed)

Notes:
1. Ports P11 to P15 are available in the 144-pin package only.
2. Undefined value is output.

9.3.4 Read and Write Signals

In 16- or 32-bit data bus, the PM02 bit in the PM0 register selects a combination of $\overline{RD}$, $\overline{WR}$, $\overline{BC0}$, $\overline{BC1}$, $\overline{BC2}$, and $\overline{BC3}$ or $\overline{RD}$, $\overline{WR0}$, $\overline{WR1}$, $\overline{WR2}$, and $\overline{WR3}$ as read or write signals.

When bits EXBW1 and EXBW0 in the PBC register are set to 00b (8-bit data bus), the PM02 bit should be set to 0 ($\overline{RD}$/$\overline{WR}$/$\overline{BC0}$/$\overline{BC1}$/$\overline{BC2}$/$\overline{BC3}$). When bits EXBW1 and EXBW0 are set to 01b (16-bit data bus) or 10b (32-bit data bus) to access an 8-bit space, the combination of $\overline{RD}$, $\overline{WR}$, $\overline{BC0}$, $\overline{BC1}$, $\overline{BC2}$, and $\overline{BC3}$ is selected irrespective of the PM02 bit setting.

Table 9.4 and Table 9.5 list each signal operation.

The read and write signals after a reset are the following combination: $\overline{RD}$, $\overline{WR}$, $\overline{BC0}$, $\overline{BC1}$, $\overline{BC2}$, and $\overline{BC3}$. To shift to another combination, $\overline{RD}$, $\overline{WR0}$, $\overline{WR1}$, $\overline{WR2}$, and $\overline{WR3}$, the PM02 bit should be set first to write data to an external memory.

Table 9.4 Signals $\overline{RD}$, $\overline{WR0}$, $\overline{WR1}$, $\overline{WR2}$, and $\overline{WR3}$ (1)

Data Bus Width	$\overline{RD}$	$\overline{WR0}$	$\overline{WR1}$	$\overline{WR2}$	$\overline{WR3}$	External Data Bus Status
32 bits (2)	L	H	H	H	H	Read 4-byte data
	H	L	H	H	H	Write 1-byte data to address 4n+0
	H	H	L	H	H	Write 1-byte data to address 4n+1
	H	H	H	L	H	Write 1-byte data to address 4n+2
	H	H	H	H	L	Write 1-byte data to address 4n+3
	H	L	L	H	H	Write 2-byte data to addresses 4n+0 to 4n+1
	H	H	L	L	H	Write 2-byte data to addresses 4n+1 to 4n+2
	H	H	H	L	L	Write 2-byte data to addresses 4n+2 to 4n+3
	H	L	L	L	H	Write 3-byte data to addresses 4n+0 to 4n+2
	H	H	L	L	L	Write 3-byte data to addresses 4n+1 to 4n+3
	H	L	L	L	L	Write 4-byte data to addresses 4n+0 to 4n+3
16 bits	L	H	H	H/L (A1)	—	Read 2-byte data
	H	L	H	H/L (A1)	—	Write 1-byte data to even address
	H	H	L	H/L (A1)	—	Write 1-byte data to odd address
	H	L	L	H/L (A1)	—	Write 2-byte data to both even and odd addresses
8 bits	L	H ($\overline{WR}$)	—	H/L (A1)	—	Read 1-byte data
	H	L ($\overline{WR}$)	—	H/L (A1)	—	Write 1-byte data

Notes:
1. Signals $\overline{WR2}$ and $\overline{WR3}$ are available in the 144-pin package only.
2. Signals for 32-bit data bus width can be set in the 144-pin package only.

Table 9.5 Signals $\overline{RD}$, $\overline{WR}$, $\overline{BC0}$, $\overline{BC1}$, $\overline{BC2}$, and $\overline{BC3}$ (1)

Data Bus Width	$\overline{RD}$	$\overline{WR}$	$\overline{BC0}$	$\overline{BC1}$	$\overline{BC2}$	$\overline{BC3}$	External Data Bus Status
32 bits (2)	L	H	L	L	L	L	Read 4-byte data
	H	L	L	H	H	H	Write 1-byte data to address 4n+0
	H	L	H	L	H	H	Write 1-byte data to address 4n+1
	H	L	H	H	L	H	Write 1-byte data to address 4n+2
	H	L	H	H	H	L	Write 1-byte data to address 4n+3
	H	L	L	L	H	H	Write 2-byte data to addresses 4n+0 to 4n+1
	H	L	H	L	L	H	Write 2-byte data to addresses 4n+1 to 4n+2
	H	L	H	H	L	L	Write 2-byte data to addresses 4n+2 to 4n+3
	H	L	L	L	L	H	Write 3-byte data to addresses 4n+0 to 4n+2
	H	L	H	L	L	L	Write 3-byte data to addresses 4n+1 to 4n+3
	H	L	L	L	L	L	Write 4-byte data to addresses 4n+0 to 4n+3
16 bits	L	H	L	L	H/L (A1)	—	Read 2-byte data
	H	L	L	H	H/L (A1)	—	Write 1-byte data to even address
	H	L	H	L	H/L (A1)	—	Write 1-byte data to odd address
	H	L	L	L	H/L (A1)	—	Write 2-byte data to both even and odd addresses
8 bits	L	H	H/L (A0)	—	H/L (A1)	—	Read 1-byte data
	H	L	H/L (A0)	—	H/L (A1)	—	Write 1-byte data

Notes:
1. Signals $\overline{BC2}$ and $\overline{BC3}$ are available in the 144-pin package only.
2. Signals for 32-bit data bus width can be set in the 144-pin package only.

9.3.5 External Bus Timing

The external bus timing is set using registers EBC0 to EBC3. The reference clock is the base clock set using bits BCD1 and BCD0 in the CCR register.

Table 9.6 lists the bit setting of MPY1, MPY0, ESUR1, and ESUR0 and the Tsu(A-R) (address setup before $\overline{RD}$), Table 9.7 lists the bit setting of MPY1, MPY0, EWR1, and EWR0 and the Tw(R) ($\overline{RD}$ pulse width), Table 9.8 lists the bit setting of MPY1, MPY0, ESUW1, and ESUW0 and the Tsu(A-W) (address setup before $\overline{WR}$), and Table 9.9 lists the bit setting of MPY1, MPY0, EWW1, and EWW0 and the Tw(W) ($\overline{WR}$ pulse width).

Table 9.6 The Tsu(A-R) and Bit Settings: MPY1, MPY0, ESUR1, and ESUR0 (unit: cycles)

ESUR1 and ESUR0 Bit Settings		Separate Bus				Multiplexed Bus			
		MPY1 and MPY0 bit settings				MPY1 and MPY0 bit settings			
		00b	01b	10b	11b	00b	01b	10b	11b
		mpy = 1	*mpy = 2*	*mpy = 3*	*mpy = 4*	*mpy = 1*	*mpy = 2*	*mpy = 3*	*mpy = 4*
00b	*sur = 0*	0.5	0.5	0.5	0.5	1	1	1	1
01b	*sur = 1*	1.5	2.5	3.5	4.5	2	3	4	5
10b	*sur = 2*	2.5	4.5	6.5	8.5	3	5	7	9
11b	*sur = 3*	3.5	6.5	9.5	12.5	4	7	10	13
Formula		Tsu(A-R) = *sur* × *mpy* + 0.5				Tsu(A-R) = *sur* × *mpy* + 1			

Table 9.7 The Tw(R) and Bit Settings: MPY1, MPY0, EWR1, and EWR0 (unit: cycles)

EWR1 and EWR0 Bit Settings		Separate Bus				Multiplexed Bus			
		MPY1 and MPY0 bit setting				MPY1 and MPY0 bit setting			
		00b	01b	10b	11b	00b	01b	10b	11b
		mpy = 1	*mpy = 2*	*mpy = 3*	*mpy = 4*	*mpy = 1*	*mpy = 2*	*mpy = 3*	*mpy = 4*
00b	*wr = 1*	1.5	2.5	3.5	4.5	0.5 (1)	1.5	2.5	3.5
01b	*wr = 2*	2.5	4.5	6.5	8.5	1.5	3.5	5.5	7.5
10b	*wr = 3*	3.5	6.5	9.5	12.5	2.5	5.5	8.5	11.5
11b	*wr = 4*	4.5	8.5	12.5	16.5	3.5	7.5	11.5	15.5
Formula		Tw(R) = *wr* × *mpy* + 0.5				Tw(R) = *wr* × *mpy* - 0.5			

Note:
1. Do not set this value.

Table 9.8 The Tsu(A-W) and the Bit Settings: MPY1, MPY0, ESUW1, and ESUW0 (unit: cycles)

ESUW1 and ESUW0 Bit Settings		MPY1 and MPY0 Bit Settings			
		00b	01b	10b	11b
		mpy = 1	*mpy = 2*	*mpy = 3*	*mpy = 4*

01b	*suw = 1*	2	3	4	5
10b	*suw = 2*	3	5	7	9
11b	*suw = 3*	4	7	10	13
Formula		Tsu(A-W) = *suw* × *mpy* + 1			

Table 9.9 The Tw(W) and the Bit Settings: MPY1, MPY0, EWW1, and EWW0 (unit: cycles)

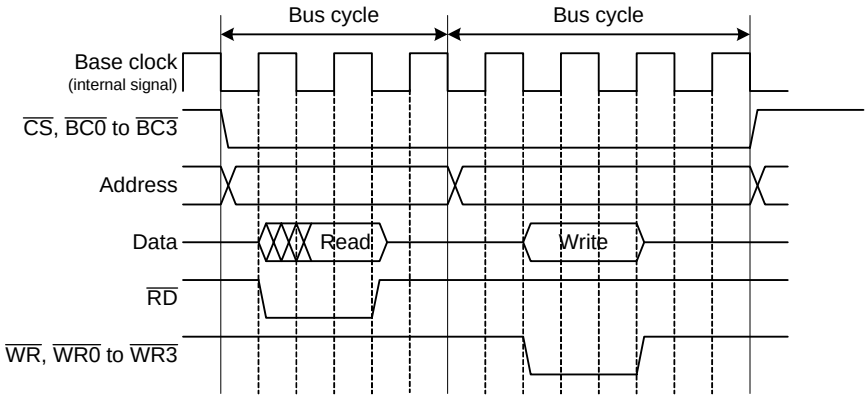
EWW1 and EWW0 Bit Settings		MPY1 and MPY0 Bit Settings			
		00b	01b	10b	11b
		mpy = 1	*mpy = 2*	*mpy = 3*	*mpy = 4*
00b	*ww = 1*	0.5 (1)	1.5	2.5	3.5
01b	*ww = 2*	1.5	3.5	5.5	7.5
10b	*ww = 3*	2.5	5.5	8.5	11.5
11b	*ww = 4*	3.5	7.5	11.5	15.5
Formula		Tw(W) = *ww* × *mpy* - 0.5			

Note:
1. Do not set this value.

Figure 9.13 and Figure 9.14 show an example of external bus timing in separate bus format (the MPX bit is set to 0) and in multiplexed bus format (the MPX bit is set to 1), respectively.
Note that the actual bus cycles are adjusted to be the integral multiple of peripheral bus clock as follows:

- Peripheral bus clock divided by 2: If the calculation result is odd, an idle cycle is inserted so that the bus cycles becomes even.
- Peripheral bus clock divided by 3: If the calculation result is not the multiples of three, (an) idle cycle(s) is/are inserted so that the bus cycles becomes the multiples of three.
- Peripheral bus clock divided by 4: If the calculation result is not the multiples of four, (an) idle cycle(s) is/are inserted so that the bus cycles becomes the multiples of four.

(1) When the EBCi register is XX01 0100 0001 0000b



(2) When the EBCi register is XX01 1001 0001 0101b

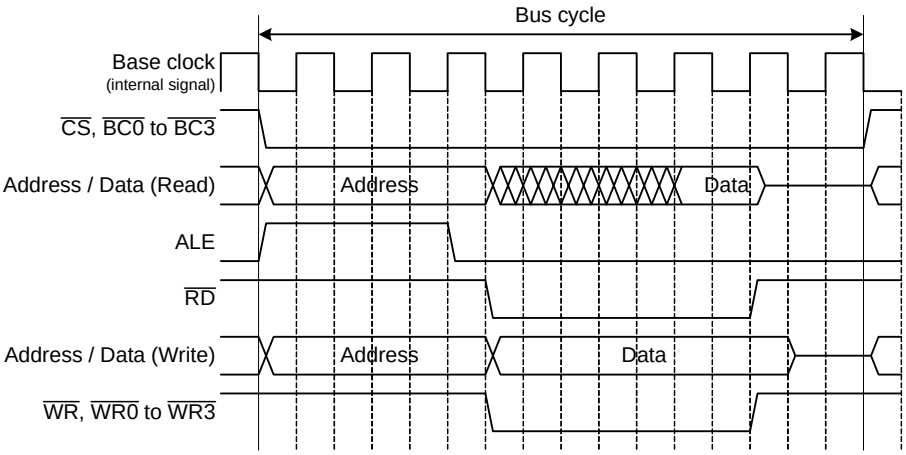

Figure 9.14 External Bus Timing in Multiplexed Bus Format (i = 0 to 3)

9.3.6 ALE Signal

The ALE signal latches an address of the multiplexed bus. The address should be latched on the falling edge of the ALE signal. This signal is output to internal space or external space.

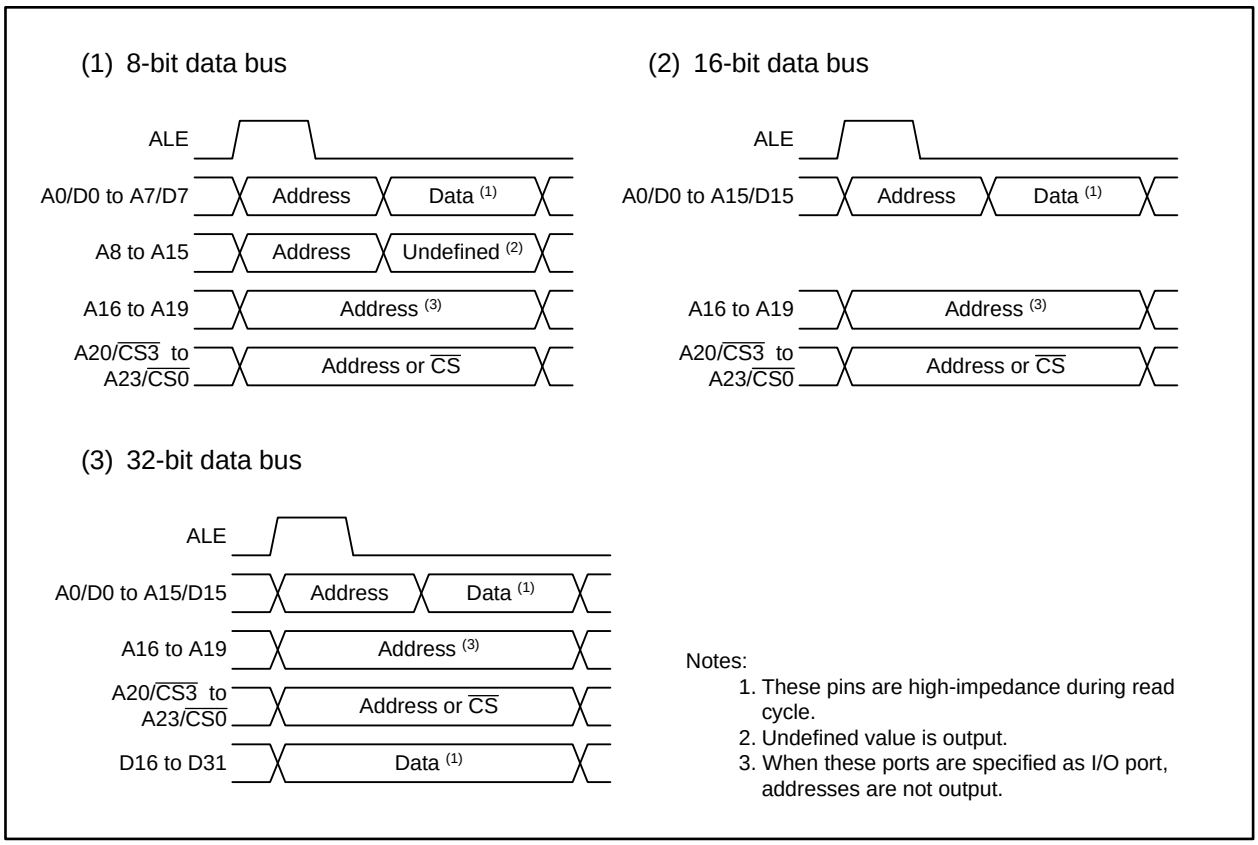

Figure 9.15 ALE Signal and Address Bus/Data Bus

The ALE signal becomes high when a bus cycle is started and changes to low 1/2 base clock before an $\overline{RD}$ or $\overline{WR}$ becomes low.

9.3.7 $\overline{\text{RDY}}$ Signal

The $\overline{\text{RDY}}$ signal facilitates access to external devices requiring longer access time. It is used when accessing an external device with lower access rate than the timing set in registers EBC0 to EBC3 or when accessing multiple devices with different access timing in a $\overline{\text{CS}}$ space.

When the RDY bit in registers EBC0 to EBC3 is set to 1 ($\overline{\text{RDY}}$ used), the $\overline{\text{RDY}}$ pin is sampled on the every mpy-th falling edge of the base clock. If the $\overline{\text{RDY}}$ pin is held low when sampled, wait states are inserted into the bus cycle. The sampling continues until the $\overline{\text{RDY}}$ pin is held high so that the bus cycle starts running again.

Since the base clock is not output to external pins, practically, the $\overline{\text{RDY}}$ signal becomes low when the signals $\overline{\text{RD}}$, $\overline{\text{WR}}$, and $\overline{\text{WR0}}$ to $\overline{\text{WR3}}$ are held in a low level and it becomes high synchronizing the rise of the BCLK signal.

Figure 9.16 shows an example of $\overline{\text{RDY}}$ signal generator and Table 9.10 lists setting conditions of registers EBC0 to EBC3 to use this circuit. Figure 9.17 shows examples of bus cycle that is extended by the $\overline{\text{RDY}}$ signal.

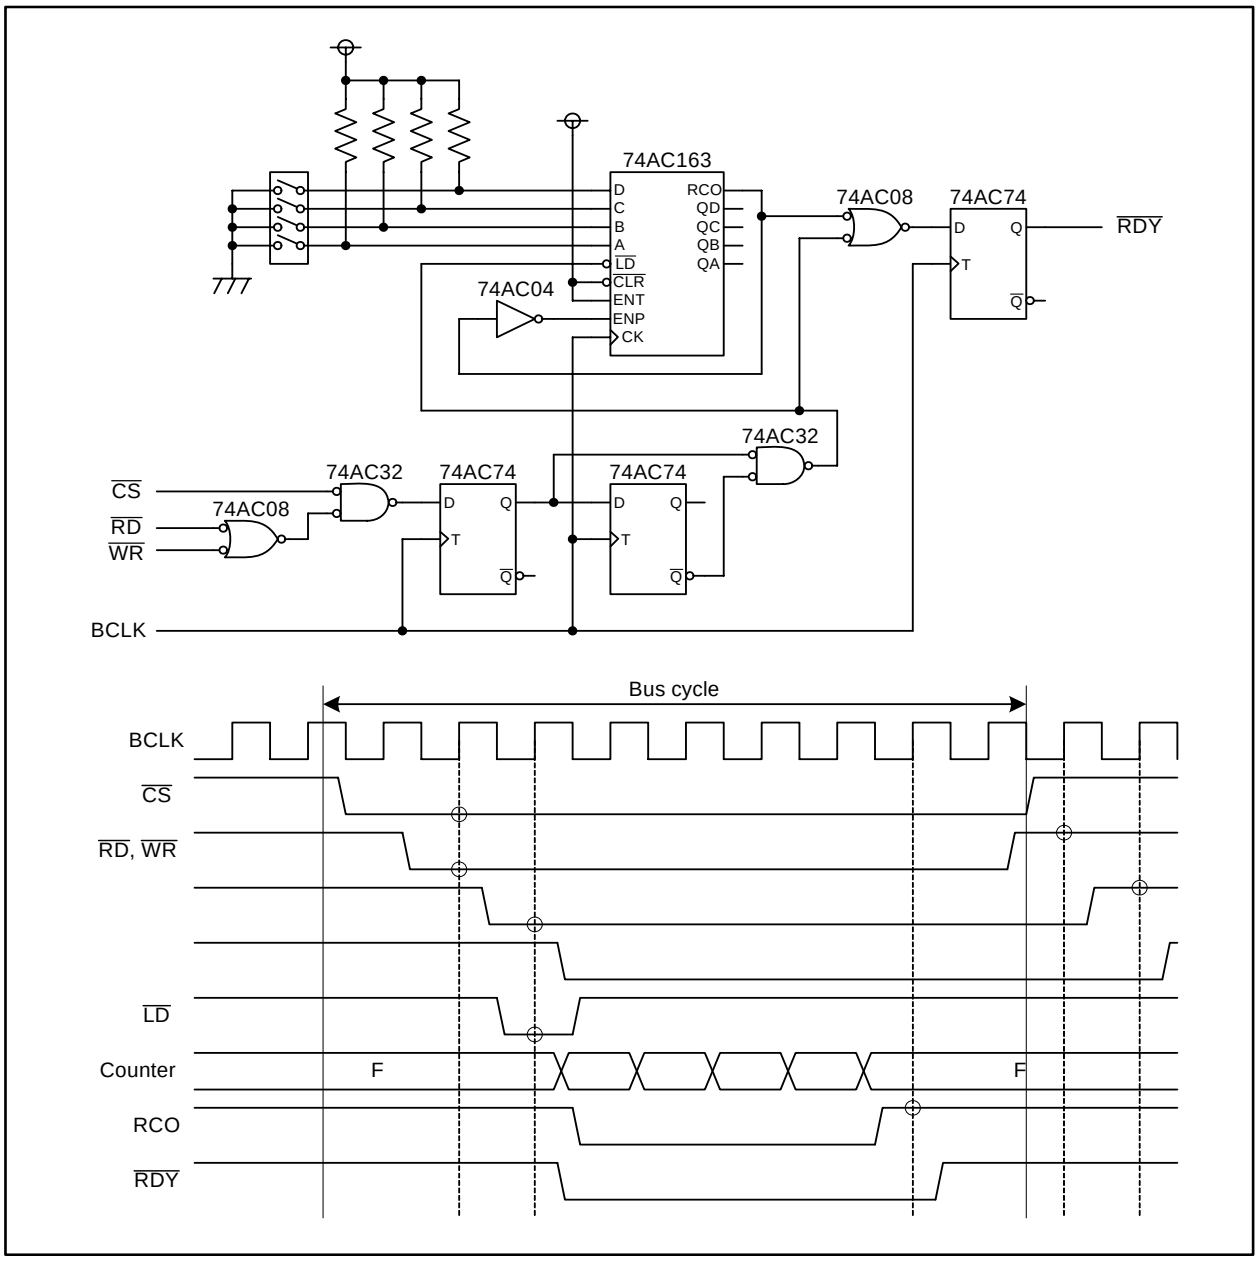

Figure 9.16 $\overline{\text{RDY}}$ Signal Generation Circuitry

Table 9.10 Setting Conditions of the EBCi register when Using the Circuit in Figure 9.16 (i = 0 to 3)

Peripheral Bus Clock Frequency	Setting Condition	Setting Example
BCLK = 1/2 base clock	*mpy* = 3 In separate bus $\overline{RD}$ pulse width ≥ 9.5 $\overline{WR}$ pulse width ≥ 11.5 $\overline{RD}$/$\overline{WR}$ high level width ≥ 2.5 In multiplexed bus $\overline{RD}$ pulse width ≥ 11.5 $\overline{WR}$ pulse width ≥ 11.5	In separate bus EBCi = XX01 1101 1011 1001b etc. In multiplexed bus EBCi = XX11 1101 1011 1101b etc.
BCLK = 1/3 base clock	*mpy* = 3 In separate bus $\overline{RD}$ pulse width ≥ 12.5 $\overline{WR}$ pulse width ≥ 11.5 $\overline{RD}$/$\overline{WR}$ high level width ≥ 3.5 In multiplexed bus $\overline{RD}$ pulse width ≥ 11.5 $\overline{WR}$ pulse width ≥ 11.5	In separate bus EBCi = XX01 1101 1011 1101b etc. In multiplexed bus EBCi = XX11 1101 1011 1101b etc.
BCLK = 1/4 base clock	*mpy* = 4 In separate bus $\overline{RD}$ pulse width ≥ 20.5 $\overline{WR}$ pulse width ≥ 19.5 $\overline{RD}$/$\overline{WR}$ high level width ≥ 4.5 In multiplexed bus $\overline{RD}$ pulse width ≥ 19.5 $\overline{WR}$ pulse width ≥ 19.5	In separate bus unavailable In multiplexed bus unavailable

X: given value

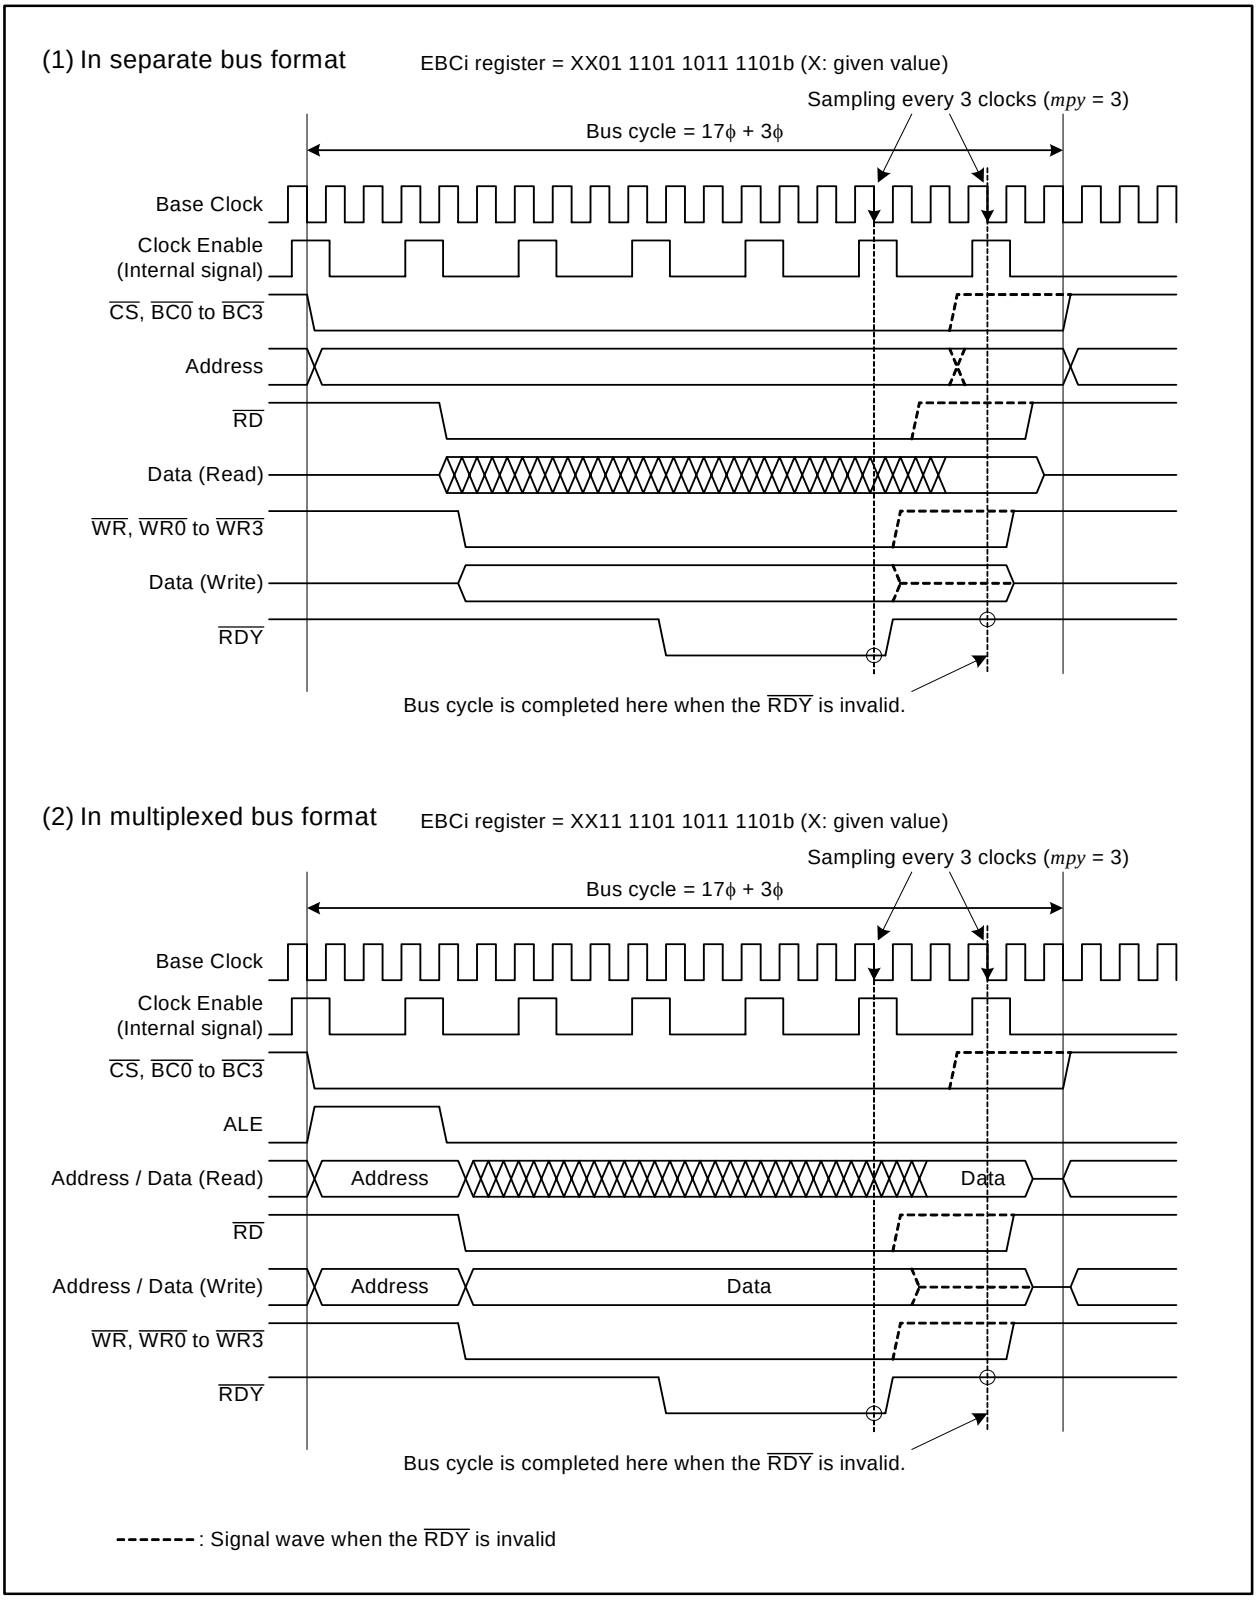

Figure 9.17 An Example of Bus Cycle Extended by $\overline{\text{RDY}}$ Signal (f(BCLK) = 1/2 f(Base)) (i = 0 to 3)

9.3.8 $\overline{\text{HOLD}}$ Signal

The $\overline{\text{HOLD}}$ signal is used when the external bus master requests the external bus from the CPU. When the external bus master drives the $\overline{\text{HOLD}}$ pin low, the CPU outputs a low signal from the $\overline{\text{HLDA}}$ pin after the ongoing bus access is completed. Then the external bus privilege is transferred to the external bus master. While the $\overline{\text{HOLD}}$ pin is held low, the CPU does not start the next bus cycle.
To return the bus privilege to the CPU, the external bus master should verify the $\overline{\text{HLDA}}$ pin is held low, and then drive the $\overline{\text{HOLD}}$ pin high.
Table 9.11 lists the MCU status in a hold state.
The bus is used in the following priority order: External bus master, DMAC, and CPU.

Table 9.11 The MCU Status in Hold State

Item	State
Oscillation	ON
Address bus, data bus, $\overline{\text{CS0}}$ to $\overline{\text{CS3}}$, $\overline{\text{BC0}}$ to $\overline{\text{BC3}}$	High-impedance
$\overline{\text{RD}}$, $\overline{\text{WR}}$, $\overline{\text{WR0}}$ to $\overline{\text{WR3}}$	High-impedance
Programmable I/O port	The state when $\overline{\text{HOLD}}$ was received is held
$\overline{\text{HLDA}}$ pin	Low is output
Internal peripheral circuit	ON (excluding the watchdog timer)
ALE pin	Low is output

9.3.9 BCLK Output

The BCLK, which has the same frequency as peripheral bus clock, is a divided clock generated by PLL. In memory expansion mode or microprocessor mode, the BCLK is output from port P5_3 when the PM07 bit in the PM0 register is set to 0 (BCLK output) and bits CM01 and CM00 in the CM0 register are set to 00b (I/O port P5_3). In single-chip mode, it cannot be output. Refer to 8. “Clock Generator” for details.

9.4 External Bus Status when Accessing Internal Space

Table 9.12 lists the external bus status when accessing an internal space.

Table 9.12 External Bus Status when Accessing Internal Space

Pin		Pin State when Accessing SFR	Pin State when Accessing Internal Memory
Address bus		Address is output	The address of SFR or external space last accessed is held
Data bus	Read Cycle	High-impedance	High-impedance
	Write Cycle	Data is output	Undefined
$\overline{\text{CS0}}$ to $\overline{\text{CS3}}$		High is output	High is output
$\overline{\text{BC0}}$ to $\overline{\text{BC3}}$		$\overline{\text{BC0}}$ to $\overline{\text{BC3}}$ are output	The address of SFR or external space last accessed is held
$\overline{\text{RD}}$, $\overline{\text{WR}}$, $\overline{\text{WR0}}$ to $\overline{\text{WR3}}$		$\overline{\text{RD}}$, $\overline{\text{WR}}$, $\overline{\text{WR0}}$ to $\overline{\text{WR3}}$ are output	High is output
ALE		ALE is output	ALE is output

9.5 Notes on Bus

9.5.1 Notes on System Designing

When the flash memory rewrite is performed in CPU rewrite mode using memory expansion mode, the use of $\overline{CS0}$ space and $\overline{CS3}$ space has the following restrictions:

- If the FEBC0 and/or FEBC3 registers are set in CPU rewrite mode, the bus format for the corresponding space functions as separate bus. Any external devices connected in multiplexed bus format become inaccessible.
- If the FEBC0 and/or FEBC3 registers are set in CPU rewrite mode, the bus timing for the corresponding space changes. This may cause external devices to become inaccessible depending on the register settings.

Devices required to be accessed in CPU rewrite mode should be allocated in $\overline{CS1}$ space and/or $\overline{CS2}$ space.

9.5.2 Notes on Register Settings

9.5.2.1 Chip Select Boundary Select Registers

When not using memory expansion mode, do not change values after a reset for registers CB01, CB12, and CB23.
When the CPU operation is performed in memory expansion mode more than once, set a value within the specified range to all of these registers irrespective of the use of them.

9.5.2.2 External Bus Control Registers

Registers EBC0 and EBC3 share respective addresses with registers FEBC0 and FEBC3. If the FEBC0 and/or FEBC3 registers are set while the flash memory is being rewritten, set the EBC0 and/or EBC3 registers again after rewriting the flash memory.

10. Protection

This function protects important registers from being easily overwritten when a program goes out of control. It contains the following registers: PRCR, PRCR2, PRCR3, and PRR.

10.1 Protect Register (PRCR Register)

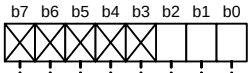
Figure 10.1 shows the PRCR register. Registers protected by the bits in the PRCR register are listed in Table 10.1.

Table 10.1 Registers Protected by the PRCR Register

Bit	Protected Registers
PRC0	CM0, CM1, CM2, and PM3
PRC1	PM0, PM2, CSOP0, CSOP1, CSOP2, INVC0, INVC1, IOBC, and I2CMR
PRC2	PLC0, PLC1, PD9, and P9_iS (i = 0 to 7)

The PRC2 bit becomes 0 (write disabled) when a write operation is performed in a given address after this bit is set to 1 (write enabled). In registers PD9, P9_iS (i = 0 to 7), PLC0, and PLC1, the write operation should be performed immediately after the instruction to set the PRC2 bit to 1. Any interrupt or DMA transfer should not be accepted between this instruction and the next one. Bits PRC0 and PRC1 are not set to 0 even if data is written to a given address. These bits should be set to 0 by a program.

Protect Register



Symbol: PRCR | Address: 4004Ah | Reset Value: XXXX X000b

Bit Symbol	Bit Name	Function	RW
PRC0	Protect Bit 0	Enable to write to registers CM0, CM1, CM2, and PM3 0: Write disabled 1: Write enabled	RW
PRC1	Protect Bit 1	Enable to write to registers PM0, PM2, CSOP0, CSOP1, CSOP2, INVC0, INVC1, IOBC, and I2CMR 0: Write disabled 1: Write enabled	RW
PRC2	Protect Bit 2 (1)	Enable to write to registers PLC0, PLC1, PD9, and P9_iS (i = 0 to 7) 0: Write disabled 1: Write enabled	RW
— (b7-b3)	No register bits; should be written with 0 and read as undefined value		—

Note:
1. The PRC2 bit becomes 0 if a write operation is performed in a given address after this bit is set to 1. Bits PRC0 and PRC1 do not automatically become 0. They should be set to 0 by a program.

Figure 10.1 PRCR Register

10.2 Protect Register 2 (PRCR2 Register)

Figure 10.2 shows the PRCR2 register which protects the CM3 register only.

Protect Register 2

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
PRCR2	4405Fh	0XXX XXXXb

Bit Symbol	Bit Name	Function	RW
— (b6-b0)	No register bits; should be written with 0 and read as undefined value		—
PRC27	CM3 Protect Bit	Enable to write to the CM3 register 0: Write disabled 1: Write enabled	RW

Figure 10.2 PRCR2 Register

10.3 Protect Register 3 (PRCR3 Register)

Figure 10.3 shows the PRCR3 register. Registers protected by the bits in the PRCR3 register are listed in Table 10.2.

Table 10.2 Registers Protected by the PRCR3 Register

Bit	Registers to be protected
PRC31	VRCR, LVDC, and DVCR

Protect Register 3

b7	b6	b5	b4	b3	b2	b1	b0
0	0	0	0	0	0		0

Symbol	Address	Reset Value
PRCR3	4004Ch	0000 0000b

Bit Symbol	Bit Name	Function	RW
— (b0)	Reserved	Should be written with 0	RW
PRC31	Protect Bit 31	Enable to write to registers VRCR, LVDC, and DVCR 0: Write disabled 1: Write enabled	RW
— (b7-b2)	Reserved	Should be written with 0	RW

Figure 10.3 PRCR3 Register

10.4 Protect Release Register (PRR Register)

Figure 10.4 shows the PRR register. Registers protected by the PRR register are as follows: CCR, FMCR, PBC, FEBC0, FEBC3, EBC0 to EBC3, CB01, CB12, and CB23.

To write to the registers above, the PRR register should be set to AAh (write enabled). Otherwise, the PRR register should be set to any value other than AAh to protect the above registers from unexpected write accesses.

Protect Release Register

b7 b0

Symbol	Address	Reset Value
PRR	0007h	00h

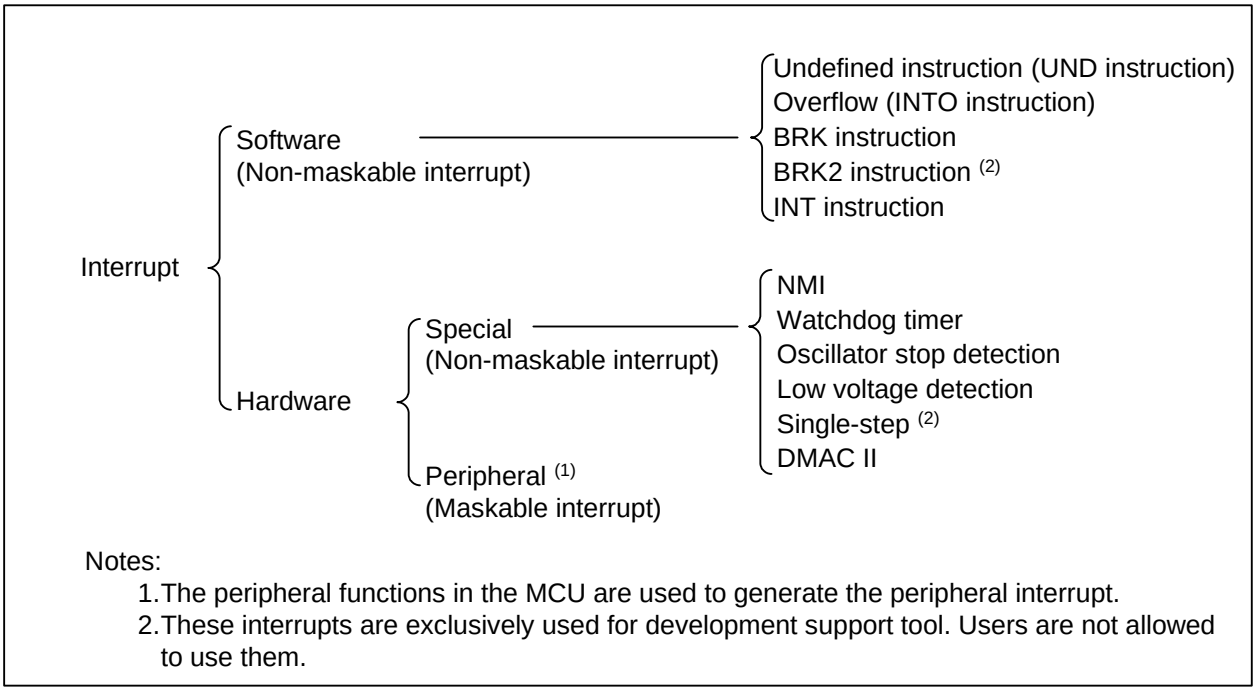
Function	Setting Range	RW
Control the protection for registers CCR, FMCR, PBC, FEBC0, FEBC3, EBC0 to EBC3, CB01, CB12, and CB23. AAh: Write enabled Value other than AAh: Write disabled	00h to FFh	RW

Figure 10.4 PRR Register

11. Interrupts

11.1 Interrupt Types

Figure 11.1 shows types of interrupts.



Notes:
1. The peripheral functions in the MCU are used to generate the peripheral interrupt.
2. These interrupts are exclusively used for development support tool. Users are not allowed to use them.

Figure 11.1 Interrupts

The interrupts are also classified into maskable/non-maskable.

(1) Maskable Interrupt

Maskable interrupts can be disabled by the interrupt enable flag (I flag).
The priority is configurable by assigning an interrupt request level.

(2) Non-maskable Interrupt

Maskable interrupts cannot be disabled by the interrupt enable flag (I flag).
The interrupt priority is not configurable.

11.2 Software Interrupt

Software interrupts are non-maskable. A software interrupt is generated by executing an instruction. There are five types of software interrupts as follows:

(1) Undefined Instruction Interrupt

This interrupt occurs when the UND instruction is executed.

(2) Overflow Interrupt

This interrupt occurs when the INTO instruction is executed while the O flag is 1. The following instructions may change the O flag to 1, depending on the operation result:
ABS, ADC, ADCF, ADD, ADDF, ADSF, CMP, CMPF, CNVIF, DIV, DIVF, DIVU, DIVX, EDIV, EDIVU, EDIVX, MUL, MULF, MULU, MULX, NEG, RMPA, ROUND, SBB, SCMPU, SHA, SUB, SUBF, SUNTIL, and SWHILE

(3) BRK Instruction Interrupt

This interrupt occurs when the BRK instruction is executed.

(4) BRK2 Instruction Interrupt

This interrupt occurs when the BRK2 instruction is executed.
This interrupt is only meant for use with the development support tool, and users are not allowed to use it.

(5) INT Instruction Interrupt

This interrupt occurs when the INT instruction is executed with a selected software interrupt number from 0 to 255. Numbers 0 to 127 are designated for peripheral interrupts. That is, the INT instruction with a number from 0 to 127 has the same interrupt handler as that for the peripheral interrupt.
The stack pointer (SP), which contains two types, is specified by the stack pointer select flag (U flag). For numbers 0 to 127, when an interrupt request is accepted, the U flag is saved to select the interrupt stack pointer (ISP) before the interrupt sequence is executed. The saved data of the U flag is restored upon returning from the interrupt handler. For numbers 128 to 255, the stack pointer used before the interrupt request acceptance remains unchanged for the interrupt sequence.

11.3 Hardware Interrupt

There are two kinds of hardware interrupts: special interrupt and peripheral interrupt.
In peripheral interrupts, only one interrupt with the highest priority can be specified as a fast interrupt.

11.3.1 Special Interrupt

Special interrupts are non-maskable. There are five interrupts as follows:

(1) NMI (Non Maskable Interrupt)

This interrupt occurs if an input signal at the $\overline{\text{NMI}}$ pin switches from high to low. Refer to 11.11 “NMI” for details.

(2) Watchdog Timer Interrupt

The watchdog timer generates this interrupt. Refer to 12. “Watchdog Timer” for details.

(3) Oscillator Stop Detection Interrupt

This interrupt occurs if the MCU detects a main clock oscillator stop. Refer to 8.2 “Oscillator Stop Detection” for details.

(4) Low Voltage Detection Interrupt

This interrupt occurs if the lowered voltage input to VCC is detected by the voltage detector. Refer to 6.2 “Low Voltage Detector” for details.

(5) Single-step Interrupt

This interrupt is only meant for use with the development support tool, and users are not allowed to use it.

11.3.2 Peripheral Interrupt

Peripheral interrupt is maskable, and is generated when an interrupt request from the peripheral functions in the MCU is accepted. It shares the interrupt vector table with software interrupt numbers 0 to 127 for the INT instruction.
Refer to Table 11.2 to Table 11.5 for details on the interrupt sources. Refer to the relevant description for details on each function.

11.4 Fast Interrupt

Fast interrupt enables the CPU to minimize the overhead of interrupt sequence. In peripheral interrupts, only one interrupt with the highest priority can be specified as the fast interrupt.

Steps to set up a fast interrupt are as follows:

(1) Set both FSIT bits in registers RIPL1 and RIPL2 to 1 (interrupt request level 7 available for fast interrupt).

(2) Set both DMAII bits in registers RIPL1 and RIPL2 to 0 (interrupt request level 7 available for interrupts).

(3) Set the start address of the fast interrupt handler to the VCT register.

Under the conditions above, bits ILVL2 to ILVL0 in the interrupt control register should be set to 111b (level 7) to enable the fast interrupt. No other interrupts should be set to interrupt request level 7.

When the fast interrupt is accepted, the flag register (FLG) and the program counter (PC) are saved to the save flag register (SVF) and the save PC register (SVP), respectively. The program is executed from the address indicated by the VCT register.

To return from the fast interrupt handler, the FREIT instruction should be executed. The values saved into the save flag register (SVF) and the save PC register (SVP) are respectively restored to the flag register (FLG) and the program counter (PC).

11.5 Interrupt Vectors

Each interrupt vector has a 4-byte memory space, in which the start address of the associated interrupt handler is stored. When an interrupt request is accepted, the instruction jumps to the address set in the interrupt vector. Figure 11.2 shows an interrupt vector.

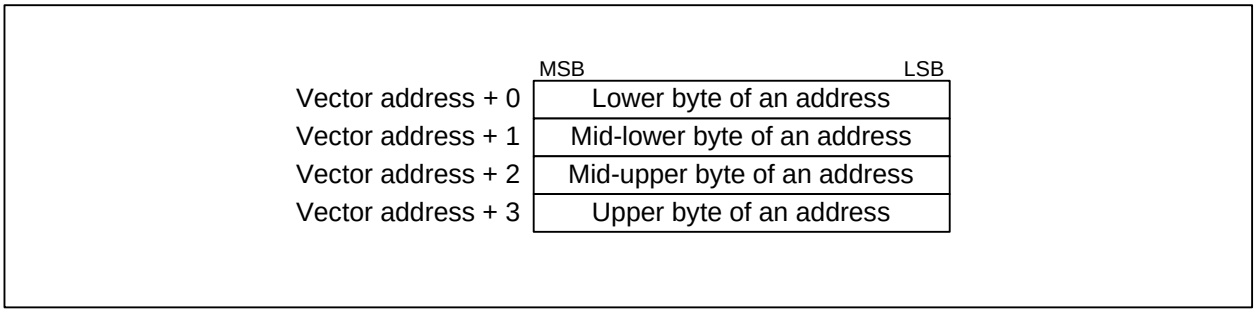


Figure 11.2 Interrupt Vector

11.5.1 Fixed Vector Table

The fixed vector table is allocated in addresses FFFFFFDCh to FFFFFFFFh. Table 11.1 lists the fixed vector table.

Table 11.1 Fixed Vector Table

Interrupt Source	Vector Table Addresses (Address (L) to Address (H))	Remarks	Reference
Undefined instruction	FFFFFFDCh to FFFFFFDFh	Interrupt by the UND instruction	R32C/100 Series Software Manual
Overflow	FFFFFFE0h to FFFFFFE3h	Interrupt by the INTO instruction	
BRK instruction	FFFFFFE4h to FFFFFFE7h	If address FFFFFFE7h is FFh, the instruction jumps to the address stored into software interrupt 0 in the relocatable vector table	
—	FFFFFFE8h to FFFFFFEBh	Reserved	
—	FFFFFFECh to FFFFFFEFh	Reserved	
Watchdog timer Oscillator stop detection Low voltage detection	FFFFFFF0h to FFFFFFF3h	These addresses are shared by the watchdog timer interrupt, oscillator stop detection interrupt, and low voltage detection interrupt	12. “Watchdog Timer” 8. “Clock Generator” 6.2 “Low Voltage Detector”
—	FFFFFFF4h to FFFFFFF7h	Reserved	
NMI	FFFFFFF8h to FFFFFFFBh	External interrupt by the $\overline{\text{NMI}}$ pin	
Reset	FFFFFFFCh to FFFFFFFFh		5. “Resets”

11.5.2 Relocatable Vector Table

The relocatable vector table occupies a 1024-byte memory space from the start address set in the INTB register. Table 11.2 to Table 11.5. list the relocatable vector table entries.
An address in multiples of 4 should be set in the INTB register for faster interrupt sequence.

Table 11.2 Relocatable Vector Table (1/4)

Interrupt Source	Vector Table Relative Addresses (Address (L) to Address (H)) (1)	Software Interrupt Number	Reference
BRK instruction (2)	+0 to +3 (0000h to 0003h)	0	R32C/100 Series Software Manual

Notes:
1. Each entry is relative to the base address in the INTB register.
2. Interrupts from this source cannot be disabled by the I flag.
3. In I^2C mode, interrupts are generated by NACK, ACK, or detection of start condition/stop condition.
4. The IFSR16 bit in the IFSR1 register selects either the interrupt source in UART5 or that in UART6.

Table 11.3 Relocatable Vector Table (2/4)

Interrupt Source	Vector Table Relative Addresses (Address (L) to Address (H)) (1)	Software Interrupt Number	Reference
UART2 transmission, NACK (2)/I2C-bus interface (3)	+132 to +135 (0084h to 0087h)	33	18. “Serial Interface”/24. “Multi-master I2C-bus Interface”

Notes:
1. Entries in this table cannot be used to exit wait mode or stop mode.
2. Each entry is relative to the base address in the INTB register.
3. Interrupts from this source cannot be disabled by the I flag.

11.6 Interrupt Request Acceptance

Software interrupts and special interrupts are accepted whenever their interrupt request is generated. Peripheral interrupts, however, are only accepted if the conditions below are met:

- I flag = 1
- IR bit = 1
- Bits ILVL2 to ILVL0 > IPL

The I flag, IPL, IR bit, and bits ILVL2 to ILVL0 do not affect each other. The I flag and IPL are in the flag register (FLG). The IR bit and bits ILVL2 to ILVL0 are in the interrupt control register.
The following section describes these flag and bits.

11.6.1 I Flag and IPL

The I flag (interrupt enable flag) enables or disables maskable interrupts. When the I flag is set to 1 (enabled), all maskable interrupts are enabled; when it is set to 0 (disabled), they are disabled. The I flag is automatically set to 0 after a reset.
The IPL (processor interrupt priority level), consisting of three bits, indicates eight interrupt priority levels from 0 to 7. An interrupt becomes acceptable when its interrupt request level is higher than the specified IPL (bits ILVL2 to ILVL0 > IPL).
Table 11.6 lists interrupt request levels classified by the IPL.

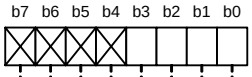
Table 11.6 Acceptable Interrupt Request Levels and IPL

Processor Interrupt Priority Level (IPL)			Acceptable Interrupt Request Levels
IPL2	IPL1	IPL0	
1	1	1	All maskable interrupts are disabled
1	1	0	Level 7 only
1	0	1	Level 6 and above
1	0	0	Level 5 and above
0	1	1	Level 4 and above
0	1	0	Level 3 and above
0	0	1	Level 2 and above
0	0	0	Level 1 and above

11.6.2 Interrupt Control Register

The interrupt control registers control each peripheral interrupt.
Figure 11.3 and Figure 11.4 show the interrupt control registers.

Interrupt Control Register



Symbol	Address	Reset Value
TA0IC to TA4IC	006Ch, 008Ch, 006Eh, 008Eh, 0070h	XXXX X000b

ILVL2			RW
IR	Interrupt Request Flag	0: No interrupt requested 1: Interrupt requested (2)	RW
POL	Polarity Select Bit	0: Select the falling edge or a low 1: Select the rising edge or a high (3)	RW
LVS	Level/Edge Sensitive Select Bit	0: Edge sensitive 1: Level sensitive (4)	RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Notes:
1. When the 16- or 32-bit data bus is used in microprocessor mode or memory expansion mode, pins $\overline{\text{INT3}}$ to $\overline{\text{INT5}}$ function as data bus. Bits ILVL2 to ILVL0 in registers INT3IC to INT5IC should be set to 000b.
2. This bit can be set to 0 only (it should not be set to 1).
3. This bit should be set to 0 (the falling edge or low level) to set the corresponding bit in registers IFSR0 and IFSR1 to 1 (both edges).
4. To select the level sensitive, the corresponding bit in registers IFSR0 and IFSR1 should be set to 0 (one edge).

Figure 11.4 Interrupt Control Register (2)

Bits ILVL2 to ILVL0

Bits ILVL2 to ILVL0 select the interrupt request level. The higher the level is, the higher interrupt priority is.

When an interrupt request is generated, its request level is compared to the IPL. This interrupt is accepted only when the interrupt request level is higher than the IPL. When bits ILVL2 to ILVL0 are set to 000b, the interrupt is disabled.

IR bit

The IR bit becomes 1 (interrupt requested) when an interrupt request is generated; this bit setting is retained until the interrupt request is accepted. When the request is accepted and the instruction jumps to the corresponding interrupt vector, the IR bit becomes 0 (no interrupt requested).

The IR bit can be set to 0 by a program. This bit should not be set to 1.

When rewriting the interrupt control register, no corresponding interrupt request should be generated. If it may be generated, disable all the maskable interrupts before the rewrite.
When enabling the maskable interrupts immediately after the rewrite, there should be sufficient time for the rewrite to complete before the interrupt enable flag (I flag) becomes 1. To delay the execution of the second instruction, insert NOPs or perform a dummy read of the interrupt control register after the first instruction.
If an interrupt request is generated for a register being rewritten, the IR bit may not become 1 depending on the instruction being used. If this is not desired, use one of the following instructions to rewrite the register:

- AND
- OR
- BCLR
- BSET

When setting the IR bit to 0 by the AND or BCLR instruction, the IR bit may not become 0. This is because an interrupt request generated while the instruction above is being executed is kept pending. If this is not desired, the register should be reconfigured by the MOV instruction. To set just the IR bit to 0, first temporarily store the read value to memory or CPU-internal registers, then execute either the AND or BCLR instruction in the stored area. After that, write the value back to the register by the MOV instruction.

11.6.3 Wake-up IPL Setting Register

The wake-up IPL setting register (registers RIPL1 and RIPL2) is used for an interrupt to exit wait or stop mode, or for the fast interrupt.
Refer to 8.7.2 “Wait Mode”, 8.7.3 “Stop Mode”, or 11.4 “Fast Interrupt” for details.
Figure 11.5 shows registers RIPL1 and RIPL2.

Wake-up IPL Setting Register i (i = 1, 2) (1)

b7	b6	b5	b4	b3	b2	b1	b0
X	X		X				

Symbol	Address	Reset Value
RIPL1, RIPL2	4407Fh, 4407Dh	XX0X 0000b

Bit Symbol	Bit Name	Function	RW
RLVL0	Interrupt Priority Level for Wake-up Select Bit (2)	b2 b1 b0 0 0 0 : Level 0 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	RW
RLVL1			RW
RLVL2			RW
FSIT	Fast Interrupt Select Bit (3)	0: Use interrupt request level 7 for normal interrupt 1: Use interrupt request level 7 for fast interrupt (4)	RW
— (b4)	No register bit; should be written with 0 and read as undefined value		—
DMAII	DMA II Select Bit (5)	0: Use interrupt request level 7 for interrupt 1: Use interrupt request level 7 for DMA II transfer (4)	RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Notes:
1. Registers RIPL1 and RIPL2 should be identically set.
2. The MCU exits wait mode or stop mode if the request level of requested interrupt is higher than the level selected using bits RLVL2 to RLVL0. These bits should be set to the same value as the IPL in the flag register (FLG).
3. When the FSIT bit is set to 1, an interrupt with interrupt request level 7 becomes the fast interrupt. In this case only one interrupt should be set to the interrupt request level 7.
4. Either the FSIT or DMAII bit should be set to 1. Simultaneous use of the fast interrupt and the DMAC II is not available.
5. Bits ILVL2 to ILVL0 in the interrupt control register should be set after the DMAII bit is set. The DMA II transfer is not affected by the I flag or the IPL.

Figure 11.5 Registers RIPL1 and RIPL2

11.6.4 Interrupt Sequence

The interrupt sequence is performed from when an interrupt request has been accepted until the interrupt handler starts.
For most instructions, when an interrupt request is generated while an instruction is being executed, the requested interrupt is evaluated in the priority resolver after the current instruction is completed. If appropriate, the interrupt sequence starts from the next cycle.
For instructions RMPA, SCMPU, SIN, SMOVB, SMOVF, SMOVU, SOUT, SSTR, SUNTIL, and SWHILE, as soon as an interrupt request is generated, the requested interrupt is evaluated suspending the current instruction being executed. If appropriate, the interrupt sequence starts immediately.
The interrupt sequence is as follows:

(1) The CPU acknowledges the interrupt request to obtain the interrupt information (the interrupt number, and the interrupt request level) from the interrupt controller. Then the corresponding IR bit becomes 0 (no interrupt requested).
(2) The state of the flag register (FLG) before the interrupt sequence is stored to a temporary register (1) in the CPU.
(3) The following bits in the flag register (FLG) become 0:
- The I flag (interrupt enable flag): interrupt disabled
- The D flag (debug flag): single-step interrupt disabled
- The U flag (stack pointer select flag): ISP selected

(4) The contents of the temporary register (1) in the CPU is saved to the stack; or to the save flag register (SVF) in case of the fast interrupt.
(5) The contents of the program counter (PC) is saved to the stack; or to the save PC register (SVP) in case of the fast interrupt.
(6) The interrupt request level for the accepted interrupt is set in the IPL (processor interrupt priority level).
(7) The corresponding interrupt vector is read from the interrupt vector table.
(8) This interrupt vector is stored into the program counter (PC).

When the interrupt sequence completes, the interrupt handler is initiated.

Note:
1. This register is inaccessible to users.

11.6.5 Interrupt Response Time

The interrupt response time, as shown in Figure 11.6, consists of two non-overlapping time segments: (a) the period from when an interrupt request is generated until the instruction being executed is completed; and (b) the period required for the interrupt sequence.

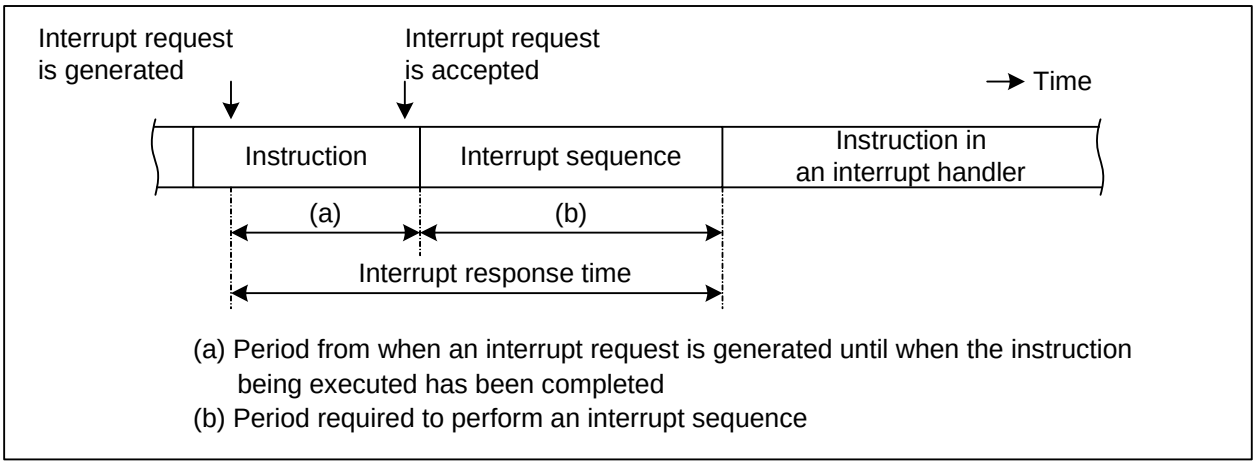

Figure 11.6 Interrupt Response Time

Period (a) varies depending on the instruction being executed. Instructions, such as LDCTX and STCTX in which registers are sequentially saved/restored into/from the stack, require the longest time. For example, the STCTX instruction requires at least 30 cycles for ten registers to be saved. It requires more time if the WAIT instruction is in the stack.
Period (b) is listed in Table 11.7.

Table 11.7 Interrupt Sequence Execution Time (1)

Interrupt	Execution Time in Terms of CPU Clock
Peripheral	13 + α cycles (2)
INT instruction	11 cycles
NMI	10 cycles
Watchdog timer Oscillator stop detection Low voltage detection	11 cycles
Undefined instruction	12 cycles
Overflow	12 cycles
BRK instruction (relocatable vector table)	16 cycles
BRK instruction (fixed vector table)	19 cycles
BRK2 instruction	19 cycles
Fast interrupt	11 cycles

Notes:
1. The interrupt vectors should be aligned in addresses in multiples of 4 of internal ROM. The fast interrupt is independent of this condition.
2. α is the number of waits to access SFR minus 2.

11.6.6 IPL After Interrupt Request Acceptance

When a peripheral interrupt request is accepted, the interrupt request level is set in the IPL (processor interrupt priority level).

Software interrupts and special interrupts have no interrupt request level. For these interrupt requests, if accepted, the value shown in Table 11.8 is set in the IPL as interrupt request level.

Table 11.8 Interrupts without Interrupt Request Level and IPL

Interrupt Sources without Interrupt Request Level	IPL Value to be Set
NMI, watchdog timer, oscillator stop detection, low voltage detection	7
Reset	0
Software	Unchanged

11.6.7 Register Saving

In the interrupt sequence, the flag register (FLG) and program counter (PC) values are saved to the stack, in that order. Figure 11.7 shows the stack status before and after an interrupt request is accepted.

In the fast interrupt sequence, the flag register (FLG) and program counter (PC) values are saved to the save flag register (SVF) and save PC register (SVP), respectively.

If there are any other registers to be saved to the stack, save them at the beginning of the interrupt handler. A single PUSHM instruction saves all registers except the frame base register (FB) and stack pointer (SP).

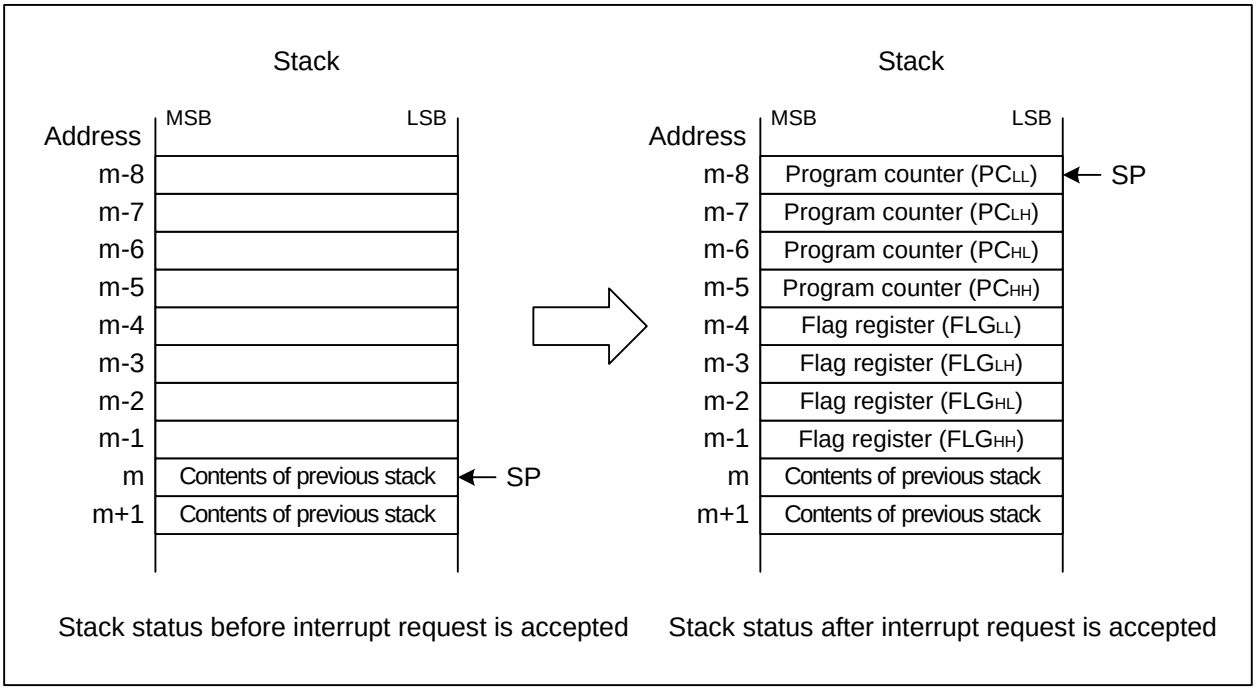

Figure 11.7 Stack Status Before and After an interrupt Request is Accepted

11.7 Register Restoring from Interrupt Handler

When the REIT instruction is executed at the end of the interrupt handler, the saved values of the flag register (FLG) and the program counter (PC) are restored from the stack, and the program resumes the operation that has been interrupted. In the fast interrupt, execute the FREIT instruction to restore them from the save registers, instead.

To restore the values of registers, which are saved by software in the interrupt handler, use an instruction such as POPM before the REIT or FREIT instruction.

If the register bank is switched in the interrupt handler, the bank is automatically switched back to the original register bank by the REIT or FREIT instruction.

11.8 Interrupt Priority

If two or more interrupt requests are detected at an interrupt request sampling point, the interrupt request with higher priority is accepted.

For maskable interrupts (peripheral interrupts), the interrupt request level select bits (bits ILVL2 to ILVL0) select a request level. If there are more than two interrupts with the same level, they are accepted according to their relative priority predetermined by the hardware.

The priorities of the reset and special interrupts, such as the watchdog timer interrupt, are determined by the hardware. Note that the reset has the highest priority. The following is the priority order of hardware interrupts:

Watchdog timer
Reset > Oscillator stop detection > NMI > Peripherals
Low voltage detection

Software interrupts are not governed by priority. They always cause execution to jump to the interrupt handler whenever the relevant instruction is executed.

11.9 Priority Resolver

The priority resolver determines which interrupt request has a higher priority if two or more interrupt requests are detected at a sampling point.

Figure 11.8 shows the priority resolver.

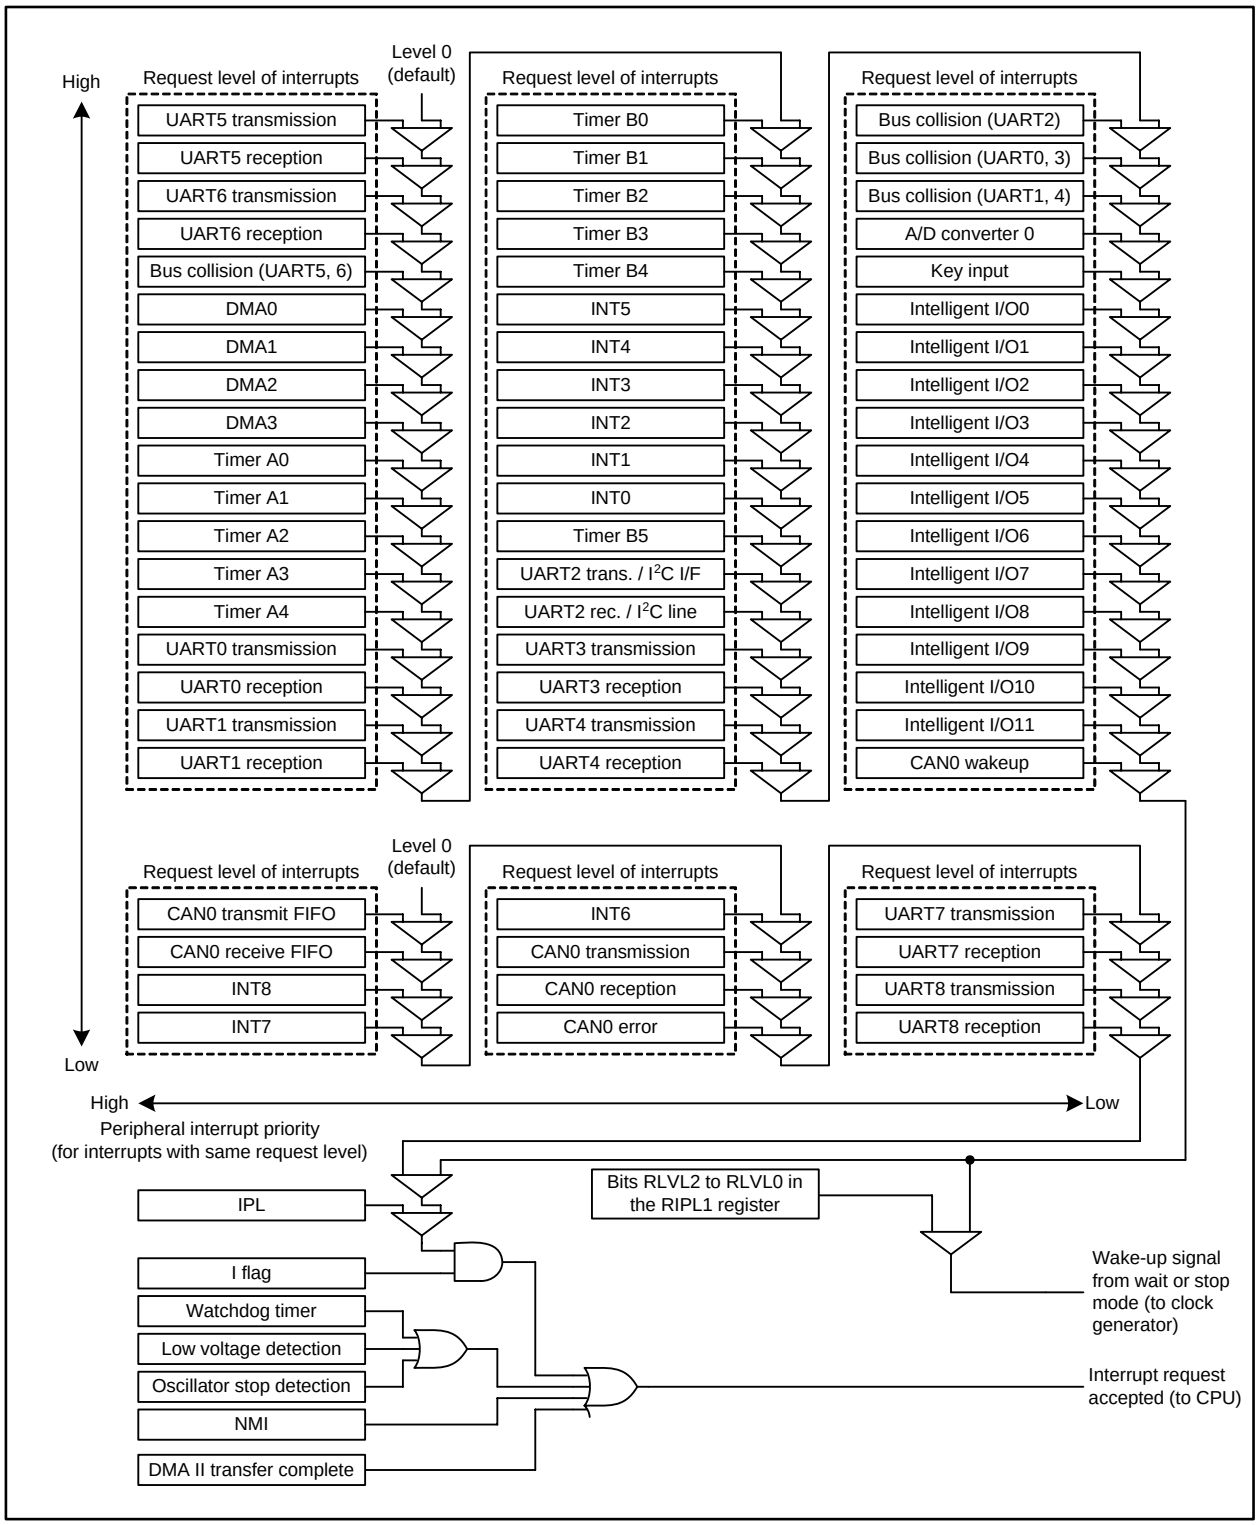

Figure 11.8 Priority Resolver

11.10 External Interrupt

An external interrupt is generated by an external input applied to the $\overline{INTi}$ pin (i = 0 to 8). The LVS bit in the INTiIC register selects whether an interrupt is triggered by the effective edge(s) (edge sensitive), or by the effective level (level sensitive) of the input signal. The polarity of the input signal is selected by the POL bit in the same register.

When using edge-triggered interrupts, setting the IFSR0j bit in the IFSR0 register to 1 (both edges) causes interrupt requests to be generated on both rising and falling edges of the external input applied to the $\overline{INTj}$ pin (j = 0 to 5). This also applies to setting the IFSR1n bit (n = m - 6) in the IFSR1 register to 1 (both edges) for the $\overline{INTm}$ pin (m = 6 to 8). When the IFSR0j bit or the IFSR1n bit is set to 1, the POL bit in the corresponding register should be set to 0 (falling edge).

When using level-triggered interrupts, set the IFSR0j or IFSR1n to 0 (one edge). When an effective level, which is selected by the POL bit, is detected on the $\overline{INTi}$ pin, the IR bit in the INTiIC register becomes 1. The IR bit remains unchanged until the INTi interrupt is accepted, or it is set to 0 by a program, even if the signal level at the $\overline{INTi}$ pin changes.

Figure 11.9 and Figure 11.10 show registers IFSR0 and IFSR1, respectively.

External Interrupt Request Source Select Register 0

b7	b6	b5	b4	b3	b2	b1	b0

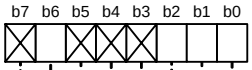
Symbol	Address	Reset Value
IFSR0	4406Fh	0000 0000b

Bit Symbol	Bit Name	Function	RW
IFSR00	$\overline{INT0}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR01	$\overline{INT1}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR02	$\overline{INT2}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR03	$\overline{INT3}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR04	$\overline{INT4}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR05	$\overline{INT5}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR06	UART0/UART3 Interrupt Source Select Bit	0: Bus collision, start condition detection, stop condition detection in UART3 1: Bus collision, start condition detection, stop condition detection in UART0	RW
IFSR07	UART1/UART4 Interrupt Source Select Bit	0: Bus collision, start condition detection, stop condition detection in UART4 1: Bus collision, start condition detection, stop condition detection in UART1	RW

Note:
1. This bit should be set to 0 to select the level sensitive input as trigger. To set this bit to 1, the POL bit in the corresponding INTiIC register (i = 0 to 5) should be set to 0 (falling edge).

Figure 11.9 IFSR0 Register

External Interrupt Request Source Select Register 1



Symbol	Address	Reset Value
IFSR1	4406Dh	X0XX X000b

Bit Symbol	Bit Name	Function	RW
IFSR10	$\overline{\text{INT6}}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR11	$\overline{\text{INT7}}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
IFSR12	$\overline{\text{INT8}}$ Pin Polarity Select Bit (1)	0: One edge 1: Both edges	RW
— (b5-b3)	No register bits; should be written with 0 and read as undefined value		—
IFSR16	UART5/UART6 Interrupt Source Select Bit	0: Bus collision, start condition detection, stop condition detection in UART5 1: Bus collision, start condition detection, stop condition detection in UART6	RW
— (b7)	No register bit; should be written with 0 and read as undefined value		—

Note:
1. This bit should be set to 0 to select the level sensitive input as trigger. To set this bit to 1, the POL bit in the corresponding INTiIC register (i = 6 to 8) should be set to 0 (falling edge).

Figure 11.10 IFSR1 Register

11.11 NMI

The NMI (Non Maskable Interrupt) occurs when an input signal at the $\overline{\text{NMI}}$ pin switches from high to low. This non maskable interrupt is disabled after a reset. To enable this interrupt, the PM24 bit in the PM2 register should be set to 1 after setting the interrupt stack pointer (ISP) at the beginning of the program. The $\overline{\text{NMI}}$ pin shares a pin with the port P8_5, which enables the P8_5 bit in the P8 register to indicate the input level at the $\overline{\text{NMI}}$ pin.

Note:
1. When not using the NMI, hold 0 as reset value of the PM24 bit in the PM2 register.

11.12 Key Input Interrupt

The key input interrupt is enabled by setting ports P10_4 to P10_7 as input ports.

The interrupt request is generated if any of the signals applied to ports P10_4 to P10_7 switches from high to low. This interrupt also functions as key wake-up to exit wait or stop mode. Figure 11.11 shows a block diagram of the key input interrupt. If any of the ports is held low, signals applied to other ports are not detected as interrupt request signals.

To use the key input interrupt, every register from P10_4S to P10_7S should be set to 00h (I/O port) and bits PD10_4 to PD10_7 should be set to 0 (input). This is the only setting available for the key input interrupt.

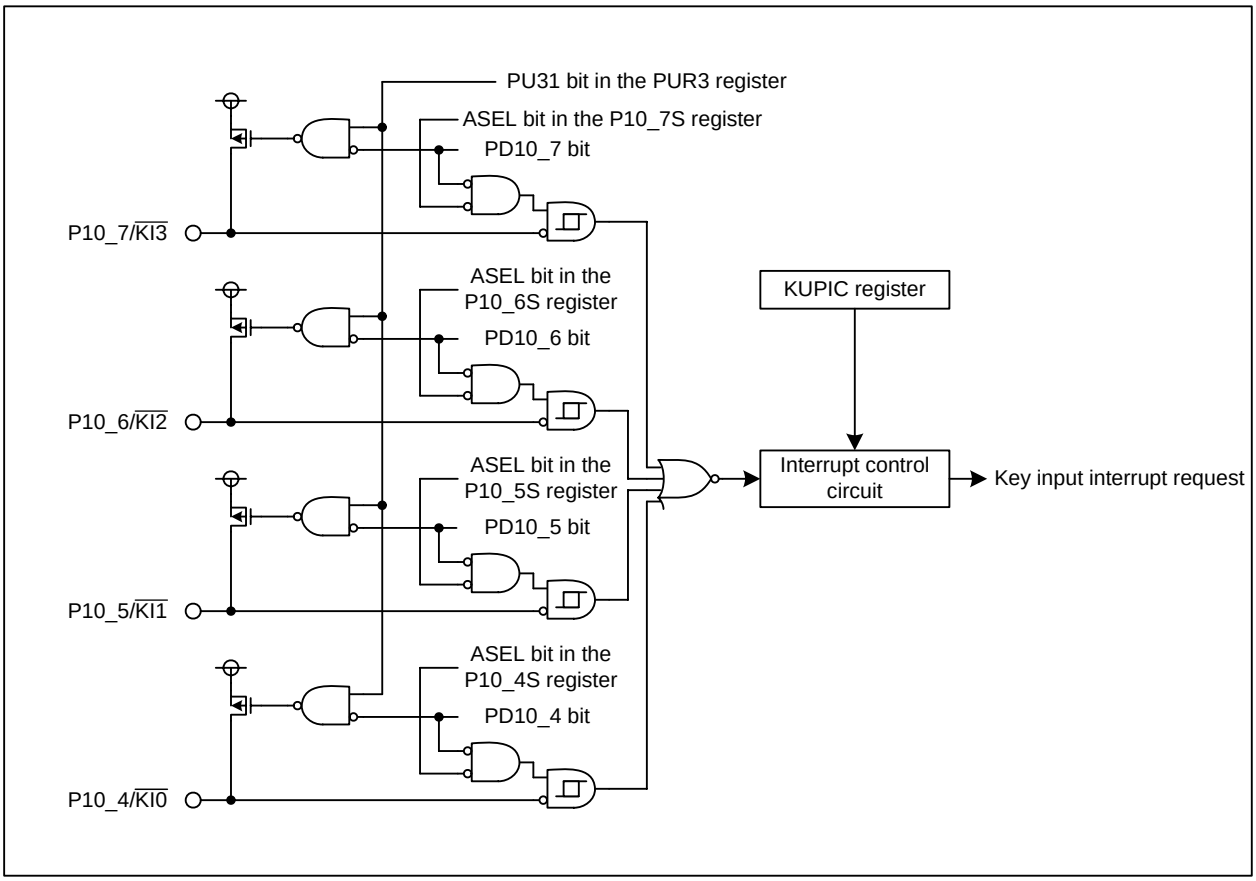


Figure 11.11 Key Input Interrupt

11.13 Intelligent I/O Interrupt

The intelligent I/O interrupt is assigned to software interrupt numbers from 44 to 55.

Figure 11.12 shows a block diagram of the intelligent I/O interrupt. Figure 11.13 and Figure 11.14 show registers IIOiIR and IIOiIE (i = 0 to 11), respectively.

To use the intelligent I/O interrupt, the IRLT bit in the IIOiIE register should be set to 1 (interrupt requests used for interrupt).

The intelligent I/O interrupt contains various request sources. When an interrupt request is generated with an intelligent I/O function, the corresponding bit in the IIOiIR register becomes 1 (interrupts requested). If the corresponding bit in the IIOiIE register is set to 1 (interrupt enabled), the IR bit in the corresponding IIOiIC register changes to 1 (interrupts requested).

After the IR bit setting changes from 0 to 1, this bit remains unchanged if a bit in the IIOiIR register is set to 1 by another interrupt request source and the corresponding bit in the IIOiIE register is set to 1.

Bits in the IIOiIR register are not set to 0 automatically even if an interrupt is accepted. They should be set to 0 by either the AND or BCLR instruction. Note that every generated interrupt request is ignored until these bit are set to 0.

To use the intelligent I/O interrupt to activate DMAC II, the IRLT bit in the IIOiIE register should be set to 0 (interrupt requests used for DMA or DMA II) and the bit for interrupt source to be used in the IIOiE register should be set to 1 (interrupt enabled).

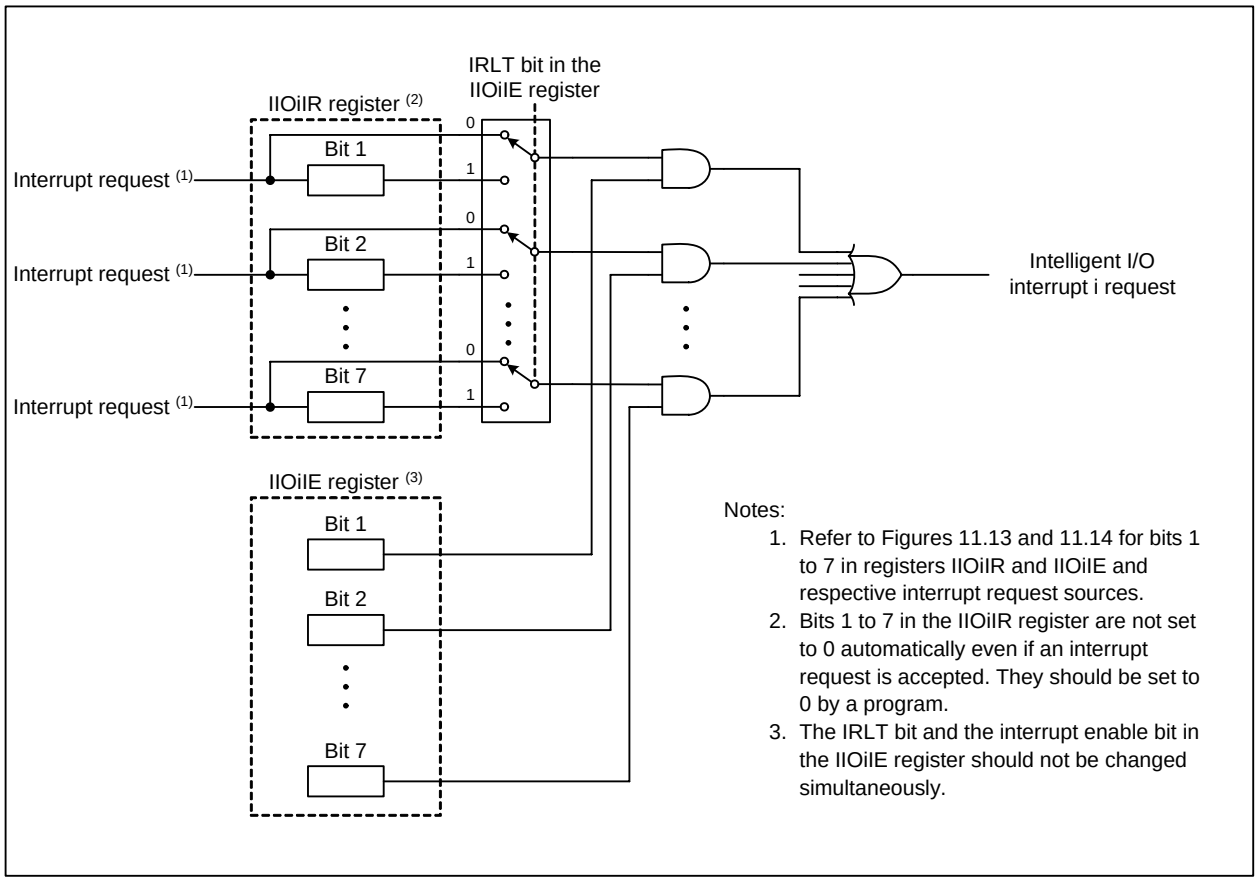

Figure 11.12 Intelligent I/O Interrupt Block Diagram (i = 0 to 11)

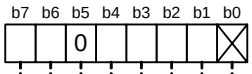
Intelligent I/O Interrupt Request Register i (i = 0 to 11)



Symbol	Address	Reset Value
IIO0IR to IIO11IR	Refer to the table below	??0? ???1b (1)

Bit Symbol	Bit Name	Function	RW
— (b0)	No register bit; this bit is read as 1		—
(Note 2)	0: No interrupt requested 1: Interrupt requested (3)		RW
(Note 2)	0: No interrupt requested 1: Interrupt requested (3)		RW
(Note 2)	0: No interrupt requested 1: Interrupt requested (3)		RW
(Note 2)	0: No interrupt requested 1: Interrupt requested (3)		RW
— (b5)	Reserved	Should be written with 0	RW
(Note 2)	0: No interrupt requested 1: Interrupt requested (3)		RW
(Note 2)	0: No interrupt requested 1: Interrupt requested (3)		RW

Notes:
1. When the register has any function-assigned bit, the reset value is X (undefined); otherwise, the reset value is 0.
2. Refer to the table below for bit symbols.
3. When this bit is function-assigned, it can be set to 0 only. It should not be set to 1. To set to 0, either the AND or BCLR instruction should be used; when the bit is not function-assigned, that is, reserved, it should be set to 0.

Figure 11.14 Registers IIO0IE to IIO11IE

11.14 Notes on Interrupts

11.14.1 ISP Setting

The interrupt stack pointer (ISP) is initialized to 00000000h after a reset. Set a value to the ISP before an interrupt is accepted, otherwise the program may go out of control. A multiple of 4 should be set to the ISP, which enables faster interrupt sequence due to less memory access.
For the use of NMI, in particular, since this interrupt cannot be disabled, the PM24 bit in the PM2 register should be set to 1 (NMI enabled) after the ISP is set at the beginning of program.

11.14.2 NMI

- The NMI cannot be disabled once the PM24 bit in the PM2 register is set to 1 (NMI enabled). This bit setting should be done only for the use of NMI.

- When the PM24 bit in the PM2 register is set to 1 (NMI enabled), the P8_5 bit in the P8 register is enabled just for monitoring the $\overline{\text{NMI}}$ pin state. It is not enabled as a general port.

11.14.3 External Interrupt

- The input signal to the $\overline{\text{INTi}}$ pin (i = 0 to 8) requires the pulse width specified by the electrical characteristics. If a pulse width is narrower than the specification, the external interrupt may not be accepted.

- When the effective level and/or edge of $\overline{\text{INTi}}$ pin (i = 0 to 8) are/is changed by the following bits: bits POL and/or LVS in the INTiIC register, the IFSR0i bit (i = 0 to 5) in the IFSR0 register, and/or the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register, the corresponding IR bit may become 1 (interrupt requested). When setting the above mentioned bits, preset bits ILVL2 to ILVL0 in the INTiIC register to 000b (interrupt disabled). After setting the above mentioned bits, set the corresponding IR bit to 0 (no interrupt requested), then set bits ILVL2 to ILVL0.

- The interrupt input signals to pins $\overline{\text{INT6}}$ to $\overline{\text{INT8}}$ are also connected to bits INT6R to INT8R in registers IIO9IR to IIO11IR. Therefore, these input signals, when assigned to the intelligent I/O, can be used as a source for exiting wait mode or stop mode. Note that these signals are enabled only on the falling edge and not affected by the following bit settings: bits POL and LVS in the INTiIC register (i = 0 to 8), IFSR0i bit (i = 0 to 5) in the IFSR0 register, and the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register.

12. Watchdog Timer

The watchdog timer monitors program executions and detects defective programs. The 15-bit watchdog counter counts downward with the cycle which is the peripheral bus clock frequency divided by the prescaler.
When the watchdog timer underflows, the CM06 bit in CM0 register selects either a watchdog timer interrupt request or a reset. Once the CM06 bit is set to 1 (reset), it cannot be changed to 0 (watchdog timer interrupt) by a program. Only after a reset, it can be set to 0.
The watchdog timer contains a prescaler which is the peripheral bus clock divided by 16 or 128. The divide ratio is selected by setting the WDC7 bit in the WDC register.
The watchdog timer is stopped in wait mode, stop mode, or when the $\overline{\text{HOLD}}$ is driven low. It resumes counting from the value held when the mode or state is exited.

The general formula to calculate a watchdog timer period is:

$$\text{Watchdog timer period} = \frac{\text{Prescaler divider factor (16 or 128)} \times 32768}{\text{Peripheral bus clock frequency}}$$

For example, when the peripheral bus clock is 1/2 of 50 MHz-CPU clock and the prescaler has a divide-by-16 operation, the watchdog timer period is approximately 21 ms. Note that marginal errors within one prescaler output cycle may occur in the watchdog timer period.

The watchdog timer is initialized when a write to the WDTS register is performed or when a watchdog timer interrupt request is generated. The prescaler is initialized only when the MCU is reset.
After a reset, both the watchdog timer and the prescaler are stopped. They start counting when a write to the WDTS register is performed.

Figure 12.1 shows a block diagram of the watchdog timer. Figure 12.2 and Figure 12.3 show registers associated with the watchdog timer.

13. DMAC

Direct Memory Access (DMA) is a system that can control data transfer without using the CPU.
The R32C/100 Series' four channel DMA controller (DMAC) transmits 8-bit (byte), 16-bit (word), or 32-bit (long word) data in cycle-steal mode from a source address to a destination address every time a transfer request is generated.
The DMAC, which shares a data bus with the CPU, has a higher bus access priority than the CPU. This allows the DMAC to perform fast data transfer when a transfer request is generated.
Figure 13.1 shows a map of the CPU-internal registers associated with DMAC. Table 13.1 lists DMAC specifications. Figure 13.2 to Figure 13.10 show registers associated with DMAC. Since the registers shown in Figure 13.1 are allocated in the CPU, the LDC or STC instruction should be used to write to the registers.

DMAC-associated Registers

DMD0	DMA0 mode register

Note:
1. Registers are used for repeat transfer, not for single transfer.

Figure 13.1 CPU-internal Registers for DMAC

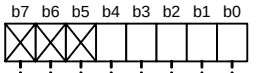
Table 13.1 DMAC Specifications

Item		Specification
Channels		4
Bus request mode		Cycle-steal mode
Transfer memory spaces		From a given address in a 64-Mbyte space (00000000h to 01FFFFFFh and FE000000h to FFFFFFFFh) to another given address in the same space
Maximum transfer bytes		64-Mbytes (when 32-bit data is transferred), 32-Mbytes (when 16-bit data is transferred), 16-Mbytes (when 8-bit data is transferred)
DMA request sources (1)		Falling edge or both edges of signals applied to pins INT0 to INT3 or pins $\overline{\text{INT6}}$ to $\overline{\text{INT8}}$ Timers A0 to A4 interrupt requests Timers B0 to B5 interrupt requests UART0 to UART8 transmit/receive interrupt requests A/D conversion interrupt requests Intelligent I/O interrupt requests Multi-master I^2C-bus interrupt requests Software trigger
Channel priority		DMA0 > DMA1 > DMA2 > DMA3 (DMA0 has the highest priority)
Transfer sizes		8 bits, 16 bits, or 32 bits
Addressing modes		Incrementing addressing or non-incrementing addressing
Transfer modes	Single transfer	Transfer is completed when the DCTi register (i = 0 to 3) is set to 00000000h
	Repeat transfer	When the DCTi register is set to 00000000h, the value of the DCRi register is reloaded into the DCTi register to continue the DMA transfer
DMA transfer complete interrupt request generation timing		When the DCTi register changes from 00000001h to 00000000h
DMA transfer start-up	Single transfer	DMA starts when a DMA transfer request is generated after the DCTi register is set to a value more than 00000001h and bits MDi1 and MDi0 in the DMDi register are set to 01b (single transfer)
	Repeat transfer	DMA starts when a DMA transfer request is generated after the DCTi register is set to a value more than 00000001h and bits MDi1 and MDi0 are set to 11b (repeat transfer)
DMA transfer stop	Single transfer	DMA stops when bits MDi1 and MDi0 are set to 00b (DMA disabled)
	Repeat transfer	DMA stops when bits MDi1 and MDi0 are set to 00b (DMA disabled)
Reload timing to DCTi, DSAi or DDAi register		When the DCTi register changes from 00000001h to 00000000h in repeat transfer mode
Minimum DMA transfer cycles		3

Note:
1. DMA transfer does not affect each interrupt.

The DMA transfer request is available by two different sources: software and hardware. More concretely, they are a write access to the DSR bit in the DMiSL2 register (i = 0 to 3) and an interrupt request output from a function specified in bits DSEL4 to DSEL0 in the DMiSL register, and in bits DSEL24 to DSEL20 in the DMiSL2 register. Unlike interrupt requests, the DMA transfer request is not affected by the I flag nor the interrupt control register. Therefore this request can be accepted even when any interrupt request cannot be because of “interrupt disabled”. Since the DMA transfer does not affect any interrupt, either, the IR bit in the interrupt control register is not changed by the DMA transfer.

DMAi Request Source Select Register (i = 0 to 3)



Symbol	Address	Reset Value
DM0SL to DM3SL	44078h, 44079h, 4407Ah, 4407Bh	XXX0 0000b

1 1 1 1 1	Intelligent I/O interrupt 6 request	Intelligent I/O interrupt 1 request	Intelligent I/O interrupt 8 request	Intelligent I/O interrupt 3 request

Notes:

1. The falling edge and both edges of signals applied to the $\overline{INTi}$ pin (i = 0 to 3) cause a DMA request generation. The external interrupts (bits POL and LVS in the INTiIC register and the IFSR0 register) are not affected by these DMA request sources, and vice versa.
2. When the $\overline{INT3}$ pin is used for data bus in memory expansion mode or microprocessor mode, it cannot be used for a signal input of DMA3 request source.
3. Registers UiSMR and UiSMR2 (i = 0 to 6) are used to switch between the UARTi receive interrupt and ACK interrupt.
4. Select an interrupt source either of UART2 or I^2C-bus interface by using the I2CEN bit in the I2CMR register.

Table 13.3 DMiSL2 Register (i = 0 to 3) Functions

Figure 13.10 Registers DDR0 to DDR3

13.1 Transfer Cycle

The transfer cycle is composed of bus cycles to read data from memory or SFR (source read) and to write data to destination address (destination write).
The read and write bus cycles vary with the setting of registers DSAi (i = 0 to 3) and DDAi, the width of data bus connected to the relevant device and bus timing.

13.1.1 Effect of Transfer Address and Data Bus Width

Table 13.4 lists the incremental bus cycles caused by transfer address alignment or data bus width.

Table 13.4 Incremental Bus Cycles Caused by Transfer Address and Data Bus Width

Transfer Data Unit	Data Bus Width	Transfer Address	Bus Cycles to be Incremented	Bus Cycles Generated
8-bit transfer	8 to 64 bits	n	0	[n]
16-bit transfer	8 bits	n	+1	[n] - [n + 1]
	16 bits	2n	0	[2n]
		2n + 1	+1	[2n + 1] - [2n + 2]
	32 bits	4n	0	[4n]
		4n + 1	0	[4n + 1]
		4n + 2	0	[4n + 2]
		4n + 3	+1	[4n + 3] - [4n + 4]
	64 bits	8n	0	[8n]
		8n + 1	0	[8n + 1]
		8n + 2	0	[8n + 2]
		8n + 3	0	[8n + 3]
		8n + 4	0	[8n + 4]
		8n + 5	0	[8n + 5]
		8n + 6	0	[8n + 6]
		8n + 7	+1	[8n + 7] - [8n + 8]
32-bit transfer	8 bits	n	+3	[n] - [n + 1] - [n + 2] - [n + 3]
	16 bits	4n	+1	[4n] - [4n + 2]
		4n + 1	+2	[4n + 1] - [4n + 2] - [4n + 4]
		4n + 2	+1	[4n + 2] - [4n + 4]
		4n + 3	+2	[4n + 3] - [4n + 4] - [4n + 6]
	32 bits	4n	0	[4n]
		4n + 1	+1	[4n + 1] - [4n + 4]
		4n + 2	+1	[4n + 2] - [4n + 4]
		4n + 3	+1	[4n + 3] - [4n + 4]
	64 bits	8n	0	[8n]
		8n + 1	0	[8n + 1]
		8n + 2	0	[8n + 2]
		8n + 3	0	[8n + 3]
		8n + 4	0	[8n + 4]
		8n + 5	+1	[8n + 5] - [8n + 8]
		8n + 6	+1	[8n + 6] - [8n + 8]
		8n + 7	+1	[8n + 7] - [8n + 8]

13.1.2 Effect of Bus Timing

In the R32C/100 Series, each device has its own bus addresses assigned. The bus width and bus timing vary with each device. Table 13.5 lists the bus width and access cycles for each device.

Table 13.5 Bus Width and Bus Cycles

Device	Addresses (1)	Bus Width	Access Cycles (2)	Reference Clock
Flash memory	FFE00000h to FFFFFFFFh	64-bit	2 or 3 (3)	CPU clock
Data flash	00060000h to 00061FFFh	64-bit	5	CPU clock
RAM	00000400h to 0003FFFFh	64-bit	1 or 2 (4)	CPU clock
SFR space	00000000h to 0000001Fh	16-bit	3 (5)	Peripheral bus clock
	00000020h to 000003FFh	16-bit	2 (5)	Peripheral bus clock
SFR2 space	00040000h to 00041FFFh	16-bit	2 (5)	Peripheral bus clock
	00042000h to 00043FFFh	32-bit	2 (5)	Peripheral bus clock
	00044000h to 000440DFh	16-bit	2 (5, 6)	Peripheral bus clock
	000440E0h to 000443FFh	16-bit	3 (5, 6)	Peripheral bus clock
	00044400h to 00045FFFh	16-bit	2 (5, 6)	Peripheral bus clock
	00046000h to 000467FFh	32-bit	3 (5, 6)	Peripheral bus clock
	00046800h to 00047FFFh	32-bit	2 (5, 6)	Peripheral bus clock
	00048000h to 0004FFFFh	64-bit	2	CPU clock
External bus	00060000h to 01FFFFFFh FE000000h to FFDFFFFFh	8-/16-/32-bit	Specified by EBCn register (n = 0 to 3) (5)	Peripheral bus clock

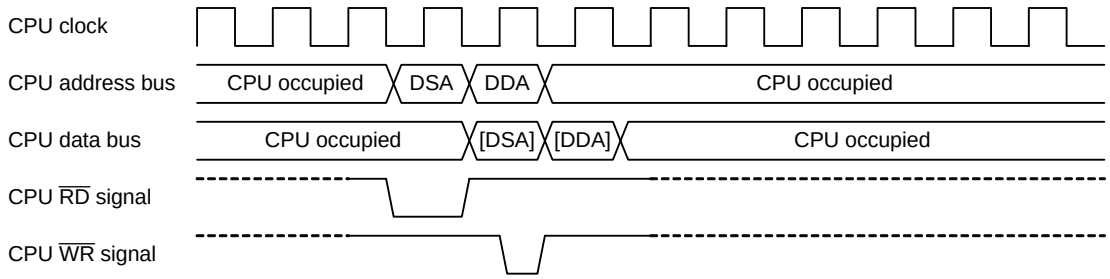
Notes:
1. Reserved spaces are included.
2. Access cycles are based on each bus clock.
3. An access to the same page as the previous time requires two cycles. Otherwise, three cycles are required.
4. If write cycles are generated sequentially, each write cycle except the initial one has two access cycles. A read cycle just after a write cycle has also two access cycles.
5. If SFR is sequentially accessed, each access except the initial one has additional one base clock cycle.
6. One or less access cycle may be added depending on the phase of peripheral bus clock.

Figure 13.11 shows an example of source-read bus cycles in a transfer cycle. In this figure, the number of source-read bus cycle is shown under different conditions, provided that the destination address is in an internal RAM with one bus cycle of destination-write. In real operation, the transfer cycles change according to conditions for destination-write bus cycles as well as for source-read bus cycles. To calculate a transfer cycle, therefore, respective conditions should be applied to both destination-write bus cycle and source-read bus cycle. In (2) of Figure 13.11, for example, if the destination-write bus cycle is generated twice, both bus cycles are two, respectively.

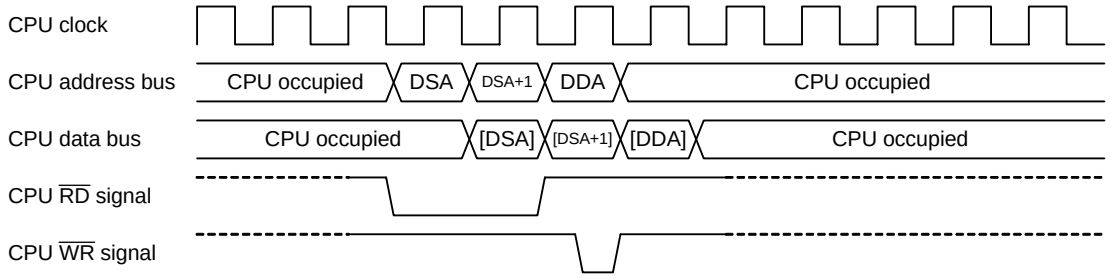
13.1.3 Effect of $\overline{\text{RDY}}$ Signal

In memory expansion mode or microprocessor mode, the $\overline{\text{RDY}}$ signal affects a bus cycle in an external space. Refer to 9.3.7 “$\overline{\text{RDY}}$ Signal” for details.

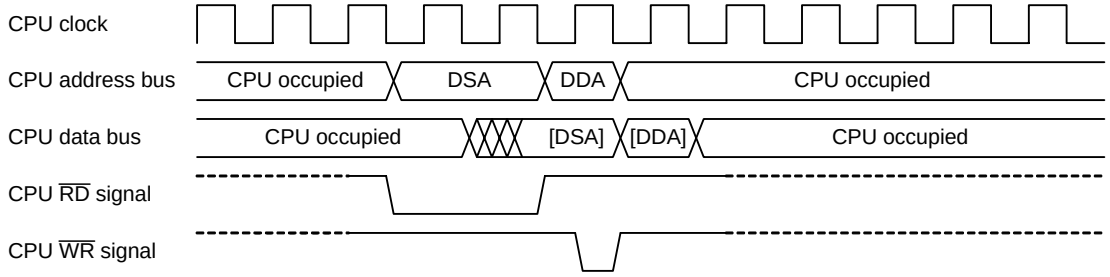
(1) One bus cycle of source-read is generated
Example: 16-bit data transfer from the address 8n of the RAM



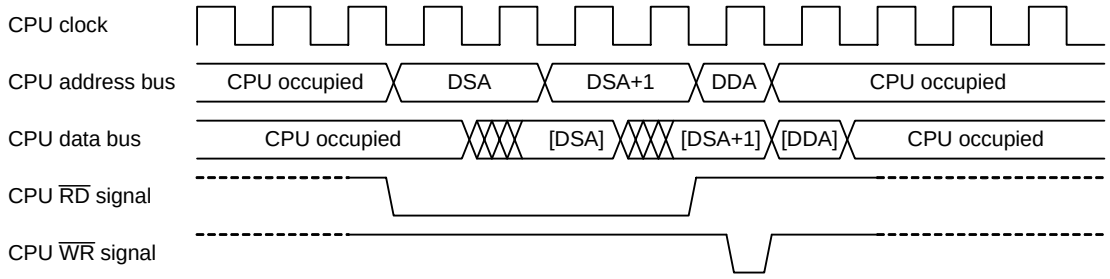
(2) Two bus cycles of source-read are generated
Example: 16-bit data transfer from the address 8n+7 of the RAM



(3) One bus cycle of source-read is generated with one wait cycle
Example: 16-bit data transfer from the address 16n of the ROM



(4) Two bus cycles of source-read is generated with one wait cycle
Example: 16-bit data transfer from the address 16n+7 of the ROM



Note:
1. The above applies under the condition of one bus cycle of destination-write. In real cases, the number of destination-write bus cycles should be considered according to the conditions such as above.

Figure 13.11 Source-read Bus Cycles in a Transfer Cycle

13.2 DMA Transfer Cycle

The DMA transfer cycles are calculated as follows:

$$Number\ of\ a\ transfer\ cycles = Source\text{-}read\ bus\ cycles \times j + Destination\text{-}write\ bus\ cycles \times k + 1$$

where:

j = access cycles for read,

k = access cycles for write (refer to Table 13.5)

Each bus cycle, source-read, and destination-write basically requires one or more cycles. In addition, more cycles may be required depending on the transfer address. Refer to Table 13.4 for required bus cycles.

"+1" in the formula above means a cycle required to decrement the value of DCTi register (i = 0 to 3).

The following are calculation examples:

To transfer 32-bit data from the address 400h of the RAM to the address 800h of the RAM,

$$Number\ of\ the\ transfer\ cycles = 1 \times 1 + 1 \times 1 + 1$$
$$= 3$$

Thus, there are three cycles.

To transfer 16-bit data from the AD00 register at address 380h to registers P1 and P0 at addresses 3C1h and 3C0h, respectively, with the peripheral bus clock (= 1/2 CPU clock),

$$Number\ of\ the\ transfer\ cycles = 1 \times 2 \times 2 + 1 \times 2 \times 2 + 1$$
$$= 9$$

Thus, there are nine cycles.

13.3 Channel Priority and DMA Transfer Timing

When multiple DMA transfer requests are generated in the same sampling period, between the falling edge of the CPU clock and the next falling edge, these requests are simultaneously input into the DMAC. Channel priority in this case is: DMA0 > DMA1 > DMA2 > DMA3.

Figure 13.12 shows an example of the DMA transfer by external source, specifically when a DMA0 request and a DMA1 request are simultaneously generated. The DMA0 request having higher priority is received first to start a transfer. After one DMA0 transfer is completed, the bus privilege is returned to the CPU. When the CPU has completed one bus access, the DMA1 transfer starts. After one DMA1 transfer is completed, the privilege is again returned to the CPU.

DMA transfer requests cannot be counted up. The transfer occurs only once even when an $\overline{\text{INTi}}$ interrupt is generated more than once before receiving the bus privilege, as the DMA1 shown in Figure 13.12.

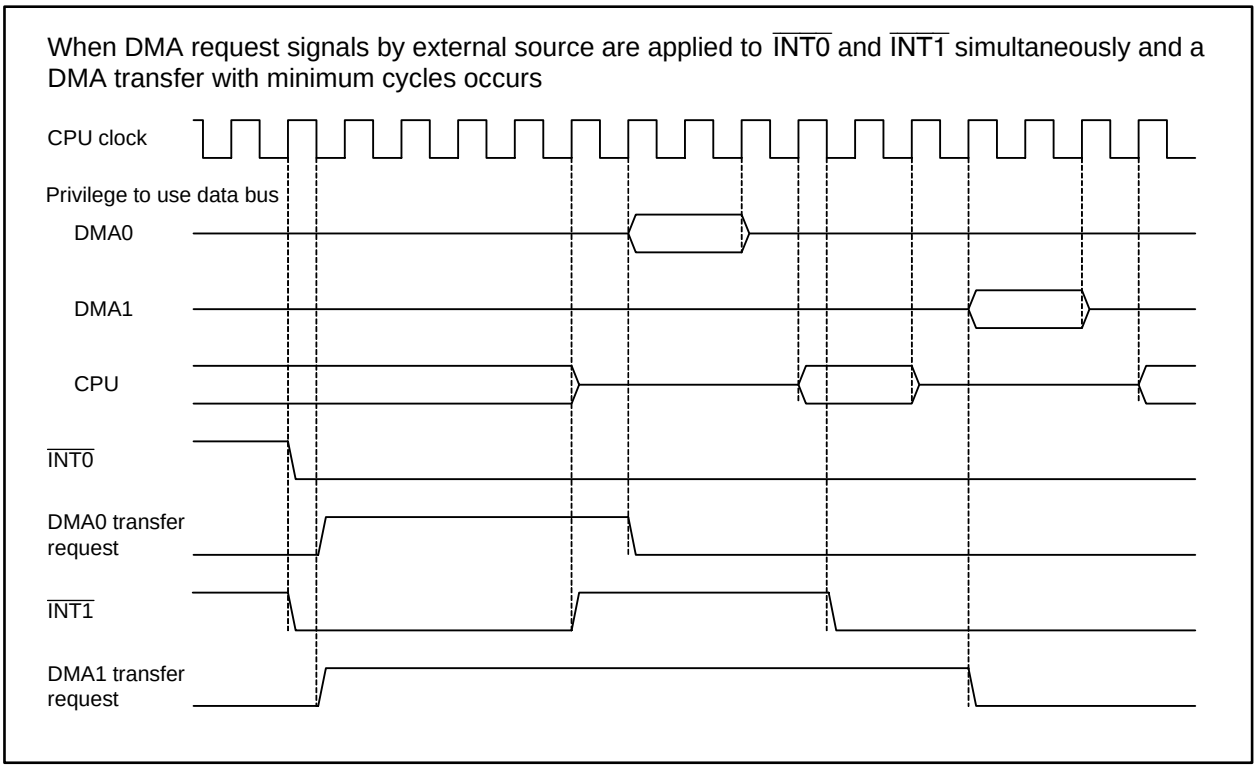


Figure 13.12 DMA Transfer by External Source

13.4 Notes on DMAC

13.4.1 DMAC-associated Register Settings

- Set the DMAC-associated registers while bits MDi1 and MDi0 (i = 0 to 3) in the DMDi register are 00b (DMA transfer disabled). Then, set bits MDi1 and MDi0 to 01b (single transfer) or 11b (repeat transfer) at the end of the setup procedure. This procedure is also applied to rewriting bits UDAi, USAi, and BWi1 and BWi0 in the DMDi register.

- In case the DMAC-associated registers are to be rewritten while DMA transfer is enabled, disable the peripheral function as DMA request source so that no DMA transfer request is generated, then set bits MDi1 and MDi0 in the DMDi register of the corresponding channel to 00b (DMA transfer disabled).

- Once a DMA transfer request is accepted, DMA transfer cannot be disabled even if setting bits MDi1 and MDi0 in the DMDi register to 00b (DMA transfer disabled). Do not change the settings of any DMAC-associated registers other than bits MDi1 and MDi0 until the DMA transfer is completed.

- Wait six or more peripheral bus clocks to set bits MDi1 and MDi0 in the DMDi register to 01b (single transfer) or 11b (repeat transfer) after setting registers DMiSL and DMiSL2.

13.4.2 Read from DMAC-associated Registers

- To sequentially read respective registers DMiSL and DMiSL2, follow the reading order as below:
  DM0SL, DM1SL, DM2SL, and DM3SL
  DM0SL2, DM1SL2, DM2SL2, and DM3SL2

14. DMAC II

DMAC II is activated by an interrupt request from any peripheral function, and performs data transfer without a CPU instruction. Transfer sources can be selected from memory, immediate data, memory + memory, and immediate data + memory.
Table 14.1 lists specifications of DMAC II.

Table 14.1 DMAC II Specifications

Item	Specification
Triggers for DMAC II	Interrupt requests generated by any of peripheral functions when bits ILVL2 to ILVL0 in the corresponding interrupt control register are set to 111b (level 7)
Transfer types	• Data in memory is transferred to memory (memory-to-memory transfer) • Immediate data is transferred to memory (immediate data transfer) • Data in memory + data in memory are transferred to memory (calculation transfer) • Immediate data + data in memory are transferred to memory (calculation transfer)
Transfer sizes	8 bits or 16 bits
Transfer memory spaces	From a given address in a 64-Mbyte space (00000000h to 01FFFFFFh and FE000000h to FFFFFFFFh) to another given address in the same space (1)
Addressing modes	Individually selectable for each source address and destination address from the following two modes: • Non-incrementing addressing: Address is held constant throughout a data transfer/a DMA II transaction • Incrementing addressing: Address increments by 1 (when 8-bit data is transferred) or 2 (when 16-bit data is transferred) after each data transfer
Transfer modes	• Single transfer: Only one data transfer is performed by one transfer request • Burst transfer: Data transfers are continuously performed for the number of times set in the transfer counter • Multiple transfer: Multiple memory-to-memory transfers are performed from different source addresses to different destination addresses by one transfer request
Chained transfer	Data transfer is sequentially performed according to a DMAC II Index (transfer information) linked with the previous transfer
DMA II transfer complete interrupt request	An interrupt request is generated when the transfer counter reaches 0000h

Note:
1. When 16-bit data is transferred to destination address at FFFFFFFFh, it is transferred to 00000000h as well as FFFFFFFFh. The same transfer is performed when the source address is FFFFFFFh.

14.1 DMAC II Settings

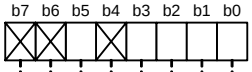
To activate DMAC II, set up the following items:
- Registers RIPL1 and RIPL2
- DMAC II index
- The interrupt control register of the peripheral function triggering DMAC II
- The relocatable vector of the peripheral function triggering DMAC II
- IIRLT bit in the IIOiIE register (i = 0 to 11) if the intelligent I/O interrupt is used. Refer to 11. “Interrupts” for details on the IIOilE register.

14.1.1 Registers RIPL1 and RIPL2

When the DMAII bits in both the RIPL1 and RIPL2 registers are set to 1 (DMA II transfer selected) and the FSIT bits are set to 0 (normal interrupt selected), DMAC II is activated by an interrupt of any peripheral function with bits ILVL2 to ILVL0 in the corresponding interrupt control register set to 111b (level 7).

Figure 14.1 shows registers RIPL1 and RIPL2.

Wake-up IPL Setting Register i (i = 1, 2) (1)



Symbol	Address	Reset Value
RIPL1, RIPL2	4407Fh, 4407Dh	XX0X 0000b

Bit Symbol	Bit Name	Function	RW
RLVL0	Interrupt Priority Level for Wake-up Select Bit (2)	b2 b1 b0 0 0 0 : Level 0 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	RW
RLVL1			RW
RLVL2			RW
FSIT	Fast Interrupt Select Bit (3)	0: Use interrupt request level 7 for normal interrupt 1: Use interrupt request level 7 for fast interrupt (4)	RW
— (b4)	No register bit; should be written with 0 and read as undefined value		—
DMAII	DMA II Select Bit (5)	0: Use interrupt request level 7 for interrupt 1: Use interrupt request level 7 for DMA II transfer (4)	RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Notes:
1. Registers RIPL1 and RIPL2 should be identically set.
2. The MCU exits wait mode or stop mode if the request level of requested interrupt is higher than the level selected using bits RLVL2 to RLVL0. These bits should be set to the same value as the IPL in the flag register (FLG).
3. When the FSIT bit is set to 1, an interrupt with interrupt request level 7 becomes the fast interrupt. In this case only one interrupt should be set to the interrupt request level 7.
4. Either the FSIT or DMAII bit should be set to 1. Simultaneous use of the fast interrupt and the DMAC II is not available.
5. Bits ILVL2 to ILVL0 in the interrupt control register should be set after the DMAII bit is set. The DMA II transfer is not affected by the I flag or the IPL.

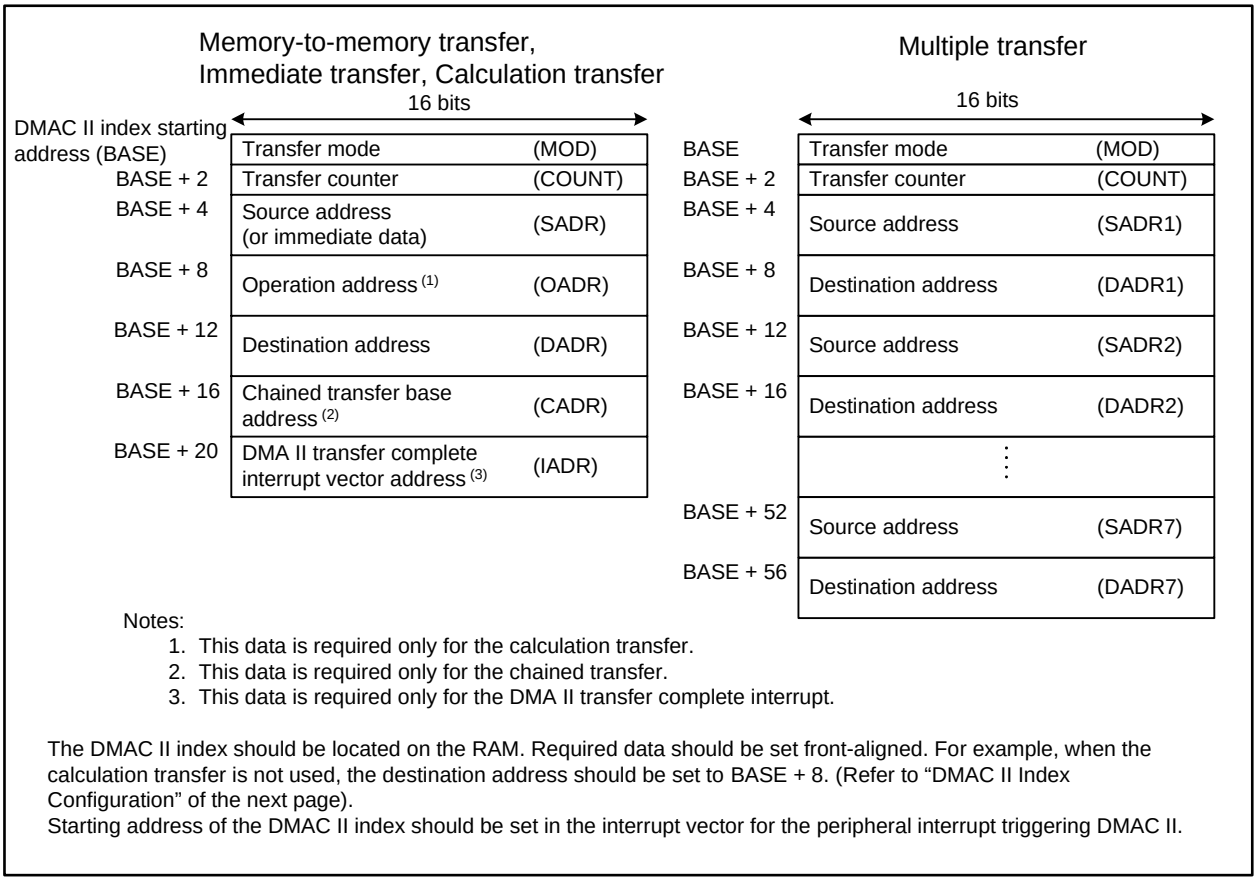
Figure 14.1 Registers RIPL1 and RIPL2

14.1.2 DMAC II Index

The DMAC II index is a data table of 12 to 60 bytes. It stores parameters for transfer mode, transfer counter, source address (or immediate data), operation address as an address to be calculated, destination address, chained transfer base address, and DMA II transfer complete interrupt vector address.

This DMAC II index should be located on the RAM.

Figure 14.2 shows a configuration of the DMAC II index and Table 14.2 lists a configuration example of the DMAC II index.



Notes:
1. This data is required only for the calculation transfer.
2. This data is required only for the chained transfer.
3. This data is required only for the DMA II transfer complete interrupt.

The DMAC II index should be located on the RAM. Required data should be set front-aligned. For example, when the calculation transfer is not used, the destination address should be set to BASE + 8. (Refer to “DMAC II Index Configuration” of the next page).
Starting address of the DMAC II index should be set in the interrupt vector for the peripheral interrupt triggering DMAC II.

Figure 14.2 DMAC II Index

The following are the details on the DMAC II index. These parameters should be aligned in the specified order listed in Table 14.2 according to the transfer mode to be performed.

- Transfer mode (MOD)
  2-byte data is required to set transfer mode. Figure 14.3 shows a configuration for transfer mode.
- Transfer counter (COUNT)
  2-byte data is required to set the transfers to be performed.
- Source address (SADR)
  4-byte data is required to set a source address in a memory or an immediate data. However, the two upper bytes of immediate data are ignored.
- Operation address (OADR)
  4-byte data is required to set an address in a memory to be calculated. This data setting is required only for the calculation transfer.
- Destination address (DADR)
  4-byte data is required to set a destination address in a memory.
- Chained transfer base address (CADR)
  4-byte data is required to set BASE, the starting address of the DMAC II index for the next transfer. This data setting is required only for the chained transfer.
- DMA II transfer complete interrupt vector address (IADR)
  4-byte data is required to set a jump address for the DMA II transfer complete interrupt handler. This data setting is required only for the DMA II transfer complete interrupt.

The symbols above are hereinafter used in place of their respective parameters.

Table 14.2 DMAC II Index Configuration

Transfer Data	Memory-to-memory Transfer/ Immediate Data Transfer				Calculation Transfer				Multiple Transfer
Chained transfer	Not used	Used	Not used	Used	Not used	Used	Not used	Used	Not available
DMA II transfer complete interrupt	Not used	Not used	Used	Used	Not used	Not used	Used	Used	Not available

Note:
1. The MOD should be located on the RAM.

Figure 14.3 MOD

14.1.3 Interrupt Control Register of the Peripheral Function

Set bits ILVL2 to ILVL0 in the interrupt control register for the peripheral interrupt triggering DMAC II to 111b (level 7).

14.1.4 Relocatable Vector Table of the Peripheral Function

Set the starting address of the DMAC II index to the interrupt vector for the peripheral interrupt triggering DMAC II.
To use the chained transfer, locate the relocatable vector table on the RAM.

14.1.5 IRLT Bit in the IIOiIE Register (i = 0 to 11)

To use the intelligent I/O interrupt as a trigger for DMAC II, set the IRLT bit in the corresponding IIOiIE register to 0 (interrupt request for DMA or DMA II used).

14.2 DMAC II Performance

To perform a DMA II transfer, the DMAII bits in registers RIPL1 and RIPL2 should be set to 1 (interrupt request level 7 used for DMA II transfer). Any peripheral interrupts with bits ILVL2 to ILVL0 set to 111b (level 7) can be a request source to activate DMAC II. These peripheral interrupt requests are available only for DMA II transfer, that is, they cannot be used for CPU.
When an interrupt request is generated with interrupt request level 7, DMAC II is activated irrespective of the state of I flag or IPL.
When a peripheral interrupt request triggering DMAC II and a higher-priority request such as watchdog timer interrupt, low voltage detection interrupt, oscillator stop detection interrupt, and NMI are simultaneously generated, the higher-priority interrupt is accepted prior to the DMA II transfer, and the DMA II transfer starts after the higher-priority interrupt sequence.

14.3 Transfer Types

DMAC II transfers three types of 8-bit or 16-bit data as follows:

- Memory-to-memory transfer: Data is transferred from a given memory location in a 64-Mbyte space (addresses 00000000h to 01FFFFFFh and FE000000h to FFFFFFFFh) to another given memory location in the same space.
- Immediate data transfer: Immediate data is transferred to a given memory location in a 64-Mbyte space.
- Calculation transfer: Two data are added together and the result is transferred to a given memory location in a 64-Kbyte space.

When 16-bit data is transferred to DADR at FFFFFFFFh, it is transferred to 00000000h as well as FFFFFFFFh. The same transfer is performed when SADR is FFFFFFFFh.

14.3.1 Memory-to-memory Transfer

Data transfer between any two memory locations can be:

- A transfer from a constant address to another constant address
- A transfer from a constant address to an address range in memory
- A transfer from an address range in memory to a constant address
- A transfer from an address range in memory to another address range in memory

When increment addressing mode is selected, SADR and DADR increment by one in a 8-bit transfer and by two in a 16-bit transfer after a data transfer for the next transfer. When SADR or DADR exceeds FFFFFFFFh as a result of address incrementation, it returns to 00000000h. Likewise, when SADR or DADR exceeds 01FFFFFFh, it must become 02000000h, but an actual transfer is performed for FE000000h.

14.3.2 Immediate Data Transfer

DMAC II transfers immediate data to any memory location. Both incrementing or non-incrementing addressing modes are available for destination address. Store the immediate data to be transferred into SADR. To transfer 8-bit immediate data, set the data to the one lower byte of SADR. For 16-bit immediate data, set the data to the two lower bytes. The three upper bytes or the two upper bytes of respective case are ignored.

14.3.3 Calculation Transfer

After two memory data or an immediate data and memory data are added together, DMAC II transfers calculated result to any memory location. Set one address to be calculated or an immediate data to SADR and set the other address to be calculated to OADR. Both incrementing or non-incrementing addressing modes are available for source and destination addresses in case of a data in memory + a data in memory calculation transfer. If the source addressing is incrementing mode, the operation addressing should be also incrementing. In case of an immediate data + a data in memory calculation transfer, the addressing mode is selectable only for destination address.

14.4 Transfer Modes

DMAC II provides three types of basic transfer modes: single transfer, burst transfer, and multiple transfer. COUNT determines the number of transfers to be performed. No transfer is performed when COUNT is set to 0000h.

14.4.1 Single Transfer

Set the BRST bit in the MOD to 0.
One data transfer is performed by one transfer request.
When incrementing addressing mode is selected for the source and/or destination address, the address(es) increment(s) after a data transfer for the next transfer.
COUNT is decremented every time a data transfer is performed. When COUNT reaches 0000h, the DMA II transfer complete interrupt request is generated if the INTE bit in the MOD is 1 (the DMA II transfer complete interrupt used).

14.4.2 Burst Transfer

Set the BRST bit in the MOD to 1.
DMAC II continuously transfers data for the number of times determined by COUNT by one transfer request. COUNT is decremented every time a data transfer is performed. When COUNT reaches 0000h, the burst transfer is completed. The DMA II transfer complete interrupt request is generated if the INTE bit is 1 (the DMA II transfer complete interrupt used).
No interrupt is accepted during burst transfer being performed.

14.4.3 Multiple Transfer

Set the MULT bit in the MOD to 1.
Multiple memory-to-memory transfers are performed from different source addresses to different destination addresses by one transfer request.
Bits CNT2 to CNT0 in the MOD select the number of transfers to be performed from 001b (once) to 111b (seven times). These bits should not be set to 000b.
Allocate required number of SDARs and DADRs alternately following MOD and COUNT.
When the multiple transfer is selected, the following transfer functions are not available: the calculation transfer, burst transfer, chained transfer, and DMA II transfer complete interrupt.

14.5 Chained Transfer

The chained transfer is available when the CHAIN bit in the MOD is set to1.
The chained transfer is performed as follows:

(1) When a transfer request is generated, a data transfer is performed according to DMAC II index specified by the corresponding interrupt vector. Either single transfer (the BRST bit in the MOD is 0) or burst transfer (the BRST bit is 1) is performed according to the BRST bit setting.
(2) When COUNT reaches 0000h, the value in the interrupt vector in (1) above is overwritten with the value in CADR. Simultaneously, the DMA II transfer complete interrupt is generated when the INTE bit in the MOD is 1.
(3) When the next DMA II transfer request is generated, the data transfer is performed according to DMAC II index specified by the peripheral interrupt vector in (2) above.

Figure 14.4 shows the relocatable vector and DMAC II index in chained transfer.
To use the chained transfer, the relocatable vector table should be located on the RAM.

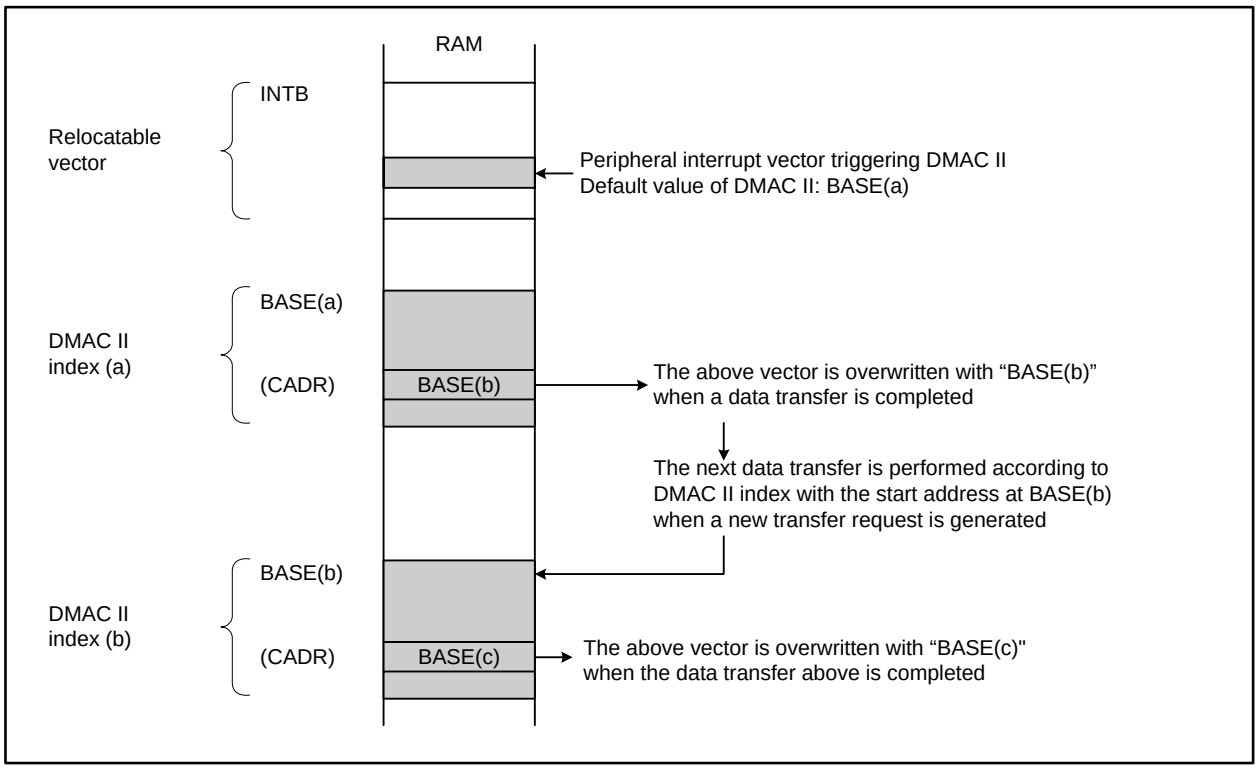

Figure 14.4 Relocatable Vector and DMAC II Index in Chained Transfer

14.6 DMA II Transfer Complete Interrupt

The DMA II transfer complete interrupt is available when the INTE bit in the MOD is set to1.
The starting address of the DMA II transfer complete interrupt handler should be set to IADR. The interrupt is generated when COUNT reaches 0000h.

The initial instruction of the interrupt handler is executed in the eighth cycle after a DMA II transfer is completed.

14.7 Execution Time

DMAC II execution cycle is calculated by the following equations:

Other than multiple transfer: t = 6 + (26 + a + b + c + d) × m + (4 + e) × n cycles
Multiple transfer: t = 21 + (11 + b + c) × k cycles

a: if IMM = 0 (transfer source is immediate data), a = 0;
if IMM = 1 (transfer source is memory), a = -1
b: if UPDS = 1 (source addressing is incrementing), b = 0;
if UPDS = 0 (source addressing is non-incrementing), b = 1
c: if UPDD = 1 (destination addressing is incrementing), c = 0;
if UPDD = 0 (destination addressing is non-incrementing), c = 1
d: if OPER = 0 (calculation transfer is not selected), d = 0;
if OPER = 1 (calculation transfer is selected) and UPDS = 0 (source addressing is immediate data or non-incrementing),
d = 7;
if OPER = 1 (calculation transfer is selected) and UPDS = 1 (source addressing is incrementing),
d = 8
e: if CHAIN = 0 (chained transfer is not selected), e = 0;
if CHAIN = 1 (chained transfer is selected), e = 4
m: if BRST = 0 (single transfer), m = 1;
if BRST = 1 (burst transfer), m = COUNT
n: if COUNT = 0001h, n = 0; if COUNT= 0002h or more, n = 1
k: The number of transfers to be performed set using bits CNT2 to CNT0

The equations above are approximate. The cycles may vary depending on CPU state, bus wait state and DMAC II index allocation.

When a DMA II transfer complete interrupt (transfer counter = 2) is generated with no chained transfer after a memory-to-memory transfer is performed twice with a incremented source address and a non-incremented destination address in single transfer mode

(a = -1, b = 0, c = 1, d = 0, e = 0, m = 1)

First DMA II transfer t = 6 + (26 - 1 + 0 + 1 + 0) × 1 + (4 + 0) × 1 = 36 cycles
Second DMA II transfer t = 6 + (26 - 1 + 0 + 1 + 0) × 1 + (4 + 0) × 0 = 32 cycles

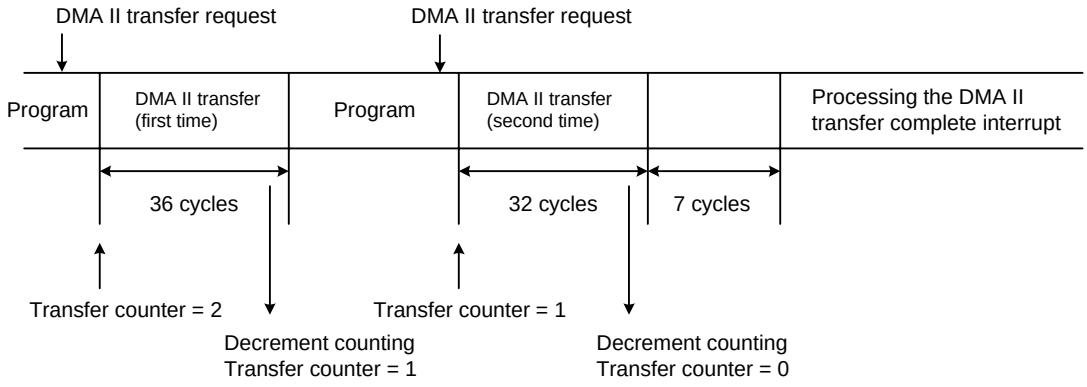

Figure 14.5 Transfer Cycles

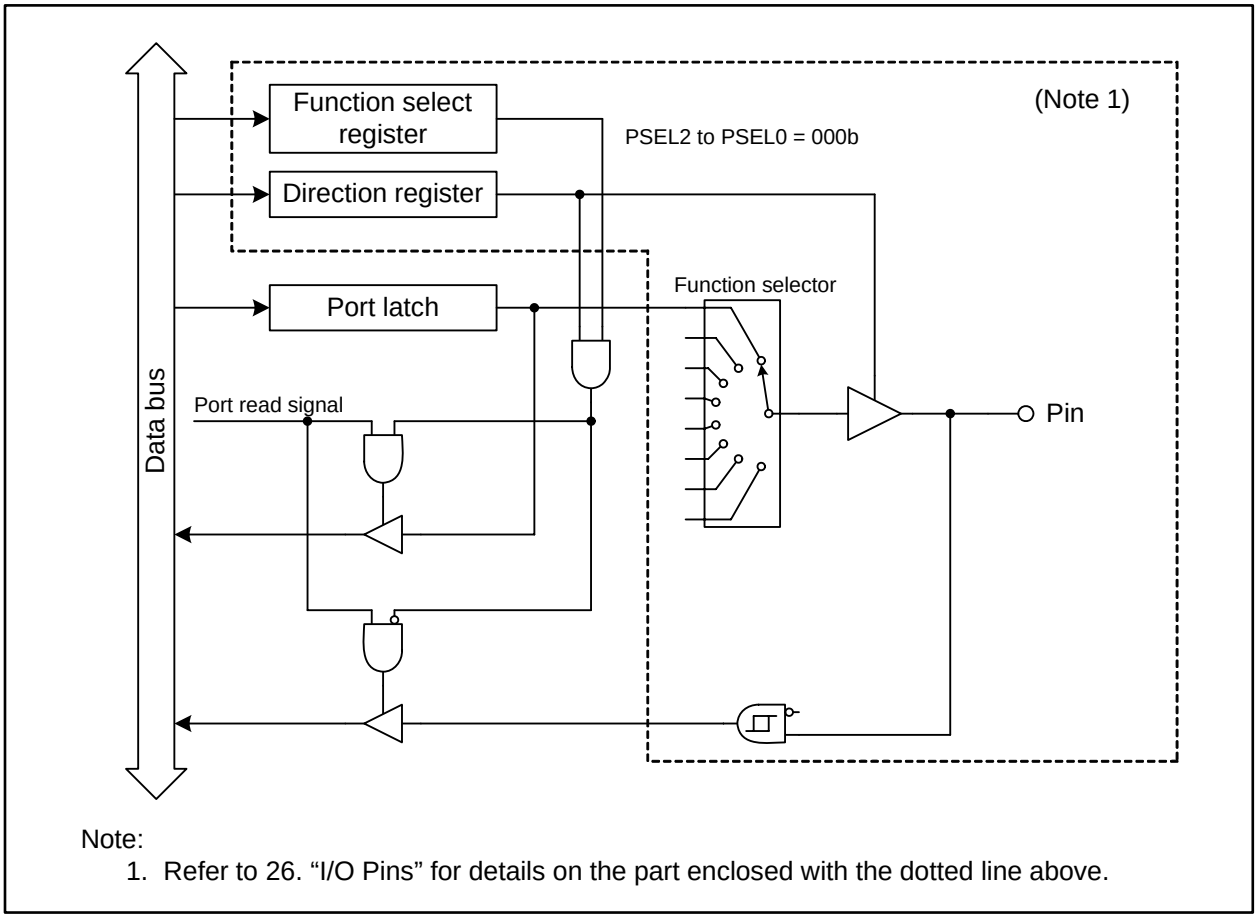
15. Programmable I/O Ports

The programmable I/O ports in each pin package are designated as follows:
100-pin package: 84 ports from P0 to P10 (excluding P8_5 and P9_0 to P9_2), and 144-pin package: 120 ports from P0 to P15 (excluding P8_5 and P14_0 to P14_2).
Each port status, input or output, can be selected using the direction register except P8_5 and P9_1/P14_1 which are input only. The P8_5 bit in the P8 register indicates an $\overline{\text{NMI}}$ input level since the P8_5 shares a pin with the $\overline{\text{NMI}}$.
Figure 15.1 shows a configuration of programmable I/O ports and Figure 15.2 to Figure 15.4 show a configuration of each input-only port.



Note:
1. Refer to 26. “I/O Pins” for details on the part enclosed with the dotted line above.

Figure 15.1 Programmable I/O Port Configuration

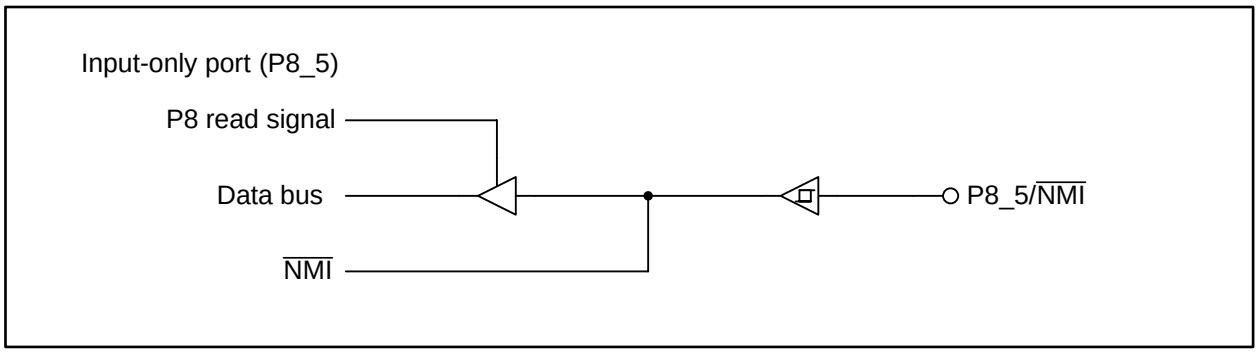


Figure 15.2 Input-only Port Configuration (1/3)

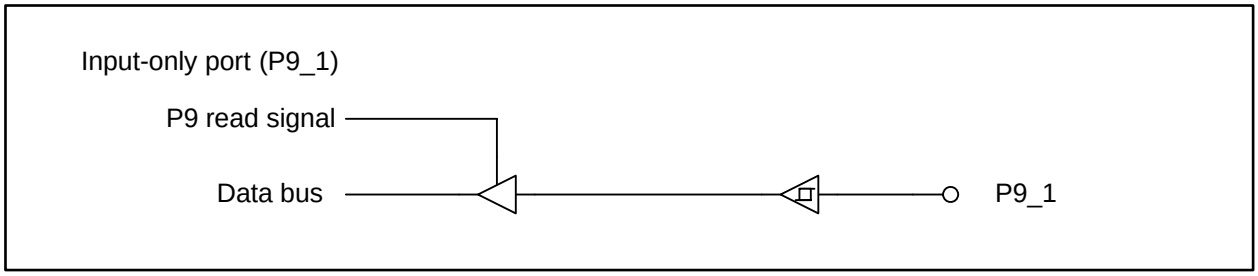

Figure 15.3 Input-only Port Configuration (2/3) (in the 100-pin package only)

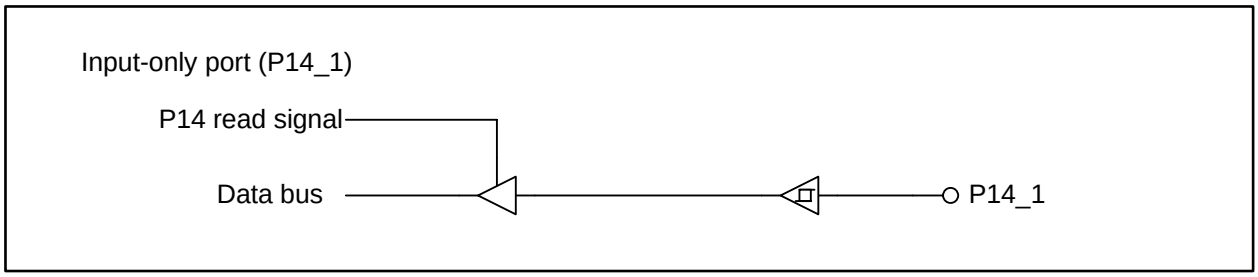

Figure 15.4 Input-only Port Configuration (3/3) (in the 144-pin package only)

15.1 Port Pi Register (Pi register, i = 0 to 15)

A write/read to the Pi register is required to communicate with external devices. This register consists of a port latch to hold output data and a circuit to read pin states. Each bit in the Pi register corresponds to a respective port.

When a programmable I/O port is selected in the output function select register, the value in the port latch as output data and pin states as input data are respectively read.

In memory expansion mode or microprocessor mode, this register cannot control pins being used as the bus control pins (A0 to A23, D0 to D31, $\overline{CS0}$ to $\overline{CS3}$, $\overline{WR}$/$\overline{WR0}$, $\overline{BC0}$, $\overline{BC1}$/$\overline{WR1}$, $\overline{BC2}$/$\overline{WR2}$, $\overline{BC3}$/$\overline{WR3}$, $\overline{RD}$, CLKOUT/BCLK, $\overline{HLDA}$, $\overline{HOLD}$, ALE, and $\overline{RDY}$).

Figure 15.5 shows the Pi register.

Port Pi Register (i = 0 to 15) (1, 2)

Notes:
1. In memory expansion mode or microprocessor mode, the PDi register cannot control pins being used as bus control pins (A0 to A23, D0 to D31, $\overline{CS0}$ to $\overline{CS3}$, $\overline{WR}$/$\overline{WR0}$, $\overline{BC0}$, $\overline{BC1}$/$\overline{WR1}$, $\overline{BC2}$/$\overline{WR2}$, $\overline{BC3}$/$\overline{WR3}$, $\overline{RD}$, CLKOUT/BCLK, $\overline{HLDA}$, $\overline{HOLD}$, ALE, and $\overline{RDY}$).
2. Registers P11 to P15 are available in the 144-pin package only.
3. The P8_5 bit in the P8 register, the P9_1 bit in the P9 register (in the 100-pin package), and the P14_1 bit in the P14 register (in the 144-pin package) are read only.
4. Bits P9_0 and P9_2 in the P9 register (in the 100-pin package) and bits P14_0 and P14_2 in the P14 register (in the 144-pin package) are reserved. These bits should be written with 0 and read as undefined values.
5. Bits P11_5 to P11_7 in the P11 register and the P14_7 bit in the P14 register are unavailable on this MCU. These bits should be written with 0 and read as undefined values.

Figure 15.5 Registers P0 to P15

16. Timers

This MCU has eleven 16-bit timers which are divided into two groups according to functions: five timer As and six timer Bs. Each timer functions individually. The count source of each timer provides the clock for timer operations including counting, reloading and so on.
Figure 16.1 and Figure 16.2 show the configuration of the timers A and B, respectively.

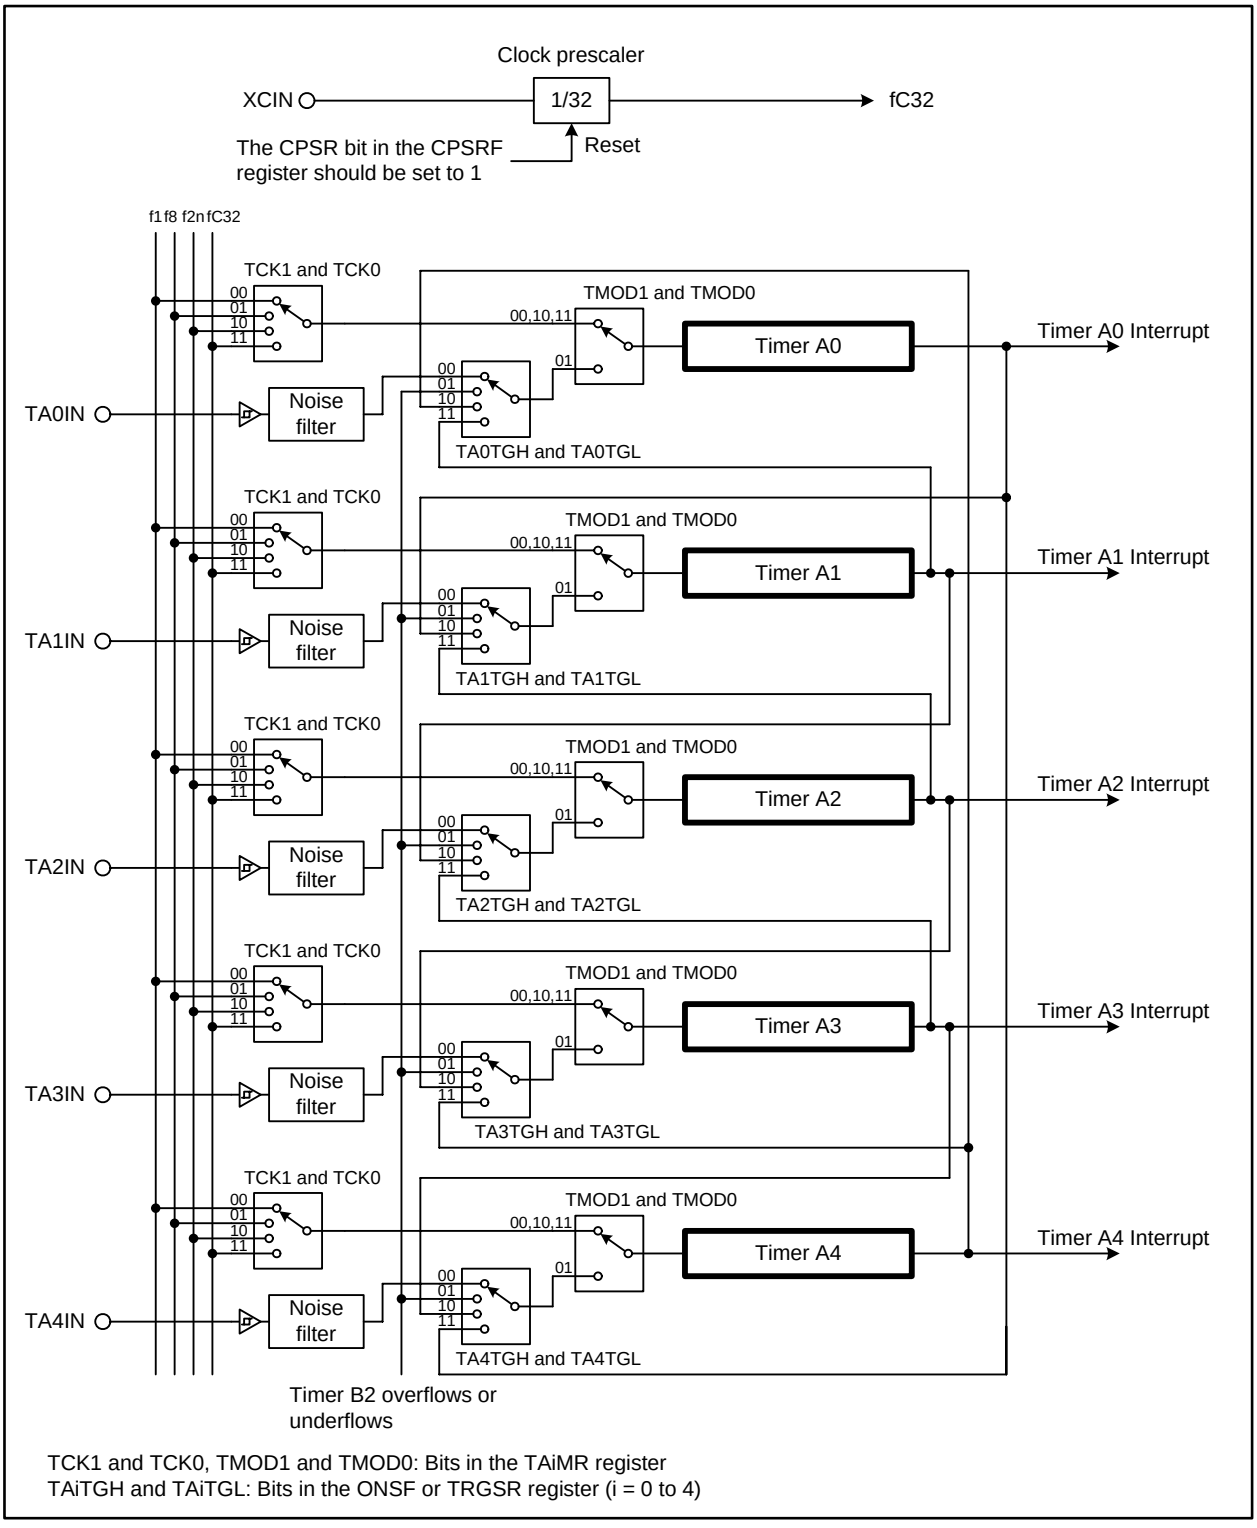

Figure 16.1 Timer A Configuration

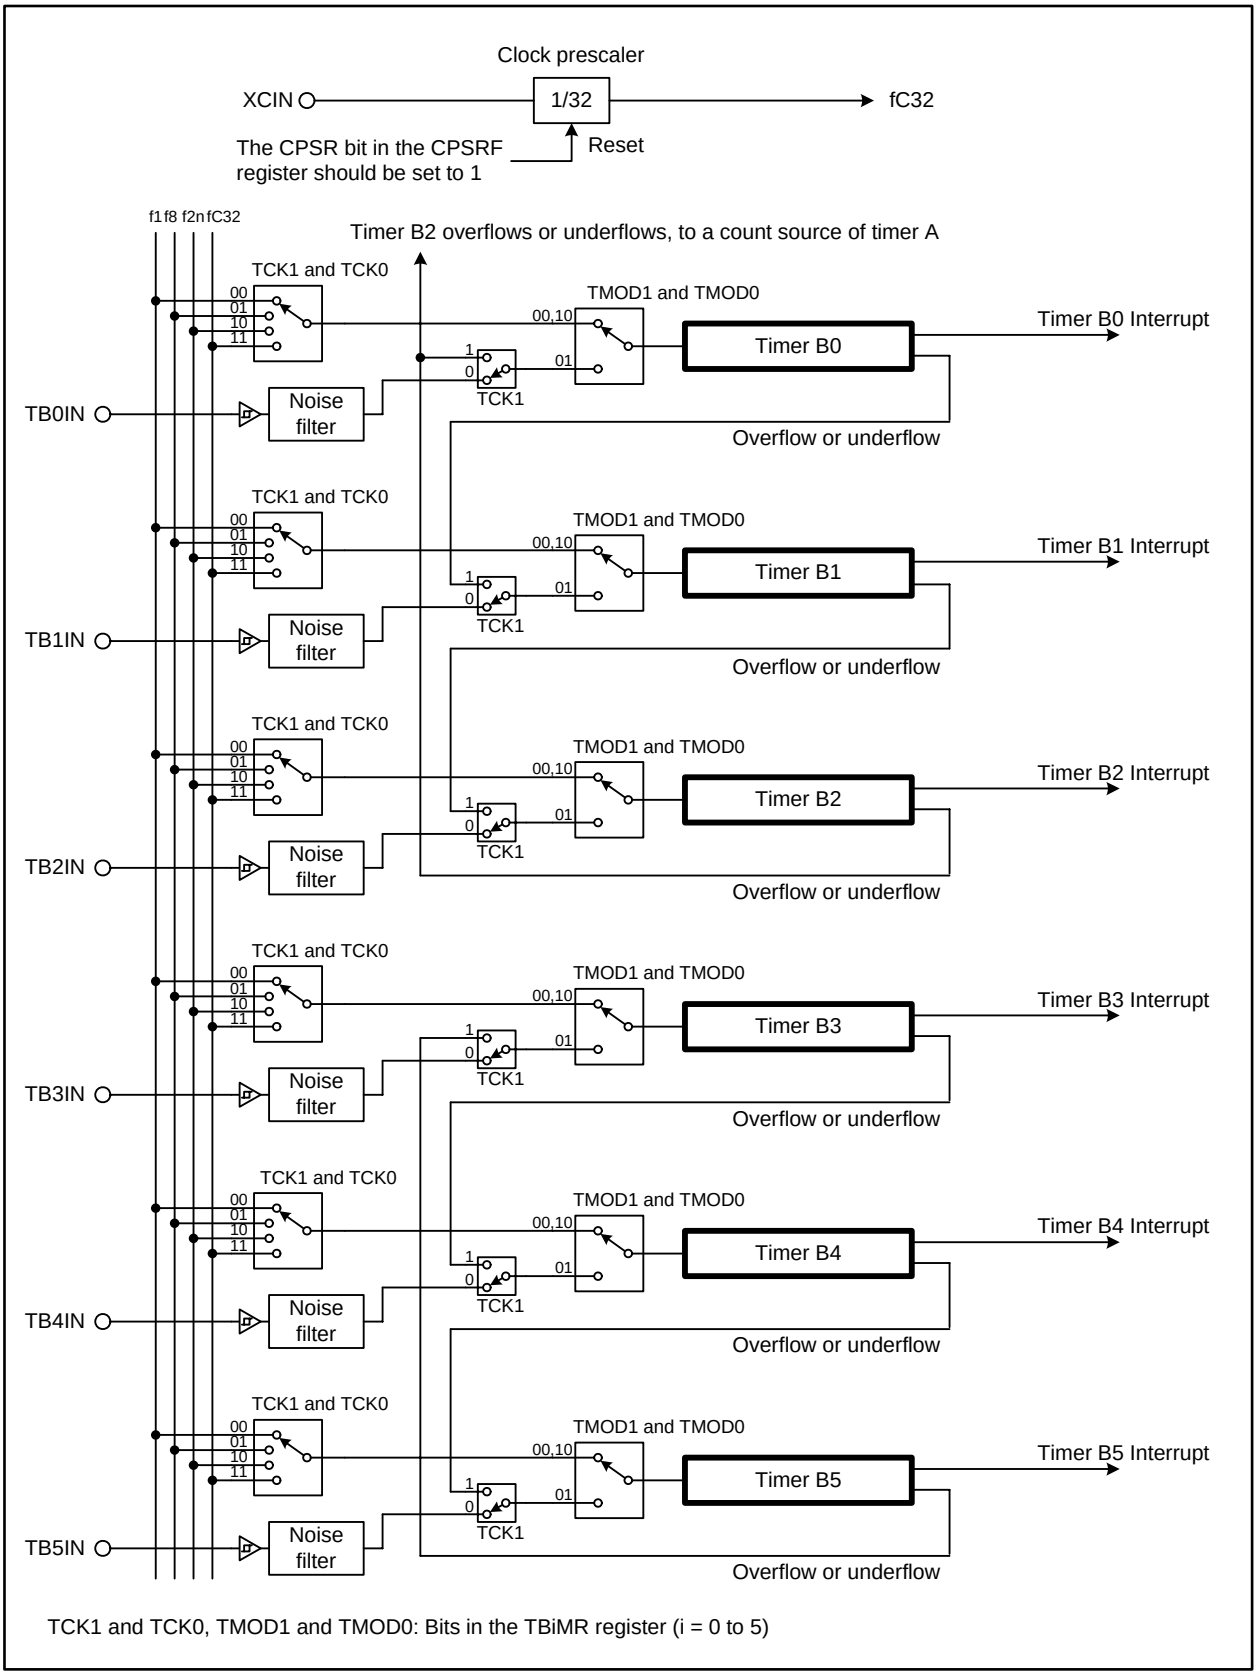

Figure 16.2 Timer B Configuration

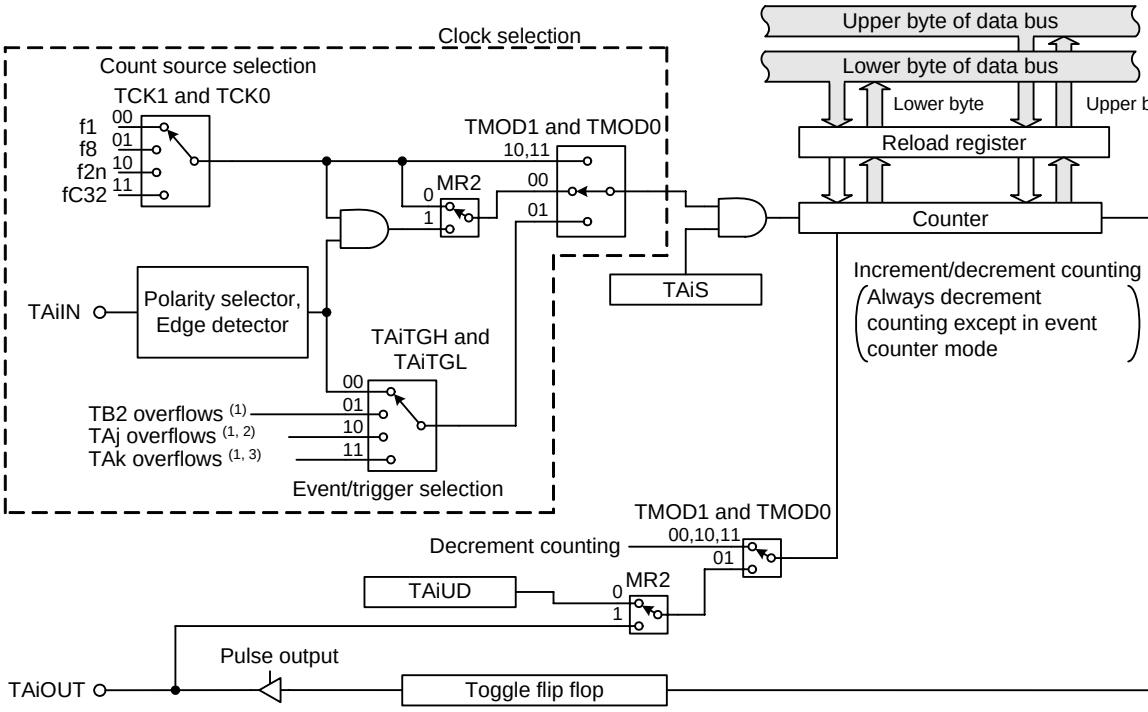
16.1 Timer A

Figure 16.3 shows a block diagram of the timer A and Figure 16.4 to Figure 16.10 show registers associated with the timer A.

The timer A supports four modes shown as below. Timers A0 to A4 in any mode other than the event counter mode have the same function. A mode is selected using bits TMOD1 and TMOD0 in the TAiMR register (i = 0 to 4).

- Timer mode: The timer counts an internal count source
- Event counter mode: The timer counts an external pulse or an overflow and underflow of other timers
- One-shot timer mode: The timer outputs one valid pulse before the counter reaches 0000h
- Pulse-width modulation mode: The timer sequentially outputs pulses of given width



TAi	TAj	TAk
Timer A0	Timer A4	Timer A1
Timer A1	Timer A0	Timer A2
Timer A2	Timer A1	Timer A3
Timer A3	Timer A2	Timer A4
Timer A4	Timer A3	Timer A0

i = 0 to 4
Notes:
1. The timer overflows or underflows.
2. j = i - 1, or j = 4 if i = 0 (Refer to the list to the right)
3. k = i + 1, or k = 0 if i = 4 (Refer to the list to the right)

TCK1 and TCK0, TMOD1 and TMOD0, MR2: Bits in the TAiMR register
TAiTGH and TAiTGL: Bits in the ONSF register (i = 0) or in the TRGSR register (i = 1 to 4)
TAiS: Bits in the TABSR
TAiUD: Bits in the UDF register

Figure 16.3 Timer A Block Diagram

Timer Ai Register (i = 0 to 4) (1)

Mode	Function	Setting Range	RW
Timer Mode	Divides the count source by n+1 (n = setting value)	0000h to FFFFh	RW
Event Counter Mode	Divides the count source by FFFFh -n+1 (on increment counting) or by n+1 (on decrement counting) (n = setting value) (2)	0000h to FFFFh	RW
One-shot Timer Mode	Divides the count source by n, then stops (n = setting value) (3)	0000h to FFFFh (4)	WO
Pulse-Width Modulation Mode (16-Bit PWM)	PWM period: (2^{16} -1) / fj High level width of PWM pulse: n / fj (fj = count source frequency, n = setting value of the TAi register) (5)	0000h to FFFEh (4)	WO
Pulse-Width Modulation Mode (8-Bit PWM)	PWM period: (2^{8} -1) × (m+1) / fj High level width of PWM pulse: (m+1)n / fj (fj = count source frequency, n = setting value of the upper byte in the TAi register, m = setting value of the lower byte in the TAi register) (5)	00h to FEh (upper byte) 00h to FFh (lower byte) (4)	WO

fj: f1, f8, f2n, fC32

Notes:
1. A 16-bit read/write access to this register should be performed.
2. The timer counts an external input pulse or an overflow and underflow of other timers.
3. When the TAi register is set to 0000h, the timer counter does not start, nor the TAi interrupt request is generated.
4. The MOV instruction should be used to set the TAi register.
5. When the TAi register is set to 0000h, the pulse-width modulator does not operate, the TAiOUT pin is held low, and the TAi interrupt request is not generated. The same situation occurs in 8-bit pulse-width modulator mode if the upper byte in the TAi register are set to 00h.

16.1.1 Timer Mode

In timer mode, the timer counts an internally generated count source. Table 16.1 lists specifications of timer mode. Figure 16.11 shows registers TA0MR to TA4MR in this mode.

Table 16.1 Timer Mode Specifications (i = 0 to 4)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement counting • If the timer counter underflows, the reload register setting is reloaded into the counter to resume counting
Divide ratio	$\frac{1}{n+1}$ n: TAi register setting value, 0000h to FFFFh
Count start condition	The TAiS bit in the TABSR register is set to 1 (count starts)
Count stop condition	The TAiS bit in the TABSR register is set to 0 (count stops)
Interrupt request generating timing	When the timer counter underflows
TAiIN pin function	A programmable I/O port or a gate input
TAiOUT pin function	A programmable I/O port or a pulse output
Read from timer	The TAi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (It is transferred to the counter at the next reload timing)
Selectable functions	• Gate function Input signal to the TAiIN pin can control to start/stop counting • Pulse output function The polarity of the TAiOUT pin is inverted whenever the timer counter underflows. A low is output while the TAiS bit holds 0 (count stops)

Figure 16.11 Registers TA0MR to TA4MR in Timer Mode

16.1.2 Event Counter Mode

In event counter mode, the timer counts an external signal or an overflow and underflow of other timers. Timers A2, A3 and A4 can count two-phase external signals. Table 16.2 lists specification in event count mode and Table 16.3 also list the specification when the timers use two-phase pulse signal processing. Figure 16.12 shows registers TA0MR to TA4MR in this mode.

Table 16.2 Event Counter Mode Specifications (without two-phase pulse signal processing) (i = 0 to 4)

Item	Specification
Count sources	• External signal applied to the TAiIN pin (valid edge is selectable by a program) • The overflow or underflow signal of timer B2, timer Aj (j = i - 1, or j = 4 if i = 0), and timer Ak (k = i + 1, or k = 0 if i = 4)
Count operations	• Increment/decrement counting can be switched by an external signal or program • If the timer counter underflows or overflows, the reload register setting is reloaded into the counter to resume counting. In the free-running count operation, the timer counter continues counting without reloading
Divide ratio	• $\frac{1}{FFFFh - n + 1}$ for increment counting • $\frac{1}{n + 1}$ for decrement counting n: TAi register setting value, 0000h to FFFFh
Count start condition	The TAiS bit in the TABSR register is set to 1 (count starts)
Count stop condition	The TAiS bit in the TABSR register is set to 0 (count stops)
Interrupt request generating timing	When the timer counter overflows or underflows
TAiIN pin function	A programmable I/O port or a count source input
TAiOUT pin function	A programmable I/O port, a pulse output, or an input for increment/decrement count switching
Read from timer	The TAi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (It is transferred to the counter at the next reload timing)
Selectable functions	• Free-running count function The reload register setting is not reloaded even if the timer counter overflows or underflows • Pulse output function The polarity of the TAiOUT pin is inverted whenever the timer counter overflows or underflows. A low is output while the TAiS bit holds 0 (count stops)

Table 16.3 Event Counter Mode Specifications (with two-phase pulse signal processing on timers A2 to A4) (i = 2 to 4)

Item	Specification
Count sources	Two-phase pulse signal applied to pins TAiIN and TAiOUT
Count operations	• Increment/decrement counting can be switched by a two-phase pulse signal • If the timer counter underflows or overflows, the reload register setting is reloaded into the counter to resume counting. In the free-running count operation, the timer counter continues counting without reloading
Divide ratio	• $\frac{1}{FFFFh - n + 1}$ for increment counting • $\frac{1}{n + 1}$ for decrement counting n: TAi register setting value, 0000h to FFFFh
Count start condition	The TAiS bit in the TABSR register is set to 1 (count starts)
Count stop condition	The TAiS bit in the TABSR register is set to 0 (count stops)
Interrupt request generating timing	When the timer counter overflows or underflows
TAiIN pin function	A two-phase pulse input
TAiOUT pin function	A two-phase pulse input
Read from timer	The TAi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (It is transferred to the counter at the next reload timing)
Selectable functions (1)	• Normal processing operation (timers A2 and A3) While the input signal applied to the TAjOUT pin (j = 2 or 3) is held high, the timer increments the count on the rising edge of the TAjIN pin and decrements the count on the falling edge  • Quadrupled processing operation (timers A3 and A4) When the input signal applied to the TAkOUT pin (k = 3 or 4) is held high on the rising edge of the TAkIN pin, the timer increments the count on both the rising and falling edges of pins TAkOUT and TAkIN. When the signal is held high on the falling edge of the TAkIN pin, the timer decrements the count on both the rising and falling edges of pins TAkOUT and TAkIN  • Counter reset by Z-phase input (the timer A3) The counter value is set to 0 by Z-phase input

Note:
1. Only the timer A3 is available for any selectable functions. The timer A2 is exclusively for the normal processing operation and the timer A4 is for the quadrupled processing operation, respectively.

Timer Ai Mode Register (i = 0 to 4) (event counter mode)

Notes:
1. Bits TAiTGH and TAiTGL in the ONSF or TRGSR register select the count source in event counter mode.
2. This bit setting is enabled only when an external signal is counted.
3. The timer decrements the count when the input signal to the TAiOUT pin is held low and increments the count when the signal is held high.
4. The TCK1 bit is enabled only in the TA3MR register.
5. For two-phase pulse signal processing, the TAjP bit in the UDF register (j = 2 to 4) should be set to 1 (two-phase pulse signal processing enabled) and bits TAiTGH and TAiTGL should be set to 00b (the input to the TAjIN pin).

Figure 16.12 Registers TA0MR to TA4MR in Event Counter Mode

16.1.2.1 Counter Reset by Two-phase Pulse Signal Processing

A Z-phase input signal resets the timer counter when a two-phase pulse signal is being processed.
This function can be used under the following conditions: timer A3 event counter mode, two-phase pulse signal processing, free-running count operation type, and quadrupled processing. The Z-phase signal is applied to the $\overline{\text{INT2}}$ pin.
When the TAZIE bit in the ONSF register is set to 1 (Z-phase input enabled), the reset of timer counter by Z-phase input is enabled. To reset the counter, the TA3 register should be set to 0000h beforehand.
A Z-phase signal applied to the $\overline{\text{INT2}}$ pin is detected on a edge. The edge polarity is selected using the POL bit in the INT2IC register. The Z-phase signal should be input in order to have a pulse width of one count source cycle for timer A3 or more. Figure 16.13 shows the two-phase pulse (phases A and B) and the Z-phase.
The timer counter is reset at the initial count source input after a Z-phase input is detected. Figure 16.14 shows the counter reset timing.
If the timer A3 overflows or underflows during a reset processing by the Z-phase input, two timer A3 interrupt requests are sequentially generated. To avoid this situation, the timer A3 interrupt request should not be used when this function is in use.

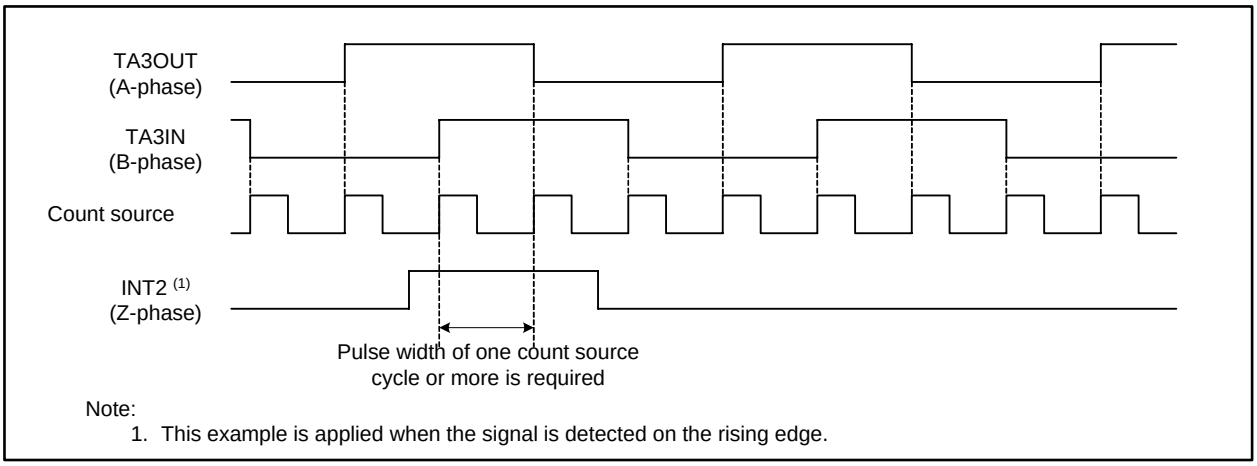

Figure 16.13 Two-phase Pulse (phases A and B) and Z-phase

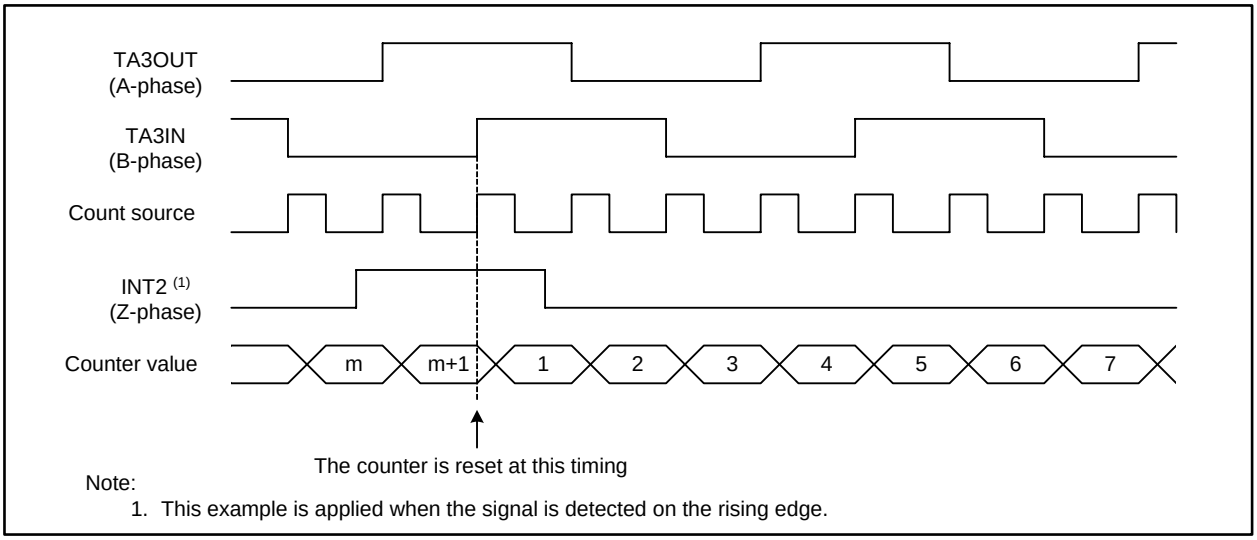

Figure 16.14 Counter Reset Timing

16.1.3 One-shot Timer Mode

In one-shot timer mode, the timer operates only once for each trigger. Table 16.4 lists specifications of one-shot timer mode. Once a trigger occurs, the timer starts and operates for a given period. Figure 16.15 shows registers TA0MR to TA4MR in this mode.

Table 16.4 One-shot Timer Mode Specifications (i = 0 to 4)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement counting • When the timer counter reaches 0000h, it stops running after the reload register setting is reloaded • If a trigger occurs while counting, the reload register setting is reloaded into the counter to continue counting
Divide ratio	$\frac{1}{n}$ n: TAi register setting value, 0000h to FFFFh (Note that the timer counter does not run if n = 0000h)
Count start conditions	The TAiS bit in the TABSR register is set to 1 (count starts) and any of following triggers occurs: • An external trigger applied to the TAiIN pin • The overflow or underflow signal of timer B2, timer Aj (j = i - 1, or j = 4 if i = 0), or timer Ak (k = i + 1, or k = 0 if i = 4) • The TAiOS bit in the ONSF register is set to 1 (the timer started)
Count stop conditions	• The timer counter reaches 0000h and the reload register setting is reloaded • The TAiS bit in the TABSR register is set to 0 (count stops)
Interrupt request generating timing	When the timer counter reaches 0000h
TAiIN pin function	A programmable I/O port or a trigger input
TAiOUT pin function	A programmable I/O port or a pulse output
Read from timer	The TAi register indicates undefined value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (It is transferred to the counter at the next reload timing)
Selectable function	• Pulse output function A low is output while the timer counter is not running and a high is output while the timer counter is running

Timer Ai Mode Register (i = 0 to 4) (one-shot timer mode)

TCK1			RW

Note:
1. The MR1 bit setting is enabled only when bits TAiTGH and TAiTGL in the TRGSR register are set to 00b (the input to the TAiIN pin). This bit can be set to either 0 or 1 when bits TAiTGH and TAiTGL are set to 01b (the overflow or underflow of TB2), 10b (the overflow or underflow of TAi), or 11b (the overflow or underflow of TAi).

Figure 16.15 Registers TA0MR to TA4MR in One-shot Timer Mode

16.1.4 Pulse-width Modulation Mode

In pulse-width modulation mode, the timer outputs pulses of given width sequentially. Table 16.5 lists specifications of pulse-width modulation mode. The timer counter functions as either 16-bit or 8-bit pulse-width modulator. Figure 16.16 shows registers TA0MR to TA4MR in this mode. Figure 16.17 and Figure 16.18 respectively show an operation example of 16-bit and 8-bit pulse-width modulators.

Table 16.5 Pulse-width Modulation Mode Specification (i = 0 to 4)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement counting (the timer counter functions as an 8-bit or a 16-bit pulse-width modulator) • The reload register setting is reloaded on the rising edge of PWM pulse to resume counting • The timer is not affected by a trigger that is generated while the counter is running
16-bit PWM	• High level width: $\frac{n}{fj}$ n: TAi register setting value, 0000h to FFFEh fj: Count source frequency • Cycle: $\frac{2^{16}-1}{fj}$ fixed
8-bit PWM	• High level width: $\frac{n \times (m+1)}{fj}$ • Cycle: $\frac{(2^{8}-1) \times (m+1)}{fj}$ n: TAi register (upper byte) setting value, 00h to FEh m: TAi register (lower byte) setting value, 00h to FFh
Count start conditions	• The TAiS bit in the TABSR register is set to 1 (count starts) • The TAiS bit is set to 1 and an external trigger applied to the TAiIN pin • The TAiS bit is set to 1 and any of following triggers occurs: The overflow or underflow signal of timer B2, timer Aj (j = i - 1, or j = 4 if i = 0), or timer Ak (k = i + 1, or k = 0 if i = 4)
Count stop condition	The TAiS bit in the TABSR register is set to 0 (count stops)
Interrupt request generating timing	On the falling edge of the PWM pulse
TAiIN pin function	A programmable I/O port or a trigger input
TAiOUT pin function	A pulse output
Read from timer	The TAi register indicates undefined value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (it is transferred to the counter at the next reload timing)

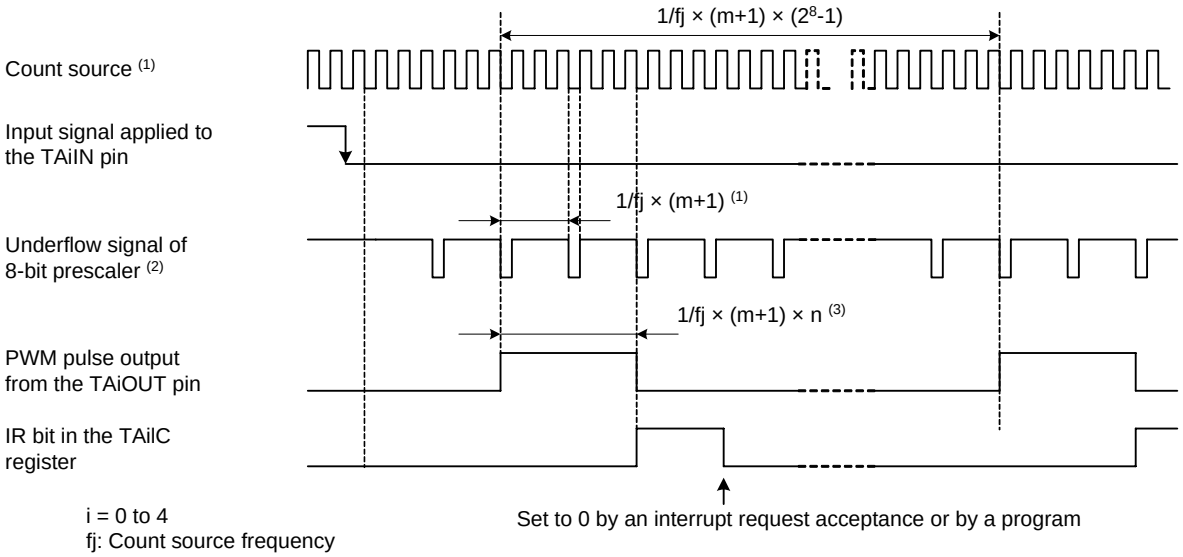
i = 0 to 4
fj: Count source frequency
(f1, f8, f2n, fC32)

Note:
1. n = 0000h to FFFEh

Figure 16.17 16-bit Pulse-width Modulator Operation

When the upper byte of the reload register is set to 02h, the lower byte is set to 02h and an external trigger (the falling edge of an input signal applied to the TAiIN pin) is selected



i = 0 to 4
fj: Count source frequency
(f1, f8, f2n, fC32)

Notes:
1. The 8-bit prescaler counts a count source.
2. The 8-bit pulse-width modulator counts underflow signals of the 8-bit prescaler.
3. m = 00h to FFh, n = 00h to FEh

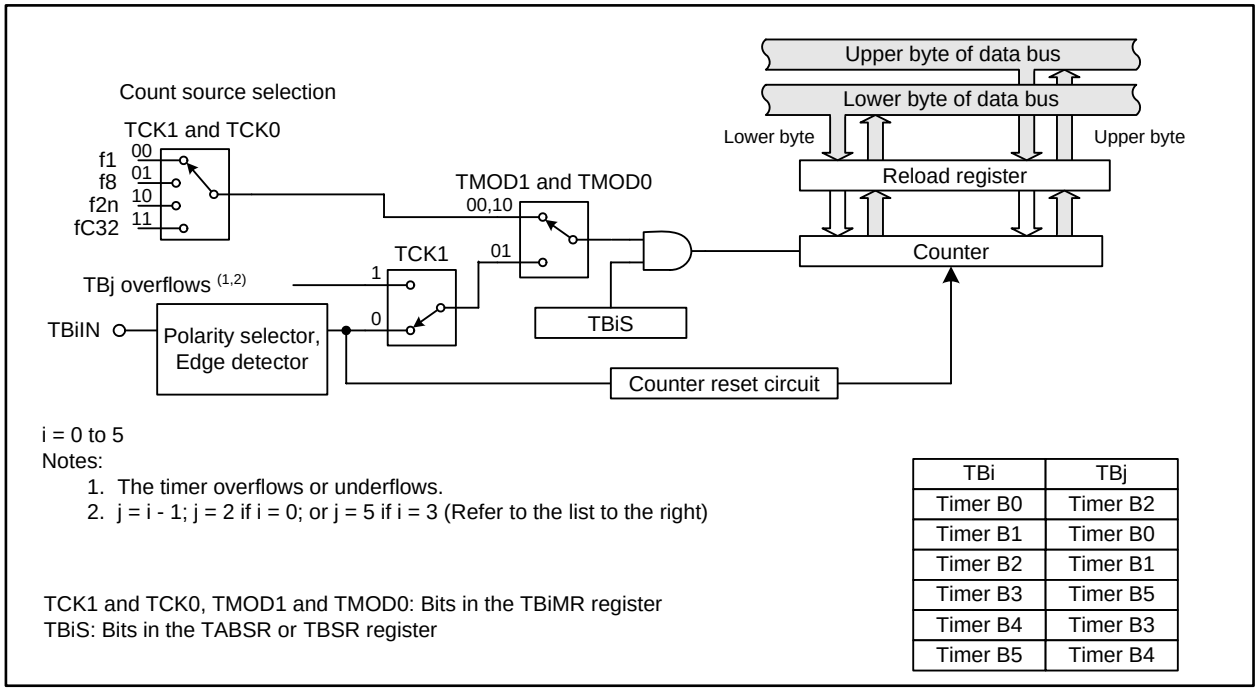
Figure 16.18 8-bit Pulse-width Modulator Operation

16.2 Timer B

Figure 16.19 shows a block diagram of the timer B and Figure 16.20 to Figure 16.23 show registers associated with the timer B.

The timer B supports three modes shown as below. A mode is selected using bits TMOD1 and TMOD0 in the TBiMR register (i = 0 to 5).

- Timer mode: The timer counts an internal count source
- Event counter mode: The timer counts an external pulse or an overflow and underflow of other timers
- Pulse period/pulse-width measure mode: The timer measures pulse period or pulse width of an external signal



i = 0 to 5

Notes:
1. The timer overflows or underflows.
2. j = i - 1; j = 2 if i = 0; or j = 5 if i = 3 (Refer to the list to the right)

Figure 16.24 Registers TB0MR to TB5MR in Timer Mode

16.2.2 Event Counter Mode

In event counter mode, the timer counts an external signal or an overflow and underflow of other timers. Table 16.7 lists specifications of event counter mode. Figure 16.25 shows the TBiMR register (i = 0 to 5) in this mode.

Table 16.7 Event Counter Mode Specifications (i = 0 to 5)

Item	Specification
Count sources	• External signal applied to the TBiIN pin (valid edge is selectable among the falling edge, the rising edge or the both by a program) • The overflow or underflow signal of TBj (j = i - 1; j = 2 if i = 0; or j = 5 if i = 3)
Count operations	• Decrement counting • If the timer counter underflows, the reload register setting is reloaded into the counter to resume counting
Divide ratio	$\frac{1}{n+1}$ n: TBi register setting value, 0000h to FFFFh
Count start condition	The TBiS bit in the TABSR or TBSR register is set to 1 (count starts)
Count stop condition	The TBiS bit in the TABSR or TBSR register is set to 0 (count stops)
Interrupt request generation timing	When the timer counter underflows
TBiIN pin function	A programmable I/O port or a count source input
Read from timer	The TBi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TBi register is written to both reload register and the counter • While the timer counter is running, the value written to the TBi register is written to the reload register (it is transferred to the counter at the next reload timing)

MR2	In registers TB0MR and TB3MR; Reserved; should be written with 0		RW
	In registers TB1MR, TB2MR, TB4MR, and TB5MR; No register bit; should be written with 0 and read as undefined value		—
MR3	Disabled in event counter mode. Should be written with 0 and read as undefined value		—
TCK0	Disabled in event counter mode. Can be set to 0 or 1		RW
TCK1	Event Clock Select Bit	0: Input signal to the TBiIN pin 1: The overflow or underflow of TBj (2)	RW

Notes:
1. These bit settings are enabled when the TCK1 bit is set to 0.
   When the TCK1 is set to 1, these bits can be set to either 0 or 1.
2. j = i - 1; j = 2 if i = 0; or j = 5 if i = 3.

Figure 16.25 Registers TB0MR to TB5MR in Event Counter Mode

16.2.3 Pulse Period/Pulse-width Measure Mode

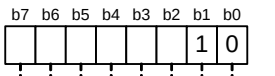
In pulse period/pulse-width measure mode, the timer measures pulse period or pulse width of an external signal. Table 16.8 lists specifications of pulse period/pulse-width measure mode. Figure 16.26 shows registers TB0MR to TB5MR in this mode. Figure 16.27 and Figure 16.28 respectively show an operation example of pulse period measurement and pulse-width measurement.

Table 16.8 Pulse Period/Pulse-width Measure Mode Specifications (i = 0 to 5)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Increment counting • The counter value is transferred to the reload register on the valid edge of a pulse to be measured, then it is set to 0000h to resume counting
Count start condition	The TBiS bit in the TABSR or TBSR register is set to 1 (count starts)
Count stop condition	The TBiS bit in the TABSR or TBSR register is set to 0 (count stops)
Interrupt request generating timing	• On the valid edge of a pulse to be measured (1) • When the timer counter overflows (when the MR3 bit in the TBiMR register becomes 1 (overflow). (2))
TBiIN pin function	A pulse input to be measured
Read from timer	The TBi register indicates a reload register value (measurement results) (3)
Write to timer	The value written to the TBi register is written to neither the reload register nor the counter

Notes:
1. No interrupt request is generated when the pulse to be measured is applied on the initial valid edge after the timer counter starts.
2. To set the MR3 bit to 0 (no overflow), wait one or more count source cycles to write to the TBiMR register after the MR3 bit becomes 1 (overflow), while the TBiS bit is set to 1 (count starts).
3. The TBi register indicates undefined value until the pulse to be measured is applied on the second valid edge after the timer counter starts.

Timer Bi Mode Register (i = 0 to 5) (pulse period/pulse-width measure mode)



Symbol	Address	Reset Value
TB0MR to TB2MR	035Bh, 035Ch, 035Dh	00XX 0000b
TB3MR to TB5MR	031Bh, 031Ch, 031Dh	00XX 0000b

Bit Symbol	Bit Name	Function	RW
TMOD0	Operating Mode Select Bit	b1 b0 1 0 : Pulse period/pulse-width measure mode	RW
TMOD1			RW
MR0	Measure Mode Select Bit (1)	b3 b2 0 0 : Pulse period measurement 1 0 1 : Pulse period measurement 2 1 0 : Pulse-width measurement 1 1 : Do not use this combination	RW
MR1			RW
MR2	In registers TB0MR and TB3MR; Reserved; should be written with 0		RW
	In registers TB1MR, TB2MR, TB4MR, and TB5MR; No register bit; should be written with 0 and read as undefined value		—
MR3	Timer Bi Overflow Flag (2)	0: No overflow 1: Overflow	RO
TCK0	Count Source Select Bit	b7 b6 0 0 : f1 0 1 : f8 1 0 : f2n 1 1 : fC32	RW
TCK1			RW

Notes:
1. Bits MR1 and MR0 select from the following measure modes:
   Pulse period measurement 1 (bits MR1 and MR0 = 00b):
   Measures between a falling edge and the next falling edge of a pulse
   Pulse period measurement 2 (bits MR1 and MR0 = 01b):
   Measures between a rising edge and the next rising edge of a pulse
   Pulse-width measurement (bits MR1 and MR0 = 10b):
   Measures between a falling edge and the next rising edge of a pulse and between the rising edge and the next falling edge of the pulse
2. The MR3 bit is undefined when the timer is reset.
   To set the MR3 bit to 0 (no overflow), wait one or more count source cycles to write to the TBiMR register after the MR3 bit becomes 1 (overflow), while the TBiS bit in the TABSR or TBSR register is set to 1 (count starts).
   The MR3 bit cannot be set to 1 by a program.

Figure 16.26 Registers TB0MR to TB5MR in Pulse Period/Pulse-width Measure Mode

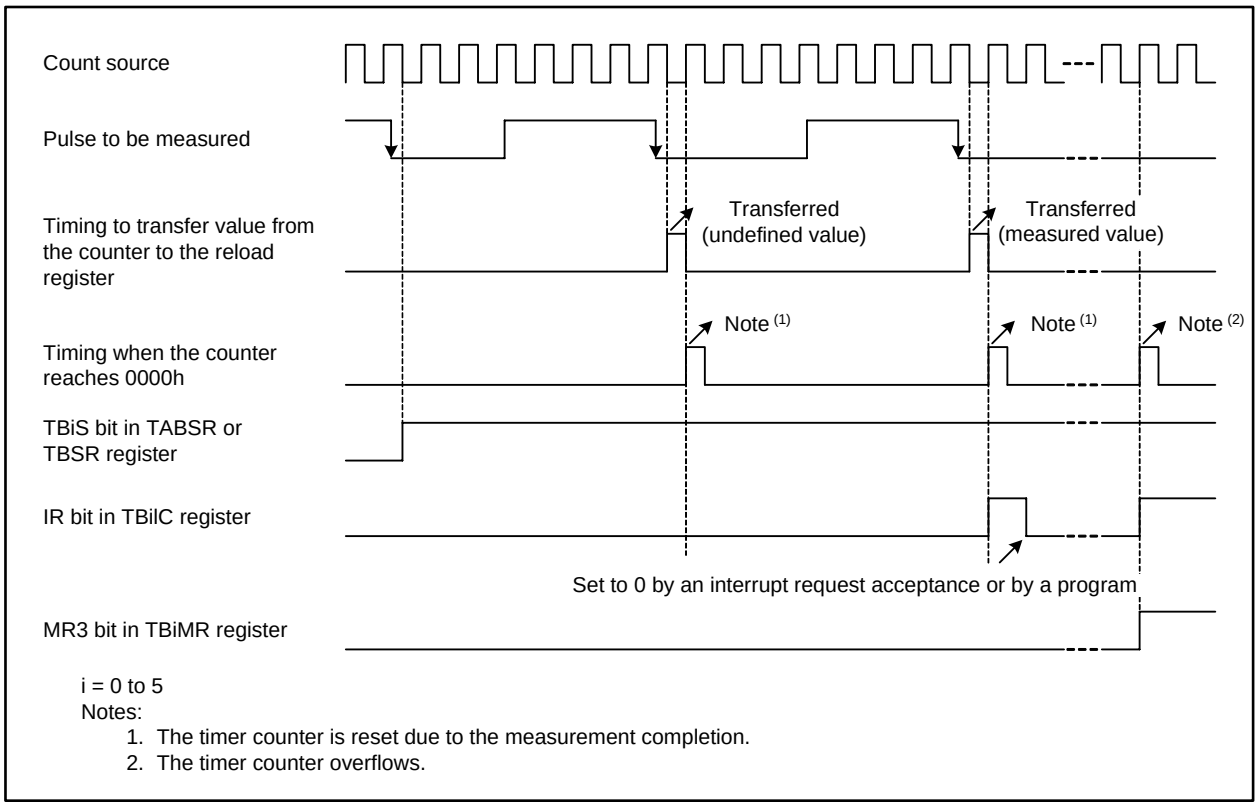


Figure 16.27 Operation Example in Pulse Period Measurement

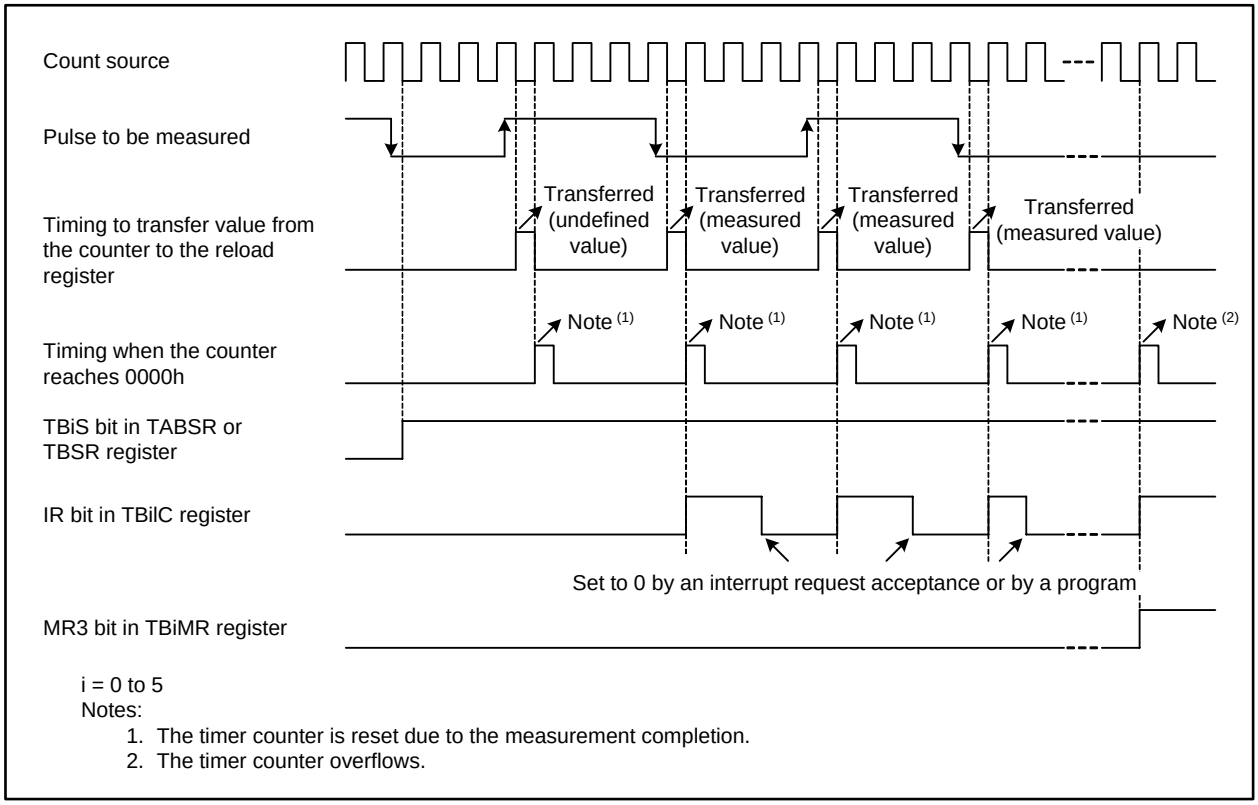

Figure 16.28 Operation Example in Pulse-width Measurement

16.3 Notes on Timers

16.3.1 Timer A and Timer B

All timers are stopped after a reset. To restart timers, configure parameters such as operating mode, count source, and counter value, then set the TAiS bit (i = 0 to 4) or TBjS bit (j = 0 to 5) in the TABSR or TBSR register to 1 (count starts).

The following registers and bits should be set while the TAiS bit or TBjS bit is 0 (count stops):

- Registers TAiMR and TBjMR
- The UDF register
- Bits TAZIE, TA0TGL, and TA0TGH in the ONSF register
- The TRGSR register

16.3.2 Timer A

16.3.2.1 Timer Mode

- While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

16.3.2.2 Event Counter Mode

- While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read if the timer counter underflows or 0000h if overflows while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

16.3.2.3 One-shot Timer Mode

- If the TAiS bit in the TABSR register is set to 0 (count stops) while the timer counter is running, the following operations are performed:
  - The timer counter stops and the setting value of the TAi register is reloaded.
  - A low signal is output at the TAiOUT pin.
  - The IR bit in the TAiIC register becomes 1 (interrupts requested) after one CPU clock cycle.

- One-shot timer is operated by an internal count source. When the trigger is an input to the TAiIN pin, the signal is output with a maximum of one count source clock delay after a trigger input to the TAiIN pin.

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt, set the IR bit to 0 after one of the settings below is done:
  - Select one-shot timer mode after a reset.
  - Switch the operating mode from timer mode to one-shot timer mode.
  - Switch the operating mode from event counter mode to one-shot timer mode.

- If a retrigger occurs while counting, the timer counter decrements by one, reloads the setting value of the TAi register, and then continues counting. To generate a retrigger while counting, wait one or more count source cycles after the last trigger is generated.

- When an external trigger input is selected to start counting in timer A one-shot mode, do not provide an external retrigger for 300 ns before the timer counter reaches 0000h. Otherwise, it may stop counting.

16.3.2.4 Pulse-width Modulation Mode

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt (i = 0 to 4), set the IR bit to 0 after one of the settings below is done:
  - Select pulse-width modulation mode after a reset.
  - Switch the operating mode from timer mode to pulse-width modulation mode.
  - Switch the operating mode from event counter mode to pulse-width modulation mode.

- If the TAiS bit in the TABSR register is set to 0 (count stops) while PWM pulse is output, the following operations are performed:
  - The timer counter stops.
  - The output level at the TAiOUT pin changes from high to low. The IR bit becomes 1.
  - When a low signal is output at the TAiOUT pin, it remains unchanged. The IR bit does not change, either.

16.3.3 Timer B

16.3.3.1 Timer Mode and Event Counter Mode

- While the timer counter is running, the TBj register (j = 0 to 5) indicates a counter value at any given time. However, FFFFh is read while reloading is in progress. A set value is read if the TBj register is set while the timer counter is stopped.

16.3.3.2 Pulse Period/Pulse-width Measure Mode

- To set the MR3 bit in the TBjMR register to 0 (no overflow), wait one or more count source cycles to write to the TBjMR register after the MR3 bit becomes 1 (overflow), while the TBjS bit is set to 1 (count starts).

- Use the IR bit in the TBjIC register to detect overflow. The MR3 bit is used only to determine an interrupt request source within the interrupt handler.

- The counter value is undefined when the timer counter starts. Therefore, the timer counter may overflow before a pulse to be measured is applied on the initial valid edge and cause a timer Bj interrupt request to be generated.

- When the pulse to be measured is applied on the initial valid edge after the timer counter starts, an undefined value is transferred to the reload register. At this time, the timer Bj interrupt request is not generated.

- The IR bit may become 1 (interrupt requested) by changing bits MR1 and MR0 in the TBjMR register after the timer counter starts. However, if the same value is rewritten to bits MR1 and MR0, the IR bit is not changed.

- Pulse width is repeatedly measured in pulse-width measure mode. Whether the measurement result is high-level width or not is determined by a program.

- If an overflow occurs simultaneously when a pulse is applied on the valid edge, this pulse is not recognized since an interrupt request is generated only once. Do not let an overflow occur in pulse period measure mode.

- In pulse-width measure mode, determine whether an interrupt source is a pulse applied on the valid edge or an overflow by reading the port level in the TBj interrupt handler.

17. Three-phase Motor Control Timers

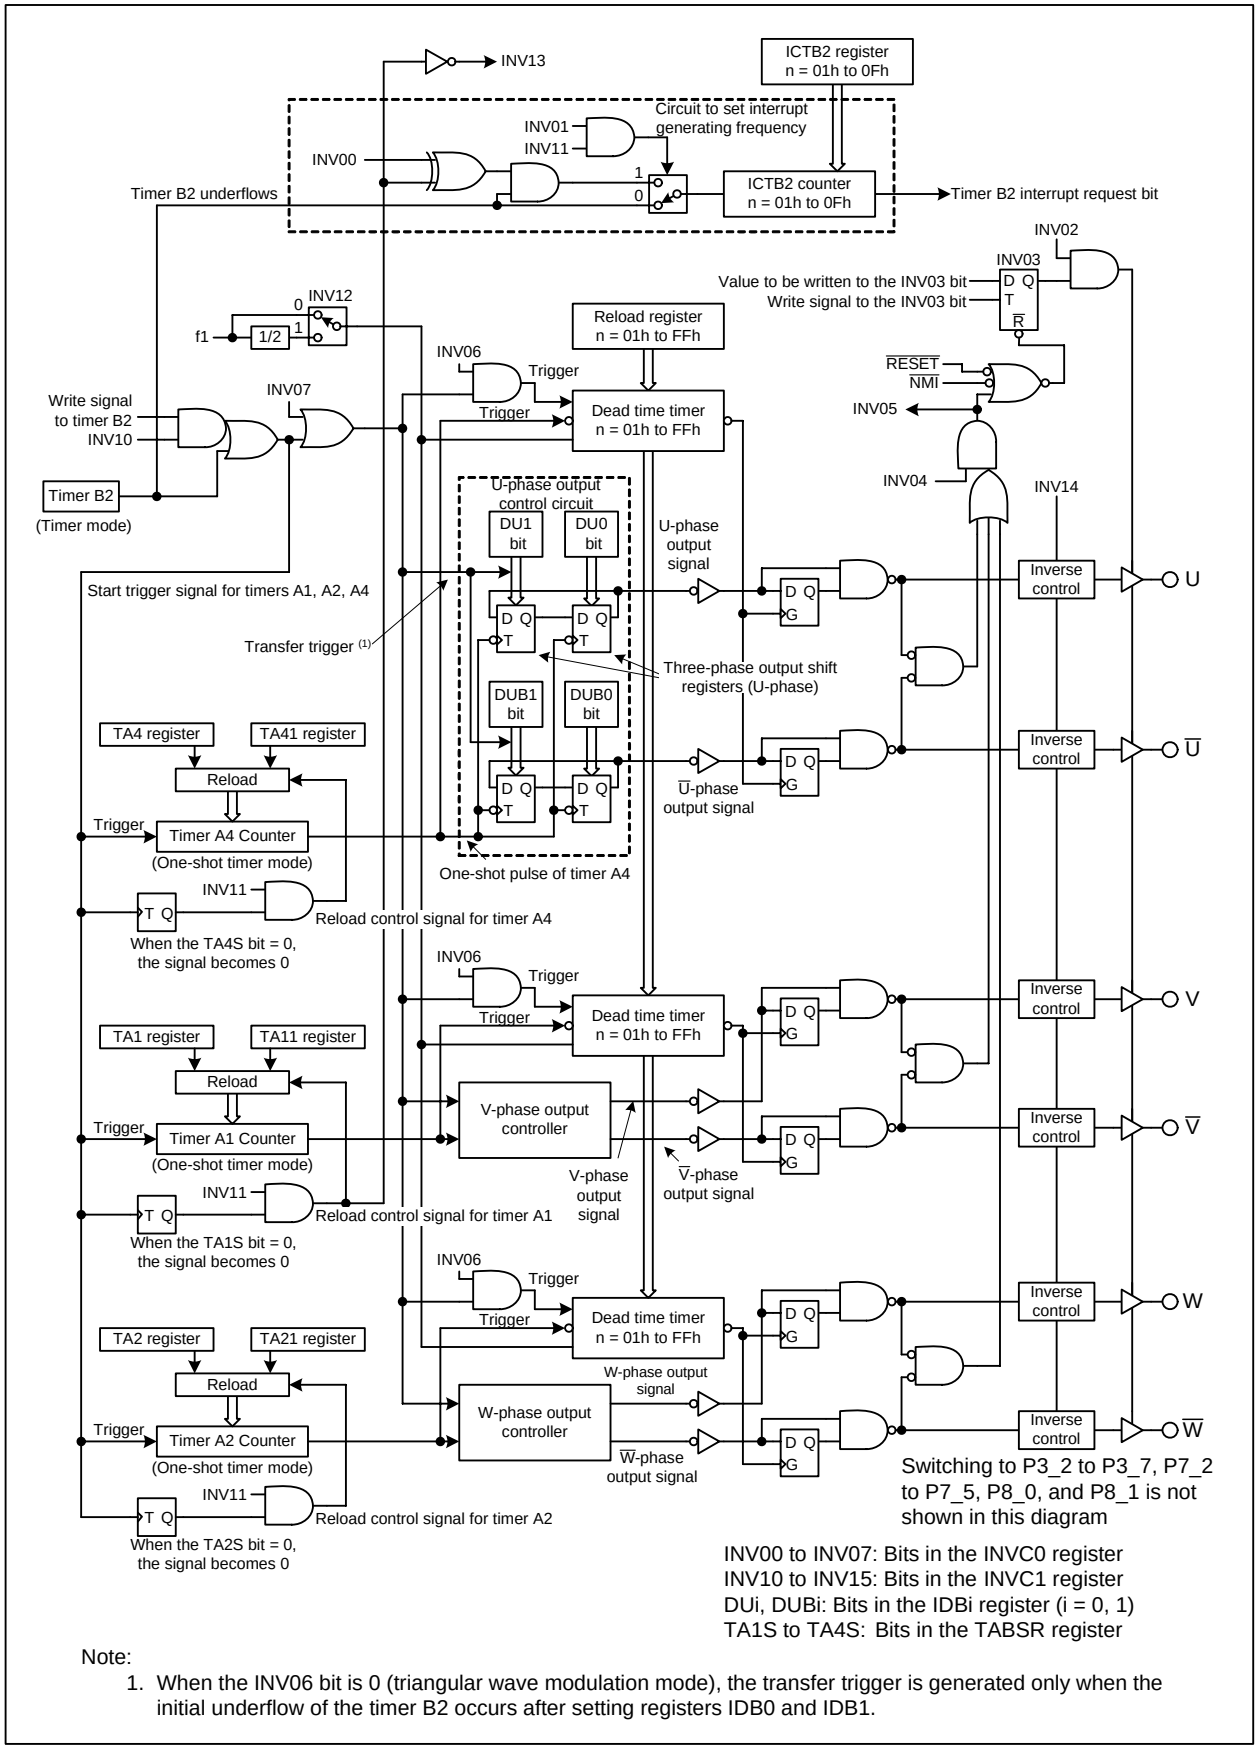
A three-phase motor driving waveform can be output by using timers A1, A2, A4, and B2. The three-phase motor control timers are enabled by setting the INV02 bit in the INVC0 register to 1. Timer B2 is used for carrier wave control, and timers A1, A2, and A4 for three-phase PWM output (U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$) control. Table 17.1 lists specifications of the three-phase motor control timers and Figure 17.1 shows its block diagram. Figure 17.2 to Figure 17.6 show registers associated with this function.

Table 17.1 Three-phase Motor Control Timers Specifications

Item	Specification
Three-phase PWM waveform output pins	Six pins: U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$
Forced cutoff (1)	A low input to the $\overline{NMI}$ pin
Timers to be used	Timers A4, A1, and A2 (used in one-shot timer mode): Timer A4: U- and $\overline{U}$-phases waveform control Timer A1: V- and $\overline{V}$-phases waveform control Timer A2: W- and $\overline{W}$-phases waveform control Timer B2 (used in timer mode) Carrier wave cycle control Dead time timer (three 8-bit timers share a reload register): Dead time control
Output waveform	Triangular wave modulation and sawtooth wave modulation • Output of a high or a low waveform for one cycle • Separately settable levels of high side and low side
Carrier wave cycle	Triangular wave modulation: count source × (m+1) × 2 Sawtooth wave modulation: count source × (m+1) m: TB2 register setting value, 0000h to FFFFh Count source: f1, f8, f2n, or fC32
Three-phase PWM output width	Triangular wave modulation: count source × n × 2 Sawtooth wave modulation: count source × n n: Setting value of registers TA4, TA1, and TA2 (registers TA4, TA41, TA1, TA11, TA2, and TA21 when the INV11 bit in the INVC1 register is set to 1), 0001h to FFFFh Count source: f1, f8, f2n, or fC32
Dead time (width)	Count source × p or no dead time p: DTT register setting value, 01h to FFh Count source: f1 or f1 divided by 2
Active level	Selectable either active high or active low
Simultaneous conduction prevention	Function to detect simultaneous turn-on signal outputs, function to disable signal output when simultaneous turn-on signal outputs are detected
Interrupt frequency	Selectable from one through 15 time- carrier wave cycle-to-cycle basis for the timer B2 interrupt

Note:

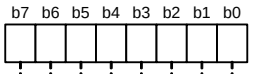
1. Forced cutoff by the signal input to the $\overline{NMI}$ pin is available when the PM24 bit in the PM2 register is set to 1 (NMI enabled), the INV02 bit in the INVC0 register is set to 1 (the three-phase motor control timers used), and the INV03 bit is set to 1 (the three-phase motor control timer output enabled).



Note:
1. When the INV06 bit is 0 (triangular wave modulation mode), the transfer trigger is generated only when the initial underflow of the timer B2 occurs after setting registers IDB0 and IDB1.

Figure 17.1 Three-phase Motor Control Timers Block Diagram

Three-Phase PWM Control Register 0 (1)



Symbol	Address	Reset Value
INVC0	0308h	0000 0000b

Bit Symbol	Bit Name	Function	RW
INV00	ICTB2 Count Condition Select Bit (2)	b1 b0 0 X : The underflow of timer B2 1 0 : The underflow of timer B2 when the reload control signal for timer A1 is set to 0 (3) 1 1 : The underflow of timer B2 when the reload control signal for timer A1 is set to 1 (3, 4)	RW
INV01			RW
INV02	Three-Phase Motor Control Timers Select Bit	0: Do not use this function 1: Use this function (5, 6, 7)	RW
INV03	Three-Phase Motor Control Timer Output Control Bit	0: Disables the three-phase motor control timer output (7) 1: Enables the three-phase motor control timer output (8)	RW
INV04	Simultaneous Conduction Prevention Bit	0: Ignores simultaneous turn-on signal output 1: Disables simultaneous turn-on signal output	RW
INV05	Simultaneous Conduction Detection Flag	0: Not detected 1: Detected (9)	RO
INV06	Modulation Mode Select Bit	0: Triangular wave modulation mode 1: Sawtooth wave modulation mode (10)	RW
INV07	Software Trigger Select Bit	A transfer trigger is generated when this bit is set to 1. When the INV06 bit is set to 1, another trigger to the dead time timer is also generated. This bit is read as 0	RW

Notes:
1. This register should be set after the PRC1 bit in the PRCR register is set to 1 (write enabled). Bits INV00 to INV02 and INV06 should be rewritten while timers A1, A2, A4, and B2 are stopped.
2. This bit is enabled when the INV11 bit in the INVC1 register is set to 1 (three-phase mode 1). When the INV11 bit is set to 0 (three-phase mode 0), the ICTB2 counter increments by one every time the timer B2 underflows irrespective of the INV00 and INV01 bit settings.
3. Set the ICTB2 register before setting the INV01 bit to 1. The timer A1 count start flag should be set to 1 before the initial timer B2 underflow occurs.
4. When the INV00 bit is set to 1, the first interrupt is generated if the timer B2 underflows n-1 times. (n is the value set in the ICTB2 counter). Subsequent interrupts are generated every n times the timer B2 underflows.
5. The INV02 bit should be set to 1 to operate the dead time timer, U-, V-, and W-phase output control circuits, and the ICTB2 counter.
6. After setting the INV02 bit to 1, pins should be configured first by the IOBC register then by the output function select register.
7. When the INV02 bit is set to 1 and the INV03 bit to 0, pins U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$, including shared pins set by another output function, become high-impedance.
8. The INV03 bit becomes 0 when any of the following occurs:
   -Reset
   -Signals of both sides high and low are simultaneously switched active when the INV04 bit is set to 1
   -The INV03 bit is set to 0 by a program
   -The $\overline{NMI}$ pin goes from high to low when the PM24 bit in the PM2 register is set to 1 (NMI enabled)
9. This bit cannot be set to 1 by a program. The INV04 bit should be set to 0 to set this bit to 0.
10. When the INV06 bit is set to 1, the INV11 bit in the INVC1 register should be set to 0 (three-phase mode 0). In this case, the PWCON bit in the TB2SC register should be set to 0 (timer B2 register reloaded if the timer B2 underflows).

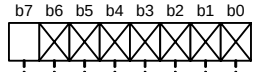
INV14	Active Level Control Bit	0: Active low output 1: Active high output	RW
INV15	Dead Time Disable Bit	0: Enables dead time 1: Disables dead time	RW
INV16	Dead Time Timer Trigger Select Bit	0: Falling edge of a one-shot pulse of timer (A4, A1, and A2) (5) 1: Rising edge of the three-phase output shift register (phases U, V, and W)	RW
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. This register should be set after the PRC1 bit in the PRCR register is set to 1 (write enabled). Bits INV00 to INV02 and INV06 should be rewritten while timers A1, A2, A4, and B2 are stopped.
2. When the INV06 bit in the INVC0 register is set to 1 (sawtooth wave modulation mode), the INV11 bit should be set to 0 (three-phase mode 0).
3. When the INV11 bit is set to 0, the PWCON bit in the TB2SC register should be set to 0 (timer B2 register reloaded if the timer B2 underflows).
4. This bit setting is enabled when the INV06 bit is set to 0 (triangular wave modulation mode) and the INV11 bit is set to 1 (three-phase mode 1).
5. If the following conditions are all met, the INV16 bit should be set to 1:
   -The INV15 bit is set to 0 (dead time enabled)
   -The Dij bit (i = U, V, or W; j = 0 to 1) has a different value from the DiBj bit whenever the INV03 bit is set to 1 (three-phase motor control timer output enabled); the high- and low-side output signals have always inverse level on the period other than dead time.
   If any of the conditions above are not met, the INV16 bit should be set to 0.

Figure 17.3 INVC1 Register

Three-Phase Output Buffer Control Register (1)



Symbol	Address	Reset Value
IOBC	40097h	0XXX XXXXb

Bit Symbol	Bit Name	Function	RW
— (b6-b0)	No register bits; should be written with 0 and read as undefined value		—
TBSOUT	Three-Phase Output Pin Select Bit (2)	0: Use pins U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$ of ports P7 and P8 1: Use pins U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$ of port P3	RW

Notes:
1. This register should be set after the PRC1 bit in the PRCR register is set to 1 (write enabled).
2. This bit should be set after the INV02 bit in the INVC0 register is set to 1. Then, the output function select register of corresponding port should be set. When the INV03 bit in the INVC0 register is set to 0, output pins for the three-phase motor control timers become high-impedance by the output enable control of output buffers. However, the output enable cannot be controlled only by the output function select register when more than two ports are assigned for output. Thus, a three-state output buffer should be selected using the TBSOUT bit.

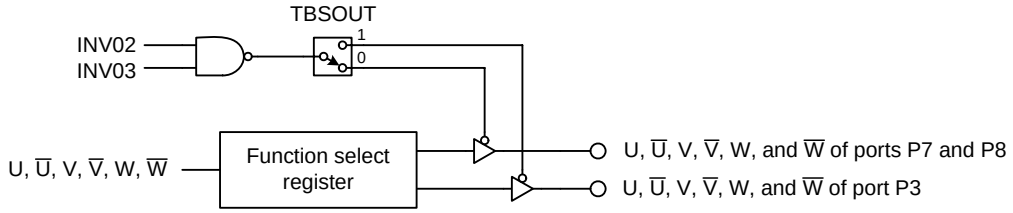


Figure 17.4 IOBC Register

Three-Phase Output Buffer Register i (i = 0, 1) (1)

Symbol: IDB0, IDB1

Address: 030Ah, 030Bh

Reset Value: XX11 1111b

Bit Symbol	Bit Name	Function	RW
DUi	U-Phase Output Buffer i	These bits should be written with an output level of the three-phase output shift register. The written value is reflected in each turn-on signal as follows: 0: Active (ON) 1: Inactive (OFF) The bits are read as the value of the three-phase output shift register	RW
DUBi	$\overline{U}$-Phase Output Buffer i		RW
DVi	V-Phase Output Buffer i		RW
DVBi	$\overline{V}$-Phase Output Buffer i		RW
DWi	W-Phase Output Buffer i		RW
DWBi	$\overline{W}$-Phase Output Buffer i		RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Note:

1. Values of registers IDB0 and IDB1 are transferred to the three-phase output shift register by a transfer trigger. The initial output signal level of each phase is determined by the value written in the IDB0 register after the transfer trigger occurs. After that, the output signal level is determined by the value written in the IDB1 register on the falling edge of a one-shot pulse of timers A1, A2, and A4.

Figure 17.5 Registers IDB0 and IDB1

Timer B2 Interrupt Generating Frequency Set Counter (1, 2, 3)

ICTB2	030Dh	Undefined

Function	Setting Range	RW
-When the INV01 bit = 0 (the ICTB2 counter increments every time the timer B2 underflows), the timer B2 interrupt request is generated every nth times the timer B2 underflows -When the INV01 bit = 1 (the ICTB2 counter increments when the timer A1 reload control signal is set to 0 or 1 and the timer B2 underflows), the timer B2 interrupt request is generated every nth times the timer B2 underflows when the timer A1 reload control signal is 0 or 1 (n = setting value)	01h to 0Fh	WO
No register bits; should be written with 0		—

Notes:
1. The MOV instruction should be used to set the ICTB2 register.
2. When the INV01 bit in the INVC0 register is set to 1, set this register when the TB2S bit in the TABSR register is 0 (timer B2 count stops). When the INV01 bit is set to 0, this register can be set irrespective of the TB2S bit setting. However, do not set the register when the timer B2 underflows.
3. When the INV00 bit in the INVC0 register is set to 1, the first interrupt is generated if the timer B2 underflows n-1 times. Subsequent interrupts are generated every n times the timer B2 underflows. (n = setting value of the ICTB2 counter)

Figure 17.6 ICTB2 Register

17.1 Modulation Modes of Three-phase Motor Control Timers

The three-phase motor control timers supports two modulation modes: triangular wave modulation mode and sawtooth wave modulation mode. The triangular wave modulation mode has three-phase mode 0 and three-phase mode 1. Table 17.2 lists bit settings and characteristics of each mode.

Table 17.2 Modulation Modes

Item	Triangular Wave Modulation Mode		Sawtooth Wave Modulation Mode
	Three-phase mode 0	Three-phase mode 1	(Three-phase mode 0)
Bit settings	INV06 = 0, INV11 = 0, PWCON = 0	INV06 = 0, INV11 = 1	INV06 = 1, INV11 = 0, PWCON = 0
Waveform	Triangular wave		Sawtooth wave
Registers TA11, TA21, and TA41	Not used	Used	Not used
Timing to transfer data from registers IDB0 and IDB1 to the three-phase output shift register	Only once when a transfer trigger (1) occurs after setting registers IDB0 and IDB1		Whenever a transfer trigger (1) occurs
Timing to trigger the dead time timer when INV16 = 0	On the falling edge of a one-shot pulse of timers A1, A2, and A4		When a transfer trigger occurs, or on the falling edge of a one-shot pulse of timers A1, A2, and A4
Bits INV00 and INV01 in the INVC0 register	Disabled. The ICTB2 counter increments every time the timer B2 underflows, irrespective of the INV00 and INV01 bit settings	Enabled	Disabled. The ICTB2 counter increments every time the timer B2 underflows, irrespective of the INV00 and INV01 bit settings
INV13 bit	Disabled	Enabled	Disabled

Note:
1. Transfer trigger: an underflow of timer B2 and a write to the INV07 bit, or a write to the TB2 register when the INV10 bit is set to 1.

17.2 Timer B2

Timer B2, which operates in timer mode, is used for carrier wave control in the three-phase motor control timers.

Figure 17.7 and Figure 17.8 show registers TB2 and TB2MR in this function, respectively. Figure 17.9 shows the TB2SC register which switches timing to change the carrier wave frequency in three-phase mode 1.

Timer B2 Register (1)

17.3 Timers A4, A1, and A2

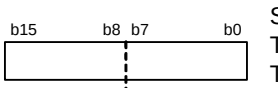
Timers A4, A1, and A2 are used for three-phase PWM output (U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$) control in the three-phase motor control timers.

These timers should operate in one-shot timer mode. Every time the timer B2 underflows, a trigger is input to timers A4, A1, and A2 to generate a one-shot pulse. If the values of registers TA4, TA1 and TA2 are rewritten every time a timer B2 interrupt is generated, the duty ratio of the PWM waveform can be varied.

In three-phase mode 1, the value of registers TAi and TAi-1 (i = 4, 1, 2) is alternately reloaded to the counter on each timer B2 interrupt, which halves timer B2 interrupt frequency. The sum of setting values for registers TAi and TAi1 should be identical to the setting value of the TB2 register in this mode.

Figure 17.10 shows registers TA1, TA2, TA4, TA11, TA21, and TA41 in the three-phase motor control timers. Figure 17.11 shows registers TA1MR, TA2MR, and TA4MR in this function. Figure 17.12 and Figure 17.13 show registers TRGSR and TABSR, respectively, in this function.

Timer Ai/Timer Ai-1 Registers (i = 1, 2, 4) (1 to 6)



Symbol	Address	Reset Value
TA1, TA2, TA4	0349h-0348h, 034Bh-034Ah, 034Fh-034Eh	Undefined
TA11, TA21, TA41	0303h-0302h, 0305h-0304h, 0307h-0306h	Undefined

Function	Setting Range	RW
The timer stops when the nth count source is counted after a start trigger is generated. Output signal for each phase is switched when timers A1, A2, and A4 stop (n = setting value)	0000h to FFFFh	WO

Notes:
1. A 16-bit write access to these registers should be performed.
2. When these registers are set to 0000h, the counter does not start, and no timer Ai interrupt request is generated.
3. The MOV instruction should be used to set these registers.
4. When the INV15 bit in the INVC1 register is set to 0 (dead time enabled), the turn-on output signal is switched to its active state with a delay. It is switched when the dead time timer stops.
5. When the INV11 bit in the INVC1 register is set to 0 (three-phase mode 0), the value of the TAi register is transferred to the reload register by a timer Ai start trigger. When the INV11 bit is set to 1 (three-phase mode 1), firstly the value of the TAi1 register is transferred to the reload register by a timer Ai start trigger. Then the value of the TAi register is transferred by the next timer Ai start trigger. After that the value of these registers TAi1 and TAi is alternately transferred to the reload register.
6. These registers should not be written when the timer B2 underflows.

17.4 Simultaneous Conduction Prevention and Dead Time Timer

The three-phase motor control timers offers two ways to avoid shoot-through, which occurs when high-side and low-side transistors are simultaneously turned on.

One is by the function called “simultaneous turn-on signal output disable function”. This function prevents high-side and low-side transistors from being inadvertently switched active caused by program errors and so on. The other is by the use of dead time timers. A dead time timer delays the turn-on of one transistor in order to ensure that an adequate time (the dead time) passes after the turn-off of the other.

To disable simultaneous turn-on output signals, the INV04 bit in the INVC0 register should be set to 1. If outputs for any pair of phases (U and $\overline{U}$, V and $\overline{V}$, or W and $\overline{W}$) are simultaneously switched to an active state, every three-phase motor control output pin becomes high-impedance. Figure 17.14 shows an example of output waveform when simultaneous turn-on signal output is disabled.

To enable the dead time timer, the INV15 bit in the INVC1 register should be set to 0. The DTT register determines the dead time. Figure 17.15 shows the DTT register and Figure 17.16 shows an example of output waveform on using dead time timer.

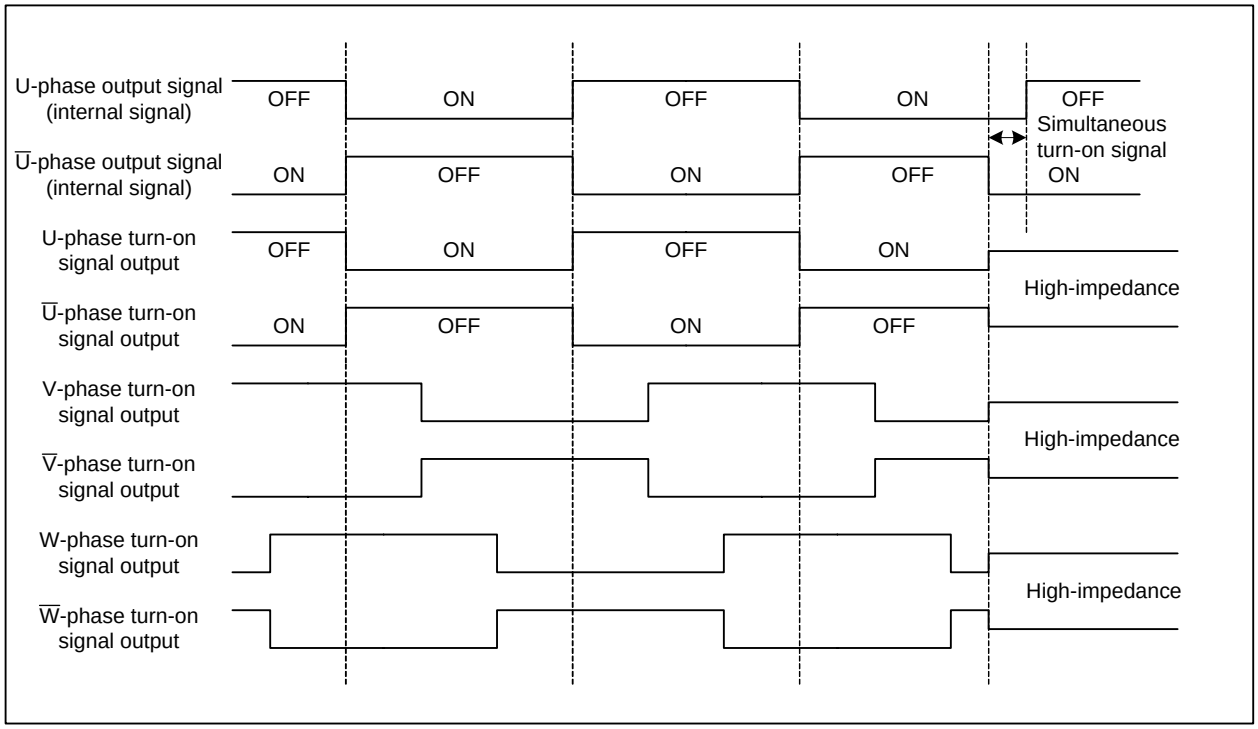

Figure 17.14 Output Waveform When Simultaneous Turn-on Signal Output is Disabled

Dead Time Timer (1, 2)

b7 b0

Symbol	Address	Reset Value
DTT	030Ch	Undefined

Function	Setting Range	RW
The dead time timer is a one-shot timer to delay the timing for a turn-on signal to be switched to its active state preventing a simultaneous conduction of high-side and low-side transistors. The timer stops when counting a count source n times after a start trigger occurs (n = setting value) (3)	01h to FFh	WO

Notes:
1. The MOV instruction should be used to set this register.
2. This register setting is enabled when the INV15 bit in the INVC1 register is set to 0 (dead time enabled). No dead time can be set when the INV15 bit is set to 1 (dead time disabled).
3. The trigger and count source should be respectively selected using bits INV06 and INV12 in the INVC1 register.

Figure 17.15 DTT Register

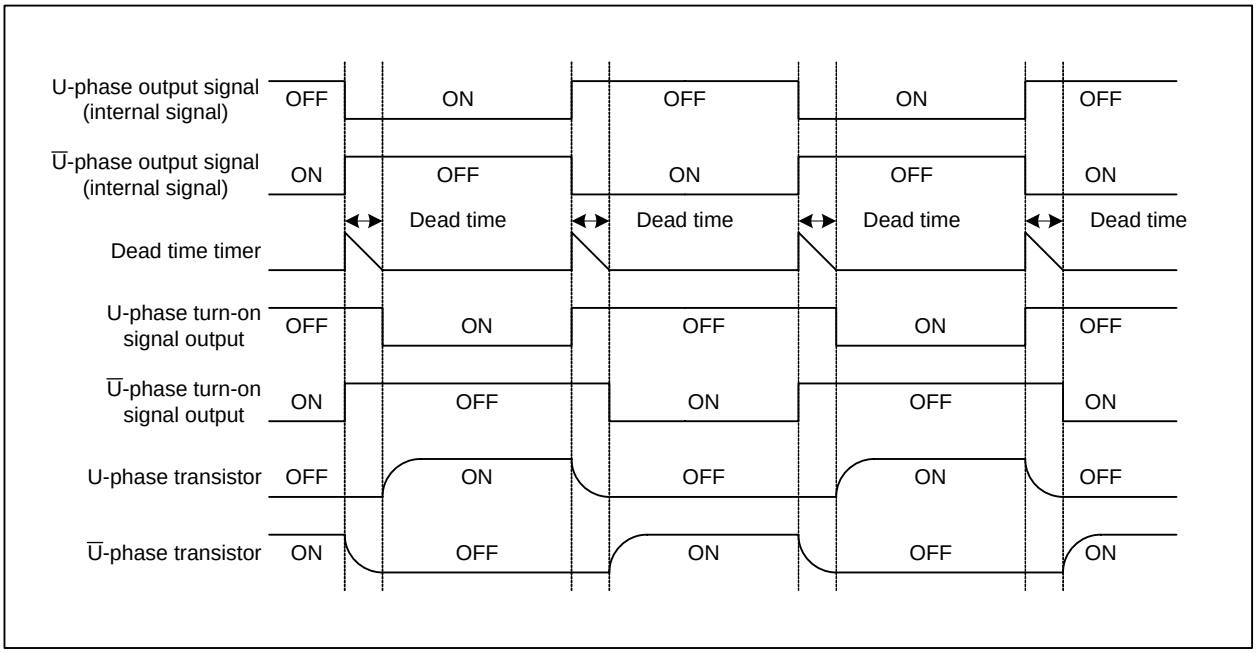

Figure 17.16 Output Waveform on Using Dead Time Timer

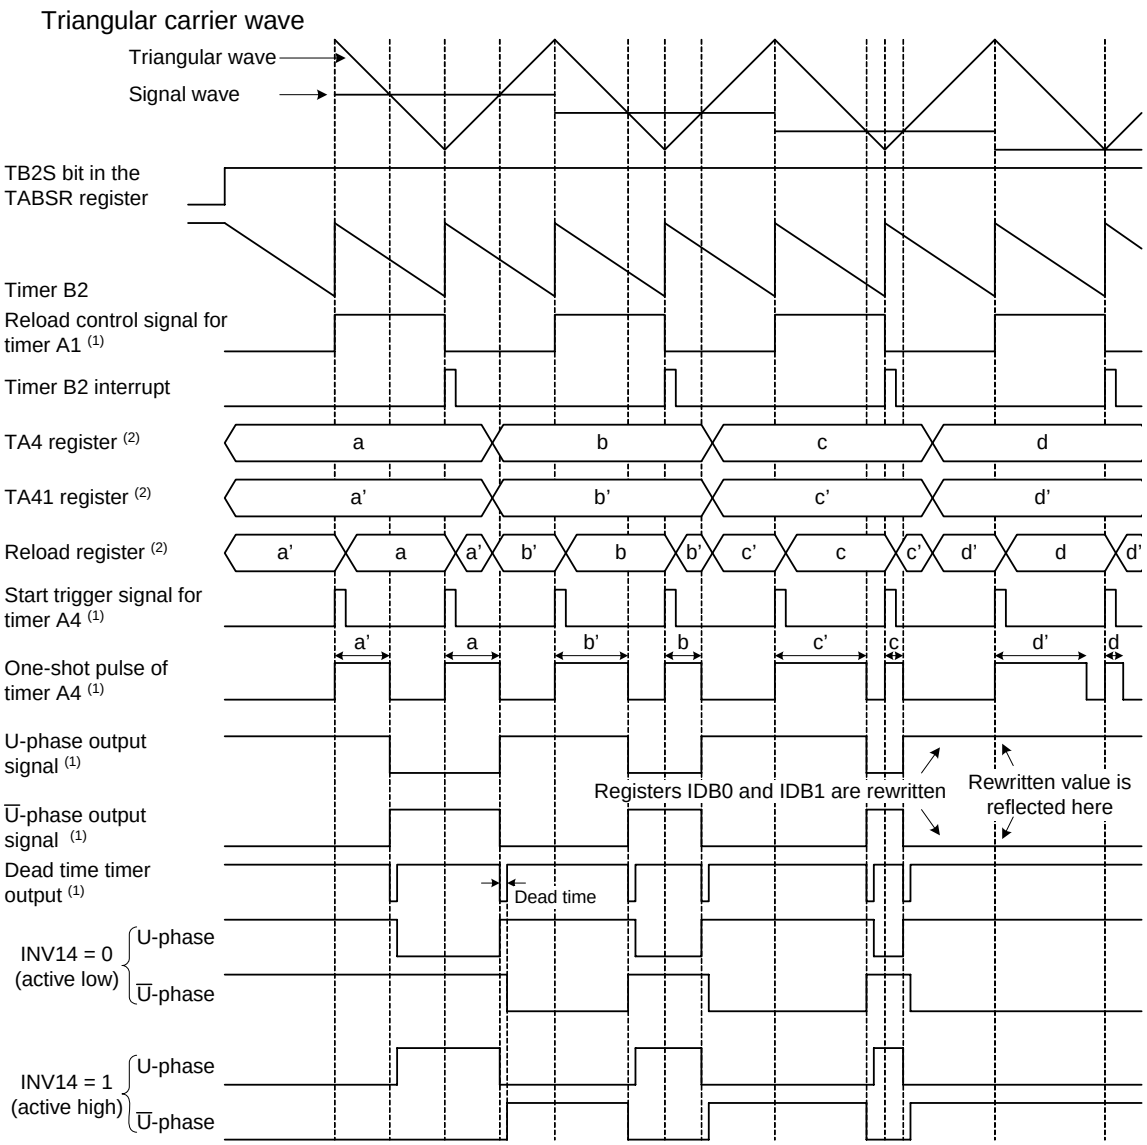
17.5 Three-phase Motor Control Timer Operation

Figure 17.17 and Figure 17.18 show an operation example of triangular wave modulation and sawtooth wave modulation, respectively.



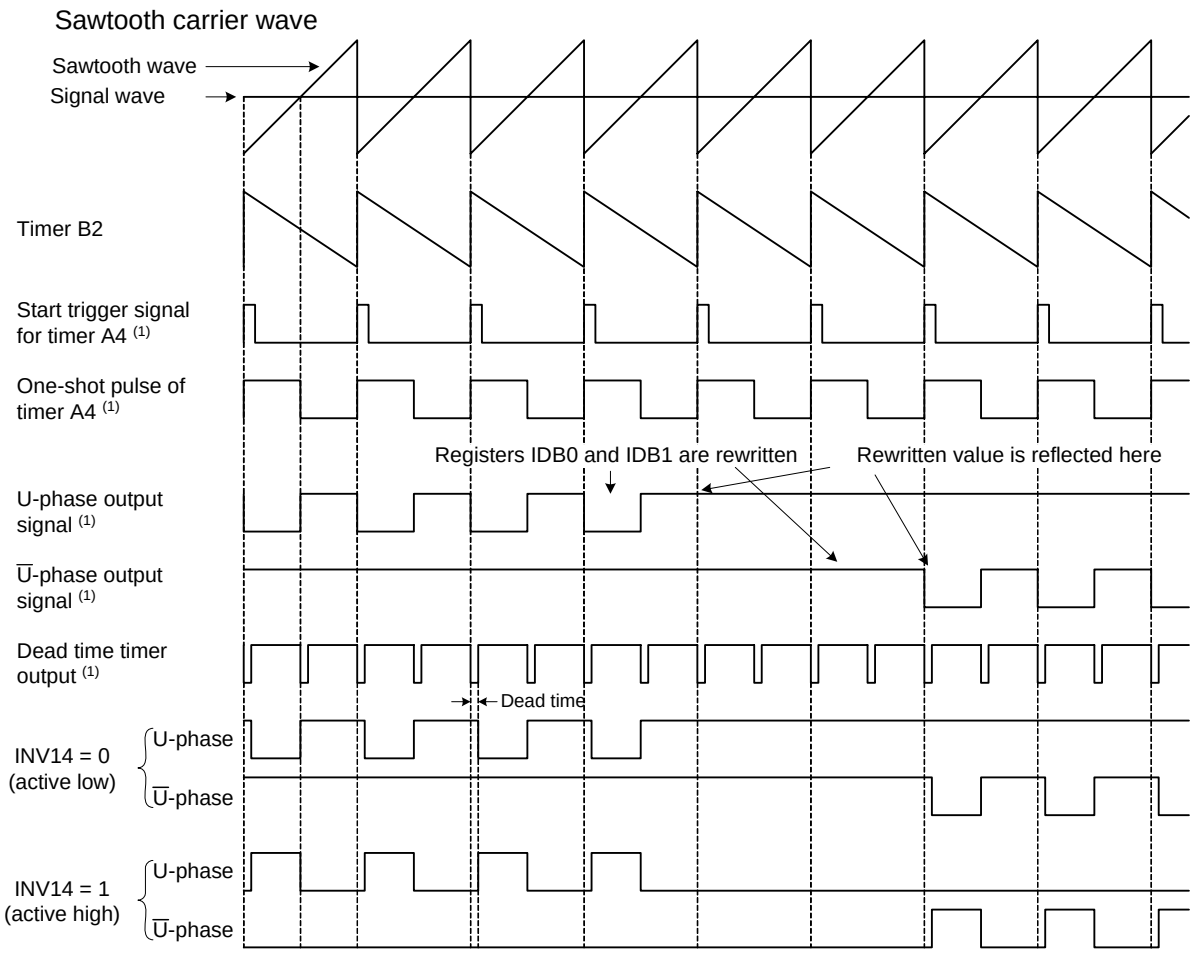
The above applies to INVC0 = 00XX11XXb (X varies depending on each system) and INVC1 = 010XXXX0b.
The PWM output may vary as follows:

Case 1: When INV11 = 1 (three-phase mode 1)
- -INV01 = 0 and ICTB2 = 2h (timer B2 interrupt generated every 2nd time the timer B2 underflows), or INV01 = 1, INV00 = 1, and ICTB2 = 1h (timer B2 interrupt generated every time the timer B2 underflows when the reload control signal for timer A1 is set to 1)
- -The setting of registers TA4 and TA41 are varied every time a timer B2 interrupt is generated,
  Default value: TA41 = a', TA4 = a
  On the first timer B2 interrupt: TA41 = b', TA4 = b; the second time: TA41 = c', TA4 = c
- -Default value of registers IDB0 and IDB1: DU0 = 1, DUB0 = 0, DU1 = 0, DUB1 = 1
  On the third time: DU0 = 1, DUB0 = 0, DU1 = 1, DUB1 = 0

Case 2: When INV11 = 0 (three-phase mode 0)
- -INV01 = 0 and ICTB2 = 1h (timer B2 interrupt generated every time timer B2 underflows)
- -TA4 register setting is varied every time a timer B2 interrupt is generated,
  Default value: TA4 = a'
  On the first timer B2 interrupt: TA4 = a; 2nd time: TA4 = b'; 3rd time: TA4 = b; 4th time: TA4 = c'; 5th time: TA4 = c
- -Default value of registers IDB0 and IDB1: DU0 = 1, DUB0 = 0, DU1 = 0, DUB1 = 1
  On the sixth time: DU0 = 1, DUB0 = 0, DU1 = 1, DUB1 = 0

Notes:
1. Internal signal. Refer to the block diagram of three-phase motor control timers.
2. Applied when the INV11 bit in the INV1 register is set to 1 (three-phase mode 1).

Figure 17.17 Triangular Wave Modulation Operation



The above applies to INVC0 = 01XX110Xb (X varies depending on each system) and INVC1 = 000XXX00b.
This bit setting is applicable to turn-on control with a phase shift of 120 degrees.

The PWM output may vary as follows:
Default value of registers IDB0 and IDB1: DU0 = 0, DUB0 = 1, DU1 = 1, DUB1 = 1
On the third timer B2 interrupt: DU0 = 1, DUB0 = 1, DU1 = 1, DUB1 = 1
On the fifth timer B2 interrupt: DU0 = 1, DUB0 = 0, DU1 = 1, DUB1 = 1

Note:
1. Internal signal. Refer to the block diagram of three-phase motor control timers.

Figure 17.18 Sawtooth Wave Modulation Operation

17.6 Notes on Three-phase Motor Control Timers

17.6.1 Shutdown

- When a low signal is applied to the $\overline{\text{NMI}}$ pin with the bit settings below, pins TA1OUT, TA2OUT, and TA4OUT become high-impedance: the PM24 bit in the PM2 register is 1 (NMI enabled), the INV02 bit in the INVC0 register is 1 (the three-phase motor control timers used) and the INV03 bit is 1 (the three-phase motor control timer output enabled).

17.6.2 Register setting

- Do not write to the TAi1 register (i = 1, 2, 4) in the timing that timer B2 underflows. Before writing to the TAi1 register, read the TB2 register to verify that sufficient time is left until timer B2 underflows. Then, immediately write to the TAi1 register so that no interrupt handler is performed during this write procedure. If the TB2 register indicates little time is left until the underflow, write to the TAi1 register after timer B2 underflows.

18. Serial Interface

Serial interface consists of nine channels (UART0 to UART8).
Each UARTi (i = 0 to 8) has an exclusive timer to generate the transmit/receive clock and operates independently.
Figure 18.1 and Figure 18.2 show respectively a block diagram of UART0 to UART6 and that of UART7 and UART8.
The UARTi supports following modes:

- Synchronous serial interface mode (for UART0 to UART8)
- Asynchronous serial interface mode (UART mode) (for UART0 to UART8)
- Special mode 1 (I^2C mode) (for UART0 to UART6)
- Special mode 2 (for UART0 to UART6)
- Special mode 4 (Bus collision detection: IE mode) (optional) (1) (for UART0 to UART6)

Figure 18.3 to Figure 18.19 show registers associated with the UARTi.
Refer to the tables listing each mode for registers and pin settings.

Note:
1. Contact a Renesas Electronics sales office to use the optional features.

Table 18.1 Functions of UART0 to UART8

Mode/Function	UART0 to UART6	UART7, UART8
Synchronous serial interface mode	Available	Available
Serial data logical inversion	Available	Not available
UART mode	Available	Available

— (b7)	No register bit; should be written with 0 and read as undefined value		—

Note:
1. This bit should be set to 0 to select the level sensitive input as trigger. To set this bit to 1, the POL bit in the corresponding INTiIC register (i = 6 to 8) should be set to 0 (falling edge).

Figure 18.19 IFSR1 Register

18.1 Synchronous Serial Interface Mode

The synchronous serial interface mode allows data transmission/reception synchronized with transmit/receive clock. Table 18.2 lists specifications of synchronous serial interface mode.

Table 18.2 Synchronous Serial Interface Mode Specifications

Item	Specification
Data format	8-bit character length
Transmit/receive clock	• The CKDIR bit in the UiMR register (i = 0 to 8) is set to 0 (internal clock): $\frac{fx}{2(m+1)}$ fx = f1, f8, f2n; m: UiBRG register setting value, 00h to FFh • The CKDIR bit is set to 1 (external clock): input into the CLKi pin
Transmit/receive control	Selectable among CTS, RTS, and CTS/RTS disabled
Transmit start conditions	The conditions for starting data transmission are as follows (1): • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register) • Input level at the $\overline{\text{CTSi}}$ pin is L when the CTS is selected
Receive start conditions	The conditions for starting data reception are as follows (1): • The RE bit in the UiC1 register is set to 1 (reception enabled) • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register) • Input level at the $\overline{\text{CTSi}}$ pin is low when the CTS is selected
Interrupt request generating timing	In transmit interrupt, one of the following conditions is selected to set the UiIRS bit in registers U0C1 to U6C1 and U78CON: • The UiIRS bit is set to 0 (transmit buffer in the UiTB register is empty): when data is transferred from the UiTB register to the UARTi transmit register (when the transmission has started) • The UiIRS bit is set to 1 (transmission is completed): when data transmission from the UARTi transmit register is completed In receive interrupt, • When data is transferred from the UARTi receive register to the UiRB register (when the reception is completed)
Error detection	Overrun error (2) This error occurs when the seventh bit of the next data has been received before the UiRB register is read
Selectable functions	• CLK polarity Selectable either rising or falling edge of the transmit/receive clock for output and input of transmit/receive data • Bit order selection Selectable either LSB first or MSB first • Continuous receive mode Data reception is enabled by a read access to the UiRB register • Serial data logical inversion (UART0 to UART6) This function logically inverses transmit/receive data

Notes:

1. In case external clock is selected, the following preconditions should be met:
   - The CLKi pin is held high when the CKPOL bit in the UiC0 register is set to 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge)
   - The CLKi pin is held low when the CKPOL bit is set to 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge)
2. If an overrun error occurs, the UiRB register is undefined. The IR bit in the SiRIC register is not changed to 1 (interrupts requested).

Table 18.3 and Table 18.4 list register settings. When UARTi (i = 0 to 8) operating mode is selected, a high is output at the TXDi pin until the transmission starts (the TXDi pin is high-impedance when the N-channel open drain output is selected).
Figure 18.20 and Figure 18.21 show respectively an example of transmit/receive operation in synchronous serial interface mode.

Table 18.3 Register Settings in Synchronous Serial Interface Mode (for UART0 to UART6)

Register	Bits	Function
UiMR	7 to 4	Set the bits to 0000b
	CKDIR	Select either the internal clock or the external clock
	SMD2 to SMD0	Set the bits to 001b
UiC0	UFORM	Select either LSB first or MSB first
	CKPOL	Select a transmit/receive clock polarity
	5	Set the bit to 0
	CRD	Select the CTS enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	7	Set the bit to 0
	UiLCH	Set the bit to 1 to use logical inversion
	UiRRM	Set the bit to 1 to use continuous receive mode
	UiIRS	Select a source for UARTi transmit interrupt
	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission/reception
UiSMR	7 to 0	Set the bits to 00h
UiSMR2	7 to 0	Set the bits to 00h
UiSMR3	7 to 0	Set the bits to 00h
UiSMR4	7 to 0	Set the bits to 00h
UiBRG	7 to 0	Set the bit rate
IFS0	IFS06	Select input pins for CLK3, RXD3, and $\overline{\text{CTS3}}$
	IFS03 and IFS02	Select input pins for CLK6, RXD6, and $\overline{\text{CTS6}}$
UiTB	7 to 0	Set the data to be transmitted
UiRB	OER	Overrun error flag
	7 to 0	Received data is read

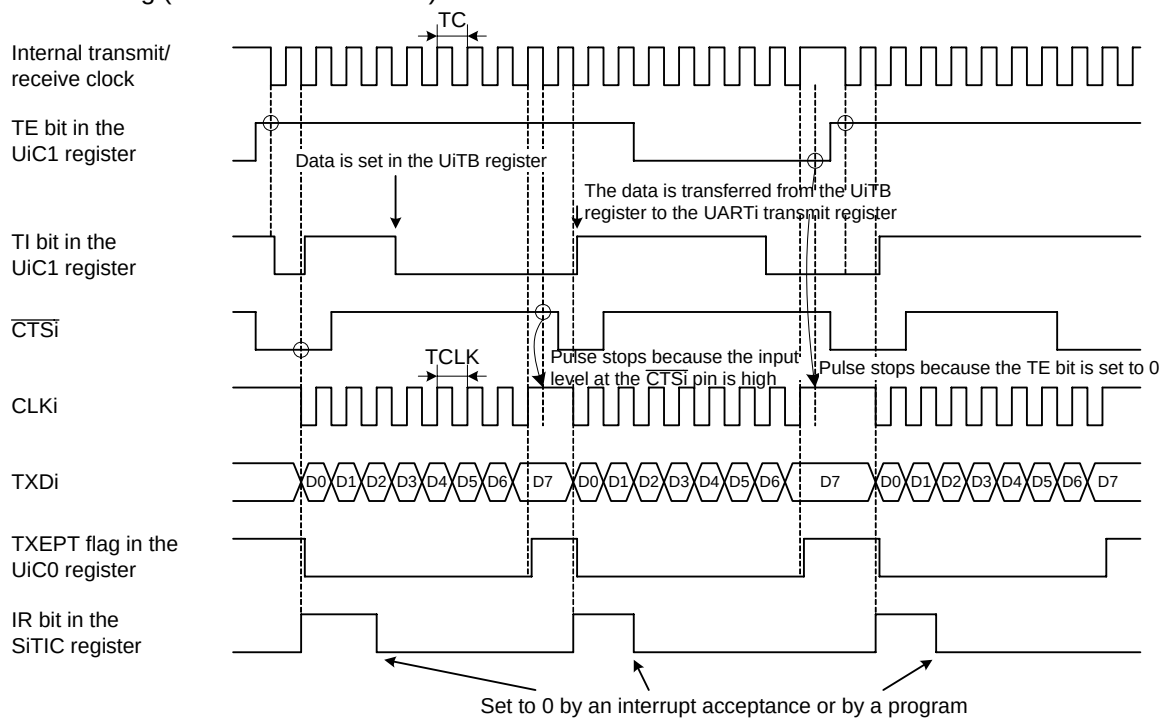
i = 0 to 6

Table 18.4 Register Settings in Synchronous Serial Interface Mode (for UART7 and UART8)

Register	Bits	Function
UiMR	7 to 4	Set the bits to 0000b
	CKDIR	Select the internal clock or the external clock
	SMD2 to SMD0	Set the bits to 001b
UiC0	UFORM	Select either LSB first or MSB first
	CKPOL	Select a transmit/receive clock polarity
	5	Set the bit to 0
	CRD	Select the CTS enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission/reception
U78CON	UiRRM	Set the bit to 1 to use continuous receive mode
	UiIRS	Select an interrupt source for UARTi transmit
IFS0	IFS05	Select input pins for CLK7, RXD7, and $\overline{\text{CTS7}}$
	IFS04	Select input pins for CLK8, RXD8, and $\overline{\text{CTS8}}$
UiBRG	7 to 0	Set the bit rate
UiTB	7 to 0	Set the data to be transmitted
UiRB	OER	Overrun error flag
	7 to 0	Received data can be read

i = 7, 8

Transmit timing (in internal clock mode)

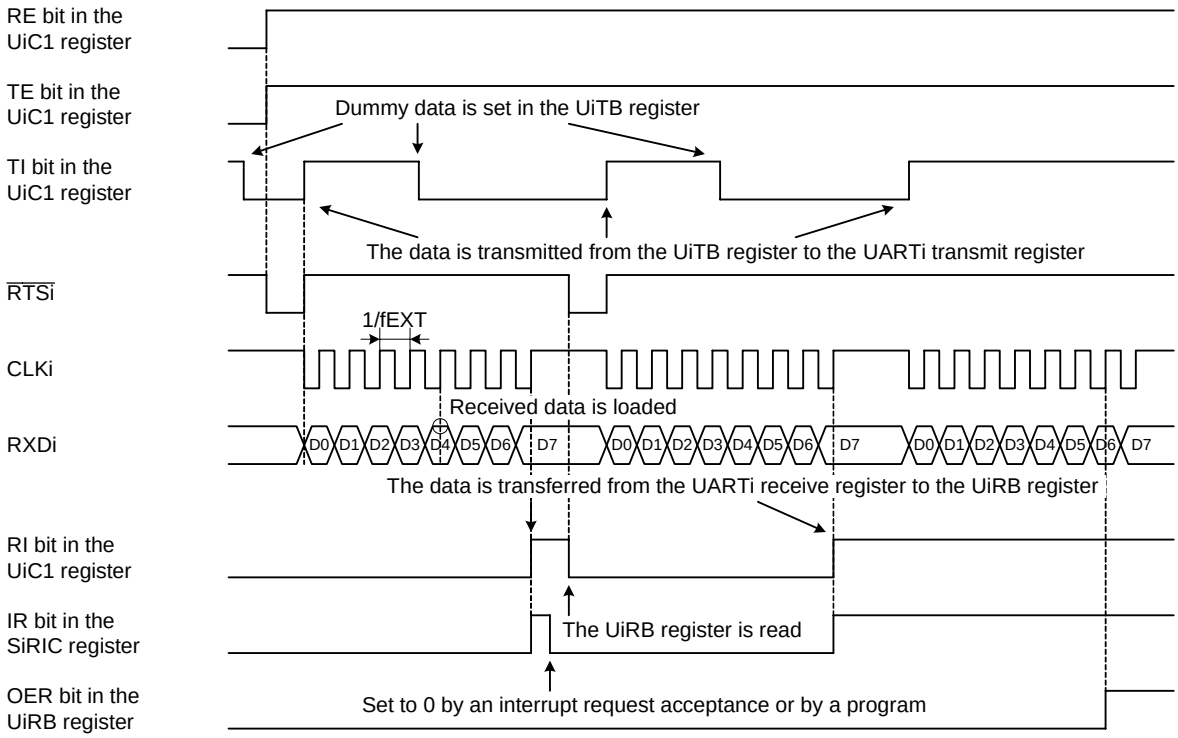


The figure above applies under the following conditions:
- -The CKDIR bit in the UiMR register = 0 (internal clock selected)
- -The CRD bit in the UiC0 register = 0 (CTS enabled)
- -The CKPOL bit in the UiC0 register = 0 (transmitted data output on the falling edge of the transmit/receive clock)
- -The UiRS bit in registers UiC1 and U78CON = 0 (an transmit interrupt request generated because the UiTB register is empty)

TC = TCLK = 2(m+1)/fx
fx: UiBRG count source frequency (f1, f8, or f2n)
m: Setting value of the UiBRG register

Figure 18.20 Transmit Operation in Synchronous Serial Interface Mode

Receive timing (in external clock mode)



The figure above applies under the following conditions:
- -The CKDIR bit in the UiMR register = 1 (external clock selected)
- -The CKPOL bit in the UiC0 register = 0 (received data input on the rising edge of the transmit/receive clock)

fEXT: External clock frequency

The following conditions should be met while an input level at the CLKi pin before receiving data is high:
- -The TE bit in the UiC1 register = 1 (transmission enabled)
- -The RE bit in the UiC1 register = 1 (reception enabled)
- -A write of dummy data to the UiTB register

Figure 18.21 Receive Operation in Synchronous Serial Interface Mode

18.1.1 Reset Procedure on Transmit/Receive Error

When a transmit/receive error occurs in synchronous serial interface mode, a reset is required as the procedure below:

A. Reset procedure for the UiRB register (i = 0 to 8)

(1) Set the RE bit in the UiC1 register to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 001b (synchronous serial interface mode selected).
(4) Set the RE bit in the UiC1 register to 1 (reception enabled).

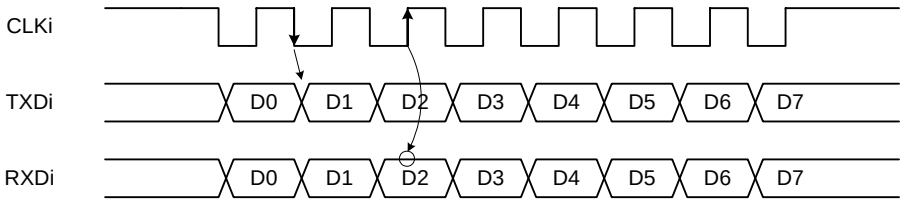
B. Reset procedure for the UiTB register

(1) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 001b (synchronous serial interface mode selected).
(3) Set the TE bit in the UiC1 register to 1 (transmission enabled) irrespective of the bit setting.

18.1.2 CLK Polarity

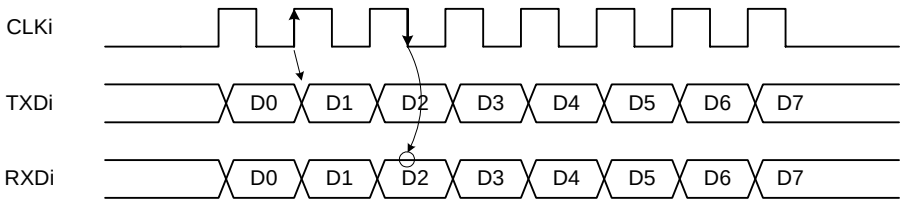
As shown in Figure 18.22, the polarity of the transmit/receive clock is selected using the CKPOL bit in the UiC0 register (i = 0 to 8).

Case 1: When the CKPOL bit in the UiC0 register is set to 0 (transmitted data output on the falling edge of the transmit/receive clock and received data input on the rising edge)



Notes:
1. The CLKi pin is held high when no data is transmitted/received.
2. The figure above applies under the following conditions:
-The UFORM bit in the UiC0 register = 0 (LSB first)
-The UiLCH bit in the UiC1 register = 0 (data is non logic-inverted)

Case 2: When the CKPOL bit in the UiC0 register is set to 1 (transmitted data output on the rising edge of the transmit/receive clock and received data input on the falling edge)



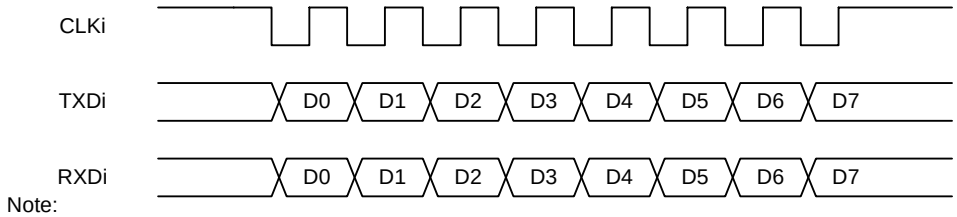
Notes:
3. The CLKi pin is held low when no data is transmitted/received.
4. The figure above applies under the following conditions:
-The UFORM bit in the UiC0 register = 0 (LSB first)
-The UiLCH bit in the UiC1 register = 0 (data is non logic-inverted)

Figure 18.22 Transmit/Receive Clock Polarity (i = 0 to 8)

18.1.3 LSB First and MSB First Selection

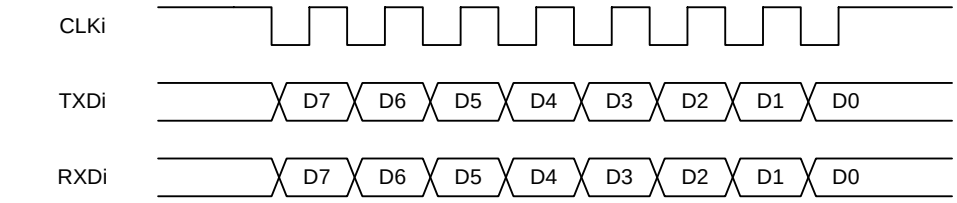
As shown in Figure 18.23, the bit order is selected using the UFORM bit in the UiC0 register (i = 0 to 8).

Case 1: When the UFORM bit in the UiC0 register is set to 0 (LSB first)



Note:
1. The figure above applies under the following conditions:
   -The CKPOL bit in the UiC0 register = 0 (transmitted data output on the falling edge of the transmit/ receive clock and received data input on the rising edge)
   -The UiLCH bit in the UiC1 register = 0 (data is non logic-inverted)

Case 2: When the UFORM bit in the UiC0 register is set to 1 (MSB first)



Note:
2. The figure above applies under the following conditions:
   -The CKPOL bit in the UiC0 register = 0 (transmitted data output on the falling edge of the transmit/ receive clock and received data input on the rising edge)
   -The UiLCH bit in the UiC1 register = 0 (data is non logic-inverted)

Figure 18.23 Bit Order (i = 0 to 8)

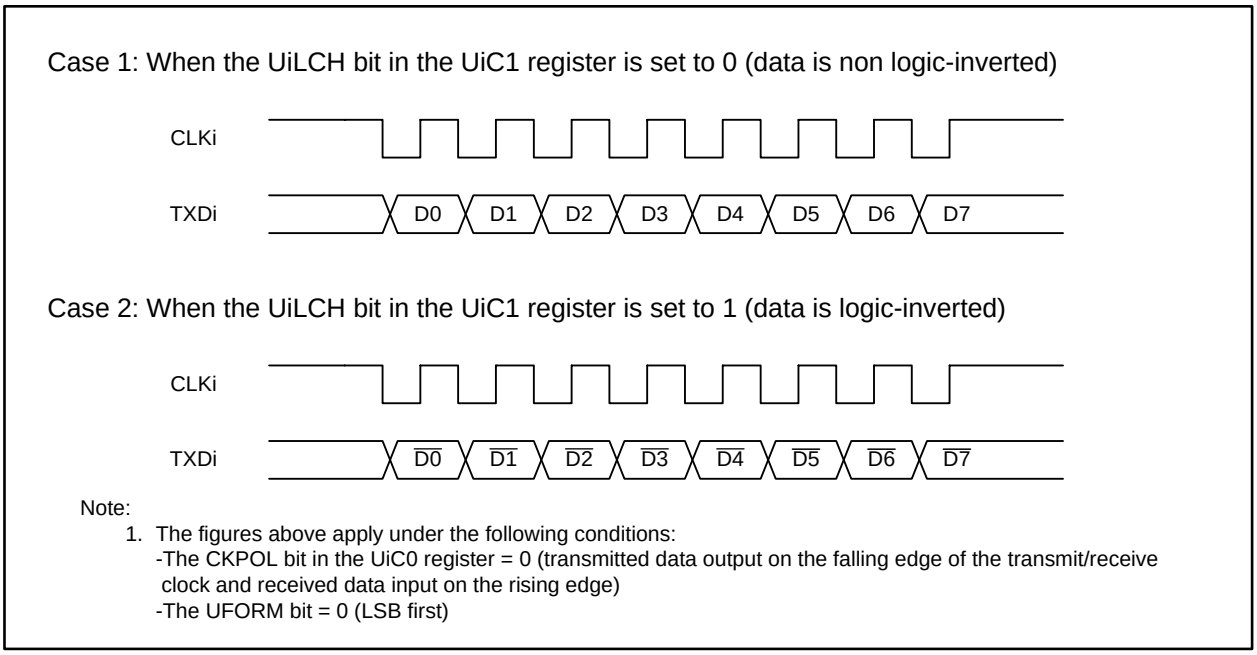
18.1.4 Continuous Receive Mode

In continuous receive mode, data reception is automatically enabled by a read access to the receive buffer register without any write of dummy data to the transmit buffer register. To start data reception, however, dummy data is required to read the receive buffer register.

When the UiRRM bit (i = 0 to 8) in registers U0C1 to U6C1 and U78CON is set to 1 (continuous receive mode enabled), the TI bit in the UiC1 register is set to 0 (data held in the UiTB register) by a read access to the UiRB register. In this UiRRM bit setting, any dummy data should not be written to the UiTB register.

18.1.5 Serial Data Logical Inversion

When the UiLCH bit in the UiC1 register (i = 0 to 6) is set to 1 (data logic-inverted), logical value written in the UiTB register is inverted to be transmitted. The UiRB register is read as logic-inverted receive data. Figure 18.24 shows the logical inversion of serial data.



Note:
1. The figures above apply under the following conditions:
-The CKPOL bit in the UiC0 register = 0 (transmitted data output on the falling edge of the transmit/receive clock and received data input on the rising edge)
-The UFORM bit = 0 (LSB first)

Figure 18.24 Serial Data Logical Inversion (i = 0 to 6)

18.1.6 CTS/RTS Function

The CTS controls data transmission using the $\overline{\text{CTSi}}/\overline{\text{RTSi}}$ pin (i = 0 to 8). When an input level at the pin becomes low, data transmission is started. If the input level changes to high during transmit operation, the transmission of the next data is stopped.

In synchronous serial interface mode, the transmitter is required to operate even during the receive operation. If the CTS is enabled, the input level at the $\overline{\text{CTSi}}/\overline{\text{RTSi}}$ pin should be low to start data reception as well.

The RTS indicates receiver status using the $\overline{\text{CTSi}}/\overline{\text{RTSi}}$ pin. When data reception is ready, the output level at the pin becomes low. It becomes high on the first falling edge of the CLKi pin.

18.2 Asynchronous Serial Interface Mode (UART Mode)

The UART mode enables data transmission/reception synchronized with an internal clock generated by a trigger on the falling edge of the start bit. Table 18.5 lists specifications of UART mode.

Table 18.5 UART Mode Specifications

Item	Specification
Data format	• Start bit: 1 bit-length • Data bit (data character) selectable among 7, 8, and 9 bit-length • Parity bit: selectable among odd, even, and none • Stop bit: selectable between 1 and 2 bit-length
Transmit/receive clock	• The CKDIR bit in the UiMR register (i = 0 to 8) is set to 0 (internal clock): $\frac{fx}{16(m+1)}$ fx = f1, f8, f2n; m: UiBRG register setting value, 00h to FFh • The CKDIR bit is set to 1 (external clock) $\frac{fEXT}{16(m+1)}$ fEXT: Clock applied to the CLKi pin
Transmit/receive control	Selectable among CTS, RTS, and CTS/RTS disabled
Transmit start conditions	The conditions for starting data transmission are as follows: • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register) • Input level at the $\overline{\text{CTSi}}$ pin is low when the CTS is selected
Receive start conditions	The conditions for starting data reception are as follows: • The RE bit in the UiC1 register is set to 1 (reception enabled) • The start bit is detected
Interrupt request generating timing	In transmit interrupt, one of the following conditions is selected to set the UiIRS bit in registers U0C1 to U6C1 and U78CON: • The UiIRS bit is set to 0 (transmit buffer in the UiTB register is empty): when data is transmitted from the UiTB register to the UARTi transmit register (when the transmission has started) • The UiIRS bit is set to 1 (transmission is completed): when data transmission from the UARTi transmit register is completed In receive interrupt, • When data is transmitted from the UARTi receive register to the UiRB register (when reception is completed)
Error detection	• Overrun error (1) This error occurs when one bit prior to the stop bit (when 1 stop bit length is selected) or the first stop bit (when 2 stop bit length is selected) of the next data has been received before the UiRB register is read • Framing error This error occurs when the required number of stop bits is not detected • Parity error This error occurs when an even number of 1's in parity and character bits is detected while the odd number is set, or vice versa. The parity should be enabled • Error sum flag This flag is set to 1 when any of overrun error, framing error, or parity error occurs
Selectable functions	• Bit order selection Selectable either LSB first or MSB first • Serial data logical inversion This function logically inverses transmit/receive data. The start bit and stop bit are not inverted • TXD/RXD I/O polarity switching The output level from the TXD pin and the input level to the RXD pin are inverted. All I/O levels are inverted

Note:

1. When an overrun error occurs, the UiRB register is undefined. The IR bit in the SiRIC register does not change to 1 (interrupts requested).

Table 18.6 and Table 18.7 list register settings. When UARTi (i = 0 to 8) operating mode is selected, a high is output at the TXDi pin until the transmission starts (the TXDi pin is high-impedance when the N-channel open drain output is selected). Figure 18.25 and Figure 18.26 show examples of transmit operation in UART mode. Figure 18.27 shows an example of receive operation.

Table 18.6 Register Settings in UART Mode (UART0 to UART6)

Register	Bits	Function
UiMR	IOPOL	Select I/O polarity of pins TXD and RXD
	PRY and PRYE	Select parity enabled or disabled, and odd or even
	STPS	Select a stop bit length
	CKDIR	Select the internal clock or the external clock
	SMD2 to SMD0	Set the bits to 100b in 7-bit character length
		Set the bits to 101b in 8-bit character length
		Set the bits to 110b in 9-bit character length
UiC0	UFORM	Selectable either LSB first or MSB first in 8-bit character length. Set the bit to 0 in 7-bit or 9-bit character length
	CKPOL	Set the bit to 0
	5	Set the bit to 0
	CRD	Select the CTS enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	7	Set the bit to 0
	UiLCH	Set the bit to 1 to use logical inversion
	UiRRM	Set the bit to 0
	UiIRS	Select an interrupt source for UARTi transmit
	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission
UiSMR	7 to 0	Set the bits to 00h
UiSMR2	7 to 0	Set the bits to 00h
UiSMR3	7 to 0	Set the bits to 00h
UiSMR4	7 to 0	Set the bits to 00h
UiBRG	7 to 0	Set the bit rate
IFS0	IFS06	Select input pins for CLK3, RXD3, and $\overline{\text{CTS3}}$
	IFS03 and IFS02	Select input pins for CLK6, RXD6, and $\overline{\text{CTS6}}$
UiTB	8 to 0	Set the data to be transmitted (1)
UiRB	OER, FER, PER, and SUM	Error flag
	8 to 0	Received data is read (1)

i = 0 to 6

Note:
1. The bits to be used are as follows: 7-bit character length: bits 6 to 0
   8-bit character length: bits 7 to 0
   9-bit character length: bits 8 to 0

Table 18.7 Register Settings in UART Mode (UART7, UART8)

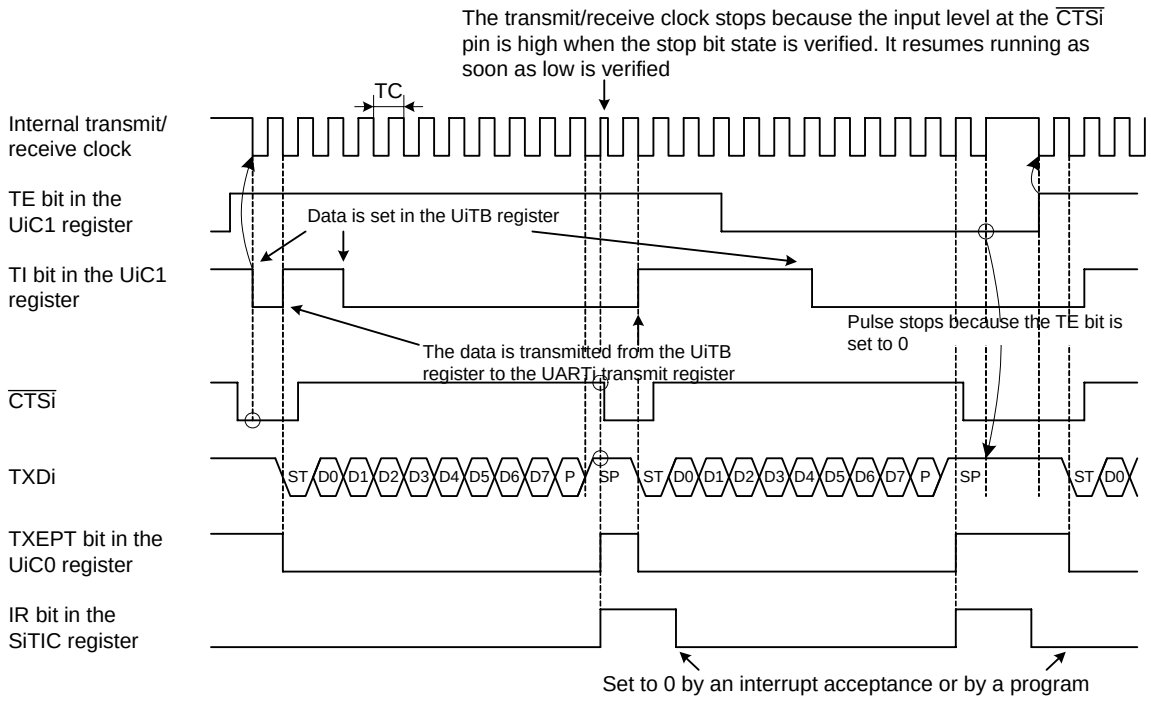
Register	Bits	Function
UiMR	PRY and PRYE	Select parity enabled or disabled, and odd or even
	STPS	Select a stop bit length
	CKDIR	Select the internal clock or the external clock
	SMD2 to SMD0	Set the bits to 100b in 7-bit character length
		Set the bits to 101b in 8-bit character length
		Set the bits to 110b in 9-bit character length
UiC0	UFORM	Selectable either LSB first or MSB first in 8-bit character length. Set the bit to 0 in 7-bit or 9-bit character length
	CKPOL	Set the bit to 0
	5	Set the bit to 0
	CRD	Select the CTS enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission
U78CON	UiRRM	Set the bit to 0
	UiIRS	Select an interrupt source for UARTi transmit
UiBRG	7 to 0	Set the bit rate
IFS0	IFS05	Select input pins for CLK7, RXD7, and $\overline{\text{CTS7}}$
	IFS04	Select input pins for CLK8, RXD8, and $\overline{\text{CTS8}}$
UiTB	8 to 0	Set the data to be transmitted (1)
UiRB	OER, FER, PER, and SUM	Error flag
	8 to 0	Received data is read (1)

i = 7, 8

Note:

1. The bits to be used are as follows: 7-bit character length: bits 6 to 0
   8-bit character length: bits 7 to 0
   9-bit character length: bits 8 to 0

8-bit character long data transmit timing (parity enabled, 1 stop bit)



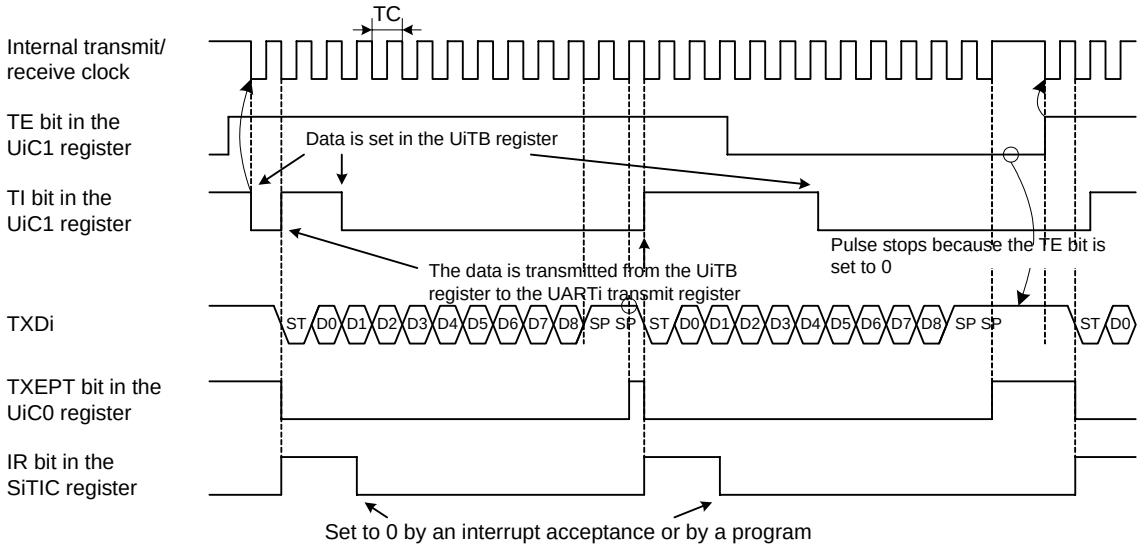
ST: Start bit
P: Parity bit
SP: Stop bit

The figure above applies under the following conditions:
- -The PRYE bit in the UiMR register = 1 (parity enabled)
- -The STPS bit in the UiMR register = 0 (1 stop bit)
- -The CRD bit in the UiC0 register = 0 (CTS enabled)
- -The UiIRS bit in the UiC1 register = 1 (transmit interrupt request generated because the UiTB register is empty)

TC = 16(m+1)/fx or 16(m+1)/fEXT
fx: UiBRG count source frequency (f1, f8, f2n)
fEXT: UiBRG count source frequency (external clock)
m: Setting value of the UiBRG register

Figure 18.25 Transmit Operation in UART Mode (1) (i = 0 to 8)

9-bit character long data transmit timing (parity disabled, 2 stop bits)



ST: Start bit
P: Parity bit
SP: Stop bit

The figure above applies under the following conditions:
- -The PRYE bit in the UiMR register = 0 (parity disabled)
- -The STPS bit in the UiMR register = 1 (2 stop bits)
- -The CRD bit in the UiC0 register = 1 (CTS disabled)
- -The UiIRS bit in the UiC1 register = 0 (transmit interrupt request generated because the transmission is completed)

TC = 16(m+1)/fx or 16(m+1)/fEXT
fx: UiBRG count source frequency (f1, f8, f2n)
fEXT: UiBRG count source frequency (external clock)
m: Setting value of the UiBRG register

Figure 18.26 Transmit Operation in UART Mode (2) (i = 0 to 8)

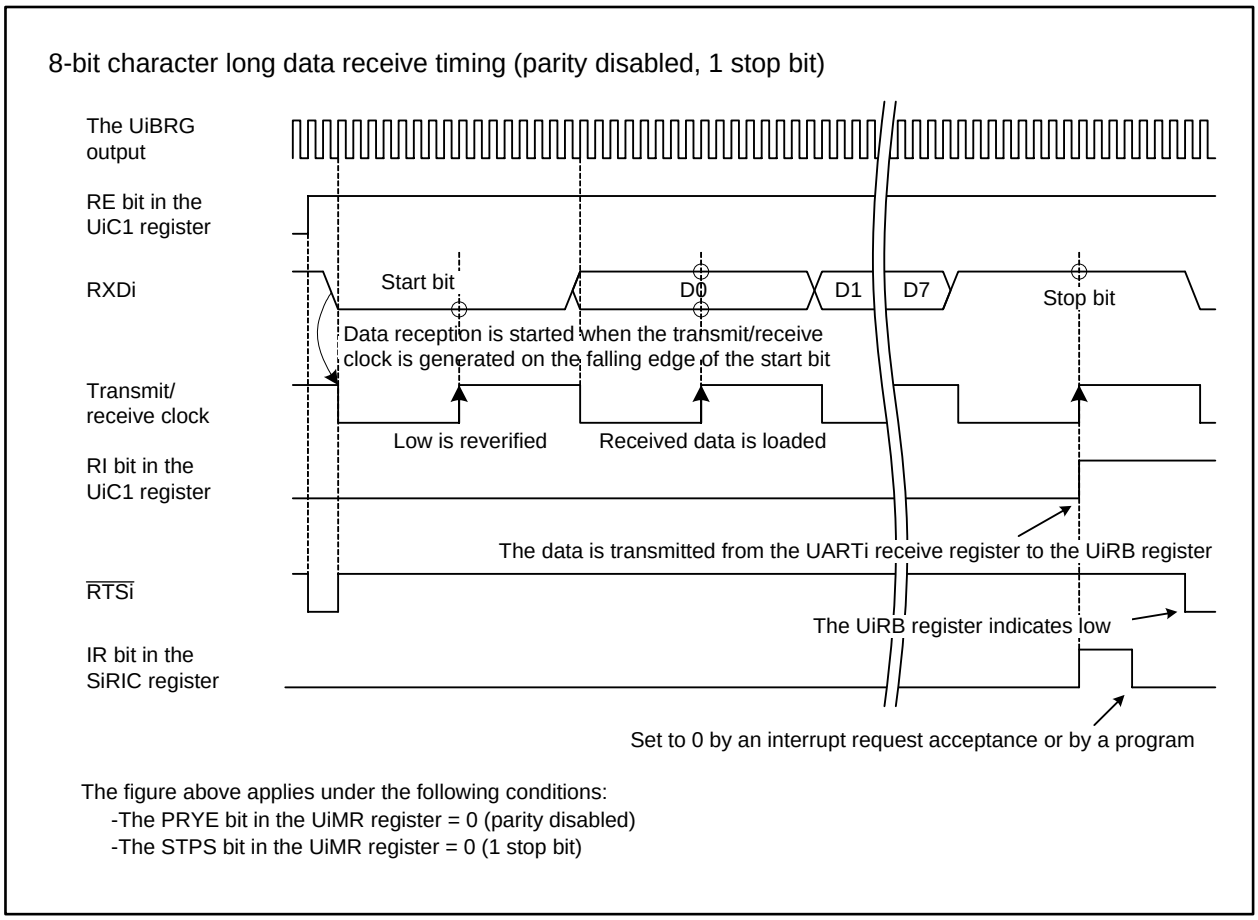


Figure 18.27 Receive Operation in UART mode (i = 0 to 8)

18.2.1 Bit Rate

In UART mode, the bit rate is clock frequency which is divided by a setting value of the UiBRG register (i = 0 to 8) and again divided by 16. Table 18.8 lists an example of bit rate setting.

Table 18.8 Bit Rate Setting

Bit Rate (bps)	Count Source of BRG	Peripheral Clock: 30 MHz		Peripheral Clock: 32 MHz	
		Setting value of BRG: n	Actual bit rate (bps)	Setting value of BRG: n	Actual bit rate (bps)
1200	f8	194 (C2h)	1202	207 (CHh)	1202
2400	f8	97 (61h)	2392	103 (67h)	2404
4800	f8	48 (30h)	4783	51 (33h)	4808
9600	f1	194 (C2h)	9615	207 (CFh)	9615
14400	f1	129 (81h)	14423	138 (8Ah)	14388
19200	f1	97 (61h)	19133	103 (67h)	19231
28800	f1	64 (40h)	28846	68 (44h)	28986
31250	f1	59 (3Bh)	31250	63 (3Fh)	31250
38400	f1	48 (30h)	38265	51 (33h)	38462
51200	f1	36 (24h)	50676	38 (26h)	51282

18.2.2 Reset Procedure on Transmit/Receive Error

When a transmit/receive error occurs in UART mode, a reset is required as the procedure below:

A. Reset procedure for the UiRB register (i = 0 to 8)

(1) Set the RE bit in the UiC1 register to 0 (reception disabled).
(2) Set the RE bit in the UiC1 register to 1 (reception enabled).

B. Reset procedure for the UiTB register

(1) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(2) Set again bits SMD2 to SMD0 to either of 001b, 101b, or 110b.
(3) Set the TE bit in the UiC1 register to 1 (transmission enabled) irrespective of the bit setting.

18.2.3 LSB First and MSB First Selection

As shown in Figure 18.28, the bit order is selected using the UFORM bit in the UiC0 register (i = 0 to 8). This function is available for the data format of 8-bit character length.

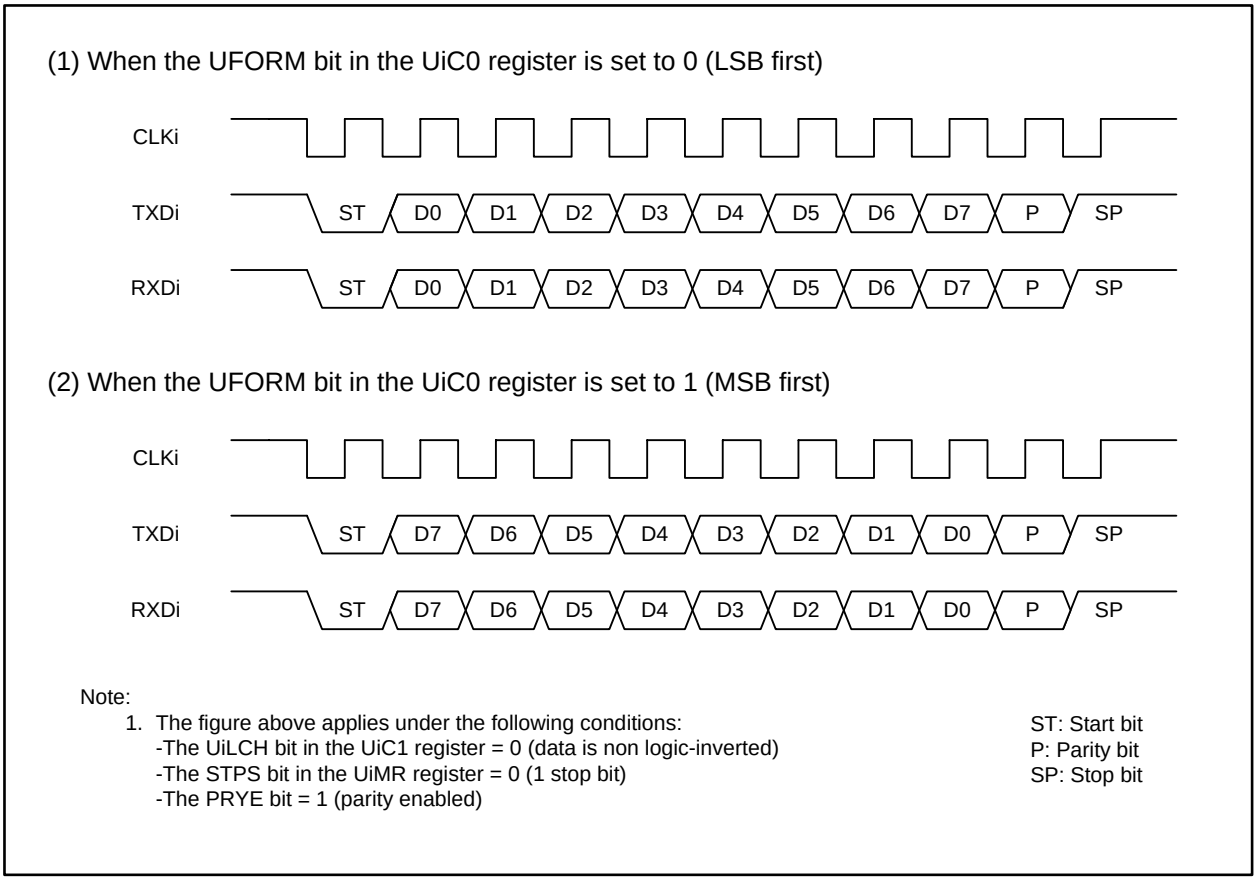

Figure 18.28 Bit Order (i = 0 to 8)

18.2.4 Serial Data Logical Inversion

When the UiLCH bit in the UiC1 register (i = 0 to 6) is set to 1 (data logic-inverted), logical value written in the UiTB register is inverted to be transmitted. The UiRB register is read as logic-inverted receive data. The parity bit is not inverted. Figure 18.29 shows the logical inversion of serial data.

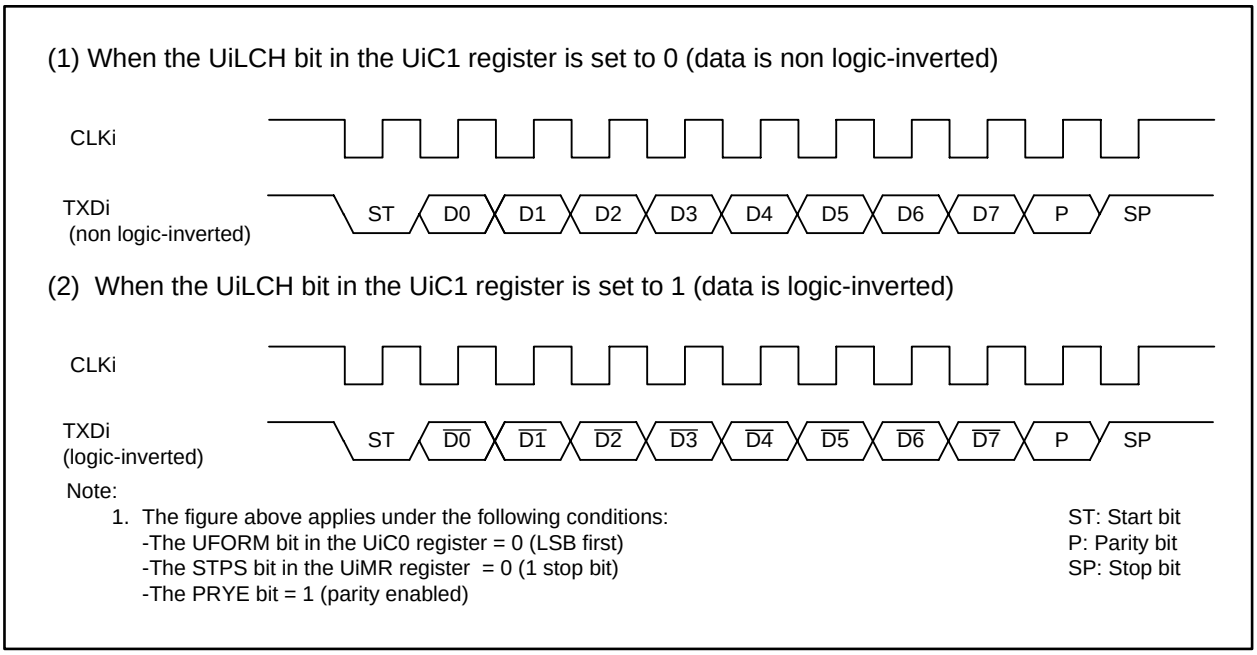

Figure 18.29 Serial Data Logical Inversion (i = 0 to 6)

18.2.5 TXD and RXD I/O Polarity Inversion

The output level at the TXD pin and the input level at the RXD pin are inverted by this function. All I/O data levels, including the start bit, stop bit, and parity bit are inverted by setting the IOPOL bit in the UiMR register (i = 0 to 6) to 1 (inverted). Figure 18.30 shows TXD and RXD I/O polarity inversion.

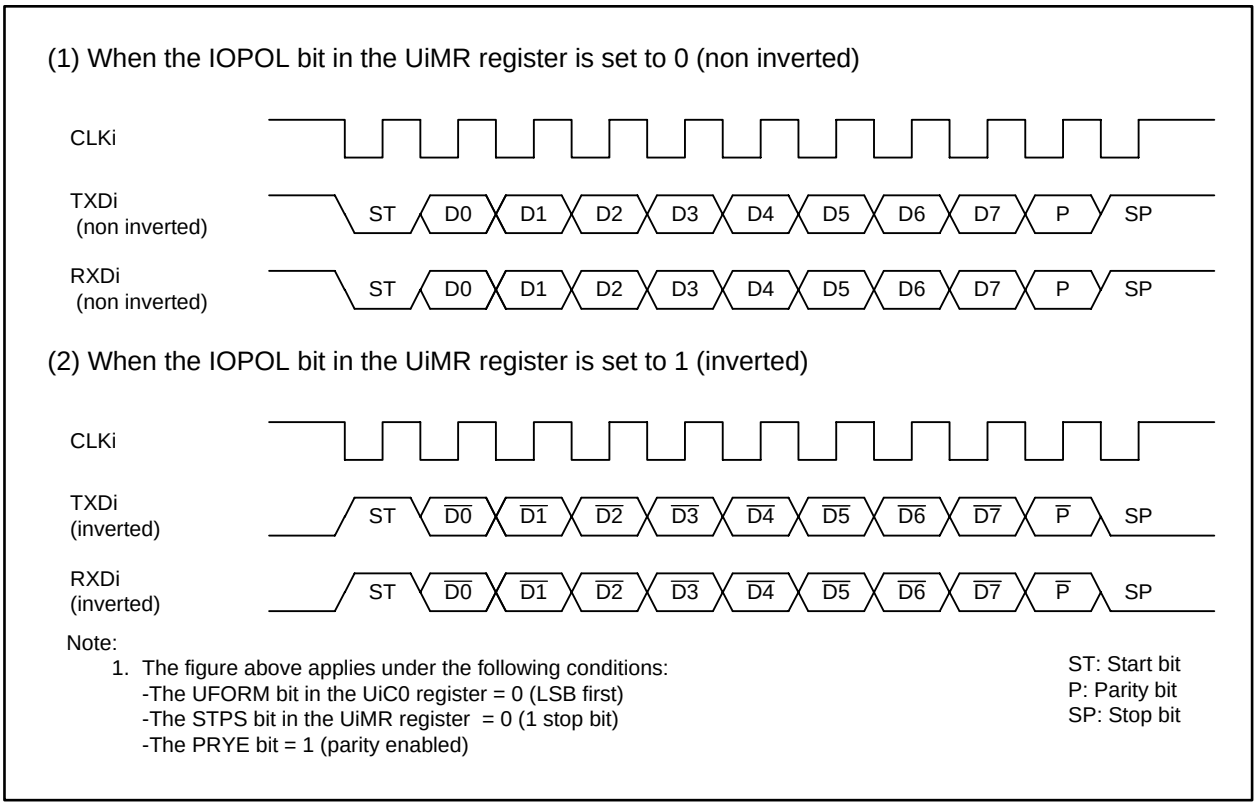

Figure 18.30 TXD and RXD I/O Polarity Inversion (i = 0 to 6)

18.2.6 CTS/RTS Function

The CTS controls data transmission using the $\overline{\text{CTSi}}/\overline{\text{RTSi}}$ pin (i = 0 to 8). When an input level at the pin becomes low, data transmission is started. If the input level changes to high during transmit operation, the transmission of the next data is stopped.

The RTS indicates receiver status using the $\overline{\text{CTSi}}/\overline{\text{RTSi}}$ pin. When the MCU is ready to receive data, the output level at the pin becomes low. It becomes high on the first falling edge of the CLKi pin.

18.3 Special Mode 1 (I^2C Mode)

This mode uses an I^2C-typed interface for communication. Table 18.9 lists specifications of the I^2C mode.

Table 18.9 I^2C Mode Specifications

Item	Specification
Data format	8-bit character length
Transmit/receive clock	In master mode • The CKDIR bit in the UiMR register (i = 0 to 6) is set to 0 (internal clock): $\frac{fx}{2(m+1)}$ fx = f1, f8, f2n m: UiBRG register setting value, 00h to FFh In slave mode • The CKDIR bit is set to 1 (external clock): input into the SCLi pin
Transmit start conditions	The conditions for starting data transmission are as follows (1): • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register)
Receive start conditions	The conditions for starting data reception are as follows (1): • The RE bit in the UiC1 register is set to 1 (reception enabled) • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register)
Interrupt request generating timing	When any of the following is detected: start condition, stop condition, NACK (Not-Acknowledge), or ACK (Acknowledge)
Error detection	Overrun error (2) This error occurs when the eighth bit of the next data has been received before the UiRB register is read
Selectable functions	• Arbitration lost Selectable update timing of the ABT bit in the UiRB register • SDAi digital delay Selectable among non digital delay and two to eight cycles of digital delay of UiBRG count source • Clock phase setting Selectable either clock delayed or no clock delay

Notes:
1. When an external clock is selected, the conditions should be met while the external clock signal is held high.
2. If an overrun error occurs, the UiRB register is undefined. The IR bit in the SiRIC register is not changed to 1 (interrupts requested).

Table 18.10 and Table 18.11 list respectively register settings and functions in I^2C mode. Figure 18.31 shows a block diagram of I^2C mode and Figure 18.32 shows timings for the transfer to the UiRB register (i = 0 to 6) and the interrupt.

As shown in Table 18.11, this mode is available when bits SMD2 to SMD0 in the UiMR register (i = 0 to 6) are set to 010b, and the IICM bit in the UiSMR register is set to 1. Since a transmit signal at the SDAi pin is output via the delay circuit, it changes after the SCLi pin is stably held low.

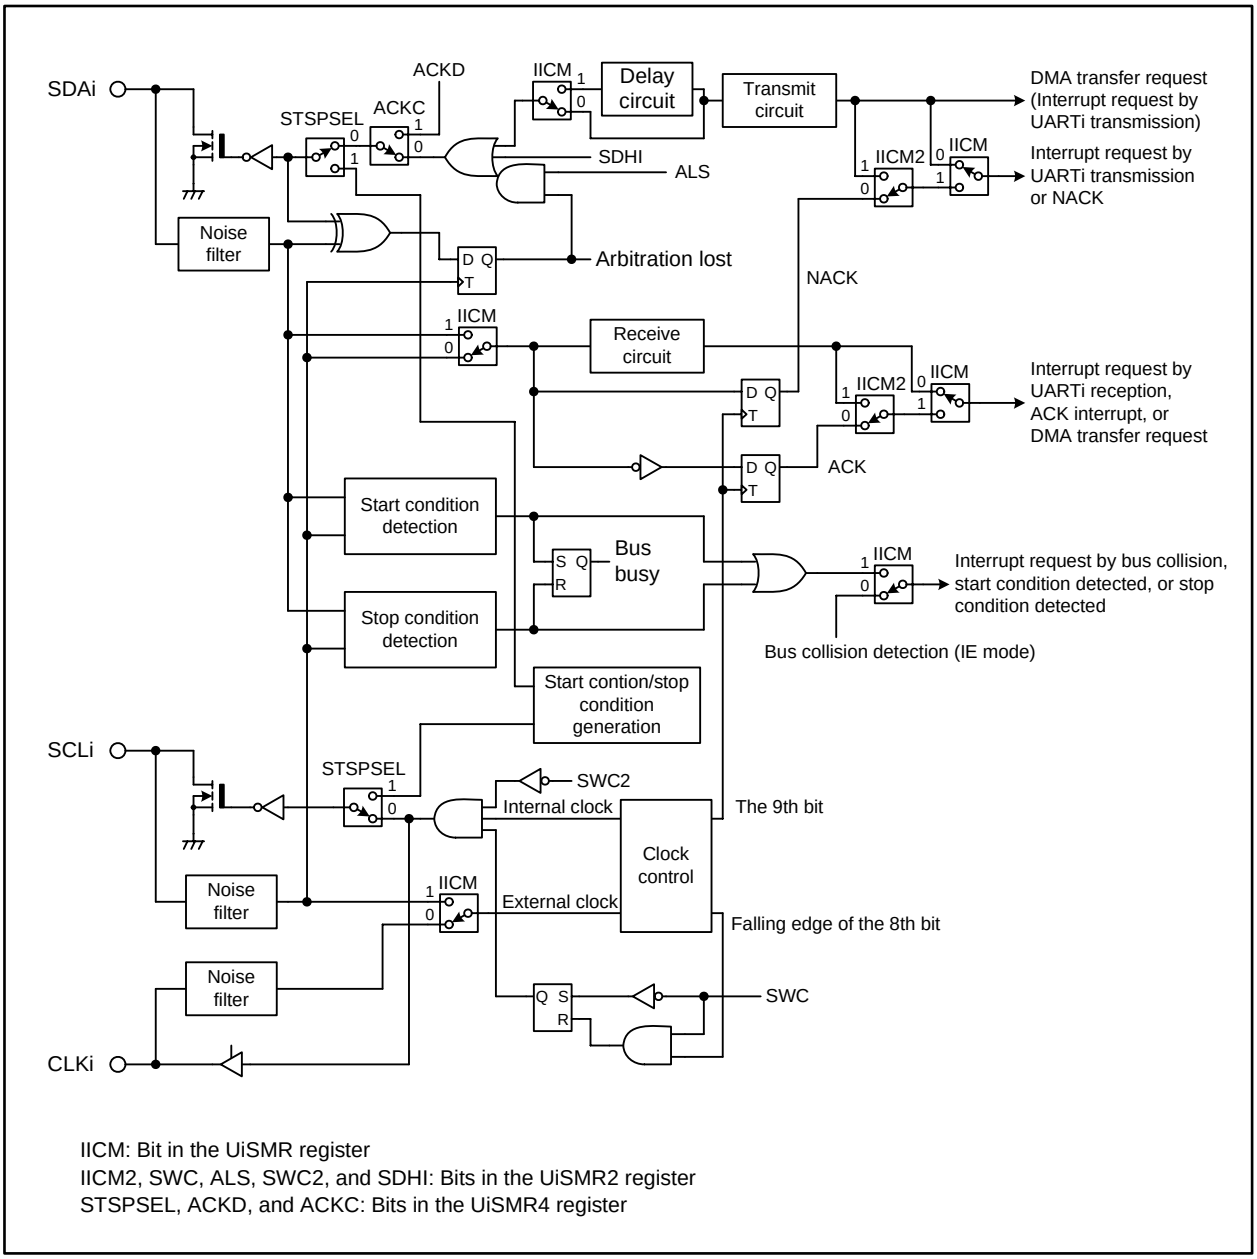

Figure 18.31 I²C Mode Block Diagram (i = 0 to 6)

Table 18.10 Register Settings in I²C Mode (i = 0 to 6)

Register	Bits	Function	
		Master	Slave
UiMR	IOPOL	Set the bit to 0	
	CKDIR	Set the bit to 0	Set the bit to 1
	SMD2 to SMD0	Set the bit to 010b	
UiC0	7 to 4	Set the bits to 1001b	
	TXEPT	Transmit register empty flag	
	2	Set the bit to 0	
	CLK1 and CLK0	Select a count source for the UiBRG register	Disabled
UiC1	7 to 5	Set the bits to 000b	
	UiIRS	Set the bit to 1	
	RI	Receive complete flag	
	RE	Set the bit to 1 to enable data reception	
	TI	Transmit buffer empty flag	
	TE	Set the bit to 1 to enable data transmission/reception	
UiSMR	7 to 3	Set the bits to 00000b	
	BBS	Bus busy flag	
	ABC	Select an arbitration lost detection timing	Disabled
	IICM	Set the bit to 1	
UiSMR2	7	Set the bit to 0	
	SDHI	Set the bit to 1 to disable the SDA output	
	SWC2	Set the bit to 1 to hold the SCL output at a forcible low	
	STC	Set the bit to 0	Set the bit to 1 to reset UARTi by detecting the start condition
	ALS	Set the bit to 1 to stop the output at the SDAi pin to detect an arbitration lost	Set the bit to 0
	SWC	Set the bit to 1 to hold a low output at the SCLi pin after receiving the eighth bit of the clock	
	CSC	Set the bit to 1 to enable clock synchronization	Set the bit to 0
	IICM2	Refer to Table 18.11	
UiSMR3	DL2 to DL0	Set the digital delay value of SDAi	
	4 to 2	Set the bit to 000b	
	CKPH	Refer to Table 18.11	
	SSE	Set the bit to 0	
UiSMR4	SWC9	Set the bit to 0	Set the bit to 1 to hold a low output at the SCLi pin after receiving the ninth bit of the clock
	SCLHI	Set the bit to 1 to stop the SCL output to detect stop condition	Set the bit to 0
	ACKC	Set the bit to 1 for ACK data output	
	ACKD	Select ACK or NACK	
	STSPSEL	Set the bit to 1 when any condition is output	Set the bit to 0
	STPREQ	Set the bit to 1 to generate a stop condition	Set the bit to 0
	RSTAREQ	Set the bit to 1 to generate a restart condition	Set the bit to 0
	STAREQ	Set the bit to 1 to generate a start condition	Set the bit to 0
UiBRG	7 to 0	Set the bit rate	Disabled
IFSR0	IFSR06 and IFSR07	Select a UART as interrupt source	
IFSR1	IFSR16	Select a UART as interrupt source	
IFS0	IFS06	Select input pins for SCL3 and SDA3	
	IFS03 and IFS02	Select input pins for SCL6 and SDA6	
UiTB	8	Set the bit to 1 on transmission. Set the bit to the value of the ACK bit on reception	
	7 to 0	Set the data to be transmitted on transmission. Set the register to FFh on reception	
UiRB	OER	Overrun error flag	
	ABT	Arbitration lost detection flag	Disabled
	8	D0 is loaded immediately after a receive interrupt is generated. ACK or NACK is loaded after a transmit interrupt is generated	
	7 to 0	D7 to D1 are read immediately after a receive interrupt is generated. D7 to D0 are read after a transmit interrupt is generated	

Table 18.11 I²C Mode Functions (i = 0 to 6)

Function	Synchronous Serial Interface Mode (SMD2 to SMD0 = 001b, IICM = 0)	I²C Mode (SMD2 to SMD0 = 010b, IICM = 1)			
		IICM2 = 0 (ACK/NACK interrupt)		IICM2 = 1 (Transmit/receive interrupt)	
		CKPH = 0 (Non clock delayed)	CKPH = 1 (Clock delayed)	CKPH = 0 (Non clock delayed)	CKPH = 1 (Clock delayed)
Source of software interrupt numbers 6, 39 to 41 (1) (Refer to Figure 18.32)	—	Start condition or stop condition detection (Refer to Table 18.12)			
Source of software interrupt numbers 2, 4, 17, 19, 33, 35, and 37 (1) (Refer to Figure 18.32)	UARTi transmission: Transmission started or completed (selected using the UiIRS register)	NACK detection: Rising edge of the ninth bit of SCLi		UARTi transmission: Rising edge of the ninth bit of SCLi	UARTi transmission: Falling edge of the ninth bit of SCLi
Source of software interrupt numbers 3, 5, 18, 20, 34, 36, and 38 (1) (Refer to Figure 18.32)	UARTi reception: Receiving at eighth bit CKPOL = 0 (rising edge) CKPOL = 1 (falling edge)	ACK detection: Rising edge of the ninth bit of SCLi		UARTi reception: Falling edge of the eighth bit of SCLi	
Data transfer timing from the UART receive register to the UiRB register	CKPOL = 0 (rising edge) CKPOL = 1 (falling edge)	Rising edge of the ninth bit of SCLi		Falling edge of the eighth bit of SCLi	Falling edge of the eighth bit and rising edge of the ninth bit of SCLi
UARTi transmit output delay	Non delayed	Delayed			
Pins P6_3, P6_7, P7_0, P7_3, P7_6, P9_2, P9_6, P11_0, P12_0, P15_0, and P15_4	TXDi output	SDAi I/O			
Pins P6_2, P6_6, P7_1, P7_5, P8_0, P9_1, P9_7, P11_2, P12_2, P15_2, and P15_5	RXDi input	SCLi I/O			
Pins P6_1, P6_5, P7_2, P7_4, P7_7, P9_0, P9_5, P11_1, P12_1, P15_1, and P15_6	Select CLKi input or output	— (Not used in I²C mode)			
Read level at pins RXDi and SCLi	Readable irrespective of the port direction bit				
Default output value at the SDAi pin	—	High (Value set in the Port Pi register (i = 0 to 7) if the I/O port is selected by output function select registers)			
SCLi default and end values	—	High	Low	High	Low
DMA source (Refer to Figure 18.32)	UARTi reception	ACK detection		UARTi reception: Falling edge of the eighth bit of SCLi	

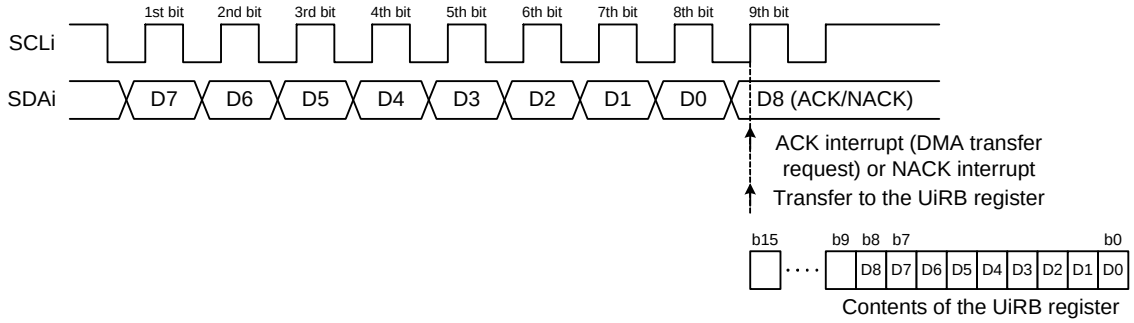
Table 18.11 I²C Mode Functions (i = 0 to 6)

Function	Synchronous Serial Interface Mode (SMD2 to SMD0 = 001b, IICM = 0)	I²C Mode (SMD2 to SMD0 = 010b, IICM = 1)			
		IICM2 = 0 (ACK/NACK interrupt)		IICM2 = 1 (Transmit/receive interrupt)	
		CKPH = 0 (Non clock delayed)	CKPH = 1 (Clock delayed)	CKPH = 0 (Non clock delayed)	CKPH = 1 (Clock delayed)
Store received data	The first to eighth bits of received data are stored into bits 0 to 7 in the UiRB register	The first to eighth bits of received data are stored into bits 7 to 0 in the UiRB register		The first to seventh bits of received data are stored into bits 6 to 0 in the UiRB register and the eighth bit is stored into bit 8	Same as on the left column on the first data storing (2). The first to eighth bits of received data are stored into 7 to 0 bits in the UiRB register and the ninth bit is stored into bit 8 on the second data storing (3)
Read received data	The UiRB register status is read as it is			Bits 6 to 0 in the UiRB register are read as bits 7 to 1 and bit 8 is read as bit 0	Same as on the left column on the first read (2). The UiRB register status is read as it is on the second read (3)

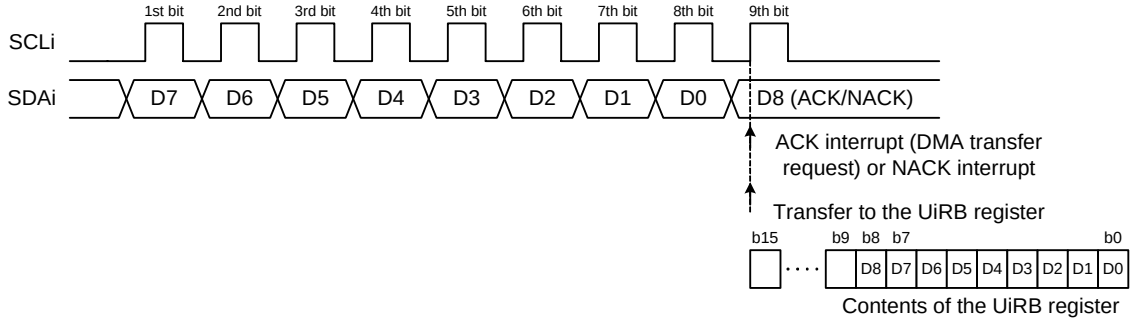
Notes:

1. Steps to change interrupt sources are as follows:
   (1) Disable the interrupt of the corresponding software interrupt number.
   (2) Change the source of interrupt.
   (3) Set the IR bit of the corresponding software interrupt number to 0 (no interrupt requested).
   (4) Set bits ILVL2 to ILVL0 of the corresponding software interrupt number.
2. The first data transfer to the UiRB register starts on the rising edge of the eighth bit of SCLi.
3. The second data transfer to the UiRB register starts on the rising edge of the ninth bit of SCLi.

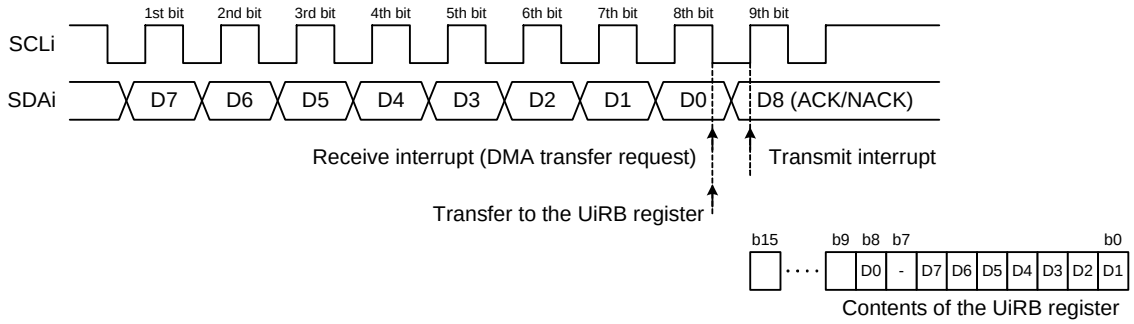
(1) When the IICM2 bit is set to 0 (ACK or NACK interrupt) and the CKPH bit is set to 0 (non clock delayed)



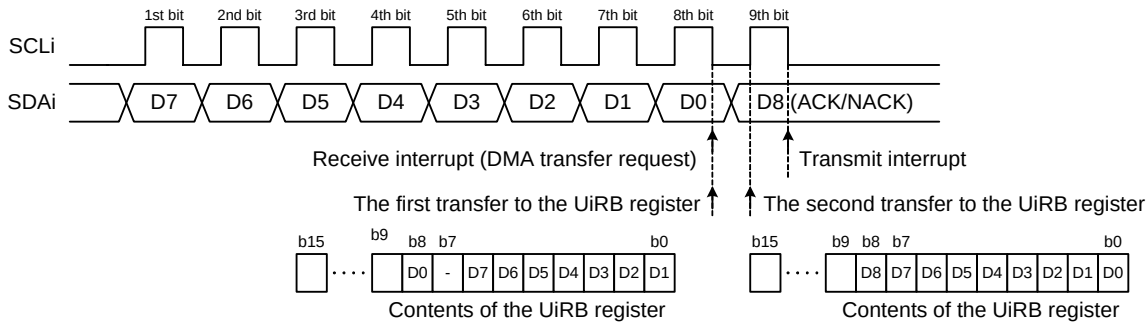
(2) When the IICM2 bit is set to 0 and the CKPH bit is set to 1 (clock delayed)



(3) When the IICM2 bit is set to 1 (transmit/receive interrupt) and the CKPH bit is set to 0



(4) When the IICM2 bit is set to 1 and the CKPH bit is set to 1



The figure above applies under the following condition:
-The CKDIR bit in the UiMR register = 0 (internal clock)

Figure 18.32 Timings for the Transfer and Interrupt to the UiRB Register (i = 0 to 6)

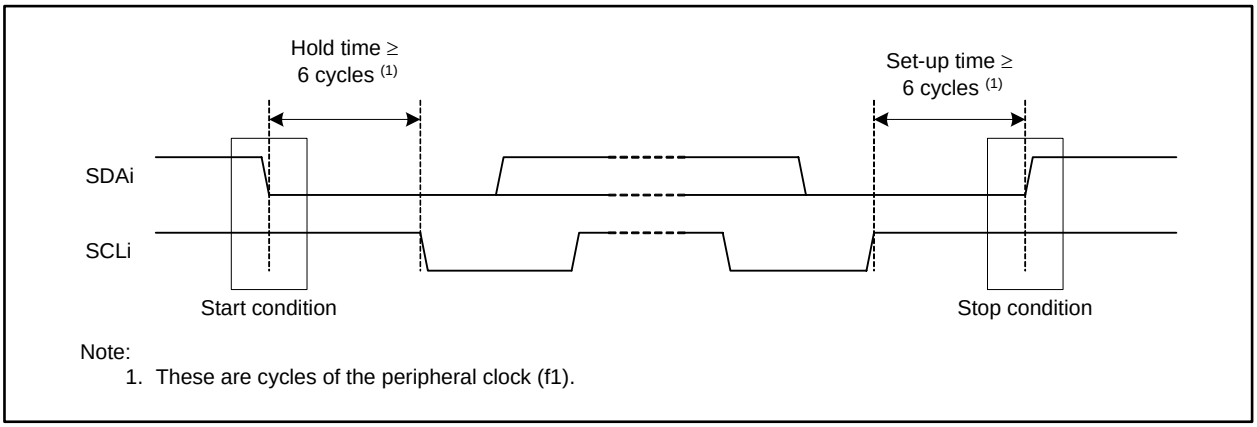
18.3.1 Start Condition and Stop Condition Detection

The start condition and stop condition are detected by their respective detectors.

The start condition detection interrupt request is generated by a high-to-low transition at the SDAi pin while the SCLi (i = 0 to 6) pin is held high. The stop condition detection interrupt request is generated by a low-to-high transition at the SDAi pin while the SCLi pin is held high.

The start condition detection interrupt shares interrupt control registers and vectors with the stop condition detection interrupt. The BBS bit in the UiSMR register determines which interrupt is requested.

To detect a start condition or stop condition, both set-up and hold times require six cycles or more of the peripheral clock (f1) as shown in Figure 18.33. To meet the condition for the Fast-mode specification, f1 is required to be 10 MHz or more.



Note:
1. These are cycles of the peripheral clock (f1).

Figure 18.33 Start Condition and Stop Condition Detection Timing (i = 0 to 6)

18.3.2 Start Condition and Stop Condition Generation

The start condition, restart condition, and stop condition are generated by bits STAREQ, RSTAREQ, and STPREQ in the UiSMR4 register (i = 0 to 6), respectively. To output the start condition, the STSPSEL bit in the UiSMR4 register should be set to 1 (start condition/stop condition generator selected) after setting the STAREQ bit to 1 (start). To output the restart condition and stop condition, the STSPSEL bit should be set to 1 after setting respective bits RSTAREQ and STPREQ to 1.

Table 18.12 and Figure 18.34 show the functions of the STSPSEL bit.

Table 18.12 STSPSEL Bit Functions

Function	STSPSEL = 0	STSPSEL = 1
Start condition and stop condition generation	Output is provided by the program with port (no auto generation by hardware)	Start condition or stop condition is output according to the STAREQ, RSTAREQ, or STPREQ bit, respectively
Start condition and stop condition interrupt request generating timing	When start condition or stop condition is detected	When start condition or stop condition generation is completed

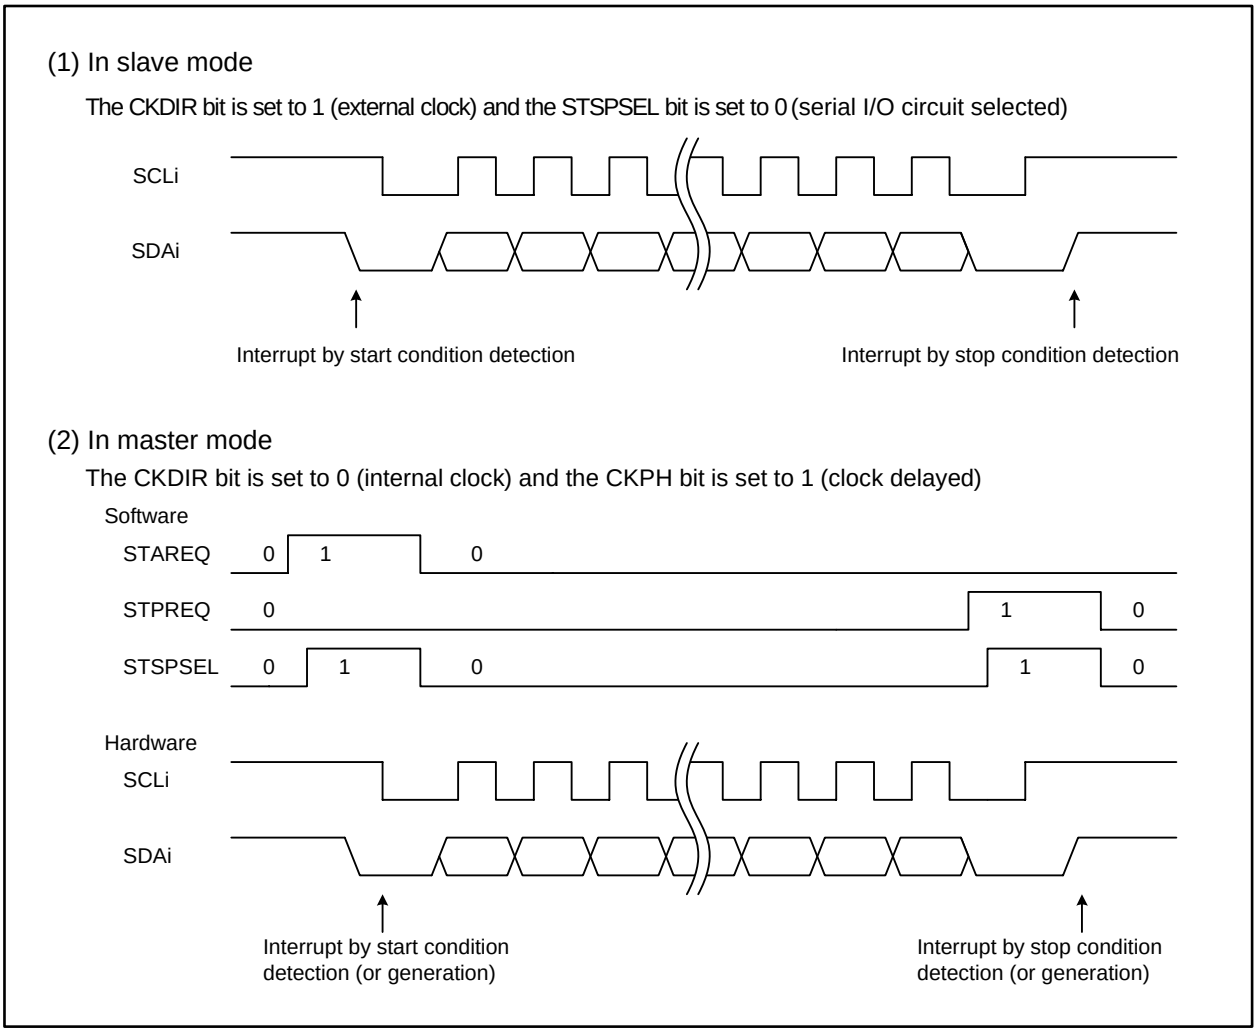


Figure 18.34 STSPSEL Bit Functions (i = 0 to 6)

18.3.3 Arbitration

The MCU determines whether the transmit data matches data input to the SDAi pin on the rising edge of the SCLi. If it does not match the input data, the arbitration takes place at the SDAi pin by switching off the data output stage.

The ABC bit in the UiSMR register (i = 0 to 6) determines the update timing for the ABT bit in the UiRB register.

When the ABC bit is set to 0 (update per bit), the ABT bit is set to 1 (arbitration is lost) as soon as a data discrepancy is detected. If not detected, the ABT bit is set to 0 (arbitration is won). When the ABC bit is set to 1 (update per byte), the ABT bit is set to 1 on the falling edge of the eighth bit of the SCLi if any discrepancy is detected. In this ABC bit setting, the ABT bit should be set to 0 to start the next 1-byte transfer.

When the ALS bit in the UiSMR2 register is set to 1 (SDA output stop enabled), an arbitration lost occurs. As soon as the ABT bit is set to 1, the SDAi pin becomes high-impedance.

18.3.4 SCL Control and Clock Synchronization

Data transmission/reception in I^2C mode uses the transmit/receive clock as shown in Figure 18.32. The clock speed increase makes it difficult to secure the required time for ACK generation and data transmit procedure. The I^2C mode supports a function of wait-state insertion to secure this required time and a function of clock synchronization with a wait-state inserted by other devices.

The SWC bit in the UiSMR2 register (i = 0 to 6) is used to insert a wait-state for ACK generation. When the SWC bit is set to 1 (the SCLi pin is held low after the eighth bit of the SCLi is received), the SCLi pin is held low on the falling edge of the eighth bit of the SCLi. When the SWC bit is set to 0 (no wait-state/ wait-state cleared), the SCLi line is released.

When the SWC2 bit in the UiSMR2 register is set to 1 (the SCLi pin is held low), the SCLi pin is forced low even during transmission or reception in progress. When the SWC2 bit is set to 0 (transmit/receive clock is output at the SCLi pin), the SCLi line is released to output the transmit/receive clock.

The SWC9 bit in the UiSMR4 register is used to insert a wait-state for checking received acknowledge bits. While the CKPH bit in the UiSMR3 register is set to 1 (clock delayed), when the SWC9 bit is set to 1 (the SCLi pin is held low after the ninth bit of the SCLi is received), the SCLi pin is held low on the falling edge of the ninth bit of the SCLi. When the SWC9 bit is set to 0 (no wait-state/wait-state cleared), the SCLi line is released.

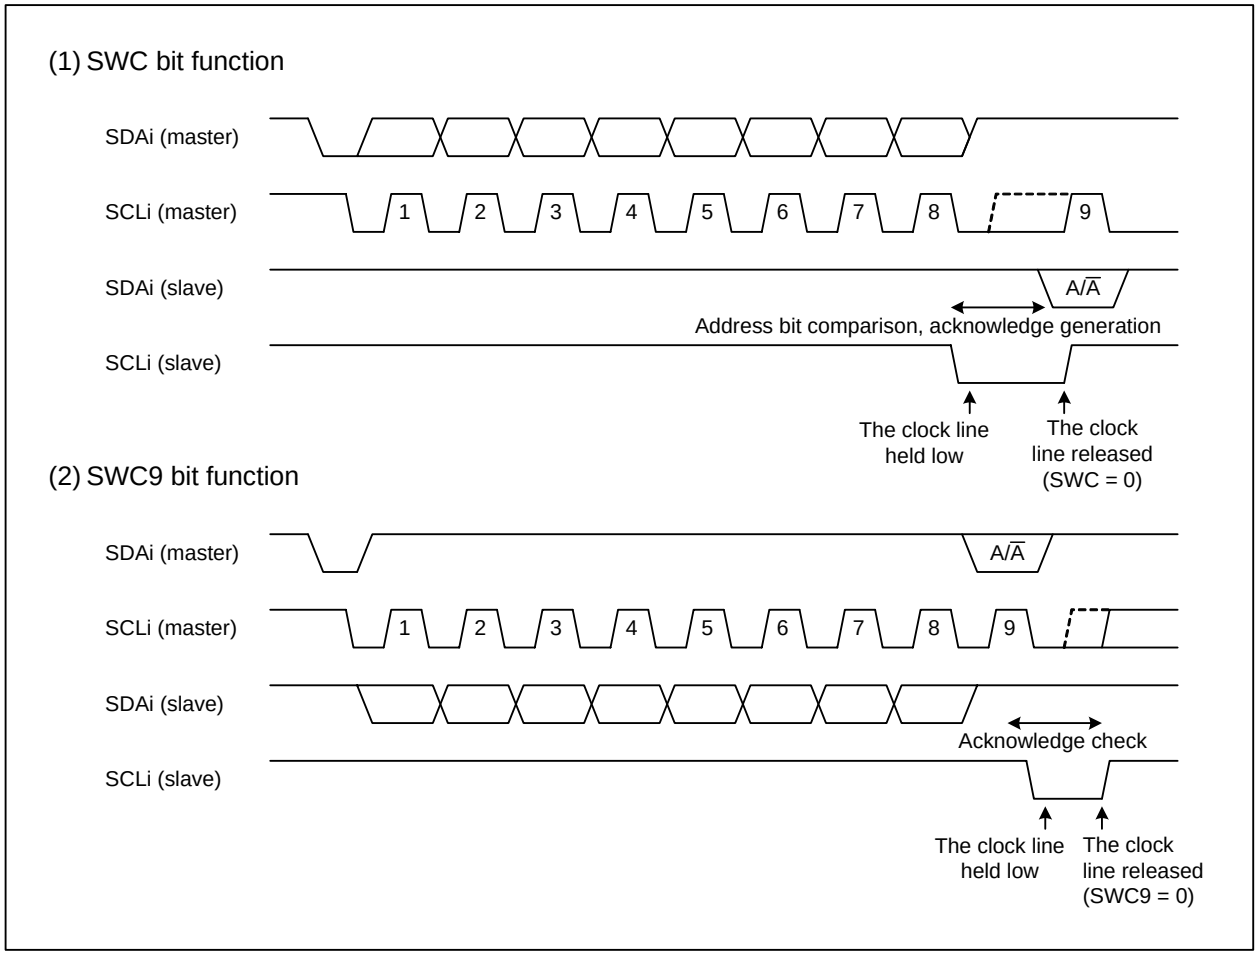

Figure 18.35 Wait-state Insertion by Bits SWC or SWC9 (i = 0 to 6)

The CSC bit in the UiSMR2 register is to synchronize an internally generated clock with the clock applied to the SCLi pin. For example, if a wait-state is inserted from other devices, the two clocks are not synchronized. While the CSC bit is set to 1 (clock synchronization enabled) and the internal clock is held high, when a high at the SCLi pin changes to low, the internal clock becomes low in order to reload the value of the UiBRG register and to resume counting. While the SCLi pin is held low, when the internal clock changes from low to high, the count is stopped until the SCLi pin becomes high. That is, the UARTi transmit/receive clock is the logical AND of the internal clock and the SCLi. The synchronized period starts from one clock prior to the first synchronized clock and ends when the ninth clock is completed. The CSC bit can be set to 1 only when the CKDIR bit in the UiMR register is set to 0 (internal clock selected).

The SCLHI bit in the UiSMR4 register is used to leave the SCLi pin open when other master generates a stop condition while the master is in transmit/receive operation. If the SCLHI bit is set to 1 (output stopped), the SCLi pin is open (the pin is high-impedance) when a stop condition is detected and the clock output is stopped.

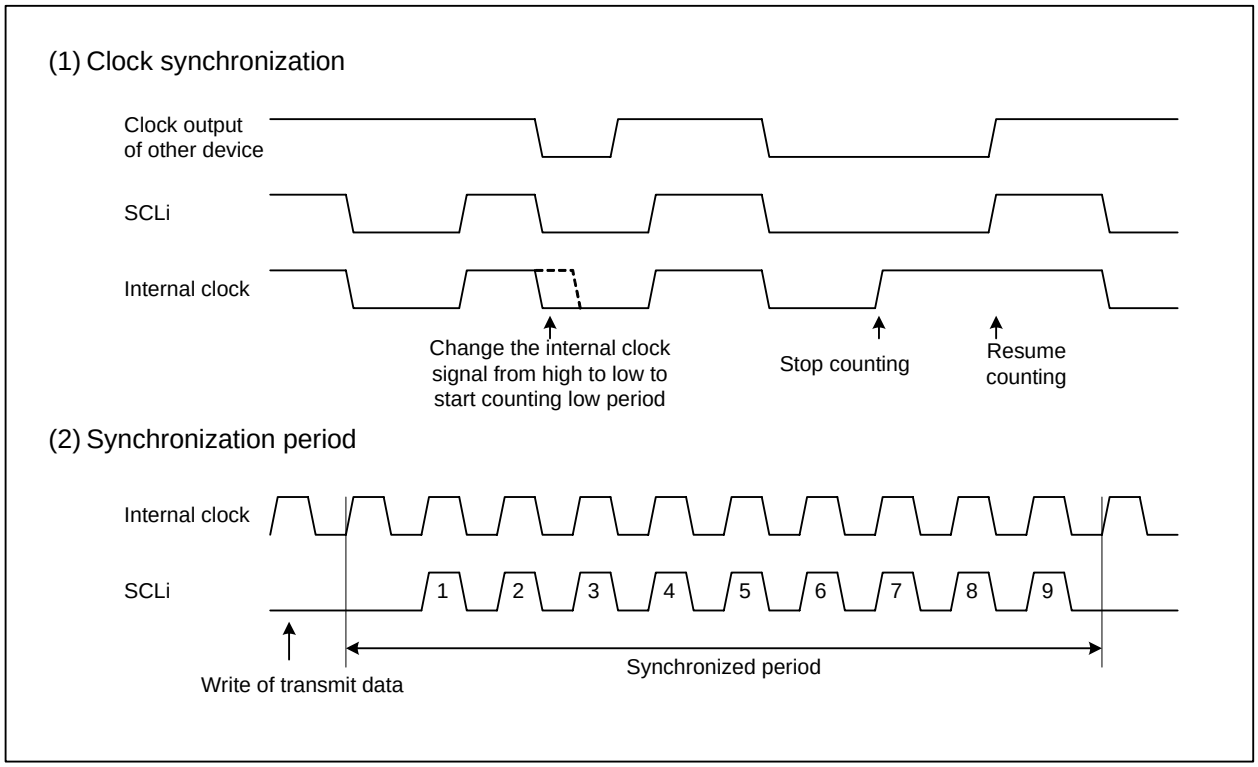

Figure 18.36 Clock Synchronization (i = 0 to 6)

18.3.5 SDA Output

Values set in bits 8 to 0 (D8 to D0) in the UiTB register (i = 0 to 6) are output starting from D7 to D0, and lastly D8, which is a bit for the acknowledge signal. When transmitting, D8 should be set to 1 to free the bus. When receiving, D8 should be set to ACK or NACK.

Bits DL2 to DL0 in the UiSMR3 register set a delay time of the SDAi on the falling edge of the SCLi. Based on the UiBRG count source, the delay time can be selected from zero cycles (no delay) and two to eight cycles.

When the SDHI bit in the UiSMR2 register is set to 1 (SDA output disabled), the SDAi pin forcibly becomes high-impedance. Output at the SDAi pin is low if the I/O port is selected for the SDAi and the pin is specified as the output port after selecting I^2C mode. In this case, if the SDHI bit is set to 1, the SDAi pin becomes high-impedance.

When the SDHI bit is rewritten while the SCLi pin is held high, a start condition or stop condition is generated. When it is rewritten immediately before the rising edge of the SCLi, an arbitration lost may be accidently detected. Therefore, the SDHI bit should be rewritten so the SDAi pin level changes while the SCLi pin is low.

18.3.6 SDA Input

When the IICM2 bit in the UiSMR2 register (i = 0 to 6) is set to 0, the first eight bits of received data (D7 to D0) are stored into bits 7 to 0 in the UiRB register and the ninth bit (ACK/NACK) is stored into bit 8.

When the IICM2 bit is set to 1, the first seven bits of received data (D7 to D1) are stored into bits 6 to 0 in the UiRB register and eighth bit (D0) is stored into bit 8.

If the IICM2 bit is set to 1 and the CKPH bit in the UiSMR3 register is set to 1 (clock delayed), the same data that is set when the IICM2 bit is 0 can be read. To read this data, read the UiRB register after data in the ninth bit is latched on the rising edge of the SCLi.

18.3.7 Acknowledge

When data is to be received in master mode, the ACK is output after eight bits are received by setting the UiTB register to 00FFh as dummy data. When the STSPSEL bit in the UiSMR4 register (i = 0 to 6) is set to 0 (serial I/O circuit selected) and the ACKC bit is set to 1 (ACK data output), the value of the ACKD bit is output at the SDAi pin.

If the IICM2 bit is set to 0, the NACK interrupt request is generated when the SDAi pin is held high on the rising edge of the ninth bit of the SCLi. The ACK interrupt request is generated when the SDAi pin is held low.

If the DMA request source is “UARTi receive interrupt request or ACK interrupt request”, the DMA transfer is activated when an ACK is detected.

18.3.8 Initialization of Transmit/Receive Operation

When the CKDIR bit in the UiMR register (i = 0 to 6) is set to 1 (external clock selected) and the STC bit in the UiSMR2 register is set to 1 (the circuit is initialized), and a start condition is detected, the following three operations are performed:

- The transmit register is reset and the content of the UiTB register is transferred to the transmit register. The new data transmission starts on the falling edge of the first bit of the next SCLi as transmit clock. The content of the transmit register before the reset is output at the SDAi pin in the period from the falling edge of the SCLi until the first data output.
- The receive register is reset and the new data reception starts on the falling edge of the first bit of the next SCLi.
- The SWC bit in the UiSMR2 register is set to 1 (the SCL pin is held low after the eighth bit of the SCLi is received).

If UARTi transmission/reception is started with this function, the TI bit in the UiC1 register does not change.

18.4 Special Mode 2

Special mode 2 enables serial communication between one or multiple masters and multiple slaves. The $\overline{SSi}$ input pin (i = 0 to 6) controls the serial bus communication. Table 18.13 lists specifications of special mode 2.

Table 18.13 Special Mode 2 Specifications

Item	Specification
Data format	8-bit character length
Transmit/receive clock	• The CKDIR bit in the UiMR register (i = 0 to 6) is set to 0 (internal clock): $\frac{fx}{2(m+1)}$ fx = f1, f8, f2n m: UiBRG register setting value, 00h to FFh • The CKDIR bit is set to 1 (external clock): input into the CLKi pin
Transmit/receive control	SS function
Transmit start conditions	The conditions for starting data transmission are as follows (1): • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register)
Receive start conditions	The conditions for starting data reception are as follows (1): • The RE bit in the UiC1 register is set to 1 (reception enabled) • The TE bit in the UiC1 register is set to 1 (transmission enabled) • The TI bit in the UiC1 register is set to 0 (data held in the UiTB register)
Interrupt request generating timing	In transmit interrupt, one of the following conditions is selected to set the UiIRS bit in registers U0C1 to U6C1: • The UiIRS bit is set to 0 (transmit buffer in the UiTB register is empty): when data is transferred from the UiTB register to the UARTi transmit register (when the transmission has started) • The UiIRS bit is set to 1 (transmission is completed): when data transmission from the UARTi transmit register is completed In receive interrupt, • When data is transferred from the UARTi receive register to the UiRB register (when the reception is completed)
Error detection	Overrun error (2) This error occurs when the seventh bit of the next data has been received before reading the UiRB register
Selectable functions	• CLK polarity Selectable either rising or falling edge of the transmit/receive clock for transfer data input and output • Bit order selection Selectable either LSB first or MSB first • Continuous receive mode Data reception is enabled by a read access to the UiRB register • Serial data logical inversion This function logically inverses transmit/receive data • Clock phase selection Selectable from one of four combinations of transmit/receive clock polarity and phases • $\overline{SSi}$ input pin function Output pin can be high-impedance when the $\overline{SSi}$ pin is high

Notes:
1. In case external clock is selected, the following preconditions should be met:
   • The CLKi pin is held high when the CKPOL bit in the UiC0 register is set to 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge)
   • The CLKi pin is held low when the CKPOL bit is set to 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge)
2. If an overrun error occurs, the UiRB register is undefined. The IR bit in the SiRIC register is not changed to 1 (interrupts requested).

Table 18.14 lists register settings in special mode 2.

Table 18.14 Register Settings in Special Mode 2 (i = 0 to 6)

Register	Bits	Function
UiMR	7 to 4	Set the bits to 0000b
	CKDIR	Set the bit to 0 in master mode and set it to 1 in slave mode
	SMD2 to SMD0	Set the bits to 001b
UiC0	UFORM	Select either LSB first or MSB first
	CKPOL	Clock phase can be set by the combination of bits CKPOL and CKPH in the UiSMR3 register
	5	Set the bit to 0
	CRD	Set the bit to 1
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	7 and 6	Set the bits to 00b
	UiRRM	Set the bit to 1 to use continuous receive mode
	UiIRS	Select a source for UARTi transmit interrupt
	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission/reception
UiSMR	7 to 0	Set the bits to 00h
UiSMR2	7 to 0	Set the bits to 00h
UiSMR3	7 to 5	Set the bits to 000b
	ERR	Mode fault flag
	3	Set the bit to 0
	DINC	Set to 0 in master mode and set to 1 in slave mode
	CKPH	Clock phase can be set by the combination of bits CKPH and CKPOL in the UiC0 register
	SSE	Set the bit to 1
UiSMR4	7 to 0	Set the bits to 00h
UiBRG	7 to 0	Set the bit rate
IFS0	IFS06	Select input pins for CLK3, RXD3, SRXD3, and $\overline{SS3}$
	IFS03 and IFS02	Select input pins for CLK6, RXD6, SRXD6, and $\overline{SS6}$
UiTB	7 to 0	Set the data to be transmitted
UiRB	OER	Overrun error flag
	7 to 0	Received data is read

18.4.1 $\overline{SSi}$ Input Pin Function (i = 0 to 6)

Special mode 2 is selected by setting the SSE bit in the UiSMR3 register to 1 (SS enabled). The $\overline{CTSi}$/$\overline{RTSi}$/$\overline{SSi}$ pin functions as $\overline{SSi}$ input.

The DINC bit in the UiSMR3 register determines which MCU performs as master or slave.

When multiple MCUs perform as master (multi-master system), the $\overline{SSi}$ pin setting determines which master MCU is active and when.

18.4.1.1 SS Function in Slave Mode

When the DINC bit is set to 1 (slave mode selected) while an input at the $\overline{SSi}$ pin is high, the STXDi pin becomes high-impedance and the clock input at the CLKi pin is ignored. When an input at the $\overline{SSi}$ pin is low, the clock input is valid and serial data is output from the STXDi pin to enable serial communication.

18.4.1.2 SS Function in Master Mode

When the DINC bit is set to 0 (master mode selected) while an input at the $\overline{SSi}$ pin is high, which means there is the only one master MCU or no other master MCU is active, the MCU as master starts communication. The master provides the transmit/receive clock output at the CLKi pin. When input at the $\overline{SSi}$ pin is low, which means that there are more masters, pins TXDi and CLKi become high-impedance. This error is called a mode fault. It can be verified using the ERR bit in the UiSMR3 register. The ongoing data transmission/reception is not stopped even if a mode fault occurs. To stop transmission/reception, bits SMD2 to SMD0 in the UiMR register should be set to 000b (serial interface disabled).

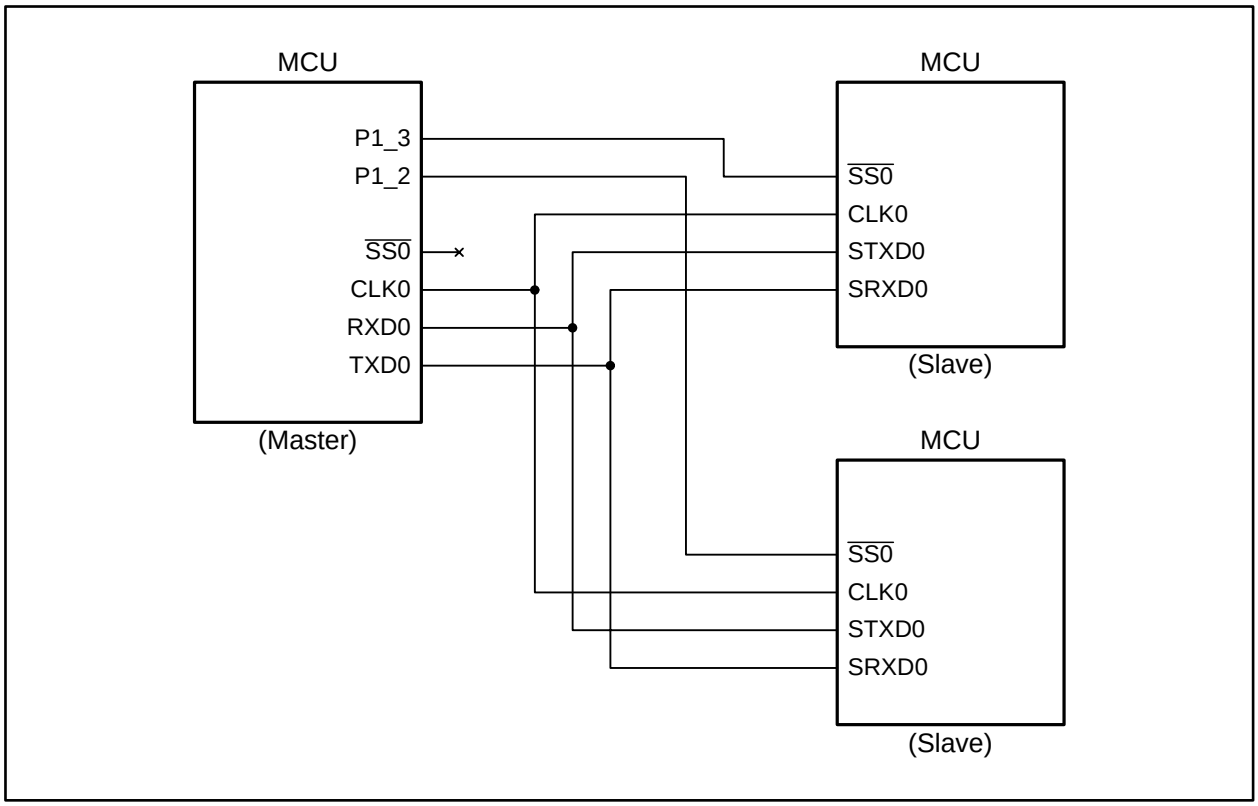

Figure 18.37 Serial Bus Communication Control with $\overline{SSi}$ Pin

18.4.2 Clock Phase Setting

The CKPH bit in the UiSMR3 register (i = 0 to 6) and the CKPOL bit in the UiC0 register select one of four combinations of transmit/receive clock polarity and serial clock phase.
The transmit/receive clock phase and polarity should be identical for the master device and the communicating slave device.

18.4.2.1 Transmit/Receive Timing in Master Mode

When the DINC bit is set to 0 (master mode selected), the CKDIR bit in the UiMR register should be set to 0 (internal clock selected) to generate the clock. Figure 18.38 shows transmit/receive timing of each clock phase.

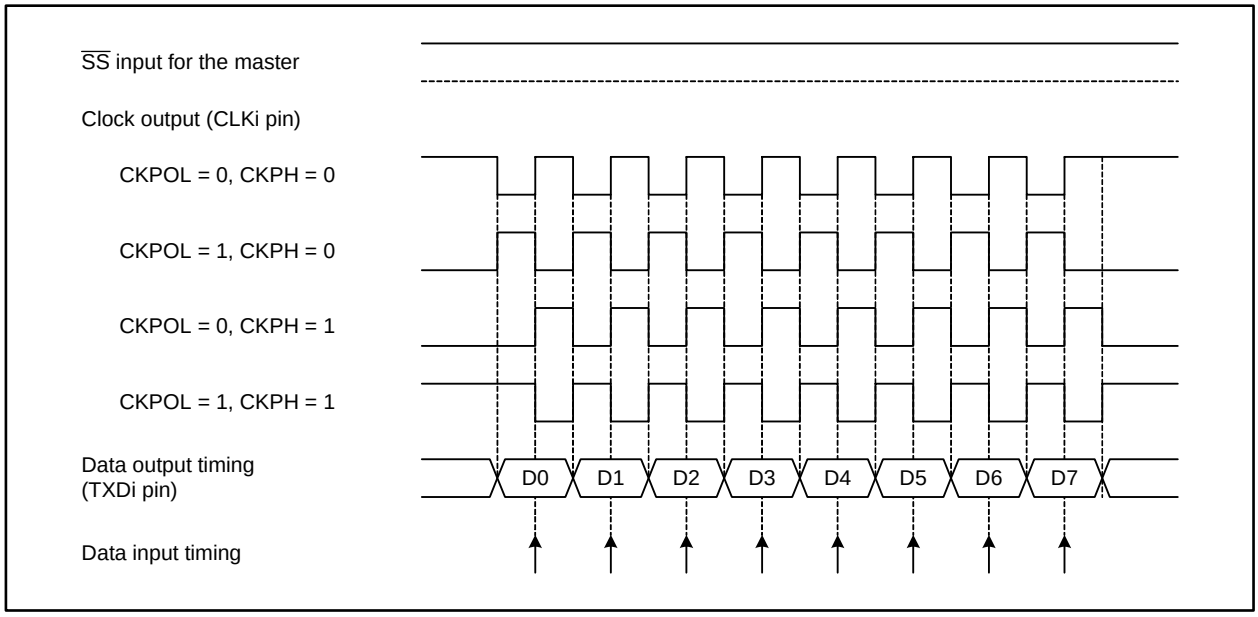

Figure 18.38 Transmit/Receive Timing in Master Mode

18.4.2.2 Transmit/Receive Timing in Slave Mode

When the DINC bit is set to 1 (slave mode selected), the CKDIR bit in the UiMR register should be set to 1 (external clock selected).

When the CKPH bit is set to 0 (non clock delayed) while input at the $\overline{SSi}$ pin is high, the STXDi pin becomes high-impedance. When input at the $\overline{SSi}$ pin is low, the conditions for data transmission are all met, but output is undefined. Then the data transmission/reception starts synchronizing with the clock. Figure 18.39 shows the transmit/receive timing.

When the CKPH bit is set to 1 (clock delayed) while an input at the $\overline{SSi}$ pin is high, the STXDi pin becomes high-impedance. When an input at the $\overline{SSi}$ pin is low, the first data is output. Then the data transmission starts synchronizing with the clock. Figure 18.40 shows the transmit/receive timing.

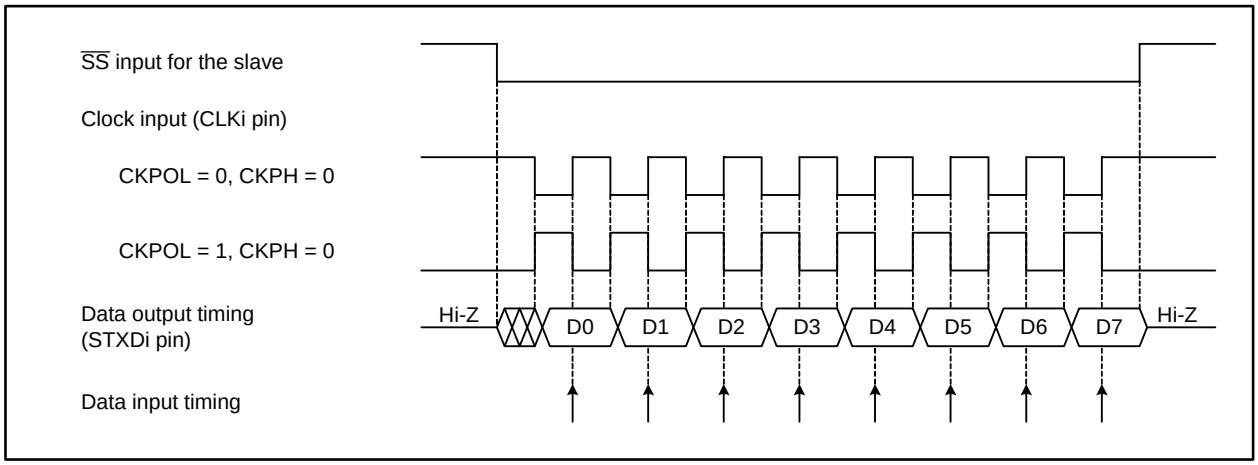

Figure 18.39 Transmit/Receive Timing in Slave Mode (CKPH = 0)

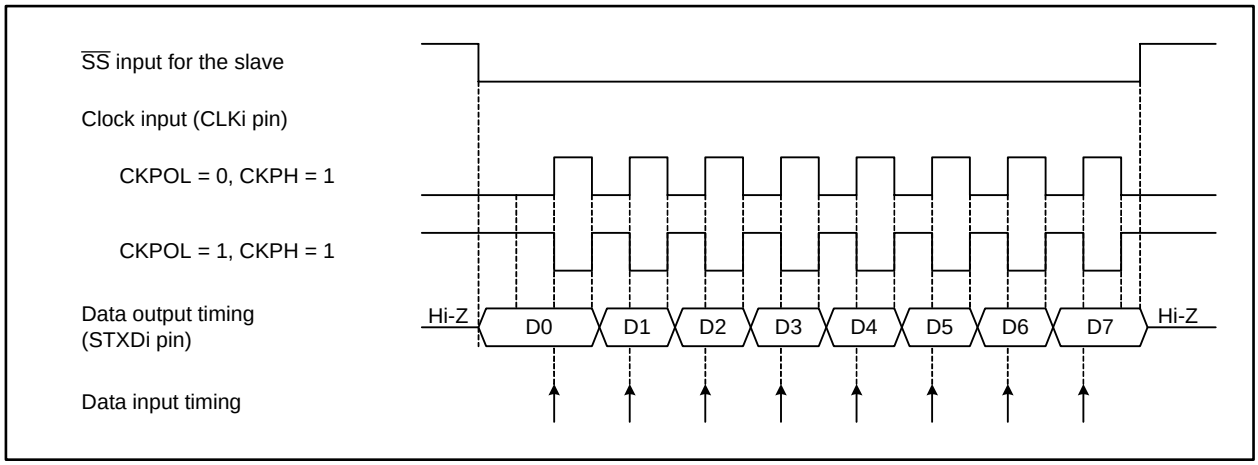

Figure 18.40 Transmit/Receive Timing in Slave Mode (CKPH = 1)

18.5 Notes on Serial Interface

18.5.1 Changing the UiBRG Register (i = 0 to 8)

- Set the UiBRG register after setting bits CLK1 and CLK0 in the UiC0 register. When these bits are changed, the UiBRG register must be set again.
- If a clock is input immediately after the UiBRG register is set to 00h, the counter reaches FFh. In this case, it requires an extra 256 clocks to reload 00h into the register. Once the 00h is reloaded, the counter performs the operation without dividing the count source according to the setting.

18.5.2 Synchronous Serial Interface Mode

18.5.2.1 Selecting an External Clock

- If an external clock is selected, the following conditions must be met while the external clock is held high when the CKPOL bit in the UiC0 register (i = 0 to 8) is set to 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge), or while the external clock is held low when the CKPOL bit is set to 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge):
  - The TE bit in the UiC1 register is set to 1 (transmission enabled).
  - The RE bit in the UiC1 register is set to 1 (reception enabled). This bit setting is not required in transmit operation only.
  - The TI bit in the UiC1 register is set to 0 (data held in the UiTB register).

18.5.2.2 Receive Operation

- In synchronous serial interface mode, the transmit/receive clock is controlled by the transmit control circuit. Set the UARTi-associated registers (i = 0 to 8) for a transmit operation, even if the MCU is used only for receive operation. Dummy data is output from the TXDi pin while receiving if the TXDi pin is set to output mode.

- If data is received continuously, an overrun error occurs when the RI bit in the UiC1 register is 1 (data held in the UiRB register) and the seventh bit of the next data is received in the UARTi receive shift register. Then, the OER bit in the UiRB register becomes 1 (overrun error occurred). In this case, the UiRB register becomes undefined. If an overrun error occurs, the IR bit in the SiRIC register is not changed to 1.

18.5.3 Special Mode 1 (I^2C Mode)

- To generate a start condition, stop condition, or restart condition, set the STSPSEL bit in the UiSMR4 register (i = 0 to 6) to 0. Then, wait a half or more clock cycles of the transmit/receive clock to change the respective condition generate bit (the STAREQ, RSTAREQ, or STPREQ bit) from 0 to 1.

18.5.4 Reset Procedure on Communication Error

- Operations which result in communication errors such as rewritting function select registers during transmission/reception should not be performed. Follow the procedure below to reset the internal circuit once the communication error occurs in the following cases: when the operation above is performed by a receiver or transmitter or when a bit slip is caused by noise.

A. Synchronous Serial Interface Mode

(1) Set the TE bit in the UiC1 register (i = 0 to 8) to 0 (transmission disabled) and the RE bit to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 001b (synchronous serial interface mode).
(4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

B. UART Mode

(1) Set the TE bit in the UiC1 register to 0 (transmittion disabled) and the RE bit to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 100b (UART mode, 7-bit character length), 101b (UART mode, 8-bit character length), or 110b (UART mode, 9-bit character length).
(4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

19. A/D Converter

The A/D converter consists of one 10-bit successive approximation A/D converter with a capacitive coupling amplifier.

The result of an A/D conversion is stored in the A/D registers corresponding to selected pins. It is stored in the AD00 register only when DMAC operating mode is enabled.

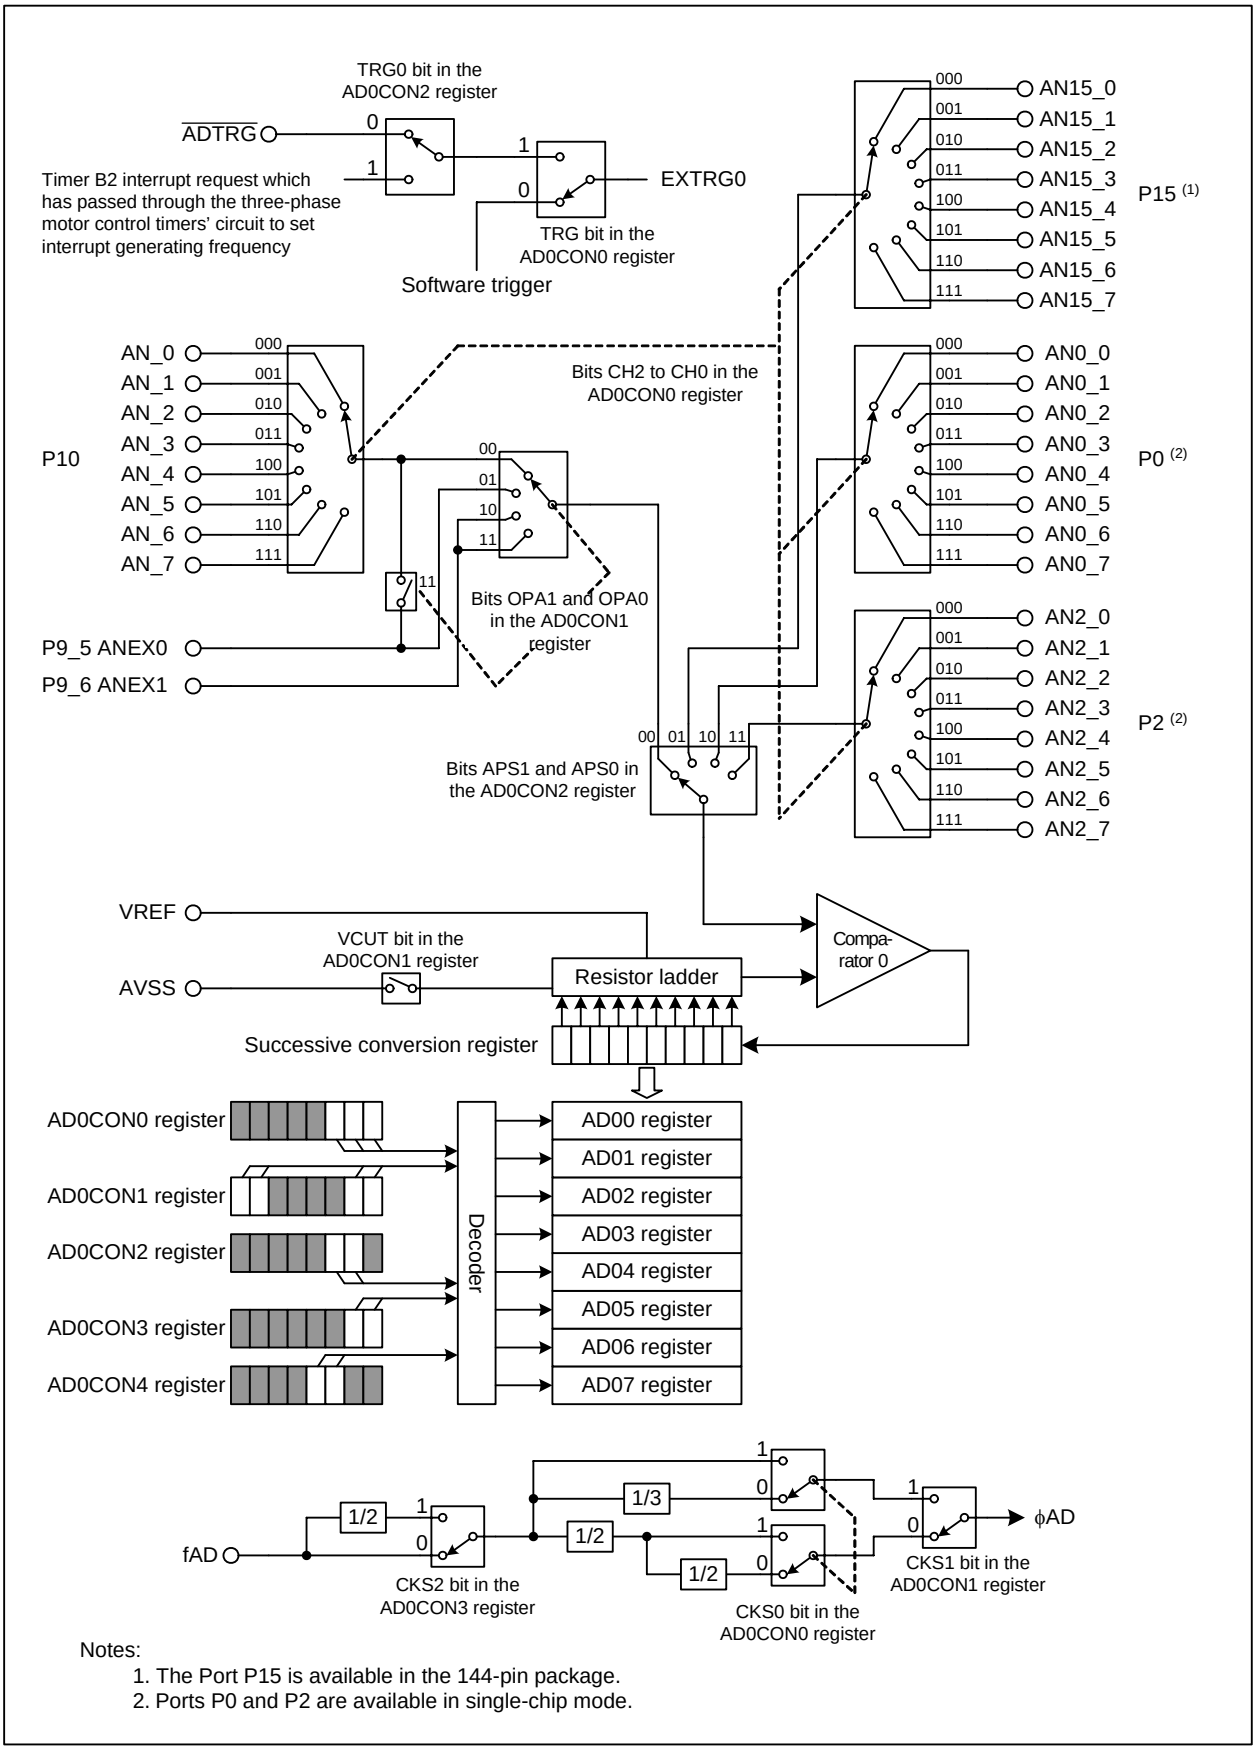
When the A/D converter is not in use, power consumption can be reduced by setting the VCUT bit in the AD0CON1 register to 0 (VREF disconnected). This bit setting enables the power supply from VREF pin to the resistor ladder to stop.

Table 19.1 lists specifications of the A/D converter. Figure 19.1 shows a block diagram of the A/D converter. Figure 19.2 to Figure 19.7 show registers associated with the A/D converter.

Table 19.1 A/D Converter Specifications

Item	Specification
A/D conversion method	Capacitance-based successive approximation
Analog input voltage (1)	0 V to AVCC (VCC)
Operating clock, ϕAD (2)	fAD, fAD/2, fAD/3, fAD/4, fAD/6, or fAD/8
Resolution	8 bits or 10 bits
Operating modes	One-shot mode, repeat mode, single sweep mode, repeat sweet mode 0, repeat sweep mode 1, multi-port single sweep mode, multi-port repeat sweep mode 0
Analog input pins (3)	34 (4) 8 pins each for AN, AN0, AN2, and AN15 (5) 2 function-extended input pins (ANEX0 and ANEX1)
A/D conversion start conditions	• Software trigger The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program • External trigger (Retrigger is enabled) An input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program • Hardware trigger (Retrigger is enabled) • Generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program
Conversion rates per pin	• Without sample and hold function 49 ϕAD cycles @ 8-bit resolution 59 ϕAD cycles @ 10-bit resolution including 2 ϕAD cycles for sampling time • With sample and hold function 28 ϕAD cycles @ 8-bit resolution 33 ϕAD cycles @ 10-bit resolution including 3 ϕAD cycles for sampling time

Notes:
1. Analog input voltage is not affected by with/without the sample and hold function.
2. The ϕAD frequency should be as follows:
   • When VCC = 4.2 to 5.5 V, 16 MHz or below
   • When VCC = 3.0 to 4.2 V, 10 MHz or below
   • Without the sample and hold function, 250 kHz or above
   • With the sample and hold function, 1 MHz or above
3. When AVCC = VREF = VCC, A/D input voltage for pins AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1 should be VCC or lower.
4. Spec of the 144-pin package. In the 100-pin package, 26 channels are available.
5. Pins AN15_0 to AN15_7 are not available in the 100-pin package.



Notes:
1. The Port P15 is available in the 144-pin package.
2. Ports P0 and P2 are available in single-chip mode.

CH1			RW
CH2			RW
MD0	A/D Operating Mode Select Bit 0 (2, 5, 6)	b4 b3 0 0 : One-shot mode 0 1 : Repeat mode 1 0 : Single sweep mode 1 1 : Repeat sweep mode 0 or 1	RW
MD1			RW
TRG	Trigger Select Bit	0: Software trigger 1: External trigger or hardware trigger (7)	RW
ADST	A/D Conversion Start Bit	0: A/D conversion stopped 1: A/D conversion started (7)	RW
CKS0	Frequency Select Bit	(Note 8)	RW

Notes:

1. When this register is rewritten during an A/D conversion, the converted result is undefined.
2. Analog input pins should be set again after the A/D operating mode is changed.
3. This bit setting is enabled in one-shot mode or repeat mode.
4. Either AN, AN0, AN2, or AN15 port should be selected by using bits APS1 and APS0 in the AD0CON2 register.
5. When the MSS bit in the AD0CON3 register is set to 1 (multi-port sweep mode enabled), bits MD1 and MD0 should be set to 10b for multi-port single sweep mode and 11b for multi-port repeat sweep mode 0.
6. When the MSS bit in the AD0CON3 register is set to 1, bits MD1 and MD0 should be set to 10b or 11b.
7. To use the external trigger or the hardware trigger, a source of trigger should be selected using the TRG0 bit in the AD0CON2 register, the TRG bit should be set to 1, then the ADST bit should be set to 1.
8. The ϕAD frequency should be as follows: 16 MHz or below when VCC = 5V,
   10 MHz or below when VCC = 3.3 V
   It is selected from the combination of bits CKS0, CKS1, and CKS2 shown as below:

The CKS2 bit in the AD0CON3 register	The CKS0 bit in the AD0CON0 register	The CKS1 bit in the AD0CON1 register	ϕAD
0	0	0	fAD divided by 4
		1	fAD divided by 3
	1	0	fAD divided by 2
		1	fAD
1	0	0	fAD divided by 8
		1	fAD divided by 6

OPA1			RW

Notes:
1. When this register is rewritten during an A/D conversion, the converted result is undefined.
2. This bit setting is enabled in single sweep mode, repeat sweep mode 0, repeat sweep mode 1, multi-port single sweep mode, or multi-port repeat sweep mode 0.
3. Either AN, AN0, AN2, or AN15 port should be selected by using bits APS1 and APS0 in the AD0CON2 register.
4. These pins are commonly used in the A/D conversion when the MD2 bit is set to 1.
5. Set bits SCAN0 and SCAN1 to 11b in multi-port single sweep mode or multi-port repeat sweep mode 0.
6. When the MSS bit in the AD0CON3 register is set to 1 (multi-port sweep mode enabled), the MD2 bit should be set to 0.
7. Refer to the note on the CKS0 bit in the AD0CON0 register.
8. This bit controls the reference voltage to the A/D converter. It does not affect the VREF performance of the D/A converter.
9. The VCUT bit should not be set to 0 during the A/D conversion.
10. When the VCUT bit is switched from 0 to 1, the A/D conversion should be started after 1 µs or more.
11. Bits OPA 0 and OPA1 can be set to 01b or 10b only in one-shot mode or repeat mode. They should be set to 00b or 11b in other modes.
12. When the MSS bit in the AD0CON3 register is set to 1 (multi-port sweep mode enabled), bits OPA0 and OPA 1 should be set to 00b.

MSF1			RO
— (b7-b5)	Reserved	Should be written with 0 and read as undefined value	RW

Notes:
1. When this register is rewritten during A/D conversion, the converted result is undefined.
2. This register may be read incorrectly during A/D conversion. It should be read or written after the A/D converter stops operating.
3. To set the MSS bit to 1, the DUS bit should be also set to 1.
4. When the DUS bit is set to 1, all A/D converted results are stored into the AD00 register.
5. To transfer converted results by DMA, configure the DMAC.
6. To set the MSS bit to 1, the following bit settings should be done:
   -the MD2 bit in the AD0CON1 register: 0 (mode other than repeat sweep mode 1)
   -bits APS1 and APS0 in the AD0CON2 register: 01b (AN15_0 to AN15_7)
   -bits OPA1 and OPA0 in the AD0CON1 register: 00b (no use of ANEX0 or ANEX1).
7. Refer to the note on the CKS0 bit in the AD0CON0 register.
8. This bit setting is enabled when the MSS bit is set to 1. The read value is undefined when the MSS bit is set to 0.

Notes:
1. If this register is read by a program while the DMAC is configured to transfer converted results, the value is undefined.
2. Register value written while the A/D converter stops operating is undefined.
3. Only the AD00 register is available when the DUS bit in the AD0CON3 register is 1 (DMAC operating mode enabled). Other registers are undefined.
4. When a converted result is transferred by DMA at 10-bit mode, the DMAC should be set for a 16-bit transfer.

Figure 19.7 Registers AD00 to AD07

19.1 Mode Descriptions

19.1.1 One-shot Mode

In one-shot mode, the analog voltage applied to a selected pin is converted into a digital code only once. Table 19.2 lists specifications of one-shot mode.

Table 19.2 One-shot Mode Specification

Item	Specification
Function	Converts only once the analog voltage applied to a pin into a digital code. The pin is selected using bits CH2 to CH0 in the AD0CON0 register, OPA1 and OPA0 in the AD0CON1 register, and APS1 and APS0 in the AD0CON2 register
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• An A/D conversion is completed (the ADST bit is set to 0 when the software trigger is selected) • The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	When the A/D conversion is completed, an interrupt request is generated
Input pin to be selected	One pin is selected from among AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1
Reading of A/D converted result	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), read the AD0j register (j = 0 to 7) corresponding to the selected pin In the DUS bit setting to 1 (DMAC operating mode enabled), configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program

19.1.2 Repeat Mode

In repeat mode, the analog voltage applied to a selected pin is repeatedly converted into a digital code. Table 19.3 lists specifications of repeat mode.

Table 19.3 Repeat Mode Specification

Item	Specification
Function	Converts repeatedly the analog voltage input to a pin into a digital code. The pin is selected using bits CH2 to CH0 in the AD0CON0 register, OPA1 and OPA0 in the AD0CON1 register, and APS1 and APS0 in the AD0CON2 register
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the ADTRG pin switches from high to low after the ADST bit is set to 1 by a program. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), no interrupt request is generated. In the DUS bit setting to 1 (DMAC operating mode enabled), every time an A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	One pin is selected from among AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1
Reading of A/D converted result	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), read the AD0j register (j = 0 to 7) corresponding to the selected pin In the DUS bit setting to 1 (DMAC operating mode enabled), • when the converted result is transferred by DMA, configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program • when the converted result is transferred by a program, read the AD00 register after the IR bit in the AD0IC register becomes 1. Set the IR bit back to 0

19.1.3 Single Sweep Mode

In single sweep mode, the analog voltage applied to selected pins is converted one-by-one into a digital code. Table 19.4 lists specifications of single sweep mode.

Table 19.4 Single sweep mode Specification

Item	Specification
Function	Converts one-by-one the analog voltage input to a set of pins into a digital code. The pins are selected using bits SCAN1 and SCAN0 in the AD0CON1 register and APS1 and APS0 in the AD0CON2 register
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the ADTRG pin switches from high to low after the ADST bit is set to 1 by a program. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• An A/D conversion is completed (the ADST bit is set to 0 when the software trigger is selected) • The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), when a sweep is completed, an interrupt request is generated. In the DUS bit setting to 1 (DMAC operating mode enabled), every time an A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	Selected from a group of 2 pins (ANi_0 and ANi_1) (i = none, 0, 2, 15), 4 pins (ANi_0 to ANi_3), 6 pins (ANi_0 to ANi_5), or 8 pins (ANi_0 to ANi_7)
Reading of A/D converted result	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), read the AD0j register (j = 0 to 7) corresponding to the selected pin In the DUS bit setting to 1 (DMAC operating mode enabled), configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program

19.1.4 Repeat Sweep Mode 0

In repeat sweep mode 0, the analog voltage applied to selected pins is repeatedly converted into a digital code. Table 19.5 lists specifications of repeat sweep mode 0.

Table 19.5 Repeat Sweep Mode 0 Specification

Item	Specification
Function	Converts repeatedly the analog voltage input to a set of pins into a digital code. The pins are selected using bits SCAN1 and SCAN0 in the AD0CON1 register and APS1 and APS0 in the AD0CON2 register
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the ADTRG pin switches from high to low after the ADST bit is set to 1 by a program. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), no interrupt request is generated. In the DUS bit setting to 1 (DMAC operating mode enabled), every time an A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	Selected from a group of 2 pins (ANi_0 and ANi_1) (i = none, 0, 2, 15), 4 pins (ANi_0 to ANi_3), 6 pins (ANi_0 to ANi_5), or 8 pins (ANi_0 to ANi_7)
Reading of A/D converted result	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), read the AD0j register (j = 0 to 7) corresponding to the selected pin In the DUS bit setting to 1 (DMAC operating mode enabled), • when the converted result is transferred by DMA, configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program • when the converted result is transferred by a program, read the AD00 register after the IR bit in the AD0IC register becomes 1. Set the IR bit back to 0

19.1.5 Repeat Sweep Mode 1

In repeat sweep mode 1, the analog voltage applied to eight selected pins including some prioritized pins is repeatedly converted into a digital code. Table 19.6 lists specifications of repeat sweep mode 1.

Table 19.6 Repeat Sweep Mode 1 Specification

Item	Specification
Function	Converts repeatedly the analog voltage input to a set of eight pins into a digital code. A/some selected pin(s) is/are converted by priority e.g. When AN_0 is prioritized, the analog voltage is converted into a digital code in the following order: AN_0→AN_1→AN_0→AN_2→AN_0→AN_3••• The eight pins are selected using bits SCAN1 and SCAN0 in the AD0CON1 register and APS1 and APS0 in the AD0CON2 register
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the ADTRG pin switches from high to low after the ADST bit is set to 1 by a program. Retrigger is invalid. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), no interrupt request is generated. In the DUS bit setting to 1 (DMAC operating mode enabled), every time an A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	8 (ANi_0 to ANi_7) (i = none, 0, 2, 15)
Prioritized pin(s)	Selected from a group of 1 pin (ANi_0), 2 pins (ANi_0 and ANi_1), 3 pins (ANi_0 to ANi_2), or 4 pins (ANi_0 to ANi_3)
Reading of A/D converted result	In the DUS bit setting in the AD0CON3 register to 0 (DMAC operating mode disabled), read the AD0j register (j = 0 to 7) corresponding to the selected pin In the DUS bit setting to 1 (DMAC operating mode enabled), • when the converted result is transferred by DMA, configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program • when the converted result is transferred by a program, read the AD00 register after the IR bit in the AD0IC register becomes 1. Set the IR bit back to 0

19.1.6 Multi-port Single Sweep Mode

In multi-port single sweep mode, the analog voltage applied to 16 selected pins is converted one-by-one into a digital code. The DUS bit in the AD0CON3 register should be set to 1 (DMAC operating mode enabled). Table 19.7 lists specifications of multi-port single sweep mode.

Table 19.7 Multi-port Single Sweep Mode Specification

Item	Specification
Function	Converts one-by-one the analog voltage input to a set of 16 selected pins into a digital code in the following order: AN_0 to AN_7→ANi_0 to ANi_7 (i = 0, 2, 15) The 16 pins are selected using bits MPS11 and MPS10 in the AD0CON4 register e.g. When bits MPS11 and MPS10 are set to 10b (AN_0 to AN_7, AN0_0 to AN0_7), the analog voltage is converted into a digital code in the following order: AN_0→AN_1→AN_2→AN_3→AN_4→AN_5→AN_6→AN_7→AN0_0→•••→AN0_6→AN0_7
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the ADTRG pin switches from high to low after the ADST bit is set to 1 by a program. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• An A/D conversion is completed (the ADST bit is set to 0 when the software trigger is selected) • The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	Every time an A/D conversion is completed (Set the DUS bit to 1)
Analog voltage input pins	A combination of pin group is selected from AN_0 to AN_7→AN15_0 to AN15_7, AN_0 to AN_7→AN0_0 to AN0_7, or AN_0 to AN_7→AN2_0 to AN2_7
Reading of A/D converted result	Set the DUS bit to 1 and configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program

19.1.7 Multi-port Repeat Sweep Mode 0

In multi-port repeat sweep mode 0, the analog voltage applied to 16 selected pins is repeatedly converted into a digital code. The DUS bit in the AD0CON3 register should be set to 1 (DMAC operating mode enabled). Table 19.8 lists specifications of multi-port repeat sweep mode 0.

Table 19.8 Multi-port Repeat Sweep Mode 0 Specification

Item	Specification
Function	Converts repeatedly the analog voltage input to a set of 16 selected pins into a digital code in the following order: AN_0 to AN_7→ANi_0 to ANi_7 (i = 0, 2, 15) The 16 pins are selected using bits MPS11 and MPS10 in the AD0CON4 register e.g. When bits MPS11 and MPS10 are set to 10b (AN_0 to AN_7, AN0_0 to AN0_7), the analog voltage is repeatedly converted into a digital code in the following order: AN_0→AN_1→AN_2→AN_3→AN_4→AN_5→AN_6→AN_7→AN0_0→•••→AN0_6→AN0_7
Start conditions	In the TRG bit setting in the AD0CON0 register to 0 (software trigger), the ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. In the TRG bit setting to 1 (external trigger or hardware trigger), external trigger request source is selected by the TRG0 bit in the AD0CON2 register. • When 0 is selected, an input signal at the ADTRG pin switches from high to low after the ADST bit is set to 1 by a program. • When 1 is selected, generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
Stop conditions	• The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	Every time an A/D conversion is completed (Set the DUS bit to 1)
Analog voltage input pins	A combination of pin group is selected from AN_0 to AN_7→AN15_0 to AN15_7, AN_0 to AN_7→AN0_0 to AN0_7, or AN_0 to AN_7→AN2_0 to AN2_7
Reading of A/D converted result	Set the DUS bit to 1 and configure the DMAC (refer to 13. “DMAC”), then A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to given memory space. Do not read the AD00 register by a program

19.2 Functions

19.2.1 Resolution Selection

The resolution is selected using the BITS bit in the AD0CON1 register. When the BITS bit is set to 1 (10-bit precision), the A/D converted result is stored into bits 9 to 0 in the AD0i register (i = 0 to 7). When the BITS bit is set to 0 (8-bit precision), the result is stored into bits 7 to 0 in the AD0i register.

19.2.2 Sample and Hold Function

This function improves the conversion rate per pin to 28 ϕAD cycles at 8-bit resolution and 33 ϕAD cycles for 10-bit resolution. To use this function, which is available in all operating modes, set the SMP bit in the AD0CON2 register to 1 (with sample and hold function). Start the A/D conversion after setting the SMP bit.

19.2.3 Trigger Selection

A trigger to start A/D conversion is specified by the combination of TRG bit in the AD0CON0 register and the TRG0 bit in the AD0CON2 register. Table 19.9 lists the settings of the trigger selection.

Table 19.9 Trigger Selection Settings

Bit and Setting		Trigger
AD0CON0 register	AD0CON2 register	
TRG = 0	—	Software trigger The ADST bit in the AD0CON0 register is set to 1
TRG = 1 (1, 2)	TRG0 = 0	External trigger Falling edge of a signal applied to the $\overline{\text{ADTRG}}$ pin
	TRG0 = 1	Hardware trigger Generation of a timer B2 interrupt request which has passed through the circuit to set interrupt generating frequency in the three-phase motor control timers

Notes:
1. The A/D converter starts operating if a trigger is generated while the ADST bit is set to 1 (A/D conversion started).
2. If an external trigger or a hardware trigger is generated during an A/D conversion, the A/D converter aborts the operation in progress. Then, it resumes the operation.

19.2.4 DMAC Operating Mode

The DMAC operating mode is available in all operating modes. When the A/D converter is in multi-port single sweep mode or multi-port repeat sweep mode 0, the DMAC operating mode should be used definitely. When the DUS bit in the AD0CON3 register is set to 1 (DMAC operating mode enabled), all A/D converted results are stored into the AD00 register. The DMAC transfers the data from the AD00 register to a given memory space every time an A/D conversion is completed at a pin. 8-bit DMA transfer should be selected for 8-bit resolution. For 10-bit resolution, 16-bit DMA transfer should be selected. Refer to 13. “DMAC” for details.

19.2.5 Function-extended Analog Input Pins

In one-shot mode and repeat mode, pins ANEX0 and ANEX1 are available as analog input by setting bits OPA1 and OPA0 in the AD0CON1 register (refer to Table 19.10). The A/D converted result of pins ANEX0 and ANEX1 are respectively stored into registers AD00 and AD01. However, when the DUS bit in the AD0CON3 register is set to 1 (DMAC operating mode enabled), all results are stored into the AD00 register.

To use function-extended analog input pins, bits APS1 and APS0 in the AD0CON2 register should be set to 00b (AN0 to AN7, ANEX0, ANEX1 as analog input port) and the MSS bit in the AD0CON3 register to 0 (multi-port sweep mode disabled).

Table 19.10 Function-extended Analog Input Pin Settings

AD0CON1 Register		ANEX0	ANEX1
OPA1	OPA0		
0	0	Not used	Not used
0	1	Analog input	Not used
1	0	Not used	Analog input
1	1	Output to an external op-amp	Input from an external op-amp

19.2.6 External Operating Amplifier (Op-AMP) Connection Mode

In external op-amp connection mode, multiple analog inputs can be amplified by one external op-amp using function-extended analog input pins ANEX0 and ANEX1.

When bits OPA1 and OPA0 in the AD0CON1 register are set to 11b (external op-amp connected), the voltage applied to pins AN0 to AN7 are output from the ANEX0 pin. This output signal should be amplified by an external op-amp and applied to the ANEX1 pin.

The analog voltage applied to the ANEX1 pin is converted into a digital code. The converted result is stored into the corresponding AD0i register (i = 0 to 7). The conversion rate varies with the response of the external op-amp. The ANEX0 pin should not be connected to the ANEX1 pin directly.

To use external op-amp connection mode, bits APS1 and APS0 in the AD0CON2 register should be set to 00b (AN0 to AN7, ANEX0, ANEX1 as analog input port).

Figure 19.8 shows an example of an external op-amp connection.

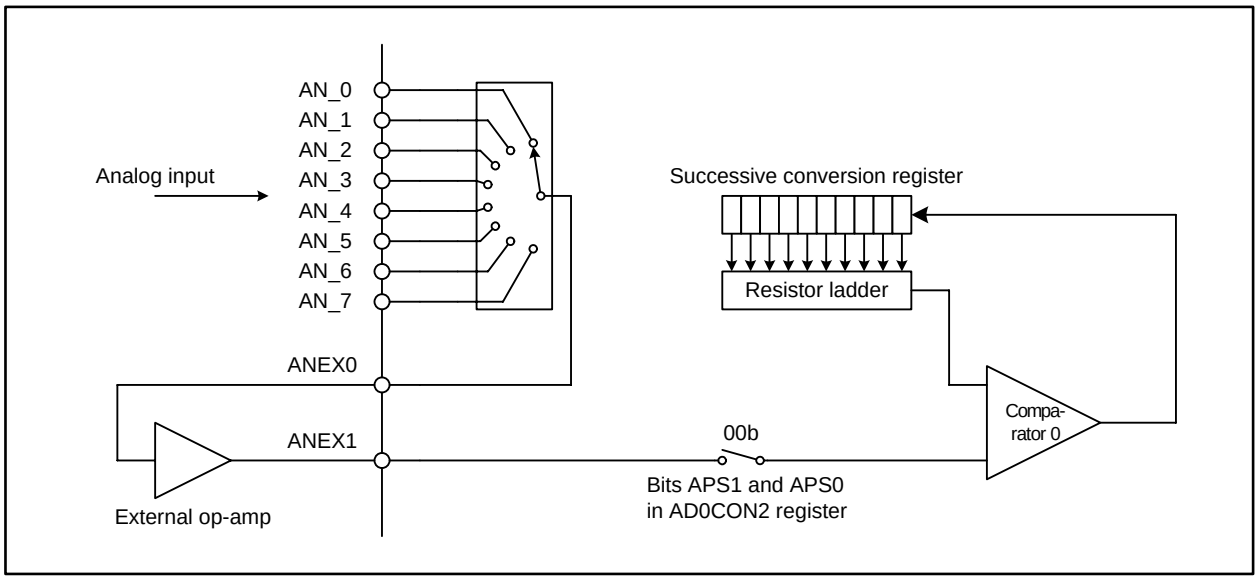

Figure 19.8 External Op-Amp Connection

19.2.7 Power Saving

When the A/D converter is not in use, power consumption can be reduced by setting the VCUT bit in the AD0CON1 to 0 (VREF disconnected). With this bit setting the reference voltage input pin (VREF) can be disconnected from the resistor ladder, which enables the power supply from the VREF to the resistor ladder to stop.

To use the A/D converter, the VCUT bit should be set to 1 (VREF connected) and 1 µs or more after, the ADST bit in the AD0CON0 register should be set to 1 (A/D conversion started). Bits ADST and VCUT should not be set to 1 simultaneously. The VCUT bit should not be set to 0 during the A/D conversion. The VCUT bit does not affect the VREF performance of the D/A converter (Refer to Figure 19.9).

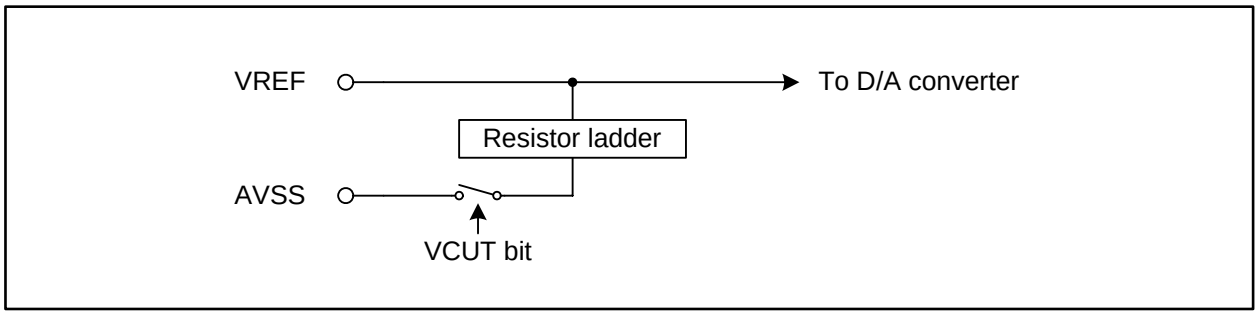

Figure 19.9 Power Supply by VCUT Bit

19.2.8 Output Impedance of Sensor Equivalent Circuit under A/D Conversion

Figure 19.10 shows an analog input pin and external sensor equivalent circuit.

To perform A/D conversion correctly, internal capacitor (C) charging, shown in Figure 19.10, should be completed within the specified period. This period, called sampling time, is 2 ϕAD cycles for conversion without the sample and hold function and 3 ϕAD cycles for conversion with this function.

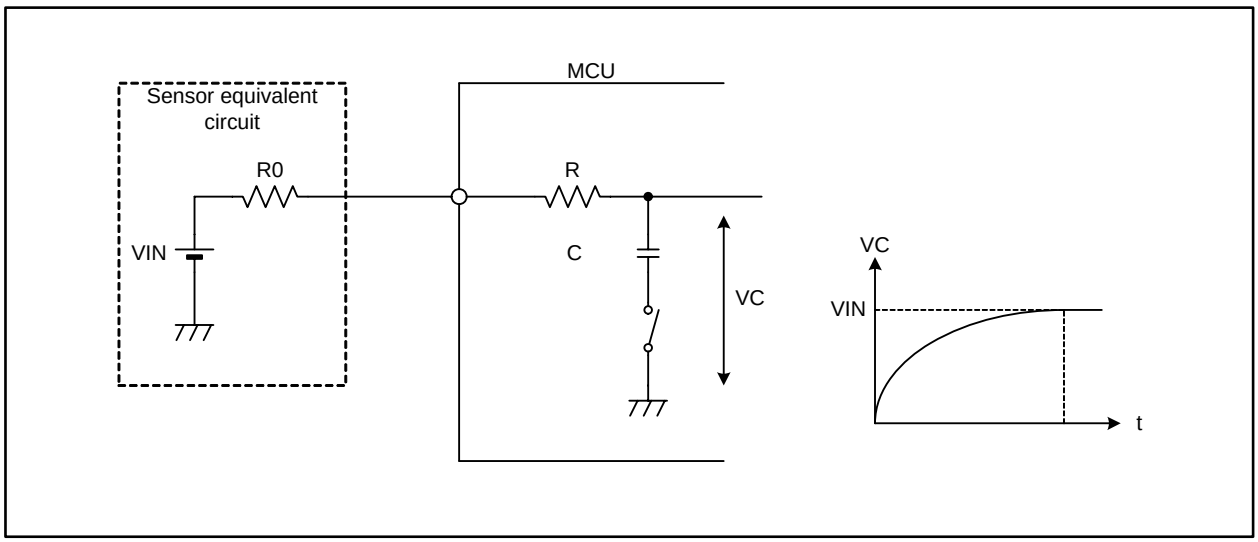

Figure 19.10 Analog Input Pin and External Sensor Equivalent Circuitry

The voltage between pins (VC) is expressed as follows:

$$VC = VIN\left\{1 - e^{-\frac{t}{C(R0+R)}}\right\}$$

When t = T and the precision (error) is x or less,

$$VC = VIN - \frac{x}{y}VIN = VIN\left(1 - \frac{x}{y}\right)$$

Thus, output impedance of the sensor equivalent circuit (R0) is determined by the following formulas:

$$e^{-\frac{T}{C(R0+R)}} = \frac{x}{y}$$

$$-\frac{T}{C(R0+R)} = \ln\frac{x}{y}$$

$$R0 = -\frac{T}{C\ln\frac{x}{y}} - R$$

where:
T[s] = Sampling time
R0[Ω] = Output Impedance of the sensor equivalent circuit
VC = Potential difference between edges of the capacitor C
R[Ω] = Internal resistance of the MCU
x[LSB] = Precision (error) of the A/D converter
y[step] = Resolution of the A/D converter (1024 steps @10-bit mode, 256 steps @ 8-bit mode)

When ϕAD = 10 MHz, the A/D conversion mode is 10-bit resolution with the sample and hold function, the output impedance (R0) with the precision (error) of 0.1 LSB or less is determined by the following formula:
Using T = 0.3 µs, R = 2.0 kΩ (reference value), C = 6.5 pF (reference value), x = 0.1, y = 1024,

$$R0 = -\frac{0.3\times10^{-6}}{6.5\times10^{-12}\times1\text{n}\frac{0.1}{1024}} - 2.0\times10^{3}$$

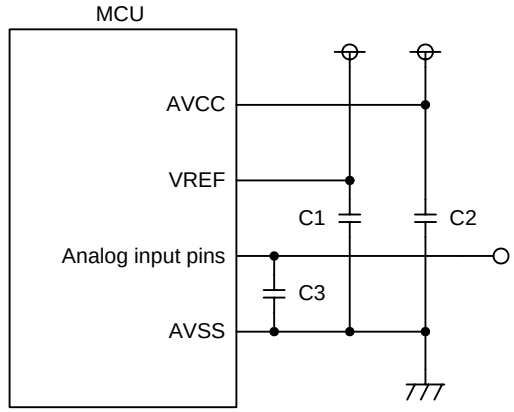
$$= 2998$$

Thus, the allowable output impedance of the sensor equivalent circuit (R0), making the precision (error) of 0.1 LSB or less, should be less than 3 kΩ.
Actual error, however, is the value of absolute precision added to 0.1 LSB mentioned above.

19.3 Notes on A/D Converter

19.3.1 Notes on Designing Boards

- Three capacitors should be respectively placed between the AVSS pin and such pins as AVCC, VREF, and analog inputs (AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, and AN15_0 to AN15_7) to avoid error operations caused by noise or latchup, and to reduce conversion errors. Figure 19.11 shows an example of pin configuration for A/D converter.



Notes:
1. C1 ≥ 0.47µF, C2 ≥ 0.47µF, and C3 ≥ 100 pF (reference values)
2. The traces for the capacitor and the MCU should be as short and wide as physically possible.

Figure 19.11 Pin Configuration for A/D Converter

- Do not use any of the four pins AN_4 to AN_7 for analog input if the key input interrupt is to be used. Otherwise, a key input interrupt request occurs when the A/D input voltage becomes VIL or lower.

- When AVCC = VREF = VCC, A/D input voltage for pins AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1 should be VCC or lower.

19.3.2 Notes on Programming

- The following registers should be written while the A/D conversion is stopped, that is, before a trigger occurs: AD0CON0 (except the ADST bit), AD0CON1, AD0CON2, AD0CON3, and AD0CON4.

- If the VCUT bit in the AD0CON1 register is switched from 0 (VREF connected) to 1 (VREF disconnected), the A/D conversion should be started after 1 µs or more. Set the VCUT bit to 0 when A/D conversion is not used to reduce power consumption.

- Set the port direction bit for the pin to be used as an analog input pin to 0 (input). Set the ASEL bit of the corresponding port function select register to 1 (the port is used as A/D input).

- If the TRG bit in the AD0CON0 register is set to 1 (external trigger or hardware trigger is selected), set the corresponding port direction bit (PD9_7 bit) for the $\overline{\text{ADTRG}}$ pin to 0 (input).

- The ϕAD frequency should be 16 MHz or below when VCC is 4.2 to 5.5 V, and 10 MHz or below when VCC is 3.0 to 4.2 V. It should be 1 MHz or above if the sample and hold function is enabled. If not, it should be 250 kHz or above.

- If A/D operating mode (bits MD1 and MD0 in the AD0CON0 register or the MD2 bit in the AD0CON1 register) has been changed, re-select analog input pins by using bits CH2 to CH0 in the AD0CON0 register or bits SCAN1 and SCAN0 in the AD0CON1 register.

- If the AD0i register (i = 0 to 7) is read when the A/D converted result is stored to the register, the stored value may have an error. Read the AD0i register after the A/D conversion has been completed.
  In one-shot mode or single sweep mode, read the respective AD0i register after the IR bit in the AD0IC register has become 1 (interrupt requested).
  In repeat mode, repeat sweep mode 0, or repeat sweep mode 1, an interrupt request can be generated each time when an A/D conversion has been completed if the DUS bit in the AD0CON3 register is set to 1 (DMAC operating mode enabled). Similar to the other modes above, read the AD00 register after the IR bit in the AD0IC register has become 1 (interrupt requested).

- If the A/D conversion in progress is halted by setting the ADST bit in the AD0CON0 register to 0, the converted result is undefined. In addition, the unconverted AD0i register may also become undefined. Consequently, the AD0i register should not be used just after A/D conversion is halted.

- The external trigger cannot be used in DMAC operating mode. When the DMAC is configured to transfer converted results, do not read the AD0i register by a program.

- If, in single sweep mode, the A/D conversion in progress is halted by setting the ADST bit in the AD0CON0 register to 0 (A/D conversion is stopped), an interrupt request may be generated even though the sweep is not completed. To halt the A/D conversion, first disable interrupts, then set the ADST bit to 0.

20. D/A Converter

The MCU has two separate 8-bit R-2R resistor ladder D/A converters.
Digital code is converted to an analog voltage when a value is written to the corresponding DAi register (i = 0,1). The DAiE bit in the DACON register determines whether the D/A conversion result is output or not. To output the converted value, the DAiE bit should be set to 1 (output enabled). This bit setting disables a pull-up resistor for the corresponding port.
Analog voltage to be output (V) is calculated based on the value (n) set in the DAi register (n = decimal).

$$V = \frac{VREF \times n}{256} \quad \text{(n = 0 to 255)}$$

VREF: reference voltage

Table 20.1 lists specifications of the D/A converter. Figure 20.1 shows a block diagram of the D/A converter. Figure 20.2 and Figure 20.3 show registers associated with the D/A. Figure 20.4 shows a D/A converter equivalent circuit.
When the D/A converter is not used, the DAi register should be set to 00h and the DAiE bit should be set to 0 (output disabled).

Table 20.1 D/A Converter Specifications

Notes:
1. The figure above applies when the DA0 register is set to 2Ah.
2. This circuitry also applies to the D/A converter 1.
3. To reduce power consumption when the D/A converter is not in use, the DAiE bit (i = 0, 1) should be set to 0 (output disabled) and the DAi register should be set to 00h to prevent the current from flowing into the R-2R resistor ladder.

Figure 20.4 D/A Converter Equivalent Circuitry

21. CRC Calculator

The CRC (Cyclic Redundancy Check) calculator is used for error detection in data blocks. A generator polynomial of CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) generates a CRC.
The CRC is a 16-bit code generated for given blocks of 8-bit data. It is set in the CRCD register every time 1-byte data is written to the CRCIN register after a default value is set to the CRCD register.
Figure 21.1 shows a block diagram of the CRC calculator. Figure 21.2 and Figure 21.3 show registers associated with the CRC. Figure 21.4 shows an example of the CRC calculation.

CRC Calculation and Setting Procedure to Generate CRC for 80C4h

- CRC Calculation for R32C

  CRC: a remainder of the division as follows: $\frac{\text{reversed-bit-position value in the CRCIN register}}{\text{generator polynominal}}$

  Generator Polynomial: $X^{16}+X^{12}+X^5+1$(1 0001 0000 0010 0001b)

- Setting Steps

  (1) Reverse the bit position of 80C4h per byte by a program

  80h to 01h, C4h to 23h

  (2) Set 0000h (default value in reversed bit position) in CRCD register

  
  (3) Set 01h (80h in reversed bit position) in CRCIN register

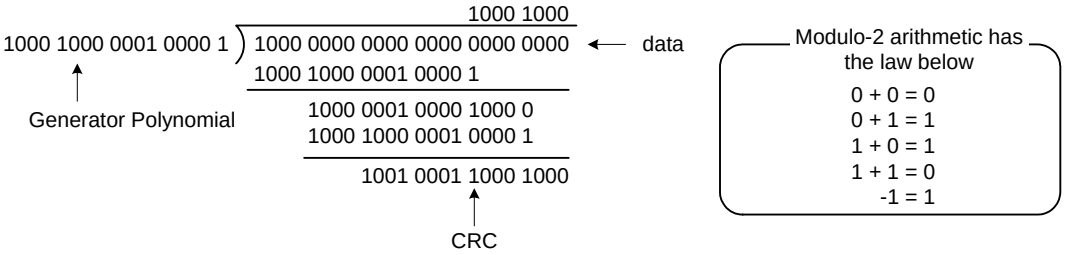
  
  1189h, CRC for 80h (9188h) in reversed bit position is stored into the CRCD register in the third cycle.

  (4) Set 23h (C4h in reversed bit position) in CRCIN register

  
  0A41h, CRC for 80C4h (8250h) in revered bit position is stored into the CRCD register in the third cycle.

- Details of CRC Calculation

As shown in (3) above, add 1000 0000 0000 0000 0000 0000b as 80h (1000 0000b) plus 16 digits to 0000 0000 0000 0000 0000 0000b as the default value of the CRCD register, 0000h plus eight digits to perform the modulo-2 division.



0001 0001 1000 1001b (1189h), the reversed-bit-position value of remainder 1001 0001 1000 1000b (9188h) can be read from the CRCD register.

When going on (4) above, add 1100 0100 0000 0000 0000 0000b as C4h (1100 0100b) plus 16 digits to 1001 0001 1000 1000 0000 0000b as the remainder of (3) left in the CRCD register plus eight digits to perform the modulo-2 division.
0000 1010 0100 0001b (0A41h), the reversed-bit-position value of remainder 1000 0010 0101 0000b (8250h) can be read from the CRCD register.

Figure 21.4 CRC Calculation

22. X-Y Conversion

The X-Y conversion rotates a 16 × 16-bit matrix data 90 degrees or reverses the bit position of 16-bit data. The X-Y conversion is set using the XYC register shown in Figure 22.1.
Data is written in write-only XiR registers (i = 0 to 15) and converted data is read in read-only YjR register (j = 0 to 15). These registers are allocated to the same address. Figure 22.2 and Figure 22.3 show registers XiR and YjR, respectively. A write/read access from an even address to the XiR/YjR registers should be performed every 16 bits. 8-bit access operation results are undefined.

Note:
1. A 16-bit read access to this register should be performed.

Figure 22.3 Registers Y0R to Y15R

22.1 Data Conversion on Reading

The XYC0 bit in the XYC register selects a read mode for the YjR register. When the XYC0 bit is set to 0 (data rotation), bit j in the corresponding registers X0R to X15R is automatically read on reading the YjR register (j = 0 to 15).

More concretely, on reading bit i (i = 0 to 15) in the Y0R register, the data of each bit 0 in the XiR register is read. That is, a read data of bit 0 in the Y15R register means the data of bit 15 in the X0R register and the data of bit 15 in the Y0R register is identical to that of bit 0 in the X15R register.

Figure 22.4 shows the conversion table when the XYC0 bit is set to 0 and Figure 22.5 shows an example of X-Y conversion.

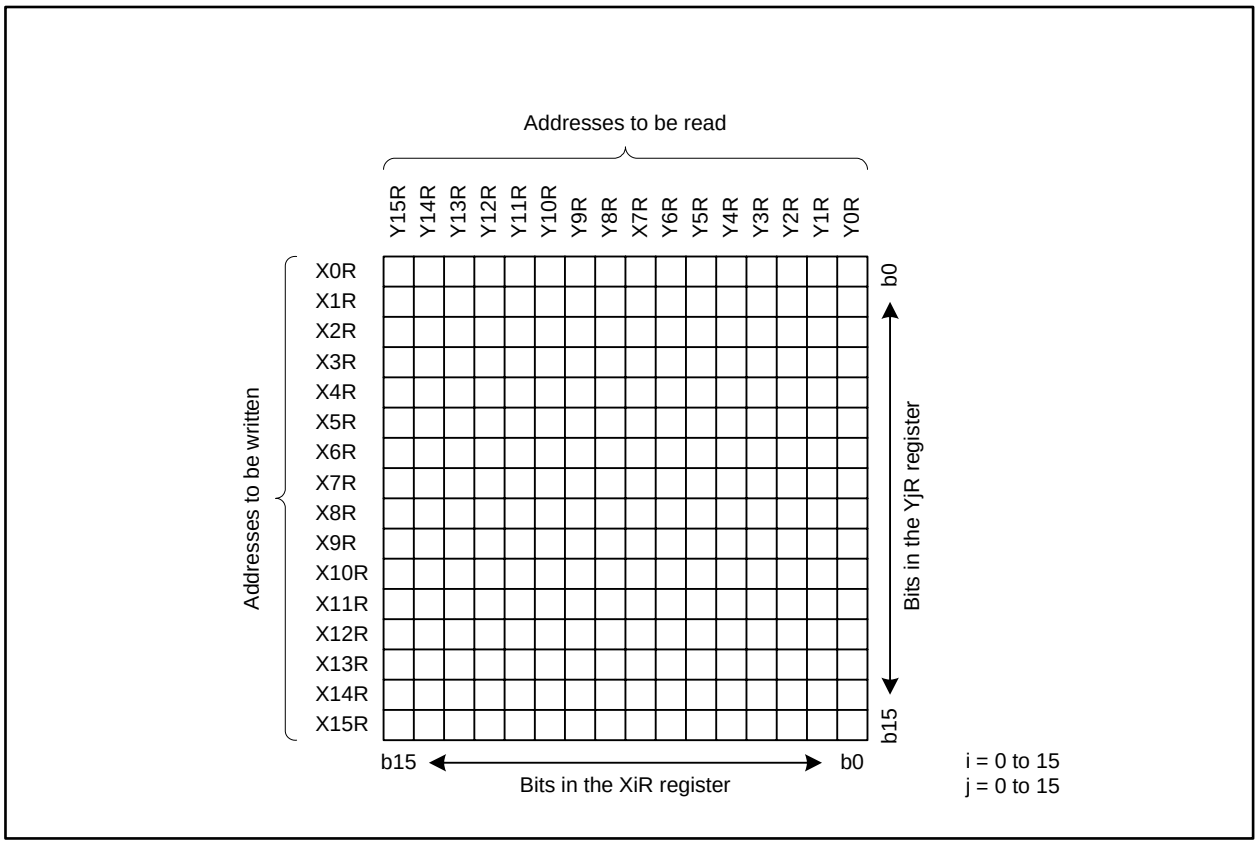

Figure 22.4 Conversion Table (XYC0 Bit = 0)

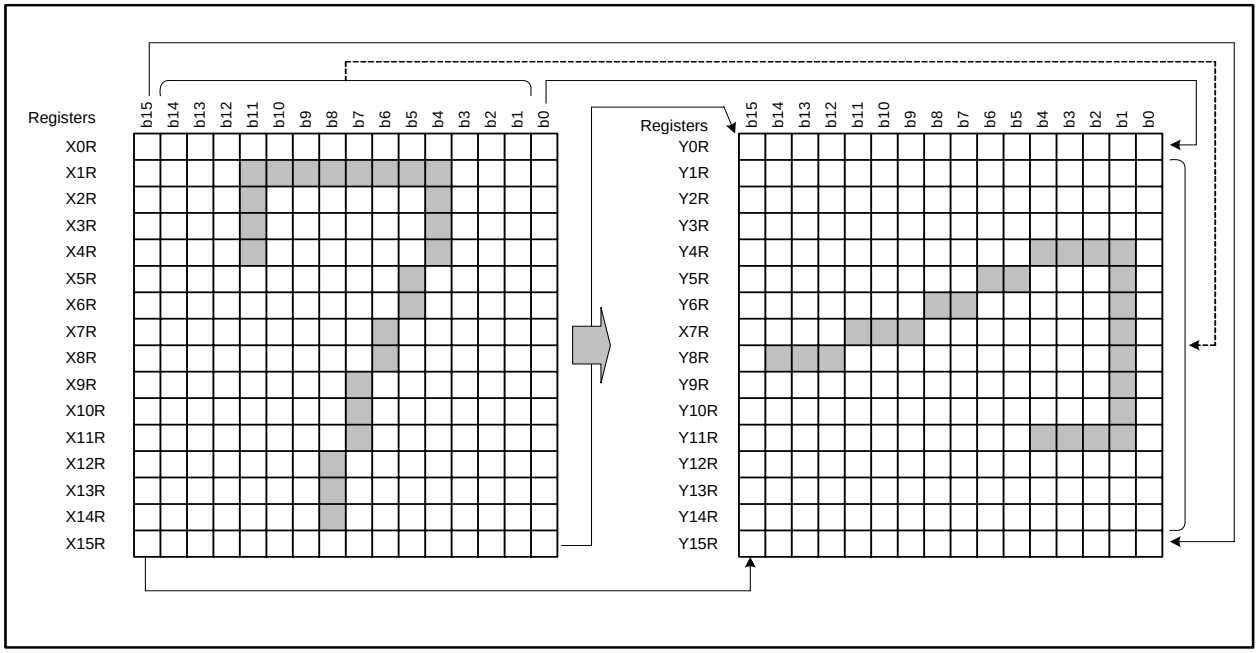

Figure 22.5 X-Y Conversion

When the XYC0 bit is set to 1 (no data rotation), the data of each bit in the YjR register is identical to that written in the XiR register. Figure 22.6 shows the conversion table when the XYC0 bit is set to 1.

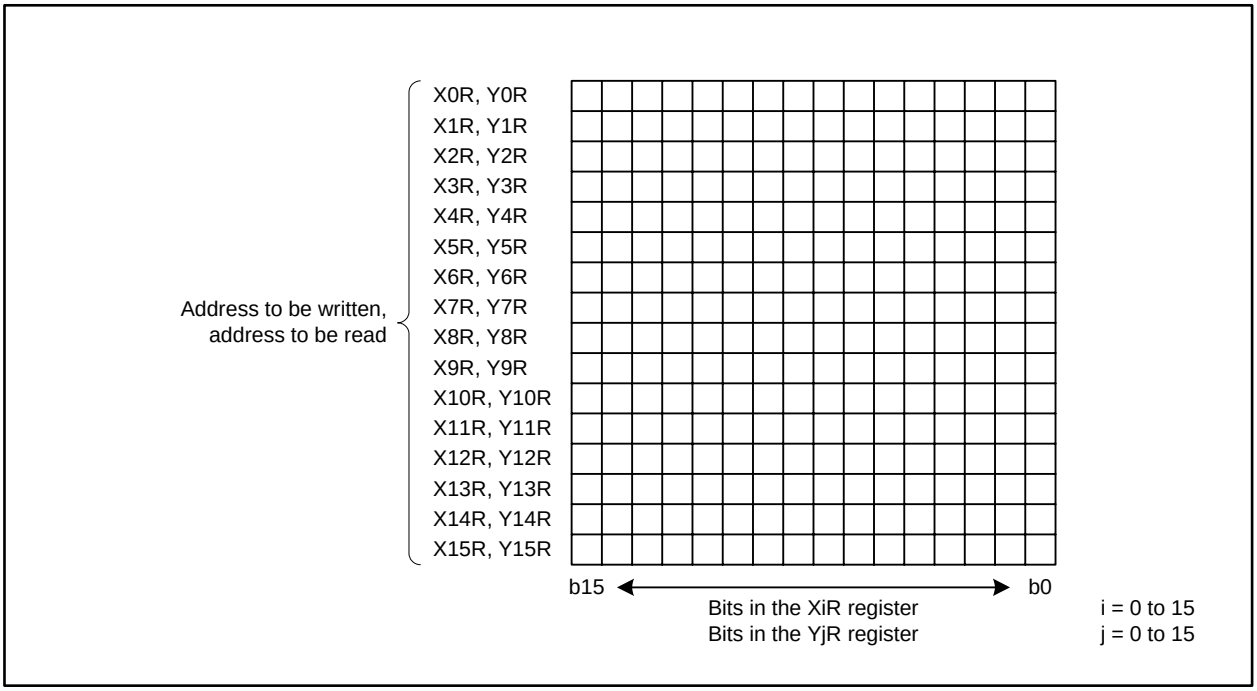

Figure 22.6 Conversion Table (XYC0 Bit = 1)

22.2 Data Conversion on Writing

The XYC1 bit in the XYC register selects a write mode for the XiR register.

When the XYC1 bit is set to 0 (no bit position reverse), the data is written in order. When it is set to 1 (bit position reverse), the data is written in reversed order. Figure 22.7 shows the conversion table when the XYC1 bit is set to 1.

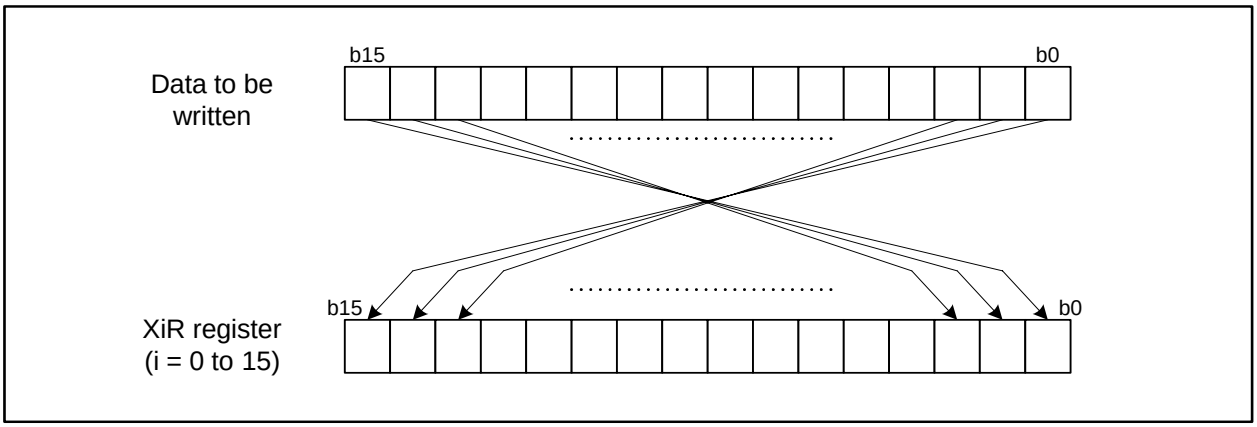

Figure 22.7 Conversion Table (XYC1 Bit = 1)

23. Intelligent I/O

The intelligent I/O is a multifunctional I/O port for time measurement, waveform generation, variable character length synchronous serial interface, and IEBus.
It consists of three groups each of which has one free-running 16-bit base timer and eight 16-bit registers for time measurement or waveform generation.
Table 23.1 lists functions and channels of the intelligent I/O.

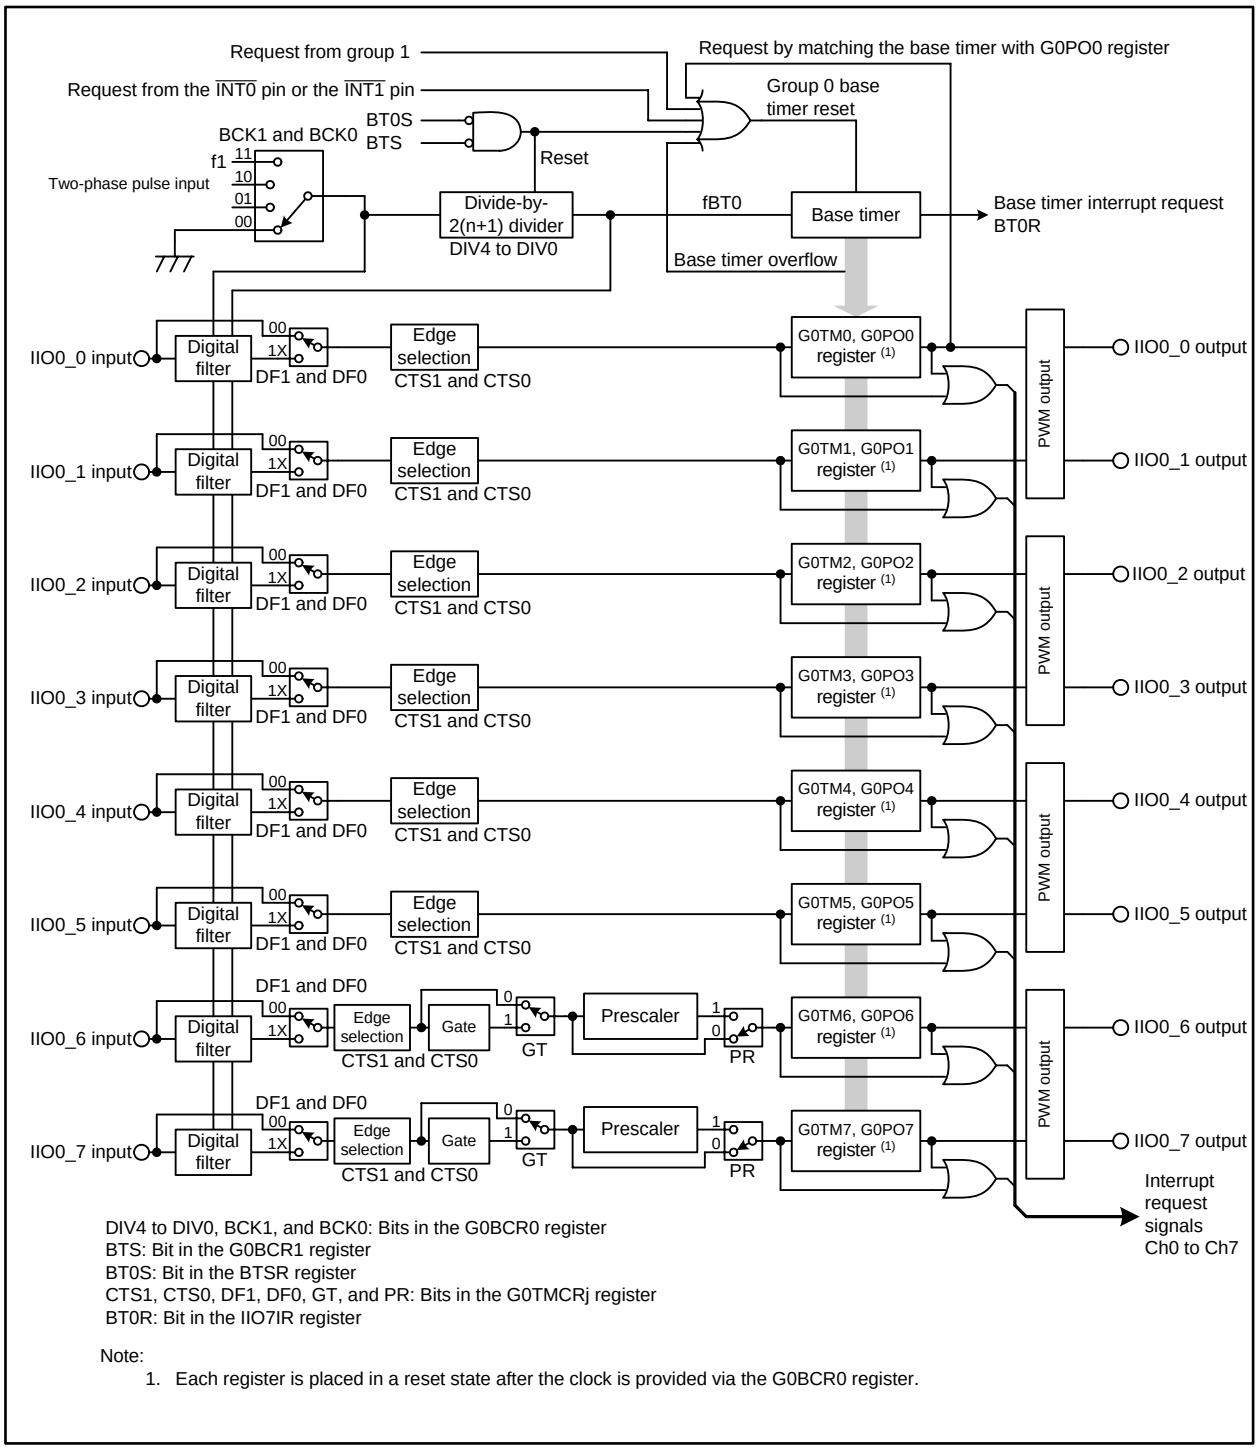
Table 23.1 Intelligent I/O Functions and Channels

Functions		Group 0	Group 1	Group 2
Time measurement (1)	Digital filter	8 channels	8 channels	Not available
	Prescaler	2 channels	2 channels	
	Gating	2 channels	2 channels	
Waveform generation (1)	Single-phase waveform output mode	8 channels	8 channels	8 channels
	Inverted waveform output mode	8 channels	8 channels	8 channels
	SR waveform output mode	8 channels	8 channels	8 channels
	Bit modulation PWM mode	Not available	Not available	8 channels
	RTP mode			8 channels
	Parallel RTP mode			8 channels
Serial interface	Variable character length synchronous serial interface mode	Not available	Not available	Available
	IEBus mode (optional (2))			

Notes:
1. Functions time measurement and waveform generation share a pin.
2. Contact a Renesas Electronics sales office to use the optional features.

Each channel individually selects a function from the time measurement and the waveform generation.

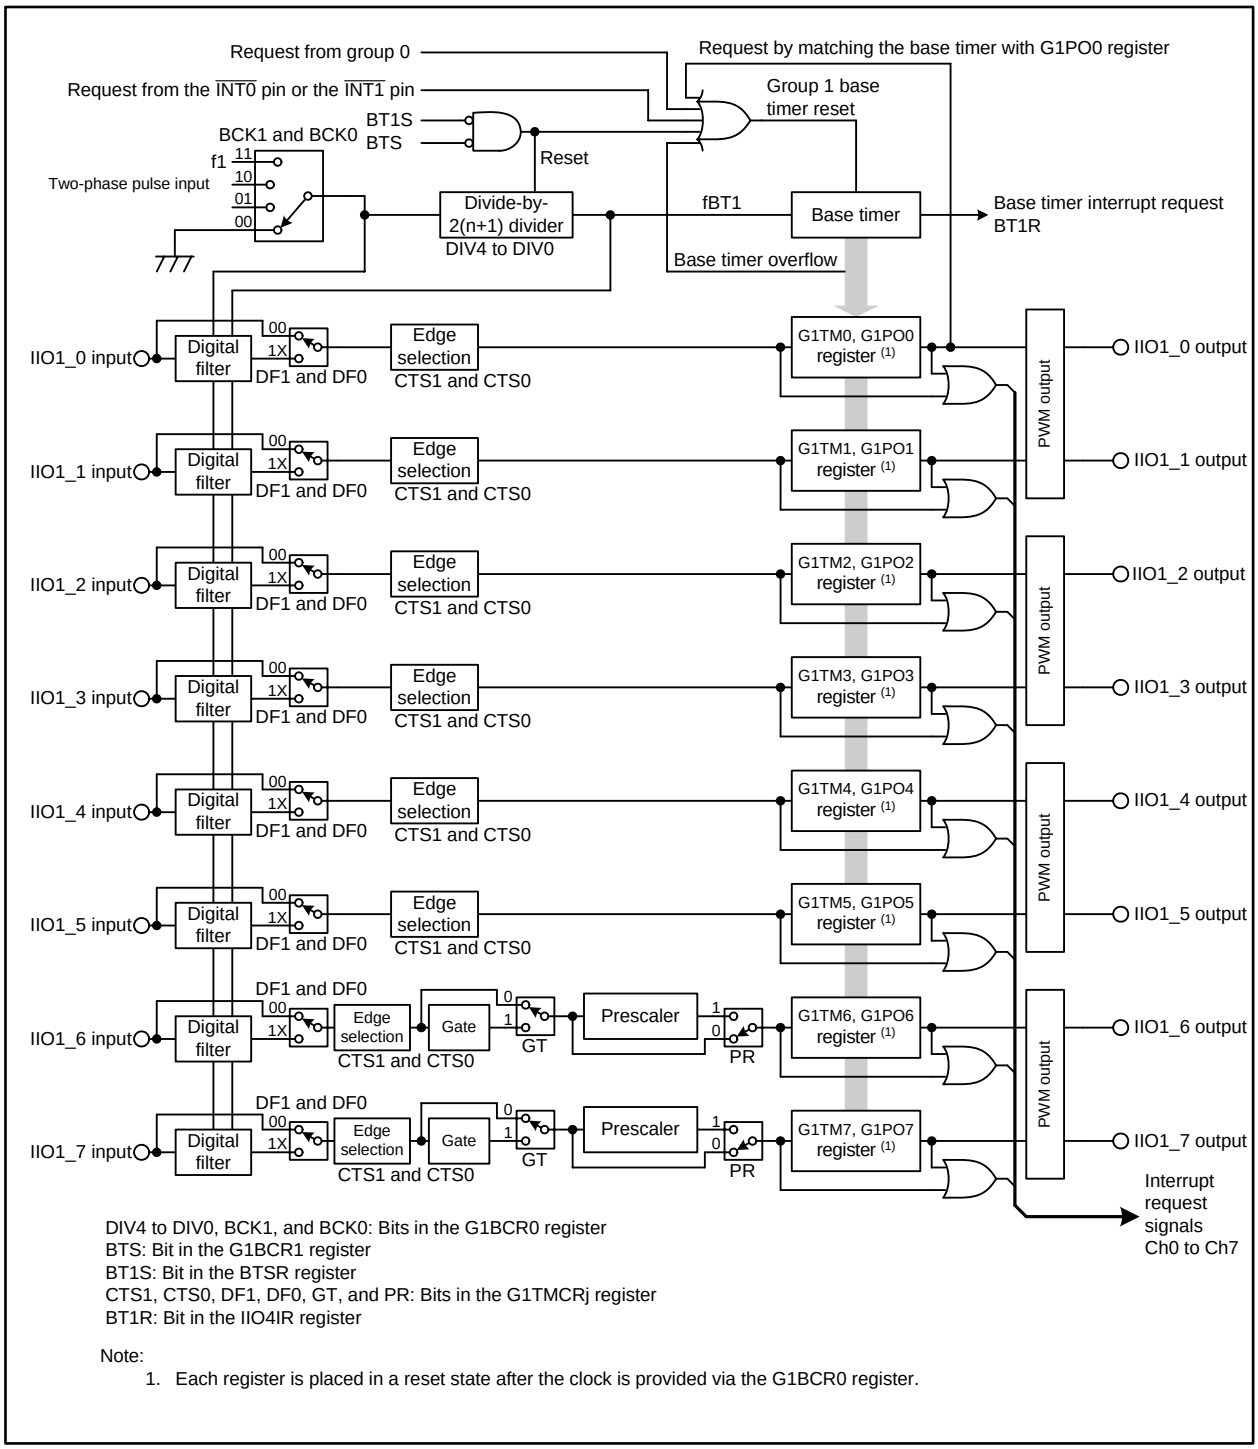
Figure 23.1 to Figure 23.3 show block diagrams of the intelligent I/O.



DIV4 to DIV0, BCK1, and BCK0: Bits in the G0BCR0 register
BTS: Bit in the G0BCR1 register
BT0S: Bit in the BTSR register
CTS1, CTS0, DF1, DF0, GT, and PR: Bits in the G0TMCRj register
BT0R: Bit in the IIO7IR register

Note:
1. Each register is placed in a reset state after the clock is provided via the G0BCR0 register.

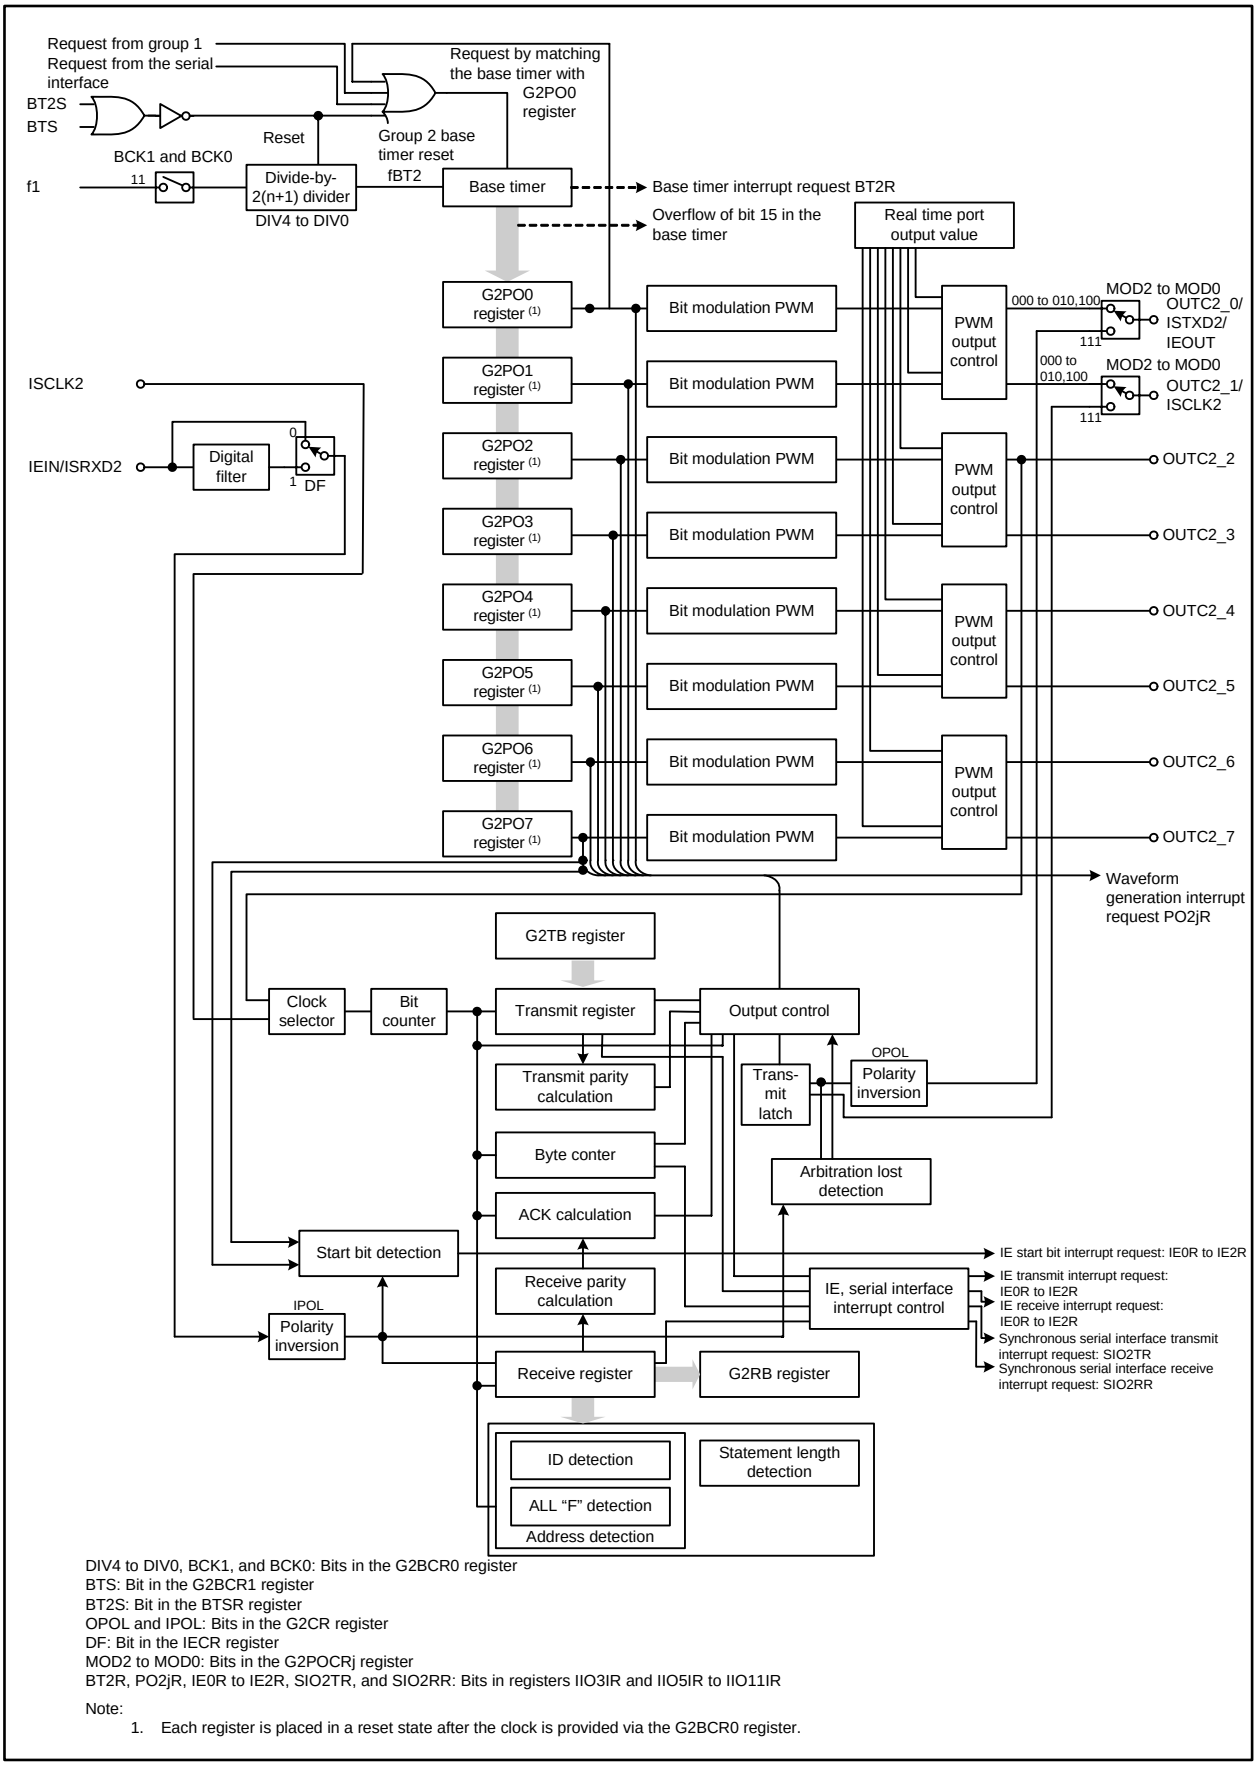
Figure 23.1 Intelligent I/O Group 0 Block Diagram (j = 0 to 7)



DIV4 to DIV0, BCK1, and BCK0: Bits in the G1BCR0 register
BTS: Bit in the G1BCR1 register
BT1S: Bit in the BTSR register
CTS1, CTS0, DF1, DF0, GT, and PR: Bits in the G1TMCRj register
BT1R: Bit in the IIO4IR register

Note:
1. Each register is placed in a reset state after the clock is provided via the G1BCR0 register.

Figure 23.2 Intelligent I/O Group 1 Block Diagram (j = 0 to 7)



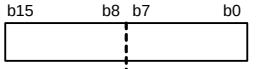
DIV4 to DIV0, BCK1, and BCK0: Bits in the G2BCR0 register
BTS: Bit in the G2BCR1 register
BT2S: Bit in the BTSR register
OPOL and IPOL: Bits in the G2CR register
DF: Bit in the IECR register
MOD2 to MOD0: Bits in the G2POCRj register
BT2R, PO2jR, IE0R to IE2R, SIO2TR, and SIO2RR: Bits in registers IIO3IR and IIO5IR to IIO11IR

Note:
1. Each register is placed in a reset state after the clock is provided via the G2BCR0 register.

Figure 23.3 Intelligent I/O Group 2 Block Diagram (j = 0 to 7)

Figure 23.4 to Figure 23.17 show registers associated with the intelligent I/O base timer, the time measurement, and the waveform generation (For registers associated with the serial interface, refer to Figure 23.33 to Figure 23.40).

Group i Base Timer Register (i = 0 to 2) (1)



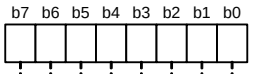
Symbol	Address	Reset Value
G0BT, G1BT	01A1h-01A0h, 0121h-0120h	Undefined
G2BT	0161h-0160h	Undefined

Function	Setting Range	RW
- While the base timer is running, this register indicates the value of base timer; when a value is written, the counter immediately starts counting from this value. The register is set to 0000h when the base timer is reset. - While the base timer is being reset, this register is set to 0000h; the register is read as undefined value; no value can be set. (2)	0000h to FFFFh	RW

Notes:
1. The GiBT register reflects the base timer value after a delay of a half fBTi cycle.
2. The base timer stops only when bits BCK1 and BCK0 in the GiBCR0 register are set to 00b (clock stopped). However, if the BTiS bit in the BTSR register and the BTS bit in the GiBCR1 register are set to 0, the base timer is held in a reset state, holding the value 0000h. That is, the base timer is in a “no counting” state. If either of these bits is set to 1, this state is cleared and the base timer starts counting.

Figure 23.4 Registers G0BT to G2BT

Group i Base Timer Control Register 0 (i = 0 to 2)



Symbol	Address	Reset Value
G0BCR0 to G2BCR0	01A2h, 0122h, 0162h	0000 0000b

Bit Symbol	Bit Name	Function	RW
BCK0	Count Source Select Bit	b1 b2 0 0 : Clock stopped 0 1 : Do not use this combination 1 0 : Two-phase pulse signal input (1) 1 1 : f1	RW
BCK1			RW
DIV0	Count Source Divide Ratio Select Bit	Divide the count source by 2(n+1). The count source is not divided when n = 31. (n = 0 to 31) b6 b5 b4 b3 b2 0 0 0 0 0 : divide-by-2 (n = 0) 0 0 0 0 1 : divide-by-4 (n = 1) 0 0 0 1 0 : divide-by-6 (n = 2) : 1 1 1 1 0 : divide-by-62 (n = 30) 1 1 1 1 1 : no division (n = 31)	RW
DIV1			RW
DIV2			RW
DIV3			RW
DIV4			RW
IT	Base Timer Interrupt Source Select Bit	0: Overflow of bit 15 or the bit 9 1: Overflow of bit 14	RW

Note:
1. This bit setting is enabled only when bits UD1 and UD0 in the GjBCR1 register (j = 0, 1) are set to 10b (two-phase pulse signal processing mode). Bits BCK1 and BCK0 should not be set to 10b in other modes or in group 2.

Figure 23.5 Registers G0BCR0 to G2BCR0

Group i Base Timer Control Register 1 (i = 0, 1)

b7	b6	b5	b4	b3	b2	b1	b0
0				0			

Symbol: G0BCR1, G1BCR1 — Address: 01A3h, 0123h — Reset Value: 0000 0000b

Bit Symbol	Bit Name	Function	RW
RST0	Base Timer Reset Source Select Bit 0	0: No reset 1: Synchronization with another base timer reset (1)	RW
RST1	Base Timer Reset Source Select Bit 1	0: No reset 1: Match with the GiPO0 register (2)	RW
RST2	Base Timer Reset Source Select Bit 2	0: No reset 1: A low signal input into the $\overline{INT0}$/$\overline{INT1}$ pin (3)	RW
— (b3)	Reserved	Should be written with 0	RW
BTS	Base Timer Start Bit (4, 5)	0: Reset the base timer 1: Start counting	RW
UD0	Increment/Decrement Counting Control Bit	b6 b5 0 0 : Increment counting mode 0 1 : Increment/decrement counting mode 1 0 : Two-phase pulse signal processing mode (6) 1 1 : Do no use this combination	RW
UD1			RW
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. The group 0 base timer is reset by synchronizing with the reset of group 1 base timer, and vice versa.
2. The base timer is reset after two fBTi clock cycles if the base timer value has matched the GiPO0 register setting (Refer to Figure 23.14 for the details on the GiPO0 register). When the RST1 bit is set to 1, the value of GiPOj register (j = 1 to 7) to be used for the waveform generation should be smaller than that of the GiPO0 register.
3. The base timer is reset by an input of low signal to the external interrupt input pin selected for the UDiZ signal by the IFS2 register.
4. To start base timers groups 0 and 1 individually, the BTS bit should be set to 1 after setting the BTkS bit (k = 0, 1) in the BTSR register to 0 (base timer is reset).
5. To start the base timers of two or all groups simultaneously, the BTSR register should be used. The BTS bit should be set to 0.
6. In two-phase pulse signal processing mode, the base timer is not reset, even though the RST1 bit is set to 1, if the timer counter decrements the count after two clock cycles when the base timer value matches the GiPO0 register.

Figure 23.6 Registers G0BCR1 and G1BCR1

Group 2 Base Timer Control Register 1

b7	b6	b5	b4	b3	b2	b1	b0
	0	0		0			

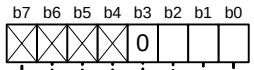
Symbol: G2BCR1 | Address: 0163h | Reset Value: 0000 0000b

Bit Symbol	Bit Name	Function	RW
RST0	Base Timer Reset Source Select Bit 0	0: No reset 1: Synchronization with group1 base timer reset	RW
RST1	Base Timer Reset Source Select Bit 1	0: No reset 1: Match with the G2PO0 register (1)	RW
RST2	Base Timer Reset Source Select Bit 2	0: No reset 1: A reset request from the serial interface	RW
— (b3)	Reserved	Should be written with 0	RW
BTS	Base Timer Start Bit (2, 3)	0: Reset the base timer 1: Start counting	RW
— (b6-b5)	Reserved	Should be written with 0	RW
PRP	Parallel Real-Time Port Select Bit (4)	0: RTP output mode 1: Parallel RTP output mode	RW

Notes:
1. The base timer is reset after two fBT2 clock cycles if the base timer value matches the G2PO0 register setting. When the RST1 bit is set to 1, the value of G2POj register (j = 1 to 7) used for the waveform generation or the serial interface should be smaller than that of the G2PO0 register.
2. To start the group 2 base timer, the BTS bit should be set to 1 after setting the BT2S bit in the BTSR register to 0 (base timer is reset).
3. To start the base timers of two or all groups simultaneously, the BTSR register should be used. The BTS bit should be set to 0.
4. This bit setting is enabled when the RTP bit in the G2POCRi register is set to 1 (real-time port used).

Figure 23.7 G2BCR1 Register

Base Timer Start Register (1, 2)



Symbol	Address	Reset Value
BTSR	0164h	XXXX 0000b

Bit Symbol	Bit Name	Function	RW
BT0S	Group 0 Base Timer Start Bit	0: Reset the base timer 1: Start counting	RW
BT1S	Group 1 Base Timer Start Bit	0: Reset the base timer 1: Start counting	RW
BT2S	Group 2 Base Timer Start Bit	0: Reset the base timer 1: Start counting	RW
— (b3)	Reserved	Should be written with 0	RW
— (b7-b4)	No register bits; should be written with 0 and read as undefined value.		—

Notes:

1. The initial settings of bits and registers for the intelligent I/O are required as follows:
   (1) Set the G2BCR0 register to provide the clock to the group 2 base timer
   (2) Set all bits BT0S to BT2S to 0 (base timer is reset)
   (3) Set other registers associated with the intelligent I/O
   The BTiS bit (i = 0 to 2) allows the base timers of two or all groups to start counting simultaneously. To start counting individually, the BTiS bit should be set to 0 and the BTS bit in the GiBCR1 register should be used.
2. The following procedure is required to start the base timers of more than two groups simultaneously:
   -Bits BCK1 to BCK0 and DIV4 to DIV0 in the GiBCR0 registers (i = two among 0, 1, and 2 or all) to be used should be set identically
   -After bits BCK1 to BCK0 or DIV4 to DIV0 are changed, start the base timers twice as following procedure:
   (1) Set the BTiS bit to 1 (base timer starts counting)
   (2) Set the BTiS bit to 0 (base timer is reset) after one fBTi clock cycle or more
   (3) Set the BTiS bit to 1 again after another one fBTi clock cycle or more

MOD1			RW
MOD2			RW
— (b3)	No register bit; should be written with 0 and read as undefined value		—
IVL	Default Output Value Select Bit (2)	0: Output low as default value 1: Output high as default value	RW
RLD	GiPOj Register Value Reload Timing Select Bit	0: Reload the value into the GiPOj register on a write access 1: Reload the value into the GiPOj register when the base timer is reset	RW
BTRE	Base Timer Reset Enable Bit (3)	0: Reset the base timer when bit 15 overflows 1: Reset the base timer when bit 9 overflows (4)	RW
INV	Output Level Inversion Select Bit (5)	0: Do not invert the output level 1: Invert the output level	RW

Notes:
1. This bit setting is enabled only for even channels. In SR waveform output mode, the corresponding odd channel (the next channel after an even channel) setting is ignored. Waveforms are only output from even channels.
2. The setting value is output by a write to the IVL bit if the FSCj bit in the GiFS register is set to 0 (the waveform generation selected) and the IFEj bit in the GiFE register is set to 1 (the function for channel j enabled).
3. This bit is available only in the GiPOCR0 register. Bit 6 in registers GiPOCR1 to GiPOCR7 should be set to 0.
4. To set the BTRE bit to 1, bits BCK1 and BCK0 in the GiBCR0 register should be set to 11b (f1) and bits UD1 and UD0 in the GiBCR1 register should be set to 00b (increment counting mode).
5. The output level inversion is the final step in waveform generation process. When the INV bit is set to 1 (output level is inverted), high is output by setting the IVL bit to 0 (output low as default value), and vice versa.

23.1 Base Timer (for Groups 0 to 2)

The base timer is a free-running counter that counts an internally generated count source. Table 23.2 lists specifications of the base timer. Figure 23.4 to Figure 23.17 show registers associated with the base timer. Figure 23.18 shows a block diagram of the base timer. Figure 23.19, Figure 23.20, and Figure 23.21 show respectively an operation example of the base timer (for groups 0 and 1) in increment counting mode, in increment/decrement counting mode, and in two-phase pulse signal processing mode.

Table 23.2 Base Timer Specifications (i = 0 to 2)

Item	Specification
Count source (fBTi)	f1 divided by 2(n+1) (for groups 0 to 2), two-phase pulse input divided by 2(n+1) (for groups 0 and 1) n: setting value using bits DIV4 to DIV0 in the GiBCR0 register n = 0 to 31; however no division when n = 31
Count operations	• Increment counting • Increment/decrement counting • Two-phase pulse signal processing
Count start conditions	• To start each base timer individually, the BTS bit in the GiBCR1 register is set to 1 (count starts) • To start base timers of two or all groups simultaneously, the BTiS bit in the BTSR register is set to 1 (count starts)
Count stop condition	The BTiS bit in the BTSR register is set to 0 (base timer is reset) and the BTS bit in the GiBCR1 register is set to 0 (base timer is reset)
Reset conditions	• The base timer value matches the GiPO0 register setting • An input of low signal into the external interrupt pin as follows: for group 0: selected using bits IFS23 and IFS22 in the IFS2 register for group 1: selected using bits IFS27 and IFS26 in the IFS2 register • The overflow of bit 15 or 9 in the base timer • The base timer reset request from the communication functions (group 2)
Reset value	0000h
Interrupt request	When the BTiR bit in the interrupt request register is set to 1 (interrupts requested) by the overflow of bit 9, 14, or 15 in the base timer (refer to Figure 11.12)
Read from base timer	• The GiBT register indicates a counter value while the base timer is running • The GiBT register is undefined while the base timer is being reset
Write to base timer	When a value is written while the base timer is running, the timer counter immediately starts counting from this value. No value can be written while the base timer is being reset

Table 23.2 Base Timer Specifications (i = 0 to 2)

Item	Specification
Selectable functions	• Increment/decrement counting mode (for groups 0 and 1) The base timer starts counting when the BTS or BTiS bit is set to 1. On reaching FFFFh, it starts decrement counting. When the RST1 bit in the GiBCR1 register is set to 1 (reset by match with the GiPO0 register), the timer counter starts decrement counting as soon as the base timer value has matched the GiPO0 register setting. When the timer counter has reached 0000h, it starts increment counting again (Refer to Figure 23.20). • Two-phase pulse signal processing mode (for groups 0 and 1) Two-phase pulse signals at pins UDiA and UDiB are counted (Refer to Figure 23.21). 

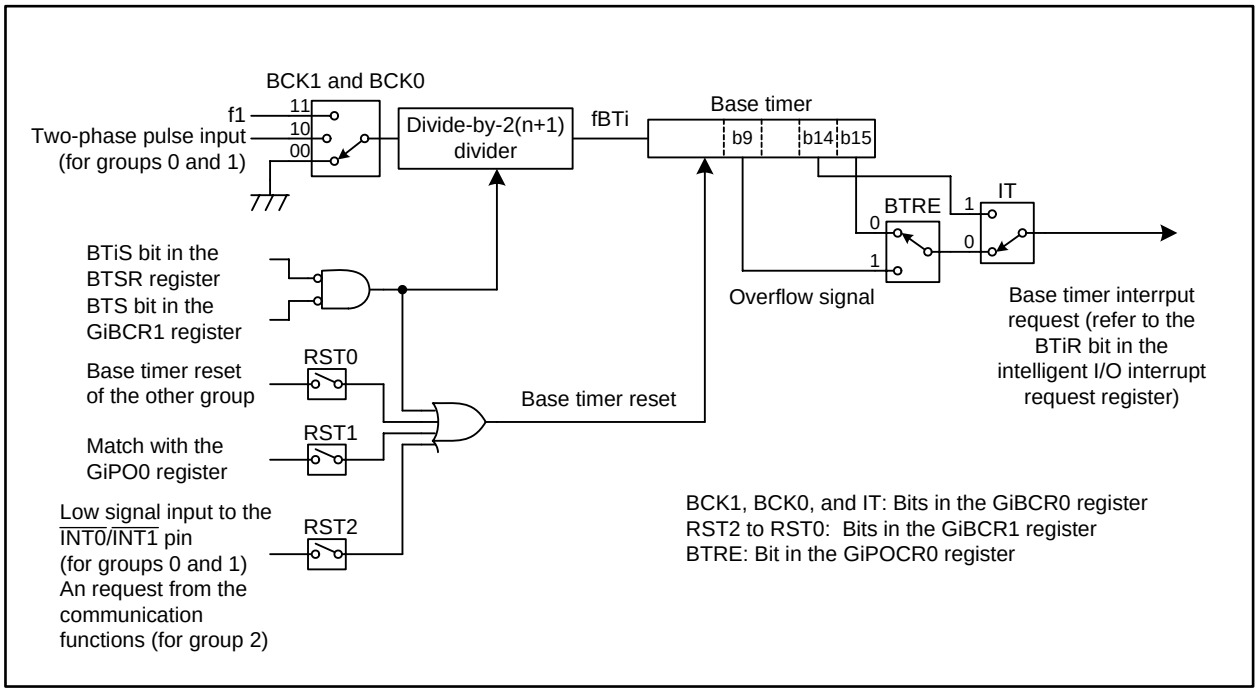

Figure 23.18 Base Timer Block Diagram (i = 0 to 2)

Table 23.3 Base Timer Associated Register Settings (Common Settings for Time Measurement, Waveform Generation, and Serial Interface) (i = 0 to 2)

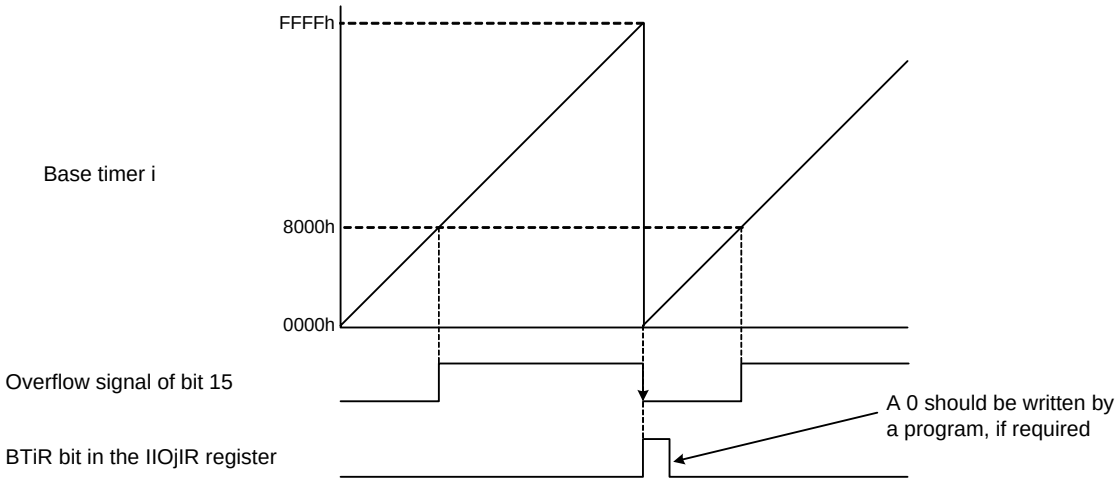
Register	Bits	Function
G2BCR0	—	Provide an operating clock to the BTSR register. Set to 0111 1111b
BTSR	—	Set to 0000 0000b
GiBCR0	BCK1 and BCK0	Select a count source
	DIV4 to DIV0	Select a divide ratio of count source
	IT	Select a base timer interrupt source
GiBCR1	RST2 to RST0	Select a timing for base timer reset
	BTS	Use this bit when each base timer individually starts counting
	UD1 and UD0	Select a count operation (in groups 0 and 1)
GiPOCR0	BTRE	Select a source for base timer reset
GiBT	—	Read or write the base timer value

The following register settings are required to set the RST1 bit to 1 (base timer is reset by match with the GiPO0 register).

GiPOCR0	MOD2 to MOD0	Set to 000b (single-phase waveform output mode)
GiPO0	—	Set the reset cycle
GiFS	FSC0	Set the bit to 0 (waveform generation)
GiFE	IFE0	Set the bit to 1 (channel operation starts)

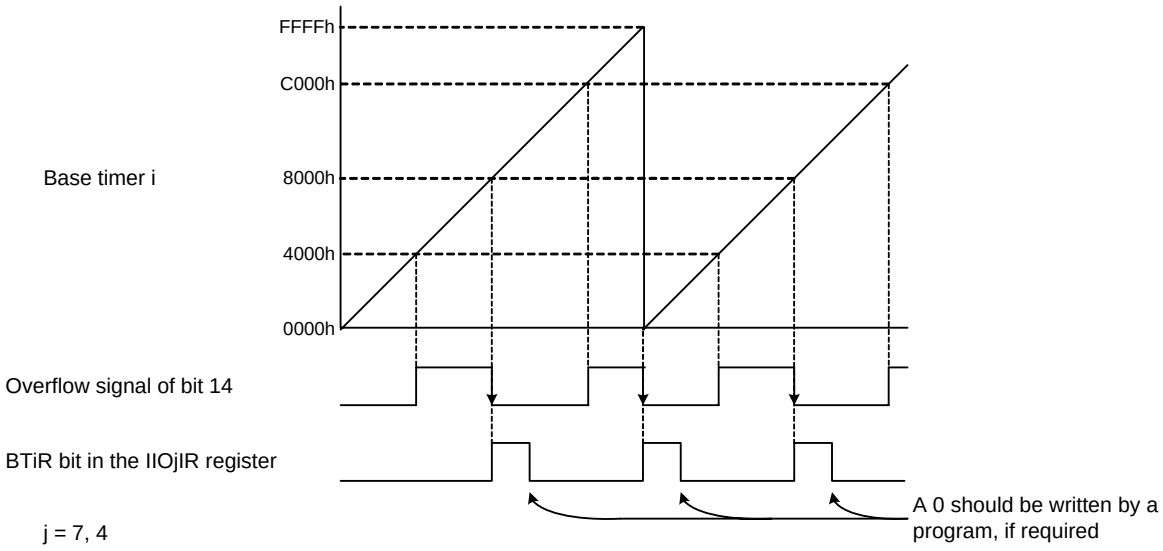
Bit configurations and functions vary with the groups.

(1) When the IT bit in the GiBCR0 register is set to 0
(an interrupt is requested by the overflow of bit 15 in the base timer)



The figure above applies under the following conditions:
- The RST1 bit in the GiBCR1 register is set to 0 (the match with the GiPO0 register is not the reset source for the base timer)
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)

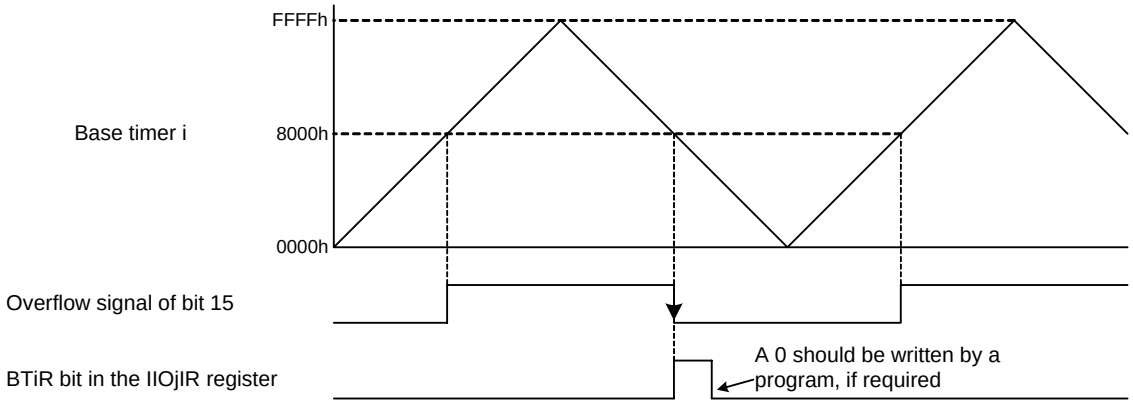
(2) When the IT bit in the GiBCR0 register is set to 1
(an interrupt is requested by the overflow of bit 14 in the base timer)



The figure above applies under the following conditions:
- The RST1 bit in the GiBCR1 register is set to 0 (the match with the GiPO0 register is not the reset source for the base timer)
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)

Figure 23.19 Base Timer Increment Counting Mode (i = 0, 1) (for Groups 0 and 1)

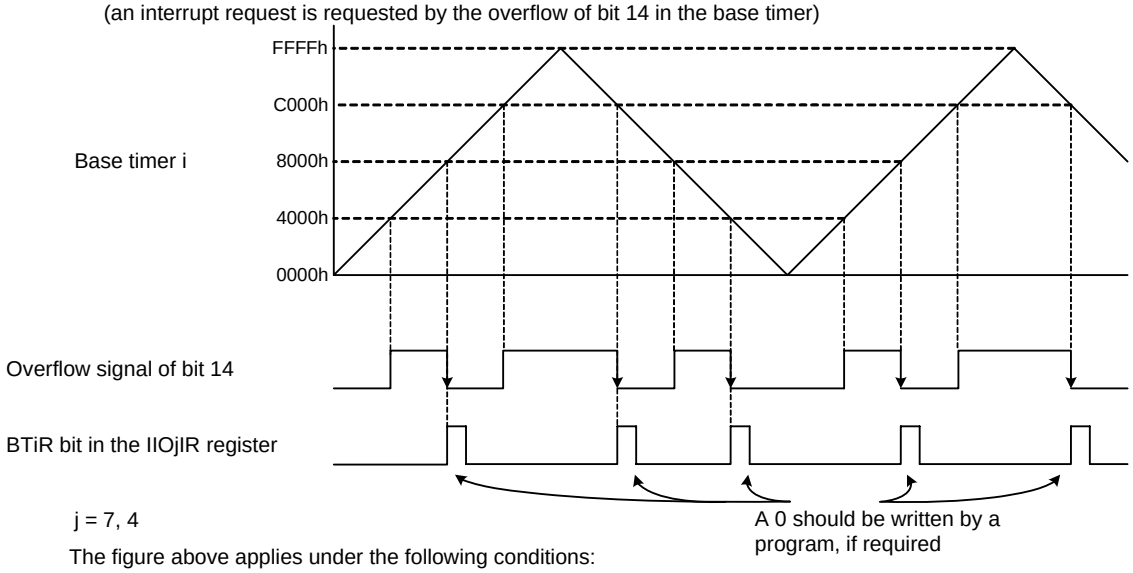
(1) When the IT bit in the GiBCR0 register is set to 0
(an interrupt is requested by the overflow of bit 15 in the base timer)



j = 7, 4

The figure above applies under the following conditions:
- The RST1 bit in the GiBCR1 register is set to 0 (the match with the GiPO0 register is not the reset source for the base timer)
- Bits UD1 and UD0 in the GiBCR1 register are set to 01b (increment/decrement counting mode)

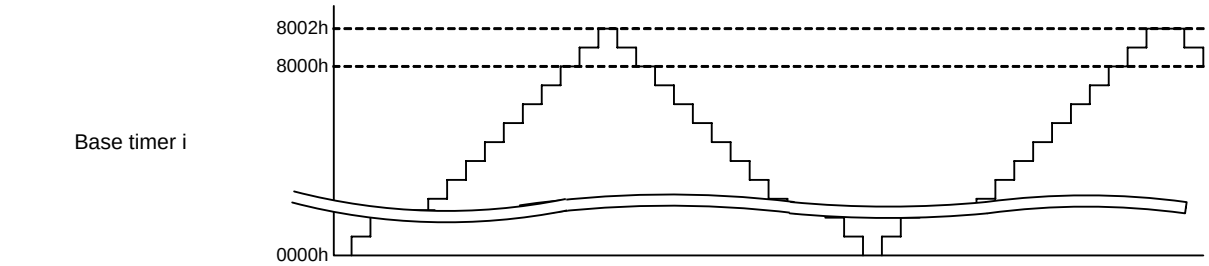
(2) When the IT bit in the GiBCR0 register is set to 1
(an interrupt request is requested by the overflow of bit 14 in the base timer)



j = 7, 4

The figure above applies under the following conditions:
- The RST1 bit in the GiBCR1 register is set to 0 (the match with the GiPO0 register is not the reset source for the base timer)
- Bits UD1 and UD0 in the GiBCR1 register are set to 01b (increment/decrement counting mode)

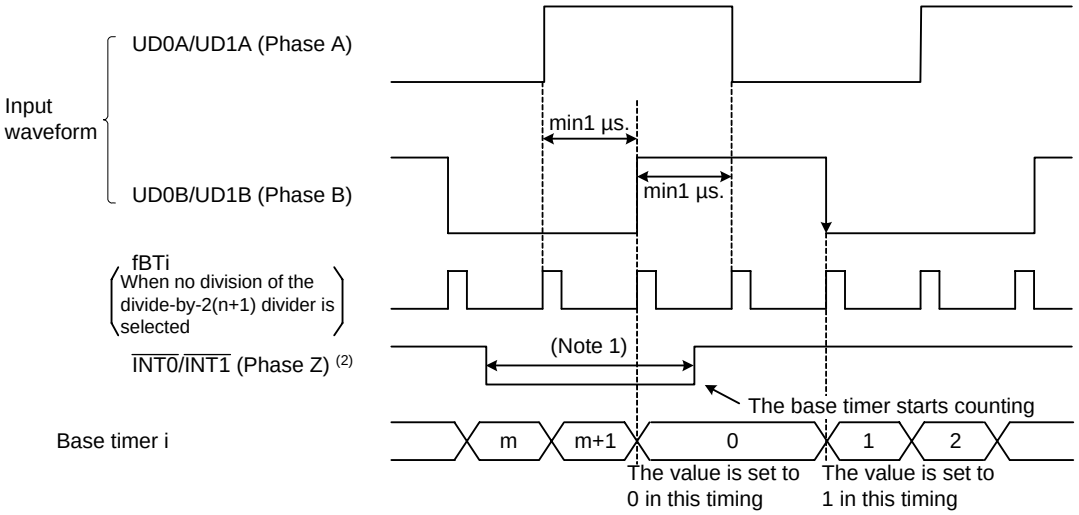
(3) When the RST bit in the GiBCR1 register is set to 1 (the base timer is reset by matching with the GiPO0 register)



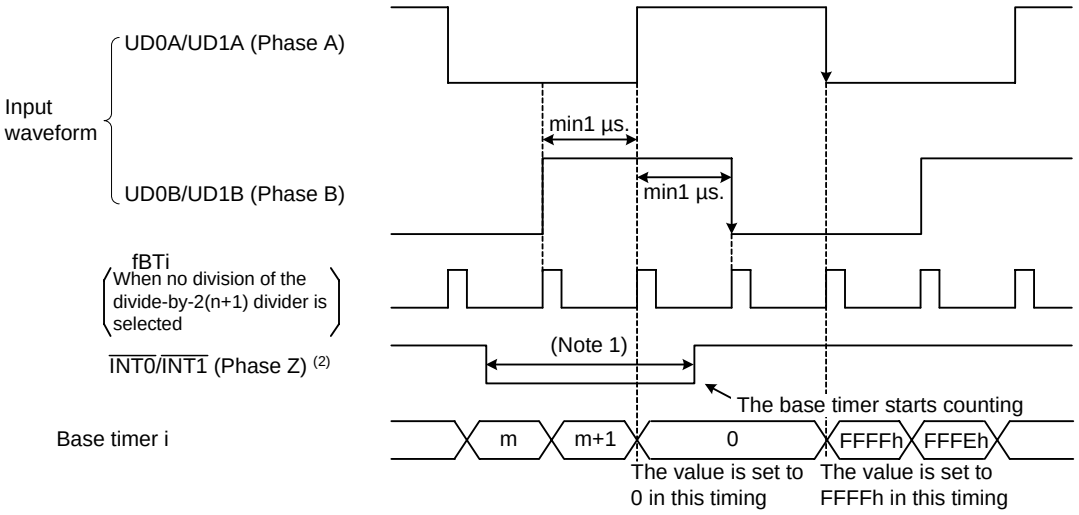
The figure above applies under the following conditions:
- The GiPO0 register value is set to 8000h
- Bits UD1 and UD0 in the GiBCR1 register are set to 01b (increment/decrement counting mode)

Figure 23.20 Base Timer Increment/Decrement Counting (i = 0, 1) (for Groups 0 and 1)

(1) When the base timer is reset while it increments the count



(2) When the base timer is reset while it decrements the count



Notes:
1. 1.5 fBTi clock cycles or more are required.
2. The RST2 bit in the GiBCR1 register should be set to 1 in two-phase pulse signal processing mode.

Figure 23.21 Base Timer Two-phase Pulse Signal Processing Mode (i = 0, 1) (for Groups 0 and 1)

23.2 Time Measurement (for Groups 0 and 1)

Every time an external trigger is input, the base timer value is stored into the GiTMj register (i = 0, 1; j = 0 to 7). Table 23.4 lists specifications of the time measurement and Table 23.5 lists its register settings. Figure 23.22 and Figure 23.23 show operation examples of the time measurement and Figure 23.24 shows operation examples with the prescaler or gate function.

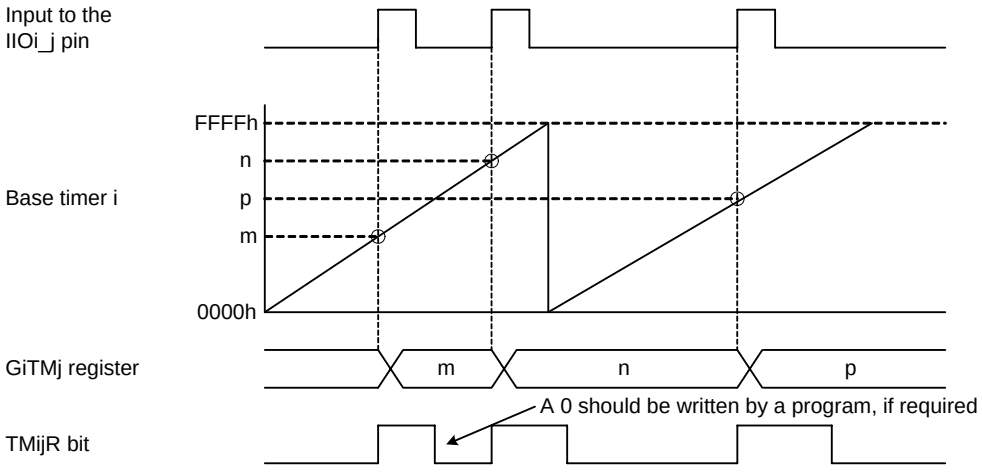
Table 23.4 Time Measurement Specifications (i = 0, 1; j = 0 to 7)

Item	Specification
Time measurement channels	Group 0: Channels 0 to 7 Group 1: Channels 0 to 7
Trigger input polarity	Rising edge, falling edge, or both edges of the IIOi_j pin
Time measurement start condition	The IFEj bit in the GiFE register is set to 1 (function for channel j enabled) while the FSCj bit in the GiFS register is set to 1 (time measurement selected)
Time measurement stop condition	The IFEj bit is set to 0 (function for channel j disabled)
Time measurement timing	• Without the prescaler: every time a trigger is input • With the prescaler (for channels 6 and 7): every (GiTPRk register (k = 6, 7) value + 1) times a trigger is input
Interrupt request	When the TMijR bit in the interrupt request register is set to 1 (interrupts requested) (Refer to Figure 11.12)
IIOi_j input pin function	Trigger input
Selectable functions	• Digital filter The digital filter determines a trigger input level every f1 or fBTi cycle and passes the signals holding the same level during three sequential cycles • Prescaler (for channels 6 and 7) Time measurement is executed every (GiTPRk register value + 1) times a trigger is input • Gating (for channels 6 and 7) This function disables any trigger input to be accepted after the time measurement by the first trigger input. However, the trigger input can be accepted again if any of following conditions are met while the GOC bit in the GiTMCRk register is set to 1 (the gating is cleared when the base timer matches the GiPOp register) (p = 4, 5; p = 4 when k = 6; p = 5 when k = 7): • The base timer value matches the GiPOp register setting • The GSC bit in the GiTMCRk register is set to 1

Table 23.5 Time Measurement (for Groups 0 and 1) Associated Register Settings (i = 0, 1; j = 0 to 7; k = 6, 7)

Register	Bits	Function
GiTMCRj	CTS1 and CTS0	Select a time measurement trigger
	DF1 and DF0	Select a digital filter
	GT, GOC, GSC	Select if the gating is used
	PR	Select if the prescaler is used
GiTPRk	—	Set the prescaler value
GiFS	FSCj	Set the bit to 1 (the time measurement selected)
GiFE	IFEj	Set the bit to 1 (function for channel j enabled)

Bit configurations and functions vary with the channels or groups.
Registers associated with the time measurement should be set after setting the base timer-associated registers.



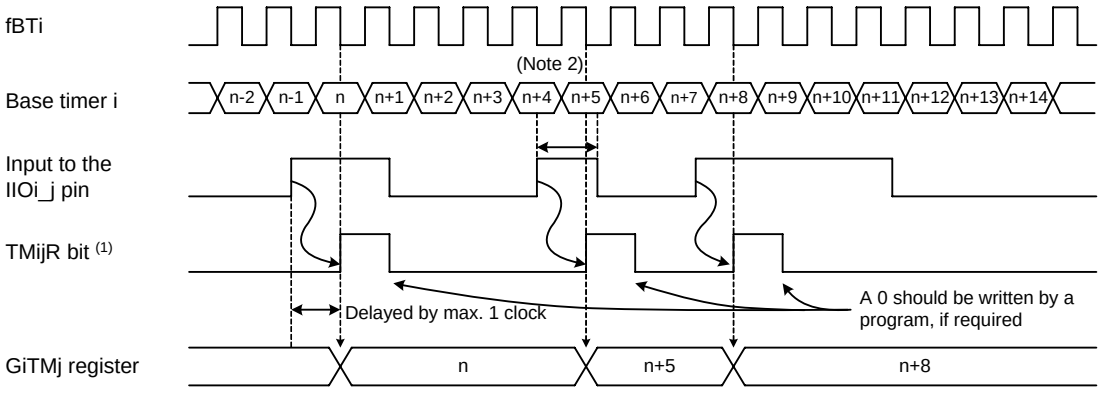
TMijR bit: Bit in registers IIO0IR to IIO11IR

This figure above applies under the following conditions:
- Bits CTS1 and CTS0 in the GiTMCRj register are set to 01b (rising edge as time measurement trigger), the PR bit is set to 0 (no prescaler is used) and the GT bit is set to 0 (no gating is used)
- Bits RST2 to RST0 in the GiBCR1 register are set to 000b (base timer is not reset) and bits UD1 and UD0 are set to 00b (increment counting mode)

The base timer reset by matching the GiPO0 register setting (bits RST2 to RST0 in the GiBCR1 register are set to 010b) is done after the base timer reaches the GiPO0 register setting value + 2.

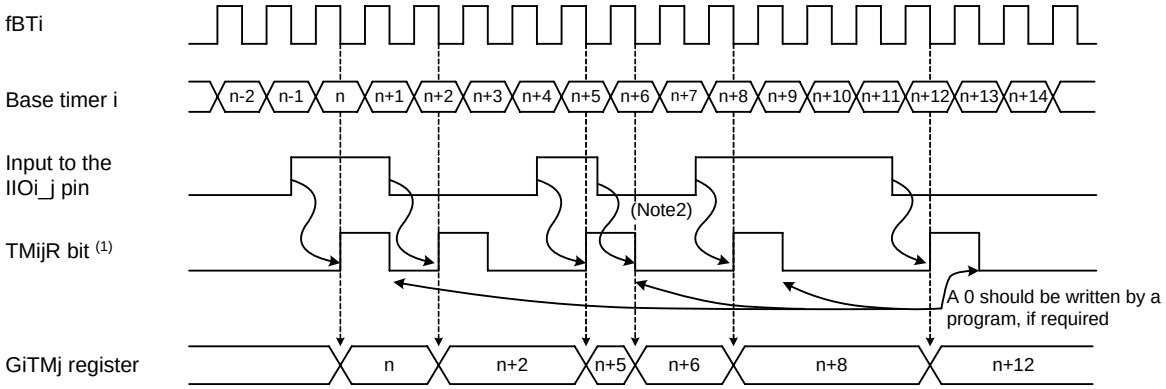
Figure 23.22 Time Measurement Operation (1) (i = 0, 1; j = 0 to 7)

Case 1: When selecting the rising edge as a time measurement trigger
(Bits CTS1 and CTS0 in the GiTMCRj register are set to 01b)



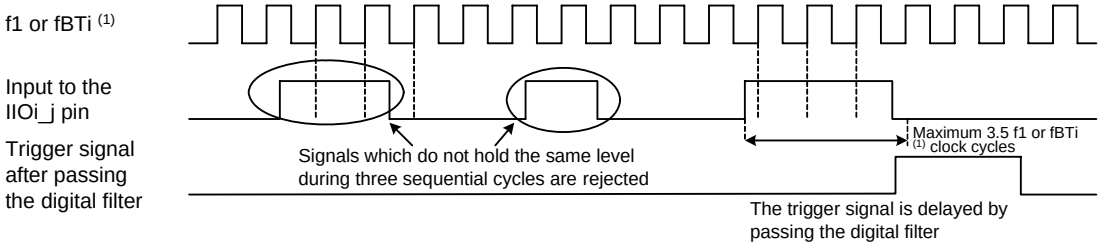
Notes:
1. Bit in registers IIO0IR to IIO11IR
2. Input pulse applied to the IIOi_j pin requires 1.5 fBTi clock cycles or more.

Case 2: When selecting both edges as a time measurement trigger
(Bits CTS1 and CTS0 in the GiTMCRj register are set to 11b)



Notes:
1. Bit in registers IIO0IR to IIO11IR
2. No interrupt is generated if the MCU receives a trigger signal when the TMijR bit is set to 1. However, the value of GiTMj register changes.

Case 3: Trigger signal when using the digital filter
(Bits DF1 and DF0 in the GiTMCRj register are set to 10b or 11b)

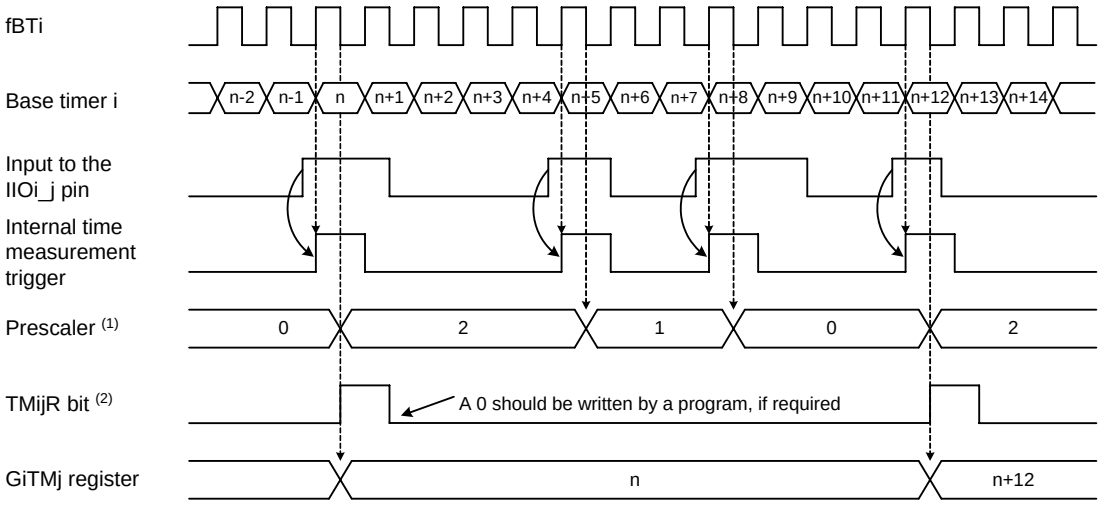


Note:
1. fBTi when bits DF1 and DF0 are set to 10b, f1 when the bits are set to 11b.

Figure 23.23 Time Measurement Operation (2) (i = 0, 1; j = 0 to 7)

Case 1: Operation with the prescaler

(The GiTPRj register is set to 02h and the PR bit in the GiTMCRj register is set to 1)

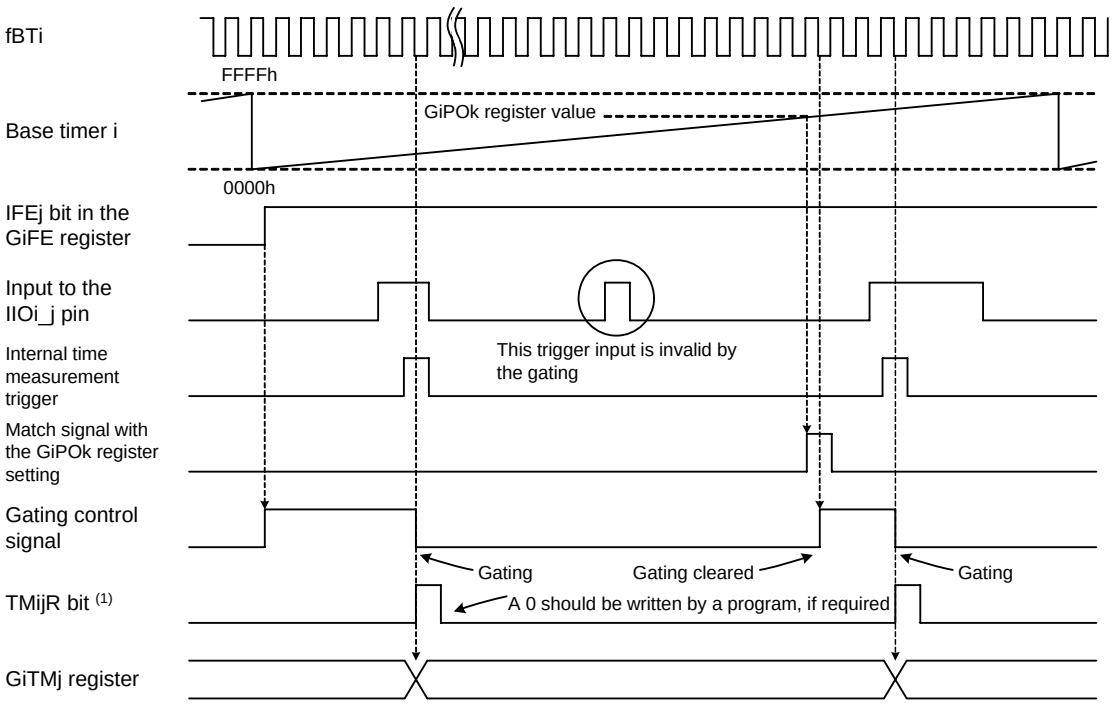


Notes:

1. This example applies to cycles following the first cycle after the PR bit in the GiTMCRj register is set to 1 (the prescaler is used)
2. Bit in registers IIO0IR to IIO11IR

Case 2: Operation with the gating

(The gating is cleared by matching the base timer value with the GiPOk register setting. Bits GT and GOC in the GiTMCRj register are respectively set to 1)



Note:

1. Bit in registers IIO0IR to IIO11IR

Figure 23.24 Prescaler and Gate Operations (i = 0, 1; j = 6, 7)

23.3 Waveform Generation (for Groups 0 to 2)

Waveforms are generated when the base timer value matches the GiPOj register setting (i = 0 to 2; j = 0 to 7).

Waveform generation has the following six modes:

- Single-phase waveform output mode (for groups 0 to 2)
- Inverted waveform output mode (for groups 0 to 2)
- Set/reset waveform output (SR waveform output) mode (for groups 0 to 2)
- Bit modulation PWM output mode (for group 2)
- Real-time port output (RTP output) mode (for group 2)
- Parallel real-time port output (parallel RTP output) mode (for group 2)

Table 23.6 lists registers associated with the waveform generation.

Table 23.6 Waveform Generation Associated Register Settings (i = 0 to 2; j = 0 to 7)

Register	Bits	Function
GiPOCRj	MOD2 to MOD0	Select a waveform output mode
	PRT (1)	Set the bit to 1 to use parallel RTP output mode
	IVL	Select a default value
	RLD	Select a timing to reload the value into the GiPOj register
	RTP (1)	Set the bit to 1 to use RTP output mode or parallel RTP output mode. The settings of bits MOD2 to MOD0 are disabled when this bit is set to 1
	INV	Select if output level is inverted
G2BCR1	PRP	Set the bit to 1 to use parallel RTP output mode
GiPOj	—	Set the timing to invert output waveform
GiFS	FSCj	Set the bit to 0 (the waveform generation selected) (for groups 0 and 1 only)
GiFE	IFEj	Set the bit to 1 (the function for channel j enabled)
G2RTP	RTP0 to RTP7	Set the RTP output value in RTP output mode or parallel RTP output mode

Bit configurations and functions vary with channels or groups.

Registers associated with the waveform generation should be set after setting the base timer-associated registers.

Note:

1. This bit is available in the G2POCRj register only. Neither the G0POCRj nor G1POCRj register has it.

23.3.1 Single-phase Waveform Output Mode (for Groups 0 to 2)

The output level at the IIOi_j pin (or OUTC2_j pin for Group 2) becomes high when the base timer value matches the GiPOj register (i = 0 to 2; j = 0 to 7). It switches to low when the base timer reaches 0000h. If the IVL bit in the GiPOCRj register is set to 1 (high level is output as default value), a high level output is provided when a waveform output starts. If the INV bit is set to 1 (output level is inverted), a waveform with inverted level is output. Refer to Figure 23.25 for details on single-phase waveform mode operation.

Table 23.7 lists specifications of single-phase waveform output mode.

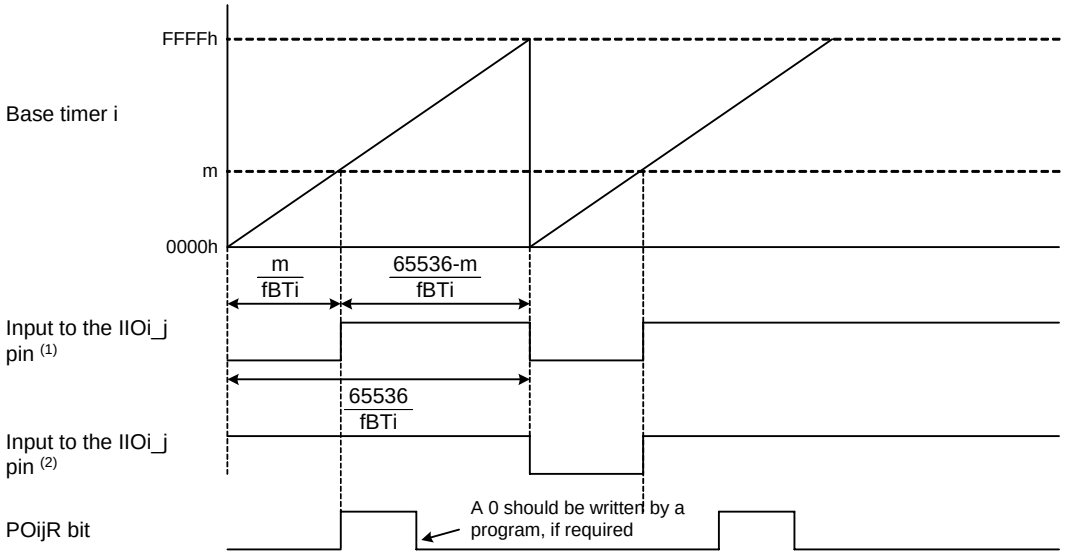
Table 23.7 Single-phase Waveform Output Mode Specifications (i= 0 to 2)

Item	Specification
Output waveform (1)	• Free-running operation (when bits RST2 to RST0 in the GiBCR1 register are set to 000b) Cycle: $\frac{65536}{fBTi}$ Low level width: $\frac{m}{fBTi}$ High level width: $\frac{65536 - m}{fBTi}$ m: GiPOj register (j = 0 to 7) setting value, 0000h to FFFFh • The base timer is reset by matching the base timer value with the GiPO0 register setting (when bits RST2 to RST0 are set to 010b) Cycle: $\frac{n + 2}{fBTi}$ Low level width: $\frac{m}{fBTi}$ High level width: $\frac{n + 2 - m}{fBTi}$ m: GiPOj register (j = 1 to 7) setting value, 0000h to FFFFh n: GiPO0 register setting value, 0001h to FFFDh If m ≥ n + 2, the output level is fixed to low
Waveform output start condition (2)	The IFEj (j = 0 to 7) bit in the GiFE register is set to 1 (the function for channel j is enabled)
Waveform output stop condition	The IFEj bit is set to 0 (the function for channel j is disabled)
Interrupt request	When the POijR bit in the intelligent I/O interrupt request register is set to 1 (interrupts requested) by matching the base timer value with the GiPOj register setting (Refer to Figure 11.12)
IIOi_j output pin (or OUTC2_j pin for Group 2) function	Pulse signal output
Selectable functions	• Default value setting This function determines the starting waveform output level • Output level inversion This function inverts the waveform output level and output the inverted signal from the IIOi_j pin (or OUTC2_j pin for Group 2)

Notes:

1. When the INV bit in the GiPOCRj register is set to 1 (output level is inverted), widths low and high are inverted.
2. To use channels shared by time measurement and waveform generation, the FSCj bit in the GiFS register should be set to 0 (waveform generation is selected).

Case 1: Free-running operation (Bits RST2 to RST0 in the GiBCR register are set to 000b)

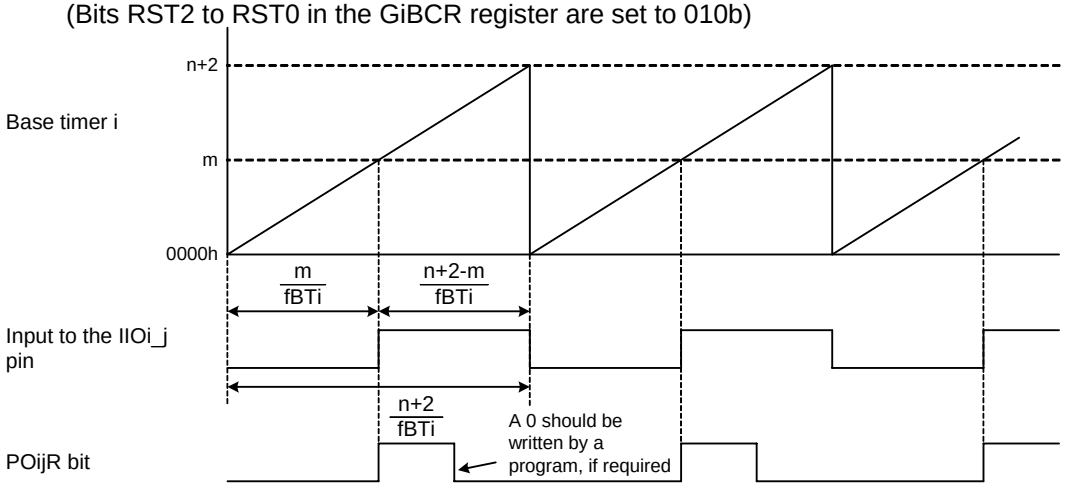


j = 0 to 7
m: GiPOj register setting value (0000h to FFFFh)
POijR bit: Bit in registers IIO0IR to IIO11IR

Notes:
1. Output waveform when the INV bit in the GiPOCRj register is set to 0 (output level is not inverted) and the IVL bit is set to 0 (low level is output as default value).
2. Output waveform when the INV bit is set to 0 (output level is not inverted) and the IVL bit is set to 1 (high level is output as default value).

This figure above applies under the following condition:
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)

Case 2: The base timer is reset by matching the base timer value with the GiPO0 register setting (Bits RST2 to RST0 in the GiBCR register are set to 010b)



j = 1 to 7
m: GiPOj register setting value (0000h to FFFFh)
n: GiPO0 register setting value (0001h to FFFDh)
POijR bit: Bit in registers IIO0IR to IIO11IR

This figure above applies under the following conditions:
- The IVL bit in the GiPOCRj register is set to 0 (low level is output as default value) and the INV bit is set to 0 (output is not inverted)
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)
- m < n+2

Figure 23.25 Single-phase Waveform Output Mode Operation (i = 0 to 2)

23.3.2 Inverted Waveform Output Mode (for Groups 0 to 2)

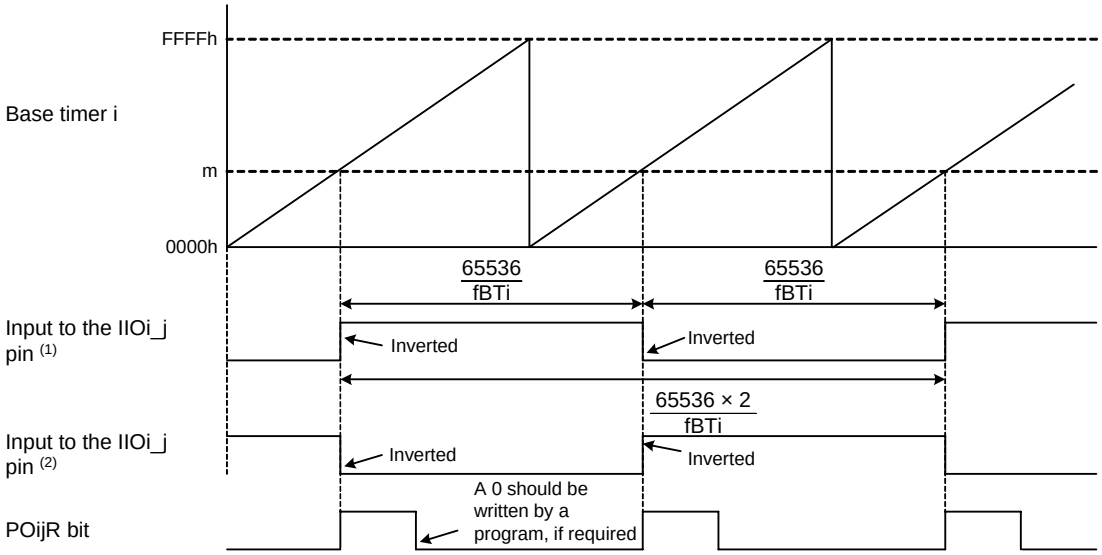
The output level at the IIOi_j pin (or OUTC2_j pin for Group 2) is inverted every time the base timer value matches the GiPOj register setting (i = 0 to 2; j = 0 to 7).
Table 23.8 lists specifications of the inverted waveform output mode. Figure 23.26 shows an example of the inverted waveform output mode operation.

Table 23.8 Inverted Waveform Output Mode Specifications (i = 0 to 2)

Item	Specification
Output waveform	• Free-running operation (when bits RST2 to RST0 in the GiBCR1 register are set to 000b) Cycle: $\frac{65536 \times 2}{fBTi}$ High or low level width: $\frac{65536}{fBTi}$ m: GiPOj register (j = 0 to 7) setting value, 0000h to FFFFh • The base timer is reset by matching the base timer value with the GiPO0 register setting (when bits RST2 to RST0 are set to 010b) Cycle: $\frac{2(n+2)}{fBTi}$ High or low level width: $\frac{n+2}{fBTi}$ n: GiPO0 register setting value, 0001h to FFFDh GiPOj register (j = 1 to 7) setting value, 0000h to FFFFh If the GiPOj register setting ≥ n+2, the output level is not inverted
Waveform output start condition (1)	The IFEj bit in the GiFE register (j = 0 to 7) is set to 1 (the function for channel j is enabled)
Waveform output stop condition	The IFEj bit is set to 0 (the function for channel j is disabled)
Interrupt request	When the POijR bit in the intelligent I/O interrupt request register is set to 1 (interrupts requested) by matching the base timer value with the GiPOj register setting (Refer to Figure 11.12)
IIOi_j output pin (or OUTC2_j pin for Group 2) function	Pulse signal output
Selectable functions	• Default value setting This function determines the starting waveform output level • Output level inversion This function inverts the waveform output level and outputs the inverted signal from the IIOi_j pin (or OUTC2_j pin for Group 2)

Note:
1. To use channels shared by time measurement and waveform generation, the FSCj bit in the GiFS register should be set to 0 (waveform generation is selected).

Case 1: Free-running operation (Bits RST2 to RST0 in the GiBCR1 register are set to 000b)

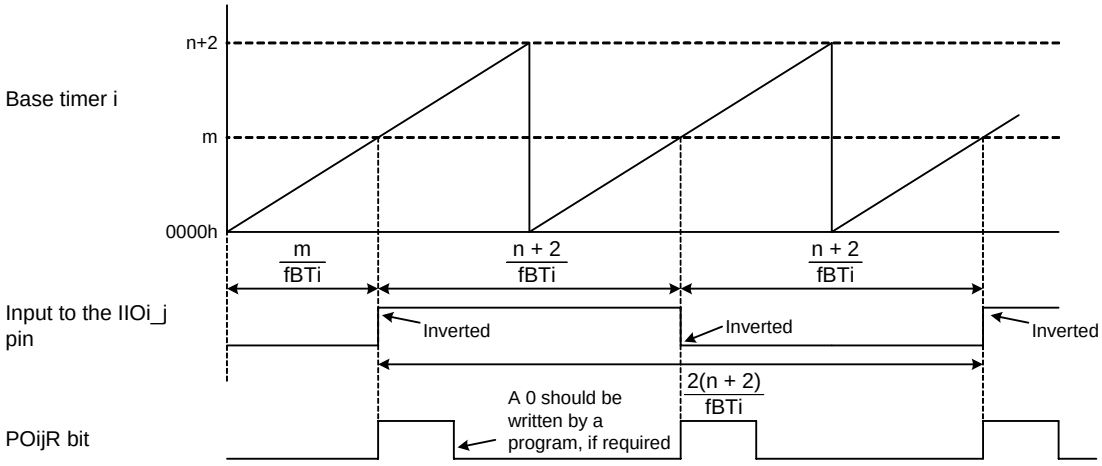


j = 0 to 7
m: GiPOj register setting value (0000h to FFFFh)
POijR bit: Bit in registers IIO0IR to IIO11IR

Notes:
1. Output waveform when the INV bit in the GiPOCRj register is set to 0 (output is not inverted) and the IVL bit is set to 0 (low level is output as default value).
2. Output waveform when the INV bit is set to 0 (output is not inverted) and the IVL bit is set to 1 (high level is output as default value).

This figure above applies under the following condition:
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)

Case 2: The base timer is reset by matching the base timer value with the GiPO0 register setting (Bits RST2 to RST0 are set to 010b)



j = 1 to 7
m: GiPOj register setting value (0000h to FFFFh)
n: GiPO0 register setting value (0001h to FFFDh)
POijR bit: Bit in registers IIO0IR to IIO11IR

This figure above applies under the following conditions:
- The IVL bit in the GiPOCRj register is set to 0 (low level is output as default value) and the INV bit is set to 0 (output is not inverted)
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)
- m < n+2

Figure 23.26 Inverted Waveform Output Mode Operation (i = 0 to 2)

23.3.3 Set/Reset Waveform Output Mode (SR Waveform Output Mode) (for Groups 0 to 2)

The output level at the IIOi_j pin (or OUTC2_j pin for Group 2) becomes high when the base timer value matches the GiPOj register setting (i = 0 to 2; j = 0, 2, 4, 6). It switches to low when the base timer value matches the GiPOk register setting (k = j + 1) or the base timer reaches 0000h. If the IVL bit in the GiPOCRj register (j = 0 to 7) is set to 1 (high level is output as default value), a high output level is provided when a waveform output starts. If the INV bit is set to 1 (output level is inverted), a waveform with inverted level is output. Refer to Figure 23.27 for details on SR waveform mode operation. Table 23.9 lists specifications of SR waveform output mode.

Table 23.9 SR Waveform Output Mode Specifications (i = 0 to 2)

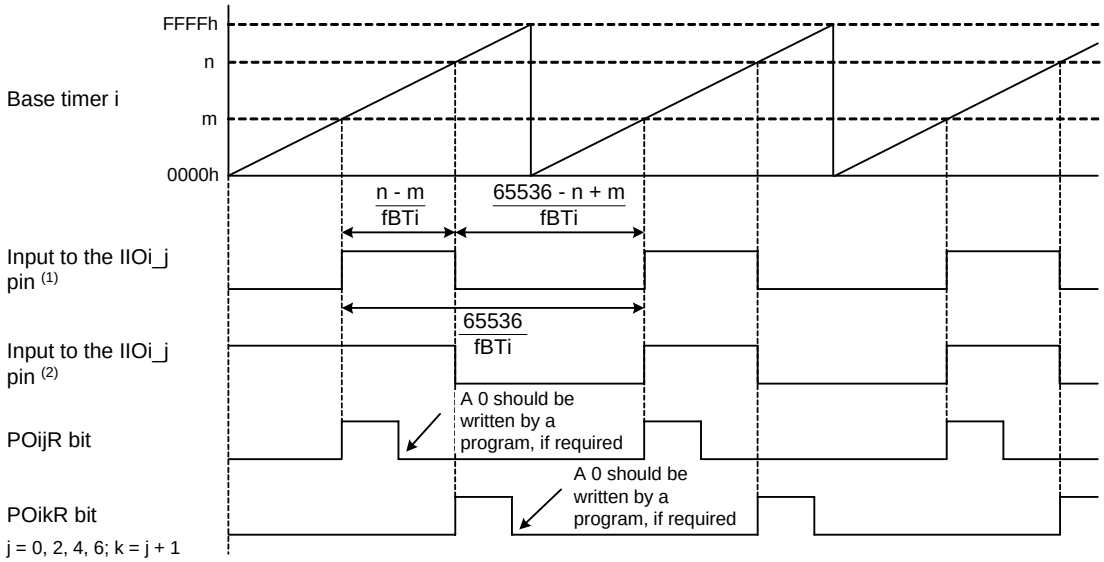
Item	Specification
Output waveform (1)	• Free-running operation (when bits RST2 to RST0 in the GiBCR1 register are set to 000b) (1) m < n High level width: $\frac{n-m}{fBTi}$ Low level width: $\frac{m}{fBTi}$ (2) + $\frac{65536-n}{fBTi}$ (3) (2) m ≥ n High level width: $\frac{65536-m}{fBTi}$ Low level width: $\frac{m}{fBTi}$ m: GiPOj register (j = 0, 2, 4, 6) setting value, 0000h to FFFFh n: GiPOk register (k = j + 1) setting value, 0000h to FFFFh • The base timer is reset by matching the base timer value with the GiPO0 register setting (when bits RST2 to RST0 are set to 010b) (4) (1) m < n < p+2 High level width: $\frac{n+m}{fBTi}$ Low width: $\frac{m}{fBTi}$ (2) + $\frac{p+2-n}{fBTi}$ (3) (2) m < p+2 ≤ n High level width: $\frac{p+2-m}{fBTi}$ Low level width: $\frac{m}{fBTi}$ (3) m ≥ p+2, output level is fixed to low p: GiPO0 register setting value, 0001h to FFFDh m: GiPOj register (j = 2, 4, 6) setting value, 0000h to FFFFh n: GiPOk register (k = j + 1) setting value, 0000h to FFFFh
Waveform output start Condition (5)	The IFEq bit (q = 0 to 7) in the GiFE register is set to 1 (the function for channel q is enabled)
Waveform output stop condition	The IFEq bit is set to 0 (the function for channel q is disabled)

Table 23.9 SR Waveform Output Mode Specifications (i = 0 to 2)

Item	Specification
Interrupt request	When the POijR bit in the intelligent I/O interrupt request register is set to 1 (interrupts requested) by matching the base timer value with the GiPOj register setting. When the POikR bit is set to 1 (interrupts requested) by matching the base timer value with the GiPOk register setting (refer to Figure 11.12)
IIOi_j output pin (or OUTC2_j pin for Group 2) function	Pulse signal output
Selectable functions	• Default value setting This function determines the starting waveform output level • Output level inversion This function inverts the waveform output level and output the inverted signal from the IIOi_j pin (or OUTC2_j pin for Group 2)

Notes:
1. When the INV bit in the GiPOCRj register is set to 1 (output is inverted), widths low and high are inverted.
2. Output period from a base timer reset until when the output level becomes high.
3. Output period from when the output level becomes low until the next base timer reset.
4. When the GiPO0 register resets the base timer, channels 0 and 1 SR waveform generation functions are not available.
5. To use channels shared by time measurement and waveform generation, the FSCj bit in the GiFS register should be set to 0 (waveform generation is selected).

Case 1: Free-running operation (Bits RST2 to RST0 in the GiBCR1 register are set to 000b)

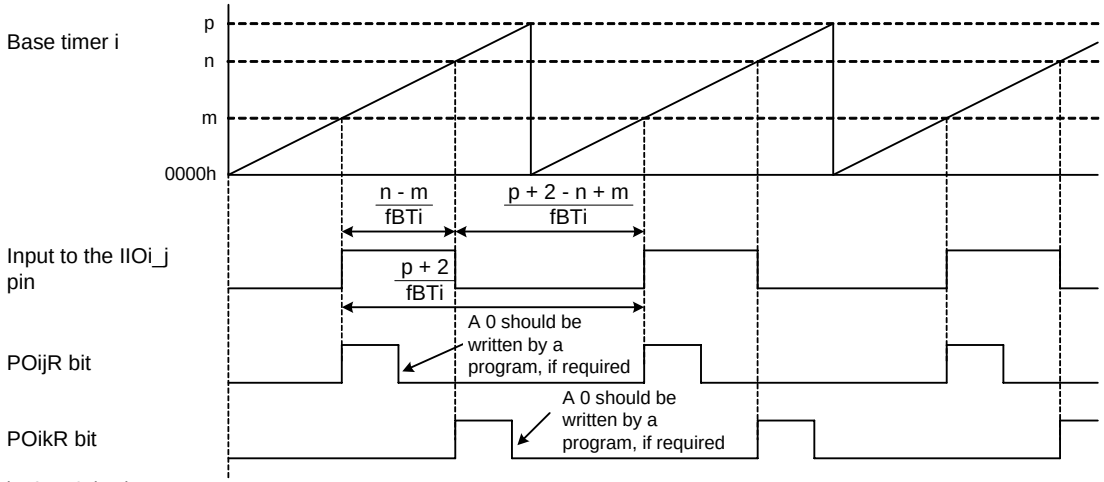


j = 0, 2, 4, 6; k = j + 1
m: GiPOj register setting value, 0000h to FFFFh
n: GiPOk register setting value, 0000h to FFFFh
POijR bit, POikR bit: Bits in registers IIO0IR to IIO11IR

Notes:
1. Output waveform when the INV bit in the GiPOCRj register is set to 0 (output is not inverted) and the IVL bit is set to 0 (low level is output as default value).
2. Output waveform when the INV bit is set to 0 (output is not inverted) and the IVL bit is set to 1 (high level is output as default value).

This figure above applies under the following conditions:
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)
- m < n

Case 2: The base timer is reset by matching the base timer value with the GiPO0 register setting (Bits RST2 to RST0 in the GiBCR1 register are set to 010b)



j = 2, 4, 6; k = j + 1
m: GiPOj register setting value, 0000h to FFFFh
n: GiPOk register setting value, 0000h to FFFDh
p: GiPO0 register setting value, 0001h to FFFDh
POijR bit, POikR bit: Bits in registers IIO0IR to IIO11IR

This figure above applies under the following conditions:
- The IVL bit is set to 0 (low level is output as default value) and the INV bit is set to 0 (output is not inverted).
- Bits UD1 and UD0 in the GiBCR1 register are set to 00b (increment counting mode)
- m < n < p + 2

Figure 23.27 SR Waveform Output Mode Operation (i = 0 to 2)

23.3.4 Bit Modulation PWM Output Mode (for Group 2)

In bit modulation PWM output mode, a PWM output has a 16-bit resolution.
Pulses are output in repetitive cycles, each cycle consisting of span t repeated 1024 times. The span t has a cycle of $\frac{64}{fBT2}$. The six upper bits in the G2POj register (j = 0 to 7) determine the base low width.
The ten lower bits determine the number of span t, within a cycle, in which low width is extended by the minimum resolution bit width, that is, 1 clock cycle.
If the INV bit is set to 1 (output level is inverted), the waveform with inverted level is output.
Table 23.10 lists specifications of bit modulation PWM output mode. Table 23.11 lists the number of modulated spans and span ts to be extended with the minimum resolution bit width. Figure 23.28 shows an example of bit modulation PWM output mode operation.

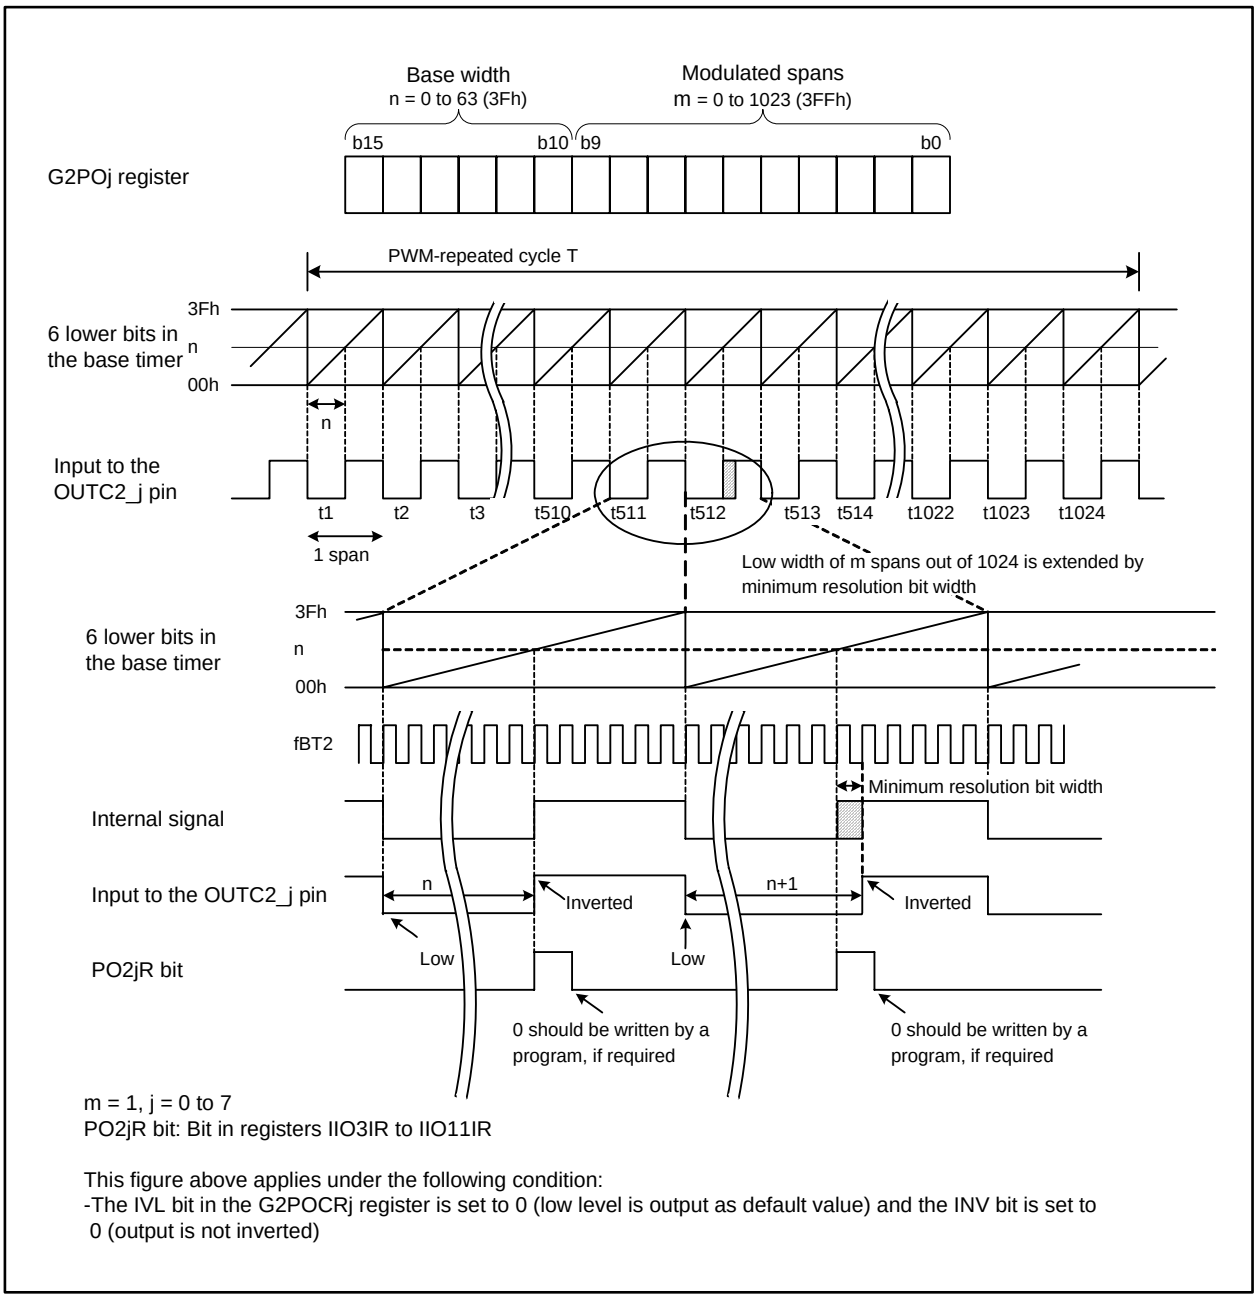
Table 23.10 Bit Modulation PWM Output Mode Specifications

Item	Specification
Output waveform (1, 2)	PWM-repeated cycle T: $\frac{65536}{fBT2}$ (= $\frac{64}{fBT2}$ × 1024) Cycle of span t: $\frac{64}{fBT2}$ Low width: $\frac{n+1}{fBT2}$ of m spans $\frac{n}{fBT2}$ of (1024-m) spans Mean low width: $\frac{1}{fBT2}$ × (n + $\frac{m}{1024}$) n: G2POj register (j = 0 to 7) setting value (6 upper bits), 00h to 3Fh m: G2POj register (j = 0 to 7) setting value (10 lower bits), 000h to 3FFh
Waveform output start condition	The IFEj bit in the G2FE register (j = 0 to 7) is set to 1 (the function for channel j is enabled)
Waveform output stop condition	The IFEj bit is set to 0 (the function for channel j is disabled)
Interrupt request	When the PO2jR bit in the interrupt request register is set to 1 (interrupts requested) by matching the 6 lower bits of the base timer value with the 6 upper bits of the G2POj register setting (Refer to Figure 11.12)
OUTC2_j pin function	Pulse signal output pin
Selectable functions	• Default value setting This function determines the starting waveform output level • Output level inversion This function inverts the waveform output level and output the inverted signal from the OUTC2_j pin

Notes:
1. Bits RST2 and RST0 in the G2BCR1 register should be set to 000b to use bit modulation PWM output mode.
2. When the INV bit in the G2POCRj register is set to 1 (output level is inverted), widths low and high are inverted.

Table 23.11 Number of Modulated Spans and Span t Extended Minimum Resolution Bit Width

Modulated Spans	Span ts to be Extended with Minimum Resolution Bit Width
00 0000 0000b	none
00 0000 0001b	t512
00 0000 0010b	t256 and t768
00 0000 0100b	t128, t384, t640, and t896
00 0000 1000b	t64, t192, t320, t448, t576, t704, t832, and t960
:	:
10 0000 0000b	t1, t3, t5, t7, ••• t1019, t1021, and t1023



m = 1, j = 0 to 7
PO2jR bit: Bit in registers IIO3IR to IIO11IR

This figure above applies under the following condition:
-The IVL bit in the G2POCRj register is set to 0 (low level is output as default value) and the INV bit is set to 0 (output is not inverted)

Figure 23.28 Bit Modulation PWM Output Mode Operation

23.3.5 Real-Time Port Output Mode (RTP Output Mode) (for Group 2)

The OUTC2_j pin (j = 0 to 7) outputs the G2RTP register setting value in one-bit units when the base timer value matches the G2POj register setting. Table 23.12 lists specifications of RTP output mode. Figure 23.29 shows a block diagram of RTP output and Figure 23.30 shows an example of RTP output mode operation.

Table 23.12 RTP Output Mode Specifications

Item	Specification
Waveform output start condition	The IFEj bit (j = 0 to 7) in the G2FE register is set to 1 (the function for channel j is enabled)
Waveform output stop condition	The IFEj bit is set to 0 (the function for channel j is disabled)
Interrupt request	When the PO2jR bit in the interrupt request register is set to 1 (interrupts requested) by matching the base timer value with the G2POj register setting (0000h to FFFFh (1)) (Refer to Figure 11.12)
OUTC2_j pin function	RTP output pin
Selectable functions	• Default value setting This function determines the starting waveform output level • Output level inversion This function inverts the waveform output level and output the inverted signal from the OUTC2_j pin

Note:
1. The G2PO0 register should be set to between 0001h and FFFDh to set the base timer value to 0000h (bits RST2 to RST0 are set to 010b) when the base timer value matches the G2PO0 register setting.

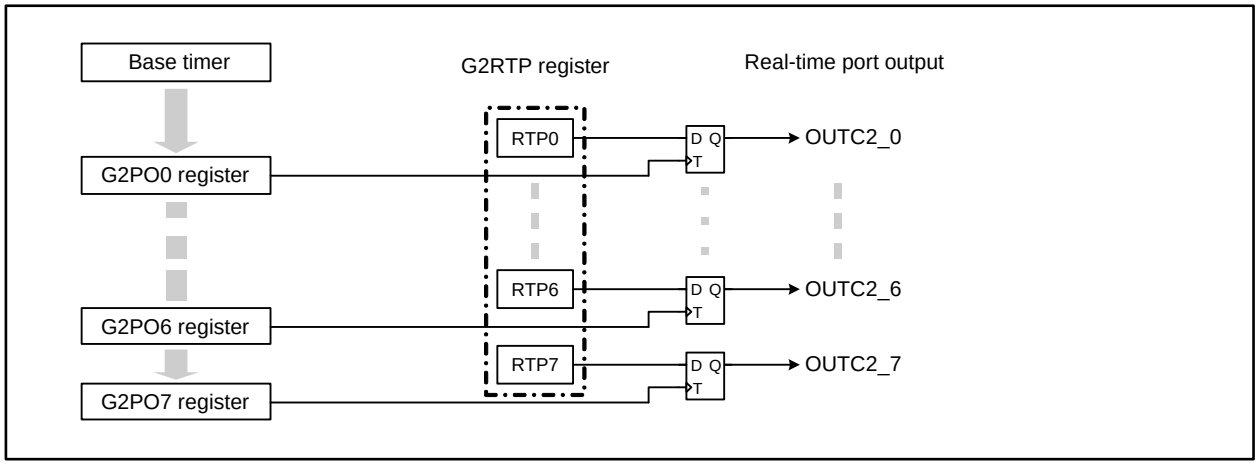


Figure 23.29 RTP Output Block Diagram

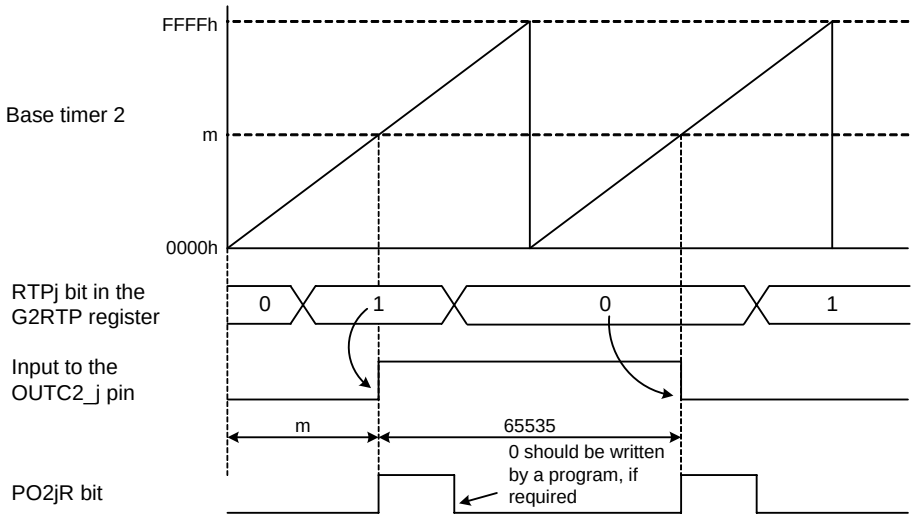
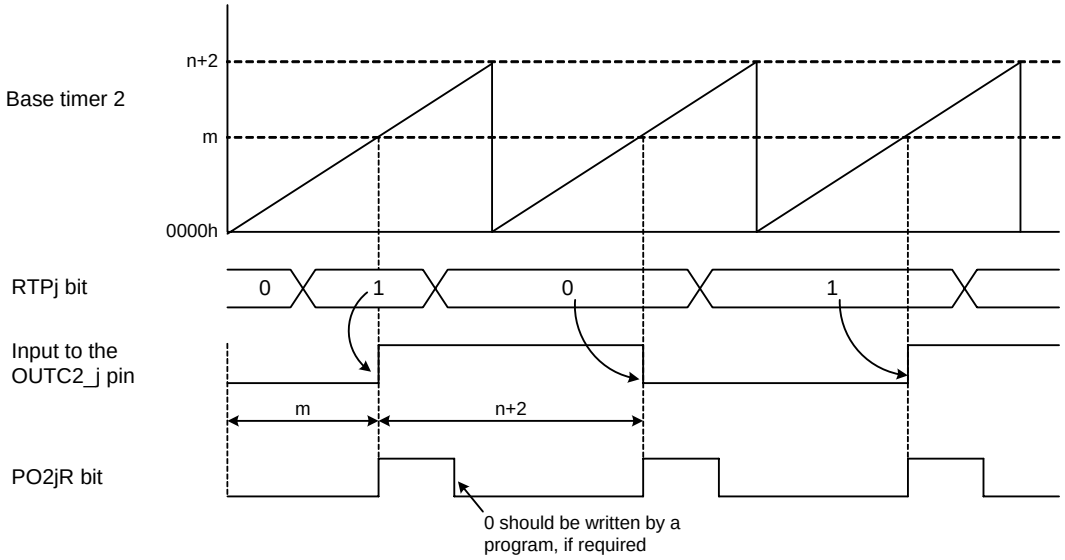
Case 1: Free-running operation (Bits RST2 to RST0 in the G2BCR1 register are set to 000b)



j = 0 to 7
m: G2POj register setting value, 0000h to FFFFh
PO2jR bit: Bit in registers IIO03R to IIO11IR

This figure above applies under the following conditions:
-The IVL bit in the G2POCRj register is set to 0 (low level is output as default value) and the INV bit is set to "0" (output is not inverted).
-Bits RST2 to RST0 in the G2BCR1 register are set to 000b (base timer is not reset)

Case 2: The base timer is reset by matching the base timer value with the G2PO0 register setting (Bits RST2 to RST0 are set to 010b)



j = 1 to 7
m: G2POj register setting value, 0000h to FFFFh
n: G2POj register setting value, 0001h to FFFDh
PO2jR bit: Bit in registers IIO03R to IIO11IR

This figure above applies under the following conditions:
-The IVL bit in the G2POCRj register is set to 0 (low level is output as default value) and the INV bit is set to 0 (output level is not inverted)
-m < n + 2

Figure 23.30 RTP Output Mode Operation

23.3.6 Parallel Real-Time Port Output Mode (RTP Output Mode) (for Group 2)

The OUTC2_j pin (j = 0 to 7) outputs all the G2RTP register setting values in one-byte units when the base timer value matches the G2POj register setting. Table 23.13 lists specifications of parallel RTP output mode. Figure 23.7 shows the G2BCR1 register. Figure 23.31 shows a block diagram of parallel RTP output and Figure 23.32 shows an example of parallel RTP output mode operation.

Table 23.13 Parallel RTP Output Mode Specifications

Item	Specification
Waveform output start condition	The IFEj bit (j = 0 to 7) in the G2FE register is set to 1 (the function for channel j is enabled)
Waveform output stop Condition	The IFEj bit is set to 0 (the function for channel j is disabled)
Interrupt request	When the PO2jR bit in the interrupt request register is set to 1 (interrupts requested) by matching the base timer value with the G2POj register setting (0000h to FFFFh (1)) (Refer to Figure 11.12)
OUTC2_j pin function	RTP output pin
Selectable functions	• Default value setting This function determines the starting waveform output level • Output level inversion This function inverts the waveform output level and output the inverted signal from the OUTC2_j pin

Note:
1. The G2PO0 register should be set to between 0001h and FFFDh to set the base timer value to 0000h (bits RST2 to RST0 are set to 010b) when the base timer value matches the G2PO0 register setting.

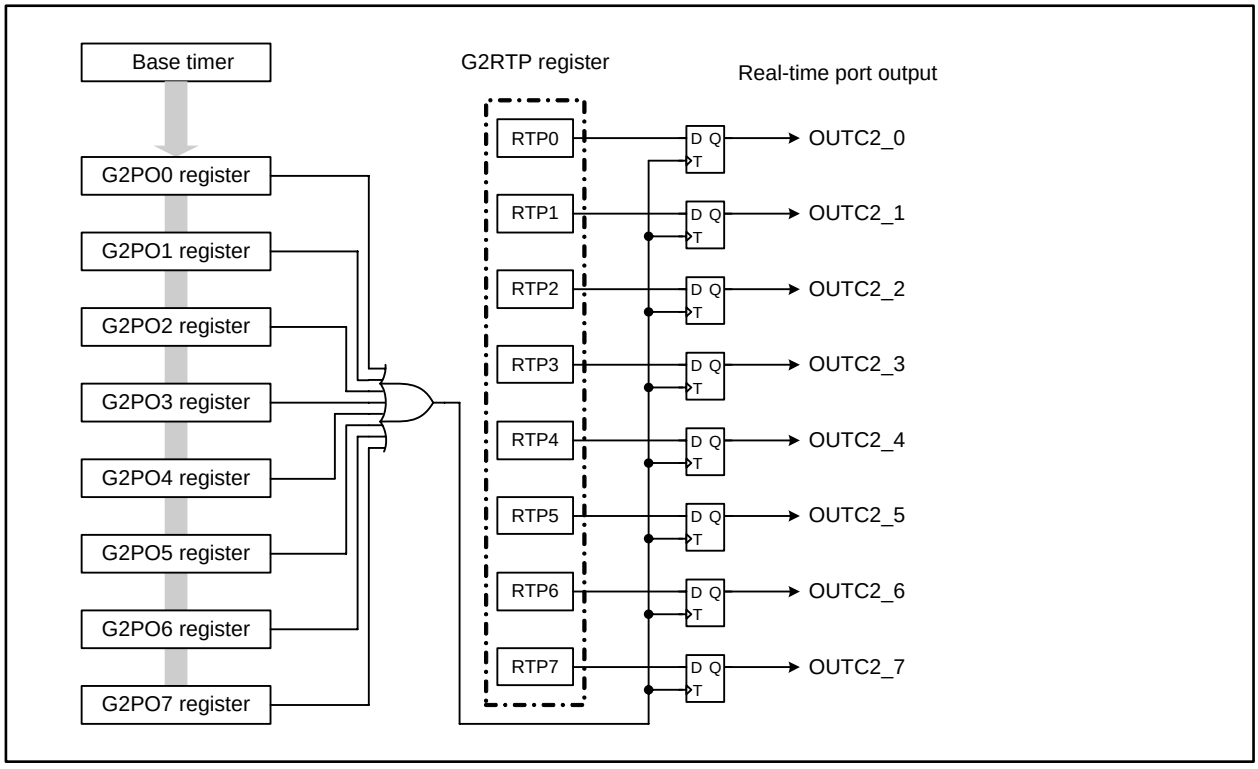


Figure 23.31 Parallel RTP Output Mode Block Diagram

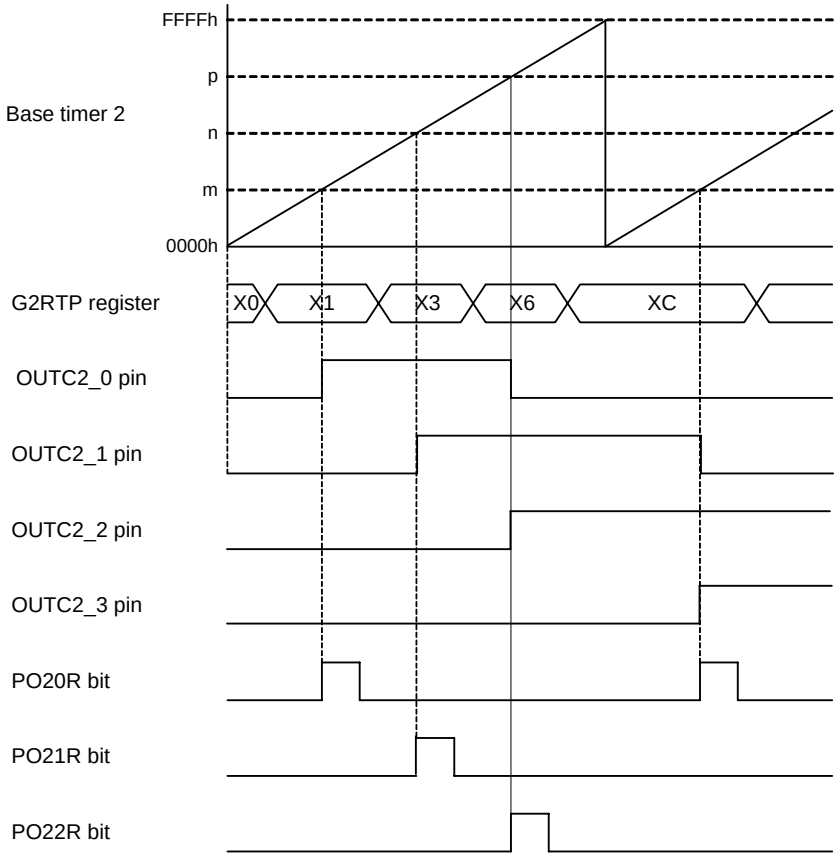
Case 1: Free-running operation



m: G2PO0 register setting value, 0000h to FFFFh

p: G2PO2 register setting value, 0000h to FFFFh
Bits PO20R, PO21R, and PO22R: Bits in registers IIO3IR to IIO11IR

This figure above applies under the following conditions:
-The IVL bit in the G2POCRj register is set to 0 (low level is output as default value) and the IVL bit is set to 0 (output level is not inverted)
-Bits RST2 to RST0 in the G2BCR1 register are set to 000b (base timer is not reset)
-m < n < p

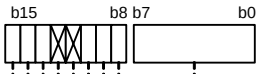
Figure 23.32 Parallel RTP Output Mode Operation

23.4 Group 2 Serial Interface

Two 8-bit shift registers and waveform generation enable the serial interface function. In group 2 of the intelligent I/O, the variable synchronous serial interface and IEBus (optional (1)) are available.
Figure 23.33 to Figure 23.40 show associated registers.

Note:
1. Contact a Renesas Electronics sales office to use the optional features.

Group 2 SI/O Transmit Buffer Register



Symbol	Address	Reset Value

Figure 23.40 IERIF Register

23.4.1 Variable Synchronous Serial Interface Mode (for Group 2)

This mode allows 1-bit to 8-bit data transmission/reception synchronized with the transmit/receive clock. The character length is selectable from 1 to 8 bits. Table 23.14 lists specifications of the group2 variable synchronous serial interface mode and Table 23.15 lists its settings. Figure 23.41 shows an operation example of data transmission/reception.

Table 23.14 Group 2 Variable Synchronous Serial Interface Mode Specifications

Item	Specification
Data format	1- to 8-bit character length
Transmit/receive clock	• The CKDIR bit in the G2MR register is set to 0 (internal clock selected): $\frac{fBT2}{2(n+2)}$ n: G2PO0 register setting value, 0000h to FFFFh (1) The bit rate is set using the G2PO0 register. The clock is generated in the inverted waveform output mode of the channel 2 waveform generation • The CKDIR bit is set to 1 (external clock selected): input into the ISCLK2 pin (2)
Transmit start conditions	The conditions for starting data transmission are as follows: • The TE bit in the G2CR register is set to 1 (transmission enabled) • The TI bit in the G2CR register is set to 0 (data held in the G2TB register)
Receive start conditions	The conditions for starting data reception are as follows: • The RE bit in the G2CR register is set to 1 (reception enabled) • The TE bit in the G2CR register is set to 1 (transmission enabled) • The TI bit in the G2CR register is set to 0 (data held in the G2TB register)
Interrupt request	In transmit interrupt, either of the following conditions is selected to set the SIO2TR bit in the IIO6IR register to 1 (interrupts requested) (Refer to Figure 11.12): • The IRS bit in the G2MR register is set to 0 (transmit buffer in the G2TB register is empty): when data is transferred from the G2TB register to the transmit shift register (when the transmission has started) • The IRS bit is set to 1 (transmission is completed): when data transmission from the transmit shift register is completed In receive interrupt, When data is transferred from the receive shift register to the G2RB register (when the reception is completed), the SIO2PR bit in the IIO5IR register is set to 1 (interrupts requested) (Refer to Figure 11.12)
Error detection	Overrun error (3) This error occurs when the last bit of the next data has been received before reading the G2RB register
Selectable functions	• Bit order selection Selectable either LSB first or MSB first • ISTXD2 and ISRXD2 I/O polarity Output level from the ISTXD2 pin and input level to the ISRXD2 pin can be respectively inverted • Character length for data transmission/reception Selectable a character length from 1 to 8 bits

Notes:
1. When using the serial interface, set 1 or above to the G2PO0 register.
2. The highest transmit/receive clock frequency should be fBT2 divided by 20.
3. If an overrun error occurs, the G2RB register is undefined.

Table 23.15 Register Settings in Group2 Variable Synchronous Serial Interface Mode

Register	Bits	Function
G2BCR0	BCK1 and BCK0	Set the bits to 11b
	DIV4 to DIV0	Select a divide ratio of count source
	IT	Set the bit to 0
G2BCR1	7 to 0	Set the bits to 0001 0010b
G2POCR0	7 to 0	Set the bits to 0000 0111b
G2POCR1	7 to 0	Set the bits to 0000 0111b
G2POCR2	7 to 0	Set the bits to 0000 0010b
G2PO0	15 to 0	Set a comparative value for waveform generation $\frac{fBT2}{2 \times (\text{setting value} + 2)}$ = transmit/receive clock frequency
G2PO2	15 to 0	Set to a value smaller than that in the G2PO0 register setting
G2FE	IFE2 to IFE0	Set the bits to 111b
G2MR	GMD1 and GMD0	Set the bits to 01b
	CKDIR	Select either the internal clock or the external clock
	UFORM	Select either LSB first or MSB first
	IRS	Select a source for transmit interrupt
G2CR	TE	Set the bit to 1 to enable data transmission/reception
	TXEPT	Transmit shift register empty flag
	TI	Transmit buffer empty flag
	RE	Set the bit to 1 to enable data reception
	RI	Receive complete flag
	OPOL	Select if the output level at the ISTXD2 pin is inverted (usually set the bit to 0)
	IPOL	Select if the input level at the ISRXD2 pin is inverted (usually set the bit to 0)
G2TB	15 to 0	Set the data to be transmitted/received and its character length
G2RB	15 to 0	Store received data and error flag

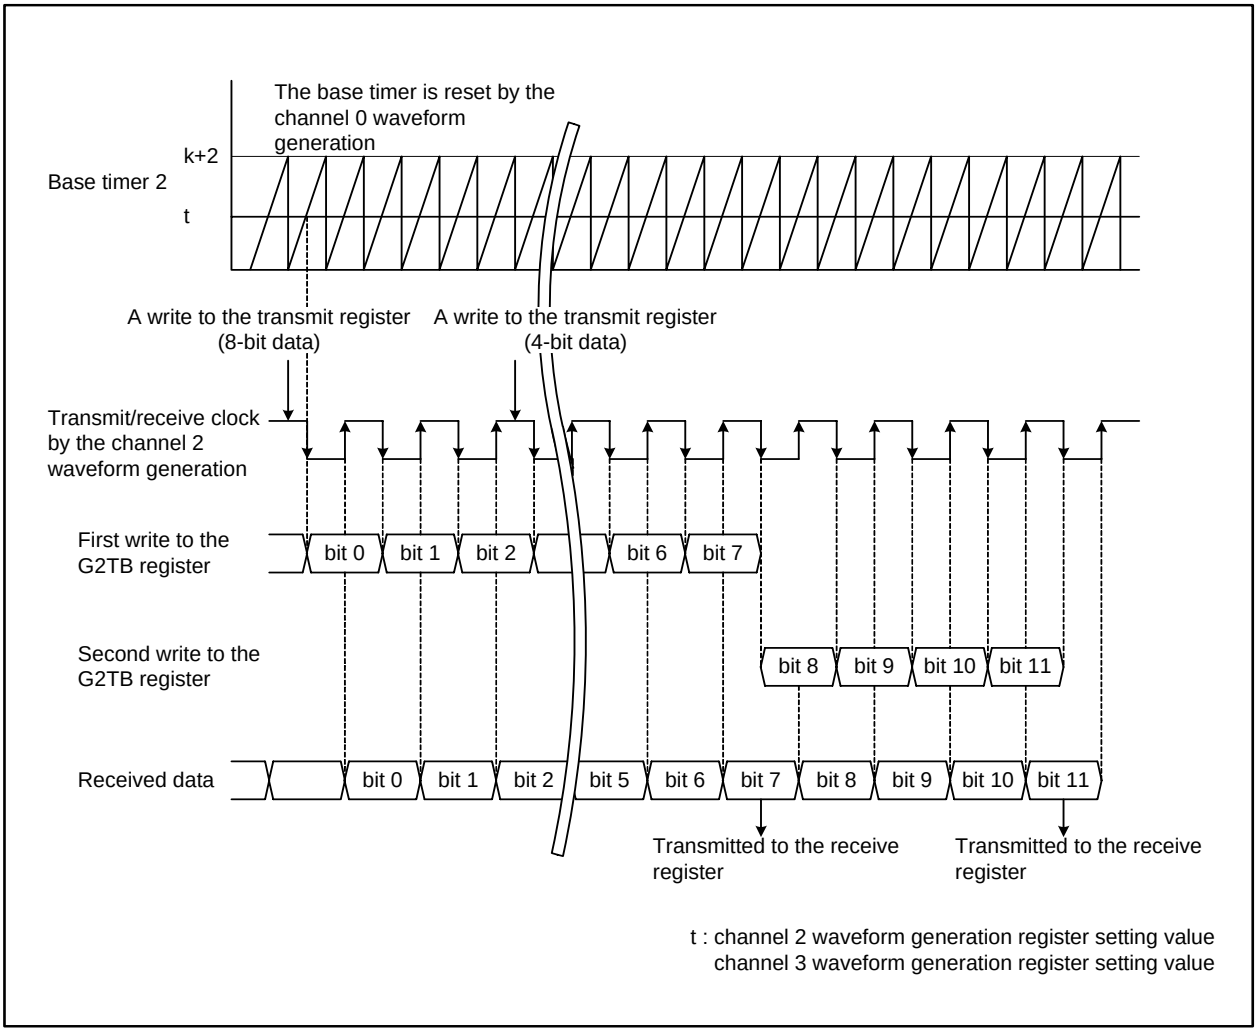

Figure 23.41 Group 2 Variable Synchronous Serial Interface Mode Transmit/Receive Operation

24. Multi-master I2C-bus Interface

The multi-master I2C-bus interface (MMI2C) is capable of serial, bi-directional data transfer in the I2C-bus data transmit and receive format. It contains an arbitration lost detector and a clock synchronization function. Table 24.1 lists specifications of the multi-master I2C-bus interface. Table 24.2 lists detectors of the multi-master I2C-bus interface. Figure 24.1 shows a block diagram of the multi-master I2C-bus interface.

Table 24.1 Multi-master I2C-bus Interface Specifications

Item	Specification
Data format	Compliant with the I2C-bus specification • 7-bit addressing format • Fast-mode • Standard-mode
Master/Slave device	Selectable
I/O pins	Serial data line: MSDA (SDA) Serial clock line: MSCL (SCL)
Transmit/Receive clock	16.1 to 400 kbps (ϕIIC = 4 MHz) ϕIIC: I2C-bus system clock
Transmit/Receive modes	Compliant with the I2C-bus specification • Master-transmit mode • Master-receive mode • Slave-transmit mode • Slave-receive mode
Interrupt request sources	• Six I2C-bus interface interrupts: Successful transmit, successful receive, slave address match detection, general call address detection, STOP condition detection, and timeout detection • Two I2C-bus line interrupts: Rising or falling edge of pins MSDA and MSCL
Selectable functions	• Timeout detector This function detects that the MSCL pin level is held high for longer than the specified time while the bus is busy • Free data format selector This function selects the free data format to generate an interrupt request, regardless of the slave address value, when the first byte is received

Table 24.2 Detectors of Multi-master I2C-bus Interface

Item	Specification
Slave address match detector	In slave-receive mode, this detects whether the address sent from the master device matches the slave address. When they match, an ACK is automatically sent. When they do not, a NACK is automatically sent and communication is stopped
General call address detector	This detects a general call address when in slave-receive mode
Arbitration lost detector	This detects an arbitration lost and then immediately stops output to the MSDA pin.
Bus busy detector	This detects that the bus is busy, and sets/resets the BBSY bit

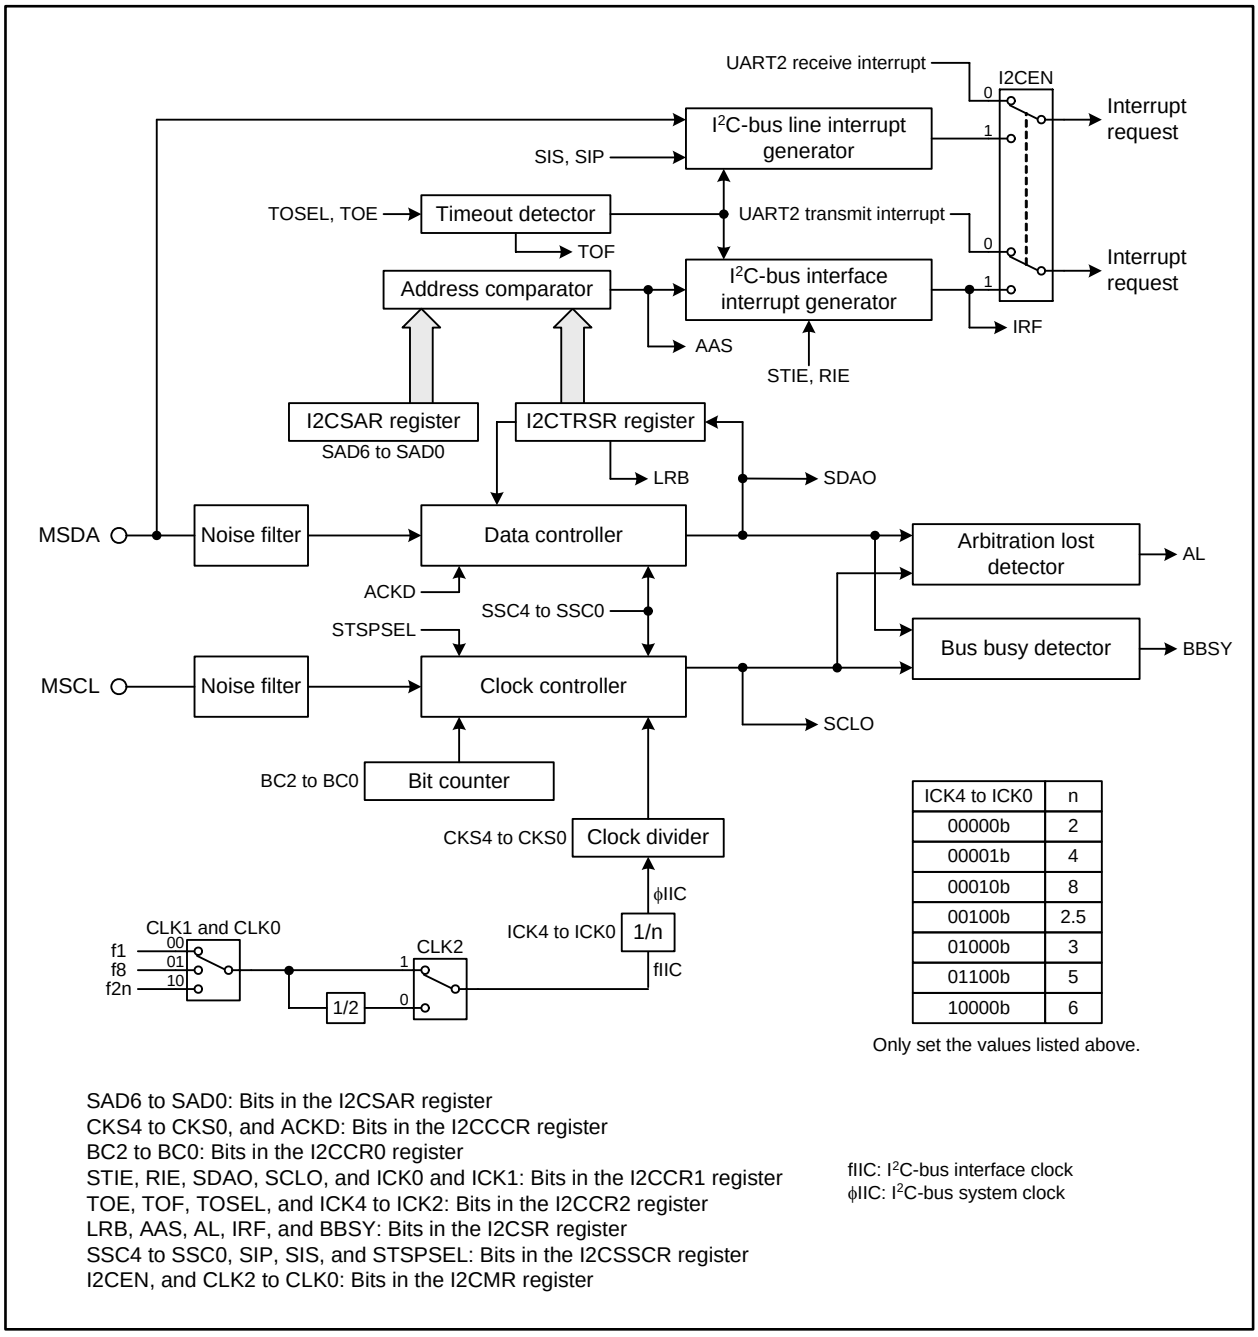

Figure 24.1 Multi-master I2C-bus Interface Block Diagram

24.1 Multi-master I2C-bus Interface-associated Registers

24.1.1 I2C-bus Transmit/Receive Shift Register (I2CTRSR)

I2C-bus Transmit/Receive Shift Register (1, 2, 3)

b7 b0

Symbol	Address	Reset Value
I2CTRSR	044400h	Undefined

Function	RW
Set transmit data in transmit mode. In receive mode, write dummy data before receiving data, and read received data after an interrupt is generated. The data being shifted can be read from this register, regardless of whether it is transmitting or receiving	RW

Notes:
1. This register is write enabled when the ICE bit in the I2CCR0 register is 1 (I2C-bus interface enabled).
2. This register is used for transmitting and receiving. Read the received data before using this register for transmitting.
3. When data is written to this register, bits BC2 to BC0 in the I2CCR0 register become 000b, and bits LRB, AAS, and AL in the I2CSR register become 0.

Figure 24.2 I2CTRSR Register

The I2CTRSR register is an 8-bit shift register where received data is stored and transmit data is written. When transmit data is written to this register, the data is synchronized with the SCL clock and shifted out in descending order from bit 7. Every time a bit is shifted out, the data is shifted to the left by 1 bit. During a receive operation, the data is synchronized with the SCL clock and stored in order starting from bit 0. 1 bit of data is shifted (to the left) for every bit that is input. Figure 24.3 shows the timing when the received data is stored to the I2CTRSR register.

The I2CTRSR register is write enabled when the ICE bit in the I2CCR0 register is 1 (I2C-bus interface enabled). When the ICE bit is 1 and the MST bit in the I2CSR register is 1 (master mode), writing data to the I2CTRSR register resets the bit counter and the SCL clock is output.

Write to the I2CTRSR register when a START condition is generated or the MSCL pin is low. The register can always be read.

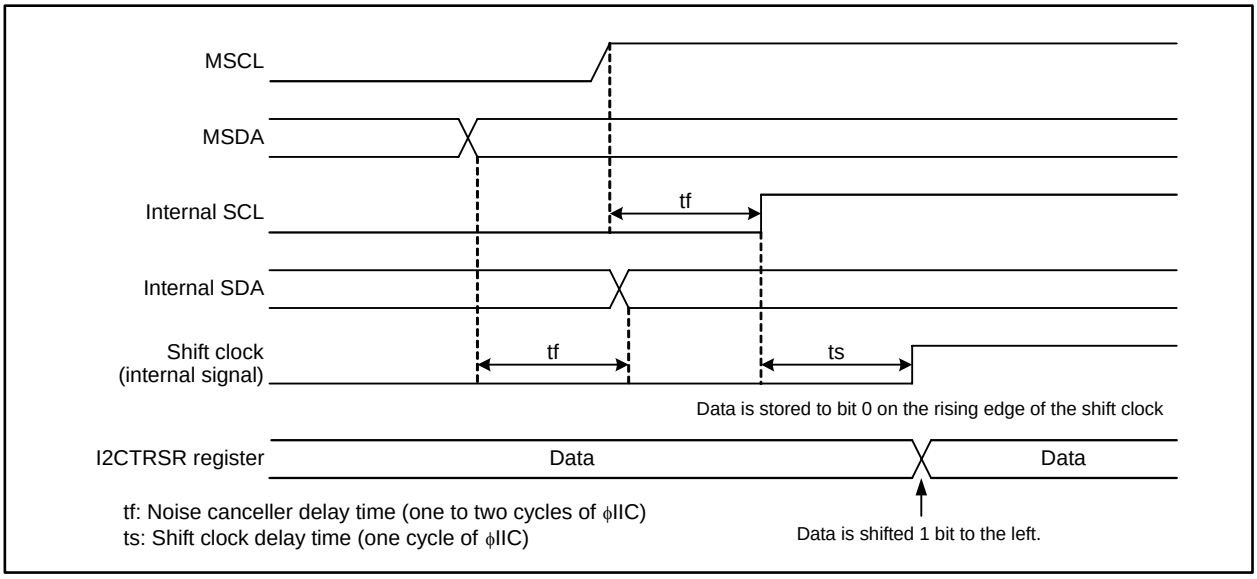

Figure 24.3 Received Data Storing Timing to the I2CTRSR Register

24.1.2 I2C-bus Slave Address Register (I2CSAR)

I2C-bus Slave Address Register

b7	b6	b5	b4	b3	b2	b1	b0

— (b5)	Reserved	Should be written with 0	RW
RST	I2C-bus Interface Reset Bit	Writing 1 to this bit resets the I2C-bus interface circuit	RW
— (b7)	Reserved	Should be written with 0	RW

Note:
1. These bits automatically become 000b in the following cases:
   - When a START or STOP condition is detected
   - When data transmission is completed
   - When data reception is completed

Figure 24.5 I2CCR0 Register

The I2CCR0 register controls data communication format.

24.1.3.1 Bits BC2 to BC0

Bits BC2 to BC0 set the data bit length to be sent or received next. When the data bit length set with bits BC2 to BC0 (acknowledge clock pulse is included in the number when the ACKCLK bit in the I2CCCR register is 1) is sent or received, an I2C-bus interface interrupt request is generated. Consequently, bits BC2 to BC0 become 000b. Note that these bits also become 000b when a START condition is detected. Address data is sent or received in 8 bits regardless of their setting.

24.1.3.2 ICE Bit

The ICE bit enables the I2C-bus interface. Set this bit to 1 to enable the I2C-bus interface and 0 to disable it. When this bit is 0, pins MSDA and MSCL are fixed high (these pins are high-impedance when the corresponding NOD bits in registers P7_0S and P7_1S are 1), therefore the I2C-bus interface cannot be used.

When the ICE bit is set to 0, the following occurs:

- Bits ADZ, AAS, AL, BBSY, TRS, and MST in the I2CSR register become 0, and the IRF bit becomes 1.
- Writing to the I2CTRSR register is disabled.
- The I2C-bus system clock (ϕIIC) is stopped, and the internal counter and flags are reset.
- The TOF bit in the I2CCR2 register becomes 0 (timeout not detected).

24.1.3.3 DFS Bit

The DFS bit enables the automatic recognition of a slave address. When the DFS bit is set to 0, the addressing format is selected and the slave address is automatically recognized. In this setting, data is received only when a general call address is received or a slave address match is detected. When the DFS bit is set to 1, the free data format is selected. In this setting, the slave address is not recognized, so all data are received.

24.1.3.4 RST Bit

The RST bit resets the I2C-bus interface when a communication error occurs. When the ICE bit is set to 1 (I2C-bus interface enabled), writing 1 (reset) to the RST bit has the following effects on the I2C-bus interface:

- Bits ADZ, AAS, AL, BBSY, TRS, and MST in the I2CSR register become 0, and the IRF bit becomes 1.
- The TOF bit in the I2CCR2 register becomes 0 (timeout not detected).
- The internal counter and flags are reset.

When the RST bit is written with 1, the multi-master I2C-bus interface is reset within a maximum of 2.5 ϕIIC cycles. Consequently, the RST bit automatically becomes 0.

Figure 24.6 shows the timing when the I2C-bus interface is reset.

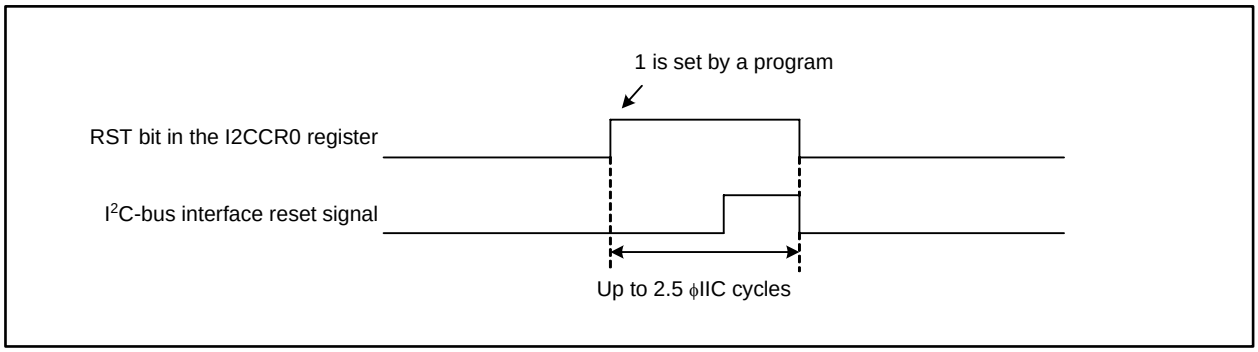

Figure 24.6 I2C-bus Interface Reset Timing

24.1.4 I2C-bus Clock Control Register (I2CCCR)

I2C-bus Clock Control Register

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
I2CCCR	044404h	0000 0000b

Bit Symbol	Bit Name	Function	RW
CKS0	Transmit/Receive Clock Frequency Control Bit	The transmit/receive clock frequency is given by ϕIIC/8n [Hz] in Standard-mode, or ϕIIC/4n [Hz] in Fast-mode, where n is a setting value. However, when 00101b is set in Fast-mode, the transmit/receive clock frequency becomes ϕIIC/2n [Hz]. Do not set to 00000b to 00010b	RW
CKS1			RW
CKS2			RW
CKS3			RW
CKS4			RW
CLKMD	Clock Mode Select Bit	0: Standard-mode 1: Fast-mode	RW
ACKD	ACK Data Bit	0: ACK sent 1: NACK sent	RW
ACKCLK	ACK Clock Generating Bit	0: ACK clock not generated 1: ACK clock generated	RW

Figure 24.7 I2CCCR Register

The I2CCCR register controls ACK and sets SCL mode and SCL clock frequency. While data is being transmitted or received, only rewrite the ACKD bit.

24.1.4.1 Bits CKS4 to CKS0

Bits CKS4 to CKS0 set the SCL clock frequency. The SCL clock frequency varies as shown in the Table 24.3, where n is a setting value of bits CKS4 to CKS0 (n = 3 to 31). Do not rewrite these bits while data is being transmitted or received.

Table 24.3 I2CCCR Register Setting Values and SCL Frequencies

Bits CKS4 to CKS0 Setting Value (n)	SCL Frequency (When ϕIIC = 4 MHz) (1)	
	Standard-mode	Fast-mode
0 to 2	Do not set (2)	Do not set (2)
3	Do not set (3)	333 kHz (ϕIIC/4n)
4	Do not set (3)	250 kHz (ϕIIC/4n)
5	100 kHz (ϕIIC/8n)	400 kHz (ϕIIC/2n) (4)
6 to 31	83 to 16 kHz (ϕIIC/8n)	166 to 32 kHz (ϕIIC/4n)

Notes:
1. The CKS value must be set so the SCL clock frequency is 100 kHz or less in Standard-mode or 400 kHz or less in Fast-mode. The high period of the SCL clock has a margin of error of +2 to -4 ϕIIC in Standard-mode, and +2 to -2 ϕIIC in Fast-mode. Note that if the high period is shortened, the low period is lengthened, so the frequency remains unchanged.
2. Do not set the CKS value to 0 to 2 regardless of the ϕIIC frequency.
3. When ϕIIC is 4 MHz or higher, do not set the CKS value to 3 or 4. The SCL clock frequency will extend beyond the specified range.
4. The normal duty cycle of the SCL clock is 50%. When the CKS value is 5 in Fast-mode, it varies from 35% to 45%.

24.1.4.2 CLKMD Bit

Set the CLKMD bit to select the SCL mode. Set this bit to 0 to select Standard-mode and 1 for Fast-mode. To use the device under the Fast-mode I2C-bus specification (up to 400 kbit/s), set ϕIIC to be 4 MHz or higher.

24.1.4.3 ACKD Bit

Set the ACKD bit to select the state of the MSDA pin with the ACK clock. When the ACKD bit is set to 0, the MSDA pin becomes low (acknowledged) by an ACK. When the ACKD bit is 1, the MSDA pin is held high with the ACK clock.
Table 24.4 lists the MSDA pin state with the ACK clock.

Table 24.4 MSDA Pin States with the ACK Clock

Received Content	DFS Bit	ACKD Bit	Slave Address	MSDA Pin State
Slave address	0	0	Match	Low (ACK)
			No match	High (NACK)
		1	—	High (NACK)
	1	0	—	Low (ACK)
		1	—	High (NACK)
Data	—	0	—	Low (ACK)
		1	—	High (NACK)

24.1.4.4 ACKCLK Bit

Set the ACKCLK bit to select whether or not to generate an ACK handshake. When this bit is 1 (ACK clock generated), an ACK clock pulse is generated after 1 byte of data is transmitted or received. When this bit is 0 (ACK clock not generated), the ACK clock is not generated after 1 byte of data is transmitted or received. In this case, the IR bit in the I2CIC register becomes 1 (I2C-bus interface interrupt requested) on the last falling edge of the clock for data transmission or reception.

24.1.5 I2C-bus START and STOP Conditions Control Register (I2CSSCR)

I2C-bus START and STOP Conditions Control Register

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
I2CSSCR	044405h	0001 1010b

Bit Symbol	Bit Name	Function	RW
SSC0	START and STOP Conditions Detection Setting Bit	The conditions for detecting START and STOP conditions (SCL open, set-up, and hold times) are set with these bits	RW
SSC1			RW
SSC2			RW
SSC3			RW
SSC4			RW
SIP	I2C-bus line Interrupt Pin Edge Select Bit	0: Falling edge 1: Rising edge	RW
SIS	I2C-bus line Interrupt Pin Select Bit	0: MSDA pin 1: MSCL pin	RW
STSPSEL	START and STOP Conditions Generating Mode Select Bit	0: Short mode 1: Long mode	RW

Figure 24.8 I2CSSCR Register

The I2CSSCR register controls the detection and generation of START and STOP conditions.

24.1.5.1 Bits SSC4 to SSC0

Bits SSC4 to SSC0 select the parameters for detecting the START and STOP conditions by setting the high period of SCL pin, set-up, and hold times. This parameter is set by referencing the I2C-bus system clock (ϕIIC). Therefore, it will change according to the XIN frequency and the setting of the I2C-bus system clock select bits (i.e. bits ICK4 to ICK0 in registers I2CCR2 and I2CCR1). Do not set an odd number or 00000b to bits SSC4 to SSC0. To detect a START or STOP condition, set the ICE bit in the I2CCR0 register to 1 (I2C-bus interface enabled). Table 24.11 lists the recommended values for bits SSC4 to SSC0.

24.1.5.2 SIP Bit

Set the SIP bit to select which of the edges of MSCL or MSDA pin generates the I2C-bus line interrupt. Set this bit to 0 to select the falling edge, and 1 to select the rising edge.

24.1.5.3 SIS Bit

Set the SIS bit to select the input signal to be used as an I2C-bus line interrupt source. To select the MSDA pin as an I2C-bus line interrupt source, set this bit to 0. To select the MSCL pin, set this bit to 1.

24.1.5.4 STSPSEL Bit

Set the STSPSEL bit to select the set-up and hold times when START and STOP conditions are generated. Set this bit to 0 to select short mode and 1 to select long mode. The STSPSEL bit must be set to 1 (long mode) when the ϕIIC frequency is higher than 4 MHz. Figure 24.16 shows the START condition generation timing. Table 24.9 lists the set-up and hold times when START and STOP conditions are generated.

24.1.6 I2C-bus Control Register 1 (I2CCR1)

I2C-bus Control Register 1 (1)

b7	b6	b5	b4	b3	b2	b1	b0
				0	0		

Symbol: I2CCR1 — Address: 044406h — Reset Value: 0011 0000b

Bit Symbol	Bit Name	Function	RW
STIE	STOP Condition Detection Interrupt Enable Bit	0: Disabled 1: Enabled	RW
RIE	Successful Receive Interrupt Enable Bit (2)	0: Disabled 1: Enabled	RW
— (b3-b2)	Reserved	Should be written with 0	RW
SDAO	Internal SDA Output Monitor Bit	0: Low 1: High	RO
SCLO	Internal SCL Output Monitor Bit	0: Low 1: High	RO
ICK0	I2C-bus System Clock Select Bit (3)	b7 b6 0 0 : fIIC divided-by-2 0 1 : fIIC divided-by-4 1 0 : fIIC divided-by-8 1 1 : Do not use this combination	RW
ICK1			RW

Notes:
1. Do not use a bit processing instruction with this register.
2. Set this bit to 0 when the ACKCLK is 0 (ACK clock is not generated).
3. These bits are enabled when bits ICK4 to ICK2 in the I2CCR2 register are 000b.

Figure 24.9 I2CCR1 Register

The I2CCR1 register controls the I2C-bus interface.

24.1.6.1 STIE Bit

The STIE bit enables the STOP condition detection interrupt. Set this bit to 1 to enable the I2C-bus interface interrupt when a STOP condition is detected. Consequently, the STOP bit in the I2CCR2 register becomes 1 (STOP condition detection interrupt requested) and the IR bit in the I2CIC register becomes 1 (I2C-bus interface interrupt requested).

24.1.6.2 RIE Bit

When the ACKCLK bit in the I2CCCR register is 1 (ACK clock generated), the RIE bit enables the interrupt which is generated when receiving the last bit of data. When the RIE bit is 1, the I2C-bus interface interrupt is generated when the last bit (the eighth falling edge of the SCL) of data is received.

Note that the I2C-bus interface interrupt is always generated when the ACK bit (the ninth falling edge of the SCL) is received regardless of the RIE bit setting. Therefore, when the RIE bit is set to 1, two I2C-bus interface interrupts are generated per data. The source of the interrupt can be identified by reading the RIE bit. The read value indicates the internal WAIT flag state. When the read value is 1, the last bit of data is the interrupt source. When the read value is 0, the ACK bit is the interrupt source.

Set the RIE bit to 0 when the ACKCLK bit in the I2CCCR register is 0 (ACK clock not generated). When the device is transmitting data or receiving a slave address, the I2C-bus interface interrupt is generated only by the ACK bit (the ninth falling edge of the SCL) regardless of the RIE bit setting. In both cases, the internal WAIT flag is 0.

Table 24.5 I2C-bus Interrupt Request Generating Timings when Data are Received and Resuming Communication

I2C-bus Interface Interrupt Generating Timing	Internal WAIT Flag	Resuming Transmission/Reception
Last bit of data (on eighth clock)	1	Write to the ACKD bit in the I2CCCR register
ACK bit (on ninth clock)	0	Write to the I2CTRSR register

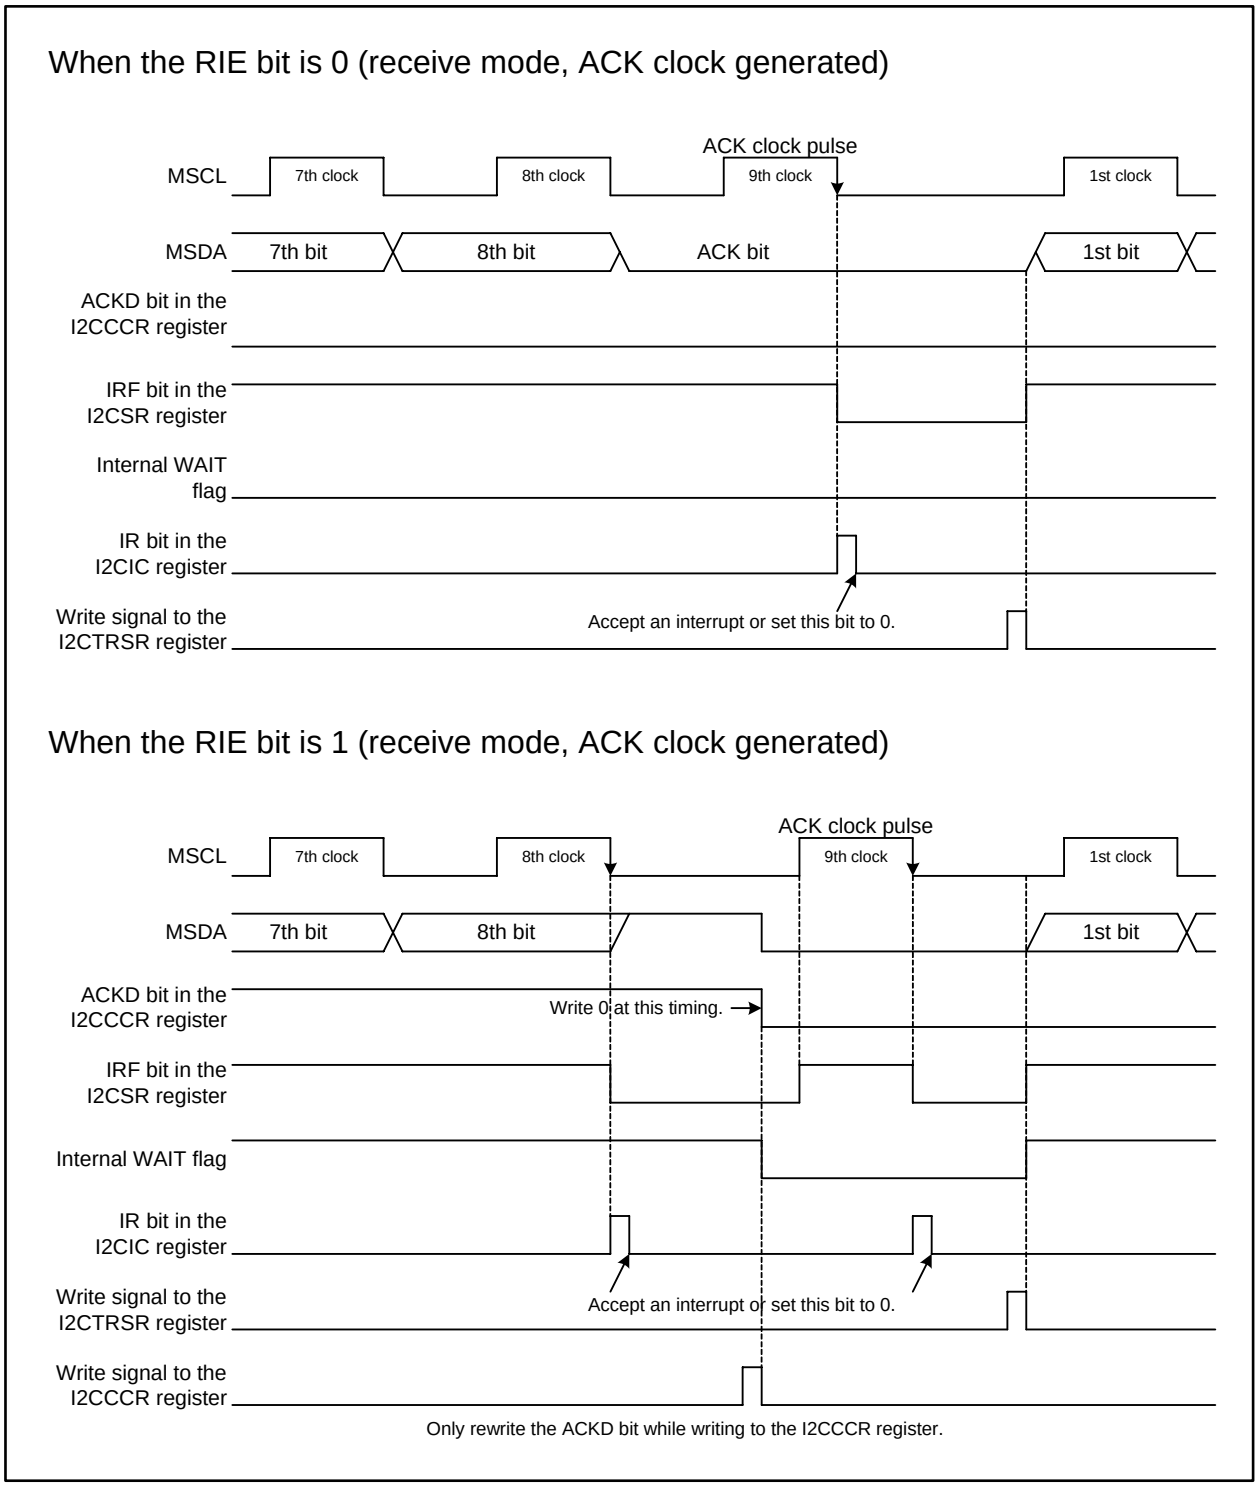

Figure 24.10 Interrupt Request Generating Timing in Receive Mode

24.1.6.3 Bits SDAO and SCLO

Bits SDAO and SCLO are read-only bits, and are used to monitor the logical values of the internal SDA output signal and internal SCL output signal, respectively. Only set these bits to 0. Note that the levels of the internal SDA and SCL output signals read from bits SDAO and SCLO are pre-influenced by the external devices, and do not indicate MSDA and MSCL pin states.

24.1.6.4 Bits ICK1 and ICK0

Set bits ICK1 and ICK0 to select the I2C-bus system clock frequency (ϕIIC). These bits are enabled when bits ICK4 to ICK2 in the I2CCR2 register are 000b. Rewrite these bits when the ICE bit in the I2CCR0 register is 0 (I2C-bus interface disabled). The I2C-bus system clock frequency (ϕIIC) is selected from fIIC divided-by-2, -4, and -8 by setting these bits. fIIC divided-by-2.5, -3, -5, and -6 are also available by setting bits ICK4 to ICK2 in the I2CCR2 register. However, the bits ICK1 and ICK0 are disabled in this case.

Table 24.6 I2C-bus System Clock (ϕIIC) Select Bit Settings

I2CCR2 Register			I2CCR1 Register		ϕIIC
ICK4 bit	ICK3 bit	ICK2 bit	ICK1 bit	ICK0 bit	
0	0	0	0	0	fIIC divided-by-2
			0	1	fIIC divided-by-4
			1	0	fIIC divided-by-8
0	0	1	0	0	fIIC divided-by-2.5
0	1	0	0	0	fIIC divided-by-3
0	1	1	0	0	fIIC divided-by-5
1	0	0	0	0	fIIC divided-by-6

Only set the values listed above.

24.1.7 I2C-bus Control Register 2 (I2CCR2)

I2C-bus Control Register 2

b7	b6	b5	b4	b3	b2	b1	b0
	0						

Symbol: I2CCR2 | Address: 044407h | Reset Value: 0X00 0000b

Bit Symbol	Bit Name	Function	RW

ICK4			RW
— (b6)	Reserved	Should be written with 0	RW
STOP	STOP Condition Detect Interrupt Request Monitor Bit	0: I2C-bus interface interrupt not requested 1: I2C-bus interface interrupt requested	RW

Figure 24.11 I2CCR2 Register

The I2CCR2 register controls communication error detection. If the SCL clock stops, each device connected to the bus is halted suspending communication. To avoid this, the multi-master I2C-bus interface supports a function to generate an I2C-bus interface interrupt when the SCL clock is held high for a specified period of time during transmission or reception.

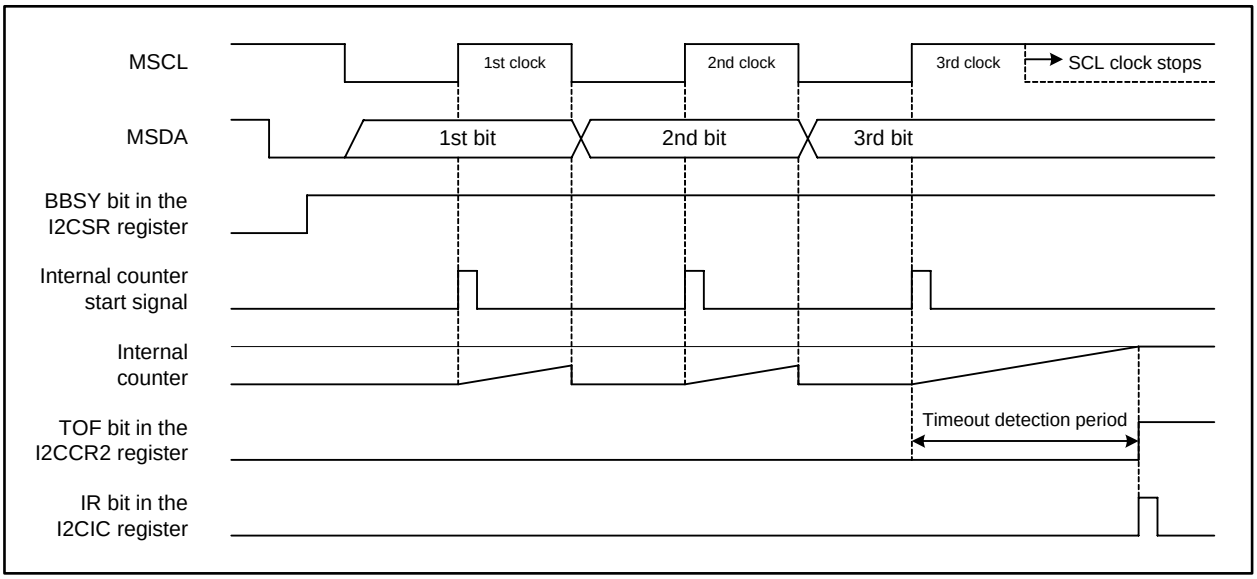

Figure 24.12 Timeout Detecting Timing

24.1.7.1 TOE Bit

The TOE bit enables the timeout detector. When this bit is set to 1, the timeout detector is enabled, and when the SCL clock is held high for a specified period of time while the BBSY bit in the I2CSR register is 1 (bus is busy), an I2C-bus interface interrupt request is generated.

The timeout detection period is determined by 1) the internal counter that uses ϕIIC as a count source, and 2) the TOSEL bit setting (selects the timeout detection period to be either long or short). Refer to 24.1.7.3 “TOSEL bit” for details.

When a timeout is detected, set the ICE bit in the I2CCR0 register to 0 (I2C-bus interface disabled) and initialize the I2C-bus interface.

24.1.7.2 TOF Bit

The TOF bit is a flag that indicates the state of a timeout detection. This bit is enabled when the TOE bit is 1. When the TOF bit becomes 1 (timeout detected), the IR bit in the I2CIC register becomes 1 (I2C-bus interface interrupt requested) simultaneously.

24.1.7.3 TOSEL Bit

The TOSEL bit selects a long or short length for a timeout detection period. This bit is enabled when the TOE bit is 1 (timeout detector enabled). Set this bit to 0 to select the long timeout period. In this setting, the internal counter functions as a 16-bit counter. Set this bit to 1 to select the short timeout period. In this setting, the internal counter functions as a 14-bit counter.

The internal counter increments using the I2C-bus system clock (ϕIIC) as a count source.

Table 24.7 lists timeout detection periods.

Table 24.7 Example Timeout Detection Periods

ϕIIC	Long Timeout Detection Period (TOSEL = 0)	Short Timeout Detection Period (TOSEL = 1)
4 MHz	16.4 ms	4.1 ms
2 MHz	32.8 ms	8.2 ms
1 MHz	65.6 ms	16.4 ms

24.1.7.4 Bits ICK4 to ICK2

Set bits ICK4 to ICK2 to select the I2C-bus system clock frequency (ϕIIC). Rewrite these bits when the ICE bit in the I2CCR0 register is 0 (I2C-bus interface disabled).

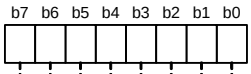
The I2C-bus system clock frequency (ϕIIC) can be selected from fIIC divided-by-2.5, -3, -5, and -6. Or, when bits ICK4 to ICK2 are 000b, the I2C-bus system clock frequency (ϕIIC) can be selected from fIIC divided-by-2, -4, and -8 by setting bits ICK1 and ICK0 in the I2CCR1 register. Refer to Table 24.6.

24.1.7.5 STOP Bit

The STOP bit monitors the STOP condition detection interrupt. When the I2C-bus interface interrupt is generated by the detection of a STOP condition, the STOP bit becomes 1. This bit is enabled when the STIE bit in the I2CCR1 register is 1 (STOP condition detection interrupt is enabled). This bit can only be set to 0. Writing 1 to this bit has no effect.

24.1.8 I2C-bus Status Register (I2CSR)

I2C-bus Status Register



Symbol: I2CSR | Address: 044408h | Reset Value: 0001 000Xb

Bit Symbol	Bit Name	Function	RW
LRB	Last Received Bit (1, 2)	0: Last received bit is 0 1: Last received bit is 1	RW
ADZ	General Call Address Detect Flag (1, 2)	0: General call address not detected 1: General call address detected	RW
AAS	Slave Address Match Flag (1, 2)	0: Address not matched 1: Address matched	RW
AL	Arbitration Lost Detect Flag (1, 2)	0: Arbitration lost not detected 1: Arbitration lost detected	RW
IRF	I2C-bus Interface Interrupt Request Flag (3)	0: Requested 1: Not requested	RO
BBSY	Bus Busy Flag (2)	0: Bus is free 1: Bus is busy	RW
TRS	Transmit/Receive Switch Bit	0: Receive mode 1: Transmit mode (1)	RW
MST	Master/Slave Select Bit	0: Slave mode 1: Master mode (1)	RW

Notes:
1. Write 1111b to the lower four bits of this register to set the TRS or MST bit to 1 without generating a START or STOP condition.
2. These bits are read-only when using them to check the status.
3. This bit is read-only. Only set this bit to 0.

Figure 24.13 I2CSR Register

The I2CSR register monitors the state of the I2C-bus interface. Write to this register only when using the functions listed in Table 24.8, and only set the values that are listed. Note that the lower six bits are not rewritten even though a value from Table 24.8 is written.

Table 24.8 I2CSR Register Settings and Functions

Values Written to the I2CSR Register								Function
MST	TRS	BBSY	IRF	AL	AAS	ADZ	LRB	
0	0	X	0	1	1	1	1	Select slave-receive mode
0	1							Select slave-transmit mode
1	0							Select master-receive mode
1	1							Select master-transmit mode
1	1	0	0	0	0	0	0	Select master-transmit mode and set the device to be on STOP condition standby.
		1						Select master-transmit mode and set the device to be on START condition standby.

24.1.8.1 LRB Bit

The LRB bit stores the data of the last received bit. It is used to check whether an ACK is received. When the ACKCLK bit in the I2CCCR register is 1 (ACK clock generated), the LRB bit becomes 0 when the ACK is received, and 1 when the ACK is not received. When the ACKCLK bit is 0 (ACK clock not generated), the last bit of data is stored to the LRB bit. When a value is written to the I2CTRSR register, the LRB bit becomes 0.

24.1.8.2 ADZ Bit

The ADZ bit is a flag that indicates that the general call address was received. When the DFS bit in the I2CCR0 register is 0 (addressing format) in slave-receive mode, the ADZ bit becomes 1 when the general call address is received.
The ADZ bit becomes 0 in any of the following cases:

- When a STOP or START condition is detected
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.8.3 AAS Bit

The AAS bit is a flag that indicates whether the received address matches its own slave address. The AAS bit becomes 1 when the received address matches its own slave address in bits SAD6 to SAD0 in the I2CSAR register, when the DFS bit in the I2CCR0 register is 0 (addressing format) in slave-receive mode, or when the received address is the general call address.
The AAS bit becomes 0 in any of the following cases:

- When data is written to the I2CTRSR register
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.8.4 AL Bit

The AL bit is a flag that indicates arbitration lost detection. In master transmit mode, if the MSDA pin is changed to low by another device, then the AL bit becomes 1. Consequently, the TRS bit in the I2CSR register becomes 0 (receive mode), and then the MST bit becomes 0 (slave mode) at the end of the byte in which an arbitration lost is detected.
The AL bit becomes 0 in any of the following cases:

- When data is written to the I2CTRSR register
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.8.5 IRF Bit

Set the IRF bit to generate the I2C-bus interface interrupt request signal. When the I2C-bus interface interrupt source is generated, first the IRF bit becomes 0, then the I2C-bus interface interrupt is generated on the falling edge of the IRF bit. Refer to Figure 24.10 for the timing.

The IRF bit becomes 0 in any of the following cases:

- When 1-byte data transmission is completed (including when an arbitration lost is detected)
- When 1-byte data reception is completed
- When the slave address is matched in addressing format in slave-receive mode
- When the general call address is received in addressing format in slave-receive mode
- When address data reception is completed in free data format in slave-receive mode

The IRF bit becomes 1 in any of the following cases:

- When data is written to the I2CTRSR register
- When data is written to the I2CCCR register (internal WAIT flag is 1)
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.8.6 BBSY Bit

The BBSY bit is a flag that indicates the availability of the I2C-bus. The BBSY bit becomes 1 when a START condition is detected, and 0 when a STOP condition is detected. When the BBSY bit is 0, the I2C-bus is not in use, and is available for the device to generate a START condition.

The detection of a START or STOP condition is dependent on the setting of bits SSC4 to SSC0 in the I2CSSCR register.

The BBSY bit becomes 0 in any of the following cases:

- When a STOP condition is detected
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.8.7 TRS Bit

The TRS bit determines the direction of data communication. When this bit is set to 0, the device enters receive mode and waits for data to be sent from another device. When this bit is set to 1, the device enters transmit mode and transmits data and address to the SDA line synchronized with the SCL clock.

The TRS bit automatically becomes 1 (transmit mode) when the received address matches its own slave address and the received R/$\overline{W}$ bit is 1 (data requested) in addressing format in slave-receive mode.

The TRS bit becomes 0 in any of the following cases:

- When this bit is set to 0
- When an arbitration lost is detected
- When a STOP condition is detected
- When the START condition redundancy prevention function is activated
- When a START condition is detected in slave mode
- When a NACK is received in slave mode
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.8.8 MST Bit

Set the MST bit to select master or slave mode. To enter slave mode, set this bit to 0. Communication is initiated in synchronization with the SCL clock generated by the master device. Set this bit to 1 to enter master mode. The device generates the SCL clock to initiate communication.

The MST bit becomes 0 in any of the following cases:

- When the MST bit is set to 0
- When an arbitration lost is detected, and transmission of the corresponding byte is completed
- When a STOP condition is detected
- When a START condition is detected
- When the START condition redundancy prevention function is enabled
- When the ICE bit in the I2CCR0 register is set to 0 (I2C-bus interface disabled)
- When the RST bit in the I2CCR0 register is written with 1 (I2C-bus interface reset)

24.1.9 I2C-bus Mode Register (I2CMR)

I2C-bus Mode Register (1)

b7 b6 b5 b4 b3 b2 b1 b0

Symbol	Address	Reset Value
I2CMR	044410h	XXXX 0000b

Bit Symbol	Bit Name	Function	RW
I2CEN	I2C-bus Interface/UART2 Switch Bit	0: UART2 1: I2C-bus interface	RW
CLK0	I2C-bus Interface Clock Source Select Bit	b3 b2 b1 0 0 0 : f1 divided-by-2 0 0 1 : f8 divided-by-2 0 1 0 : f2n divided-by-2 0 1 1 : Do not use this combination 1 0 0 : f1 1 0 1 : f8 1 1 0 : f2n 1 1 1 : Do not use this combination	RW
CLK1			RW
CLK2			RW
— (b7-b4)	No register bits; should be written with 0 and read as undefined value		RW

Note:
1. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.

Figure 24.14 I2CMR Register

The I2CMR register selects signals for the I2C-bus interface and to select the clock source. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.

24.1.9.1 I2CEN Bit

The I2CEN bit switches between signals for UART2 and the I2C-bus interface. Set this bit to 1 to use the following signals: MSDA, MSCL, the I2C-bus interface interrupt, and the I2C-bus line interrupt. When this bit is set to 0, signals for UART2 are enabled.

24.1.9.2 Bits CLK2 to CLK0

Bits CLK2 to CLK0 select the clock source for the I2C-bus interface clock (fIIC). It is selected from f1 divided-by-2, f8 divided-by-2, f2n divided-by-2, f1, f8, or f2n.

The clock source selected for the I2C-bus interface (fIIC) is used as the clock source for the I2C-bus system clock (ϕIIC).

24.2 Generating a START Condition

To enter a START condition standby state, write E0h to the I2CSR register while the ICE bit in the I2CCR0 register is 1 (I2C-bus interface enabled) and the BBSY bit in the I2CSR register is 0 (bus is free). When in standby, write a slave address to the I2CTRSR register to generate a START condition. Consequently, the bit counter becomes 000b, 1 byte of the SCL clock is output, and the slave address is transmitted. Figure 24.15 shows how to generate a START condition.

Note that after a STOP condition is generated, writing to the I2CSR register is disabled for 1.5 cycles of ϕIIC after the BBSY bit becomes 0 (bus is free). To generate a START condition immediately after generating a STOP condition, first write E0h to the I2CSR register, then confirm that bits STR and MST in the I2CSR register are 1. After that, write a slave address to the I2CTRSR register.

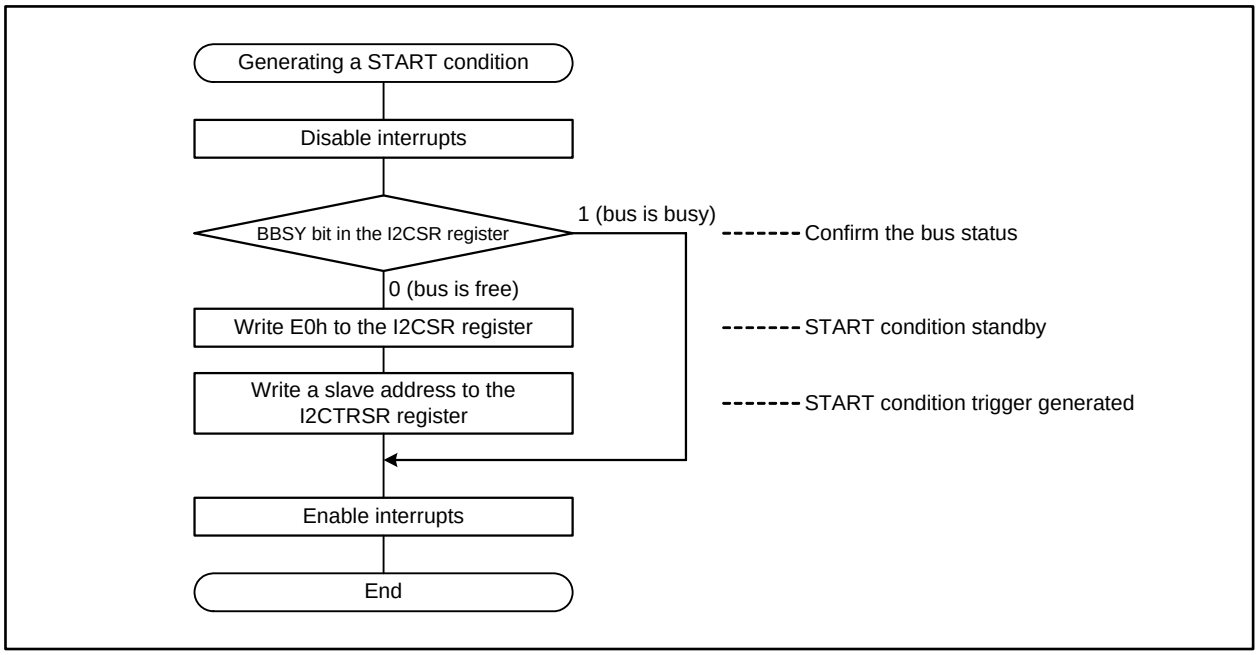


Figure 24.15 Generating a START Condition

The timing to generate a START condition differs between Standard-mode and Fast-mode. Figure 24.16 shows START condition generating timing. Table 24.9 lists the set-up and hold times when a START or STOP condition is generated.

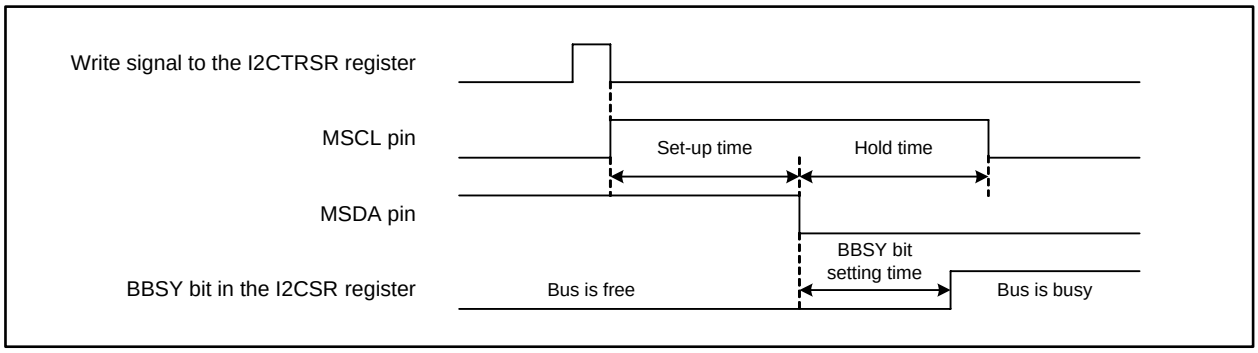

Figure 24.16 START Condition Generating Timing

Table 24.9 Set-up and Hold Times When Generating a START or STOP Condition

Parameter	SCL Mode	Short Mode (STSPSEL = 0)	Long Mode (STSPSEL = 1)
Set-up time	Standard-mode (CLKMD = 0)	5.0 µs (20)	13.0 µs (52)
	Fast-mode (CLKMD = 1)	2.5 µs (10)	6.5 µs (26)
Hold time	Standard-mode (CLKMD = 0)	5.0 µs (20)	13.0 µs (52)
	Fast-mode (CLKMD = 1)	2.5 µs (10)	6.5 µs (26)

CLKMD: Bit in the I2CCCR register
STSPSEL: Bit in the I2CSSCR register
ϕIIC cycle numbers are in parentheses.

24.3 Generating a STOP Condition

To enter a STOP condition standby state, write C0h to the I2CSR register while the ICE bit in the I2CCR0 register is 1 (I2C-bus interface enabled). Consequently, the MSDA pin becomes low. When in a standby state, write dummy data to the I2CTRSR register to generate a STOP condition. Figure 24.17 shows how to generate a STOP condition.

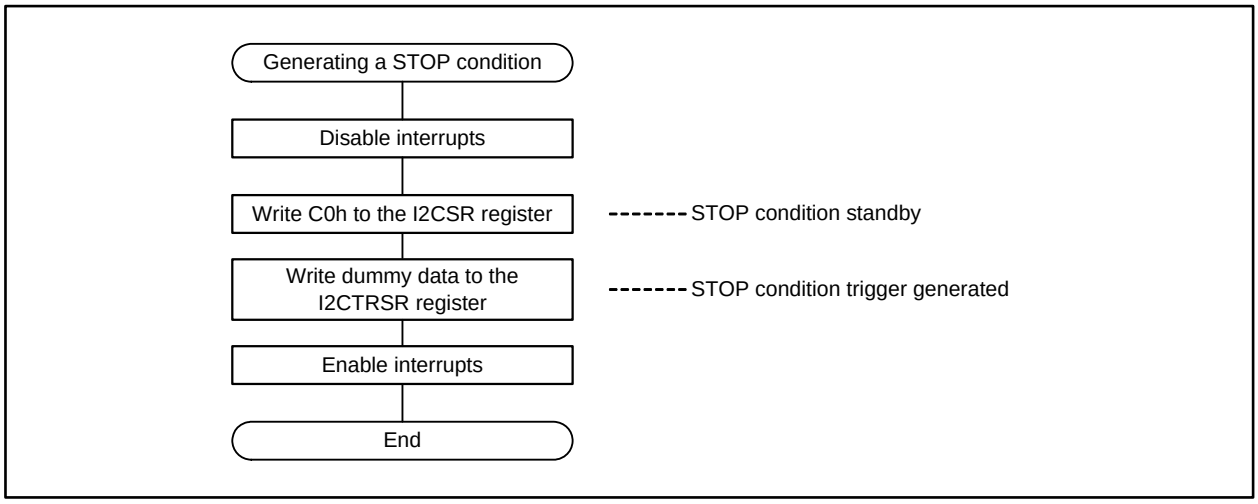

Figure 24.17 Generating a STOP Condition

The timing for generating a STOP condition differs between Standard-mode and Fast-mode. Figure 24.18 shows STOP condition generating timing. Table 24.9 lists the set-up and hold times when a START or STOP condition is generated.

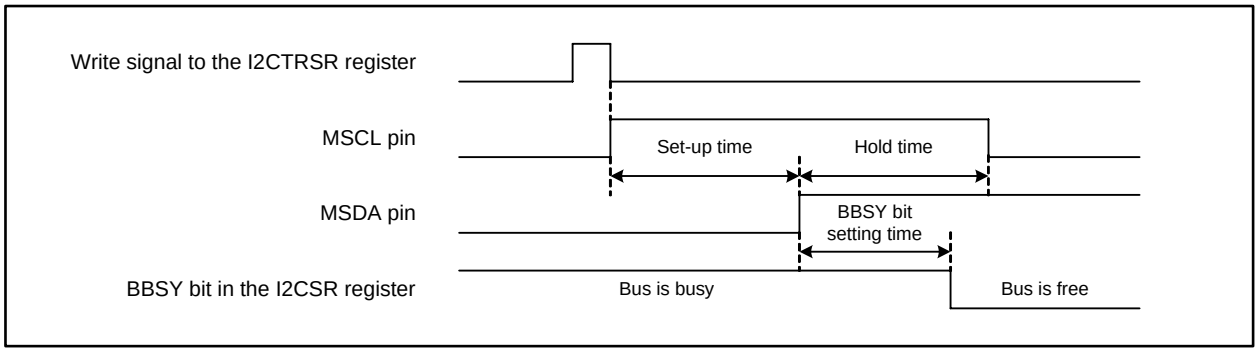

Figure 24.18 STOP Condition Generating Timing

To ensure the successful generation of a STOP condition, after the standby setting, do not write to the I2CSR or I2CTRSR register before the BBSY bit in the I2CSR register becomes 0 (bus is free), otherwise the STOP condition might not be generated successfully.
Furthermore, after the standby setting, if the MSCL pin input signal becomes low after the MSCL pin level becomes high, before the BBSY bit in the I2CSR register becomes 0 (bus is free), then the internal SCL output becomes low. In this case, low output from the MSCL pin is stopped (clock line released) by generating a STOP condition, by setting the ICE bit in the I2CCR0 register to 0 (I2C-bus interface disabled), or by setting the RST bit to 1 (I2C-bus interface reset)

24.4 START Condition Redundancy Prevention Function

A START condition is generated when the bus is free (confirmed with the BBSY bit in the I2CSR register). However, before a START condition is generated, if a different master device generates another START condition, the BBSY bit may become 1. In this case, the START condition redundancy prevention function terminates the generation of its own START condition.

The START condition redundancy prevention functions as follows:

- The START condition standby setting is disabled (exits from standby state)
- Writing to the I2CTRSR register is disabled (generation of the START condition trigger is disabled)
- Bits MST and TRS in the I2CSR register become 0 (enters into slave-receive mode)
- The AL bit in the I2CSR register becomes 1 (arbitration lost is detected)

Figure 24.19 shows the operation of the START condition redundancy prevention function.

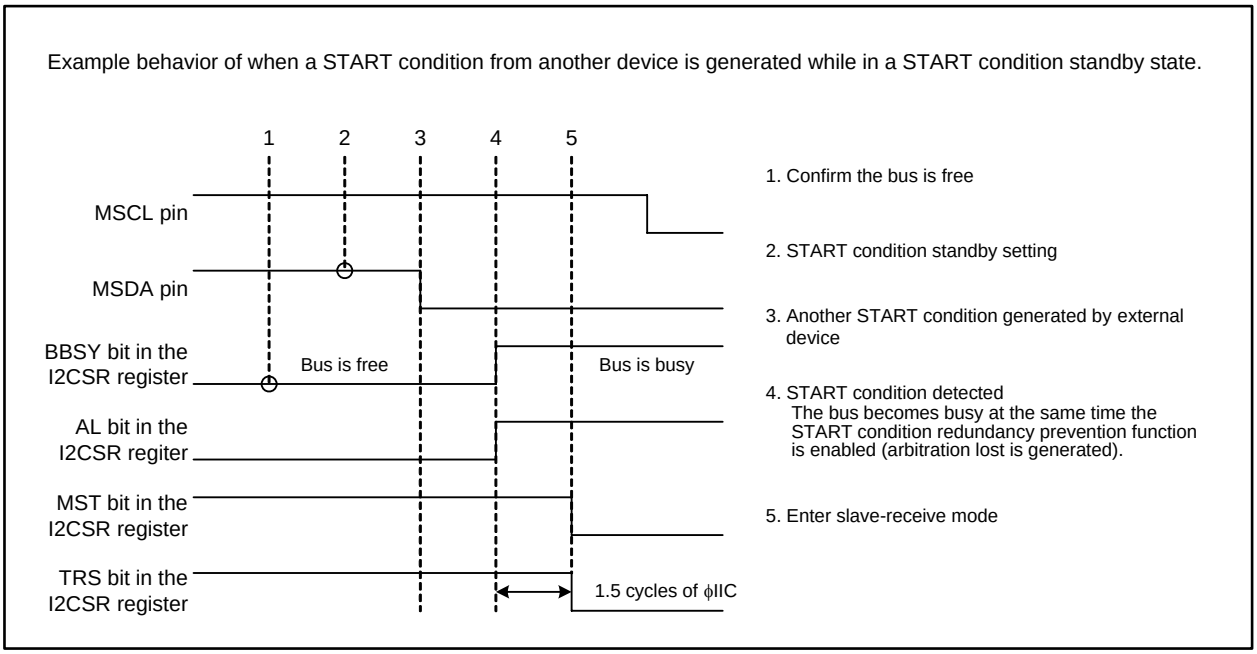

Figure 24.19 Example Operation of the START Condition Redundancy Prevention Function

The START condition redundancy prevention function is enabled from the falling edge of an SDA line in a START condition until the slave address is completely received. This means, when registers I2CSR and I2CTRSR are written during this period, then the START condition redundancy prevention function is enabled. Figure 24.20 shows the duration.

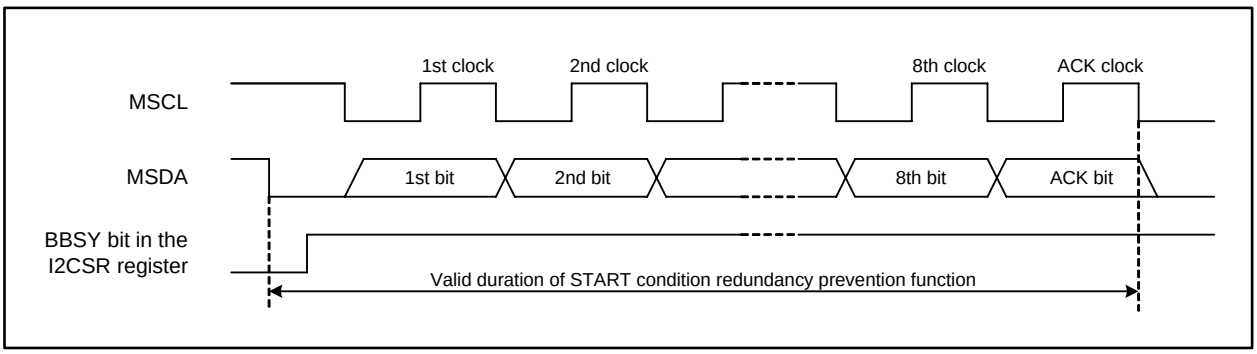

Figure 24.20 Enabled Duration of the START Condition Redundancy Prevention Function

24.5 Detecting START and STOP Conditions

Figure 24.21 shows START condition detection, Figure 24.22 shows STOP condition detection, and Table 24.10 lists the parameters for detecting START and STOP conditions. The parameters to detect START and STOP conditions are set with bits SSC4 to SSC0 in the I2CSSCR register. These parameters are detectable only when the input signals of pins MSCL and MSDA meet all the conditions of the high period of MSCL pin, set-up, and hold times in Table 24.10.

The BBSY bit in the I2CSR register becomes 1 when a START condition is detected, and 0 when a STOP condition is detected. The timing for setting the BBSY bit differs between Standard-mode and Fast-mode. Refer to Table 24.11 for BBSY bit setting time. Table 24.11 lists the recommended settings for bits SSC4 to SSC0 in Standard-mode.

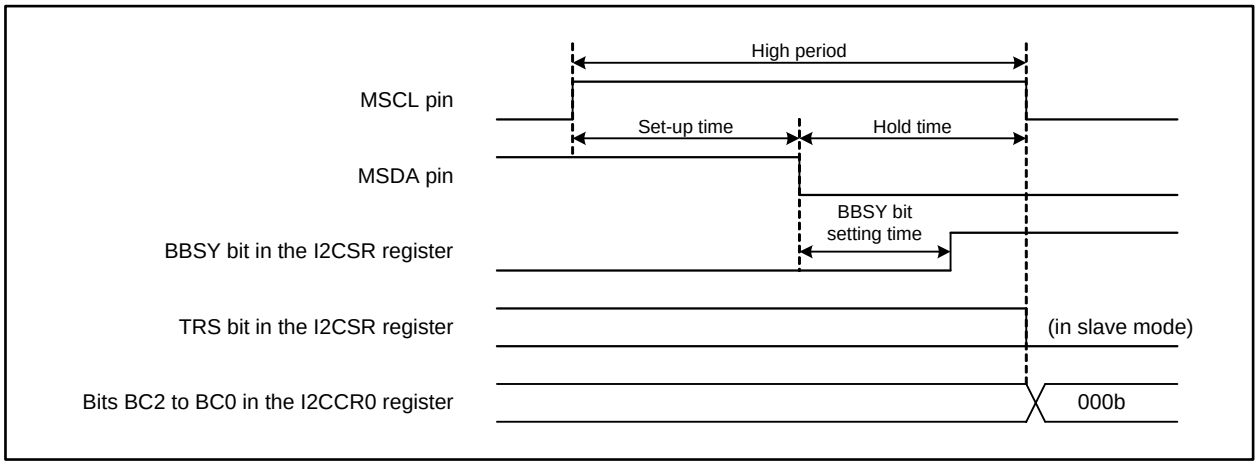

Figure 24.21 Detecting a START Condition

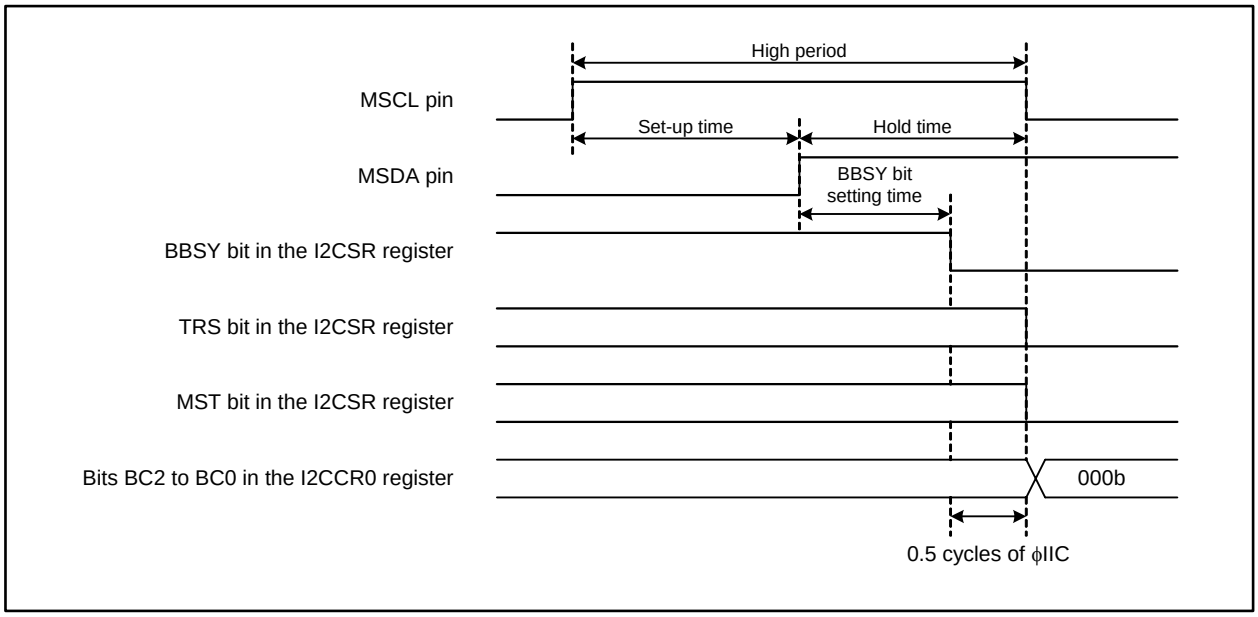

Figure 24.22 Detecting a STOP Condition

Table 24.10 Parameters for Detecting START and STOP Conditions

Parameter	Standard-mode	Fast-mode
High period of MSCL pin	SSC value + 1 cycle (6.25 µs)	4 cycles (1.0 µs)
Set-up time	$\frac{\text{SSC value}}{2}$ + 1 cycle < 4.0 µs (3.25 µs)	2 cycles (0.5 µs)
Hold time	$\frac{\text{SSC value}}{2}$ cycles < 4.0 µs (3.0 µs)	2 cycles (0.5 µs)
BBSY bit set/reset time	$\frac{\text{SSC value - 1}}{2}$ + 2 cycles (3.375 µs)	3.5 cycles (0.875 µs)

Unit: ϕIIC cycles
SSC value: Setting value of bits SSC4 to SSC0 in the I2CSSCR register. Do not set these bits to 0 or an odd number.
Example times of when ϕIIC = 4 MHz and the I2CSSCR register = 18h are in parentheses.

Table 24.11 Recommended Values for Bits SSC4 to SSC0 in Standard-mode

ϕIIC	SSC Recommended Value	Parameters for Detecting START and STOP Conditions			BBSY Bit Set/Reset Time
		High period of MSCL pin	Set-up time	Hold time	
5 MHz	30	6.2 µs (31)	3.2 µs (16)	3.0 µs (15)	4.125 µs (16.5)
4 MHz	26	6.75 µs (27)	3.5 µs (14)	3.25 µs (13)	3.625 µs (14.5)
	24	6.25 µs (25)	3.25 µs (13)	3.0 µs (12)	3.375 µs (13.5)
2 MHz	12	6.5 µs (13)	3.5 µs (7)	3.0 µs (6)	3.75 µs (7.5)
	10	5.5 µs (11)	3.0 µs (6)	2.5 µs (5)	3.25 µs (6.5)
1 MHz	4	5.0 µs (5)	3.0 µs (3)	2.0 µs (2)	3.5 µs (3.5)

The number of ϕIIC cycles are in parentheses.
SSC recommended values: Decimal value of bits SSC4 to SSC0 in the I2CSSCR register.

24.6 Data Transmission and Reception

Examples of the data transmission and reception format for master-transmission or slave-reception in a 7-bit address format are shown in section 24.6.1 “Master Transmission” and 24.6.2 “Slave Reception”. These examples assume communication starts after initialization using the parameters set in Table 24.12.

Table 24.12 Example of Initial Settings

Register	Setting Value	Parameter	Initial Setting
I2CSAR	02h	Slave address	1
I2CCCR	85h	SCL frequency	100 kHz (ϕIIC = 4 MHz)
		Clock mode	Standard-mode
		ACK clock generation	ACK clock generated
I2CCR2	00h	Timeout Detector	Disabled
I2CCR1	13h	STOP condition detection interrupt	Enabled
		Successful data receive interrupt	Enabled
		ϕIIC	fIIC divided-by-2
I2CSR	0Fh	Communication mode	Slave-receive mode
I2CSSCR	98h	SSC value (see Table 24.11)	24
		START and STOP conditions generation mode	Long mode
I2CCR0	08h	Number of bits to be transmitted or received	8 bits
		I2C-bus interface	Enabled (communication enabled)
		Data format	Addressing format
I2CMR	09h	I2C-bus interface/UART2	I2C-bus interface selected
		I2C-bus interface clock source	fIIC = f2n

24.6.1 Master Transmission

The operation and procedures of master transmission are described in this section. Figure 24.23 shows an example of master transmission operation. For (A) to (C) in the figure, see A to C in the descriptions and procedures below. (1) to (3) show the program's instructions. Arrows indicate that the procedure is performed by the MCU automatically.

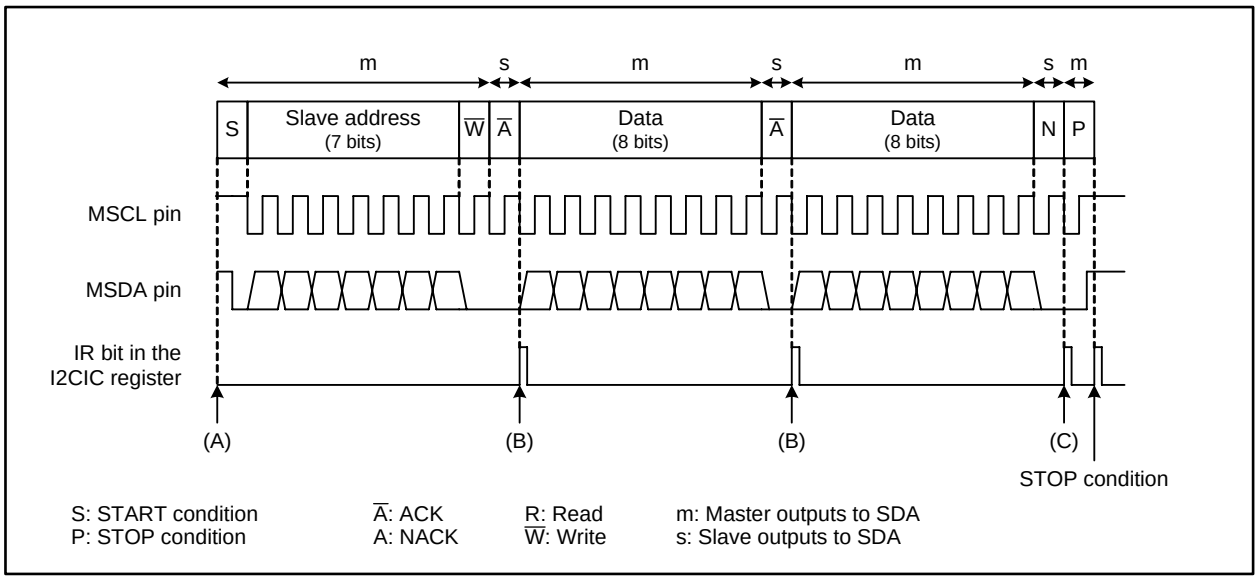

Figure 24.23 Example Operation of Master Transmission

A. Transmitting a slave address

(1) Confirm the BBSY bit in the I2CSR register is 0 (bus is free)
(2) Write E0h to the I2CSR register
→ The device enters the START condition standby state
(3) Write an address of a receiver (slave address) to the upper 7 bits of the I2CTRSR register
→ A START condition is generated
→ The slave address is sent

B. Transmitting data (processed in the I2C-bus interrupt routine)

(1) Write transmit data to the I2CTRSR register
→ Data is sent
To send multiple bytes of data, write them to the I2CTRSR register in succession

C. Completing master transmission (processed in the I2C-bus interrupt routine)

(1) Write C0h to the I2CSR register
→ The device enters the STOP condition standby state
(2) Write dummy data to the I2CTRSR register
→ A STOP condition is generated

In addition to the case where transmission is completed, procedure (C) is required when no ACK from the slave device is received (when a NACK is received as shown in Figure 24.23).

24.6.2 Slave Reception

The operation and procedures of slave reception are described in this section. Figure 24.24 shows an example of slave reception operation. For (A) to (D) in the figure, see A to D in the descriptions and procedures below. (1) to (3) show the program's instructions. Arrows indicate that the procedure is performed by the MCU automatically.

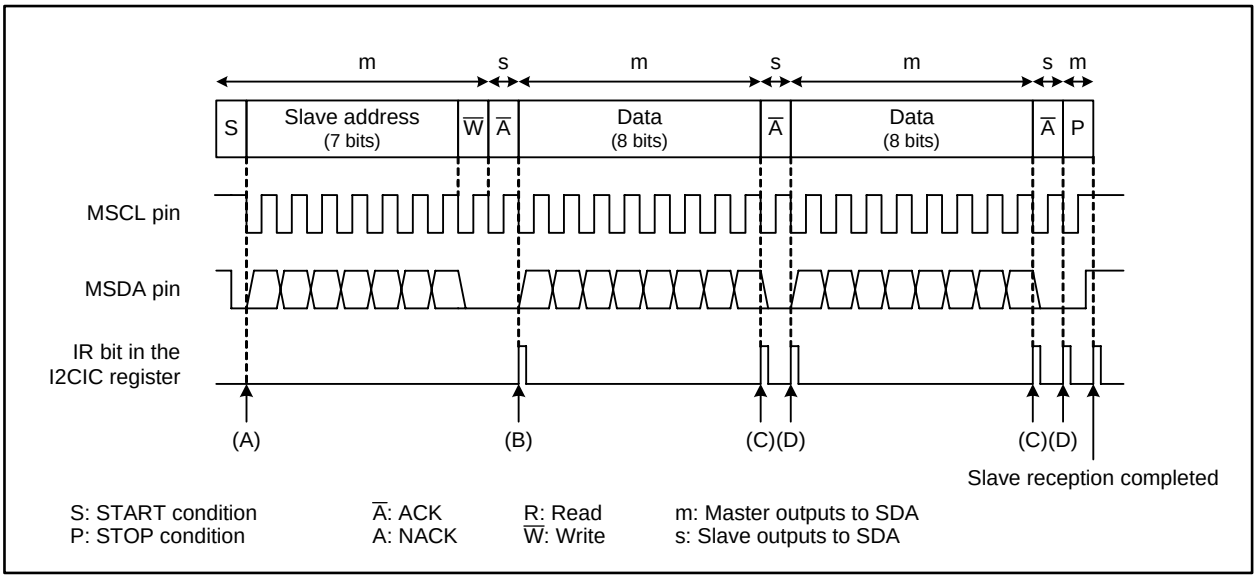

Figure 24.24 Example Operation of Slave Reception

A. Receiving a slave address (performed by the MCU automatically)
   → A START condition is detected
   → A slave address is received
   → An ACK is sent and the I2C-bus interface interrupt is generated in either of the following cases
   -When the general call address is received (the ADZ bit in the I2CSR register is 1)
   -When an address match is detected (the AAS bit in the I2CSR register is 1)

B. Starting slave reception (processed in the I2C-bus interrupt routine)
   (1) Confirm the content of the I2CSR register. When the TRS bit is 0, start the slave reception.
   (2) Write dummy data to the I2CTRSR register
   → Data reception starts

C. Completing slave reception (processed in the I2C-bus interrupt routine)
   (1) Read the received data from the I2CTRSR register
   (2) Set the ACKD bit in the register to 1 (NACK) when the data is the last received data
   (3) Set the ACKD bit in the register to 0 (ACK) when the data is not the last received data
   → An ACK or NACK is sent and an I2C-bus interface interrupt is generated

D. Completing ACK transmission (processed in the I2C-bus interrupt routine)
   (1) Write dummy data to the I2CTRSR register
   → If the data is the last received data, a STOP condition is detected
   → If not, data reception restarts

24.7 Notes on Using Multi-master I2C-bus Interface

24.7.1 Accessing Multi-master I2C-bus Interface-Associated Registers

Notes on writing to and reading I2C-bus interface-associated registers.

- I2CTRSR register
  Do not write to this register during data transmission or reception. Doing so resets the transmit/receive counter and the register is unable to perform normal data transmission or reception.

- I2CCR0 register
  This register becomes 000b when a START condition is detected or 1 byte of data transmission or reception is completed. Do not write to or read this register at these two timings. Doing so may change the register value to an unexpected value. Figure 24.26 and Figure 24.27 show the bit counter reset timings.

- I2CCCR register
  Do not rewrite bits other than the ACKD bit during transmission or reception. Otherwise the I2C-bus clock circuit is reset and a normal transmission or reception will not be performed as a result.

- I2CCR1 register
  Rewrite bits ICK4 to ICK0 only when the ICE bit in the I2CCR0 register is 0 (I2C-bus interface disabled). When the I2CCR1 register is read, the internal WAIT flag status is read from this register. Therefore, do not use a bit processing instruction (read-modify-write instruction) with this register.

- I2CSR register
  Do not use a bit processing instruction (read-modify-write instruction) since the value of each bit in the I2CSR register changes depending on the communication state. Also, do not access this register when MST bit or TRS bit, which select the communication mode, changes. Doing so may change the register value to an unexpected value. Figure 24.25 to Figure 24.27 show the timing of bits MST and TRS to change.

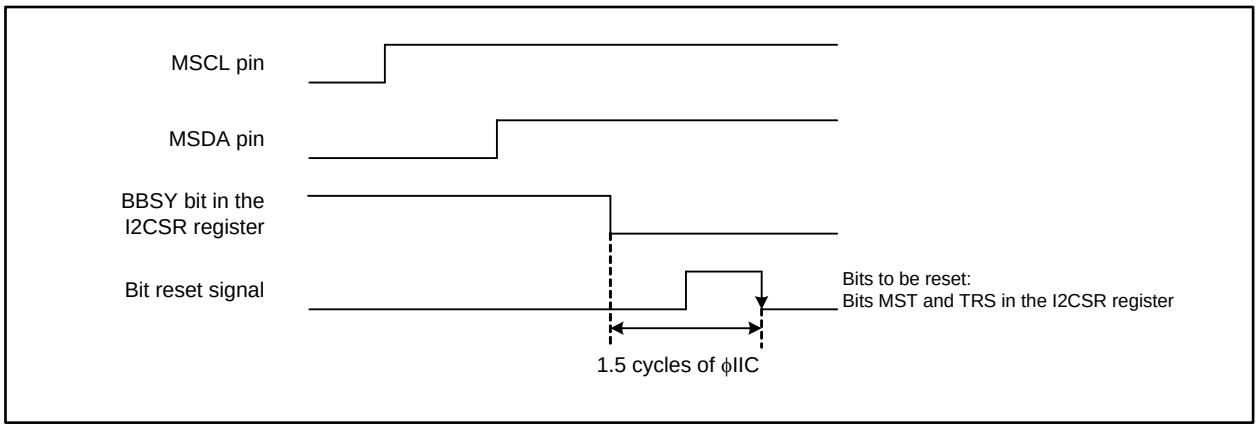

Figure 24.25 Bit Resetting Timing (when a STOP condition is detected)

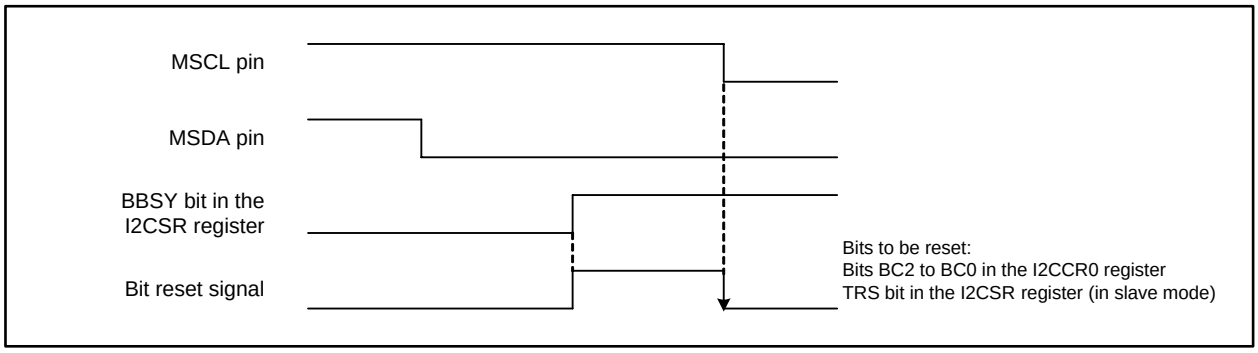

Figure 24.26 Bit Resetting Timing (when a START condition is detected)

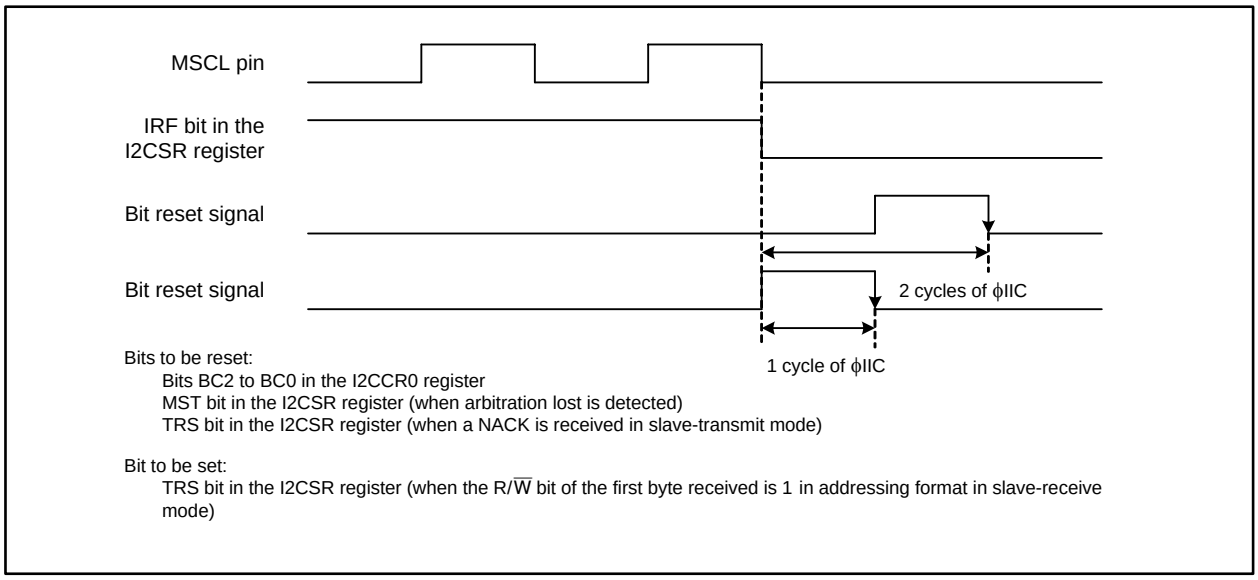

Figure 24.27 Bit Setting/Resetting Timing (when data transmission/reception is completed)

24.7.2 Generating a Repeated START condition

Use the following steps to generate a repeated START condition after transmitting 1-byte of data:

(1) Write E0h (the START condition standby state, and the MSDA pin is high) to the I2CSR register
(2) Wait until the MSDA pin becomes high
(3) Write a slave address to the I2CTRSR register to generate a START condition trigger

Figure 24.28 shows the repeated START condition generating timing.

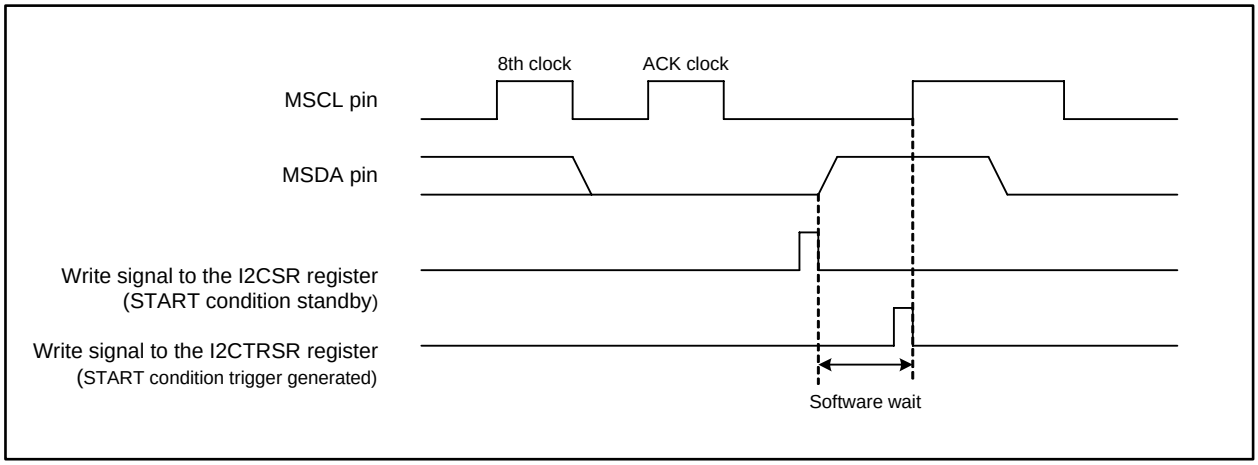

Figure 24.28 Repeated START Condition Generating Timing

25. CAN Module

The R32C/117 Group implements one channel (referred to as CAN0) of the Controller Area Network (CAN) module that complies with the ISO11898-1 Specifications. The CAN module transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier hereafter referred to as ID) and extended ID (29 bits).
Table 25.1 and Table 25.2 list the CAN module specifications, and Figure 25.1 shows the CAN module block diagram.
Connect the CAN bus transceiver externally.

Table 25.1 CAN Module Specifications (1)

Item	Specifications
Protocol	ISO11898-1 compliant
Bit rate	Up to 1 Mbps
Message boxes	32 mailboxes: Two selectable mailbox modes: • Normal mailbox mode All 32 mailboxes can be configured for transmission or reception. • FIFO mailbox mode: 24 mailboxes can be configured for transmission or reception. The remaining mailboxes can be configured as 4-stage FIFO for transmission and 4-stage FIFO for reception.
Reception	• Data frames and remote frames can be received. • Selectable receiving ID format (only standard ID, only extended ID, or both ID) • Programmable one-shot reception function • Selectable overwrite mode (message overwritten) or overrun mode (message discarded) • The reception complete interrupt can be individually enabled or disabled for each mailbox.
Acceptance filtering	8 acceptance masks: one mask every 4 mailboxes The mask can be individually enabled or disabled for each mailbox.
Transmission	• Data frame and remote frame can be transmitted. • Selectable transmitting ID format (only standard ID, only extended ID, or both ID). • Programmable one-shot transmission function • Selectable ID priority transmit mode or mailbox number priority transmit mode • Transmission request can be aborted. (The completion of abort can be confirmed with a flag.) • The transmission complete interrupt can be individually enabled or disabled for each mailbox.
Mode transition for bus-off recovery	Mode transition for the recovery from the bus-off state can be selected: • ISO11898-1 compliant • Automatic entry to CAN halt mode at bus-off entry • Automatic entry to CAN halt mode at bus-off end • Entry to CAN halt mode by a program • Transition to the error-active state by a program

Table 25.2 CAN Module Specifications (2)

Item	Specifications
Error status monitoring	• CAN bus errors (stuff error, form error, ACK error, CRC error, bit error, and ACK delimiter error) can be monitored. • Transition to error states can be detected (error-warning, error-passive, bus-off entry, and bus-off recovery). • The error counters can be read.
Time stamp function	Time stamp function using a 16-bit counter The reference clock can be selected from either 1-, 2-, 4- or 8-bit time periods.
Interrupt sources	6 types: • Reception complete • Transmission complete • Receive FIFO • Transmit FIFO • Error • Wake-up
CAN sleep mode	Current consumption can be reduced by stopping the CAN clock.
Software support units	3 software support units: • Acceptance filter support • Mailbox search support (receive mailbox search, transmit mailbox search, and message lost search) • Channel search support
CAN clock source	Selectable peripheral bus clock or main clock
Test mode	3 test modes available for user evaluation: • Listen-only mode • Self-test mode 0 (external loop back) • Self-test mode 1 (internal loop back)

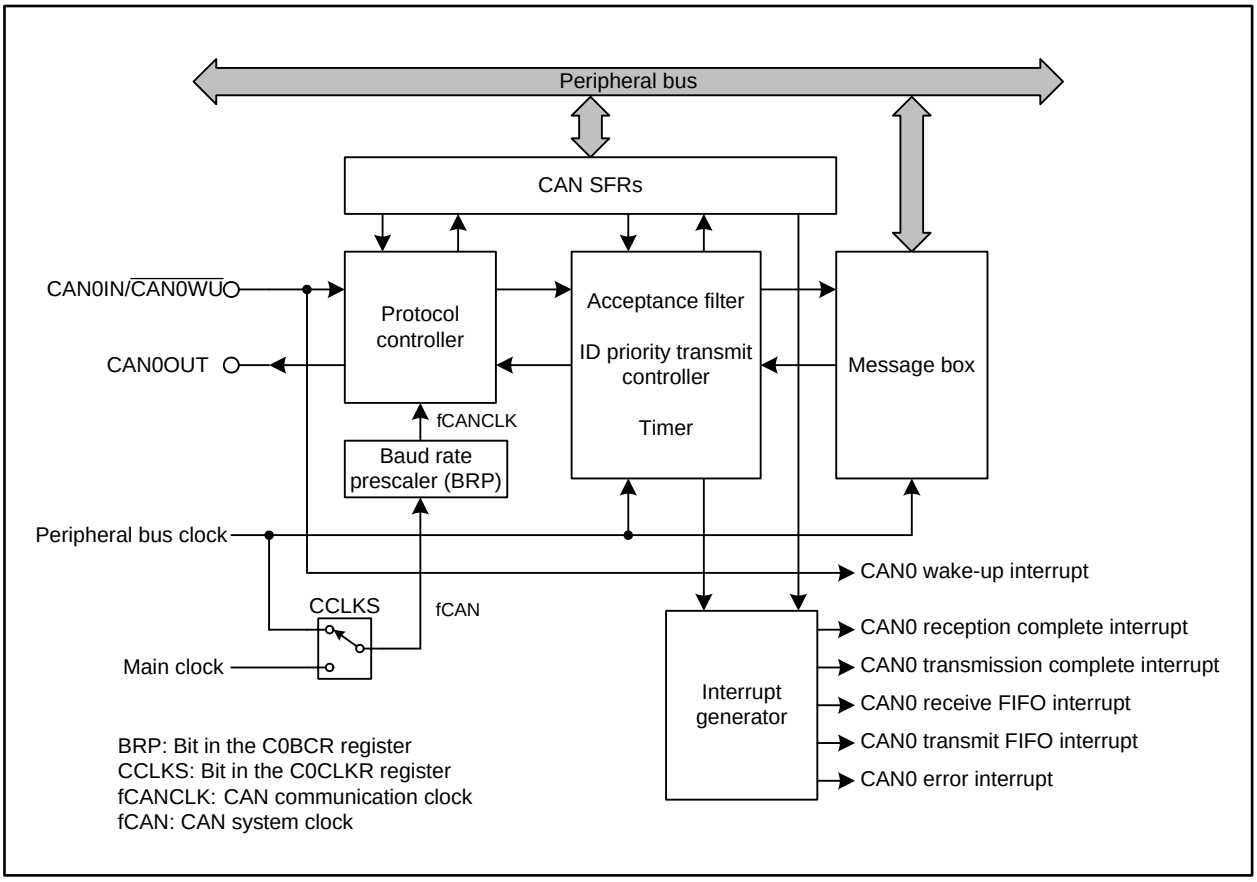

Figure 25.1 CAN Module Block Diagram

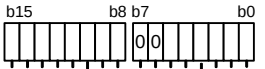
- CAN0IN/CAN0OUT: CAN input/output pins
- Protocol controller: Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, and error handling, etc.
- Message box: Consists of 32 mailboxes which can be configured as either transmit or receive mailboxes. Each mailbox has an individual ID, data length code, a data field (8 bytes), and a time stamp.
- Acceptance filter: Performs filtering of received messages. Registers C0MKR0 to C0MKR7 are used for the filtering process.
- Timer: Used for the time stamp function. The timer value when storing a message into the mailbox is written as the time stamp value.
- Wake-up function: Generates a CAN0 wake-up interrupt request when a message is detected on the CAN bus.
- Interrupt generator: Generates the following five types of interrupts:
  - CAN0 reception complete interrupt
  - CAN0 transmission complete interrupt
  - CAN0 receive FIFO interrupt
  - CAN0 transmit FIFO interrupt
  - CAN0 error interrupt
- CAN SFRs: CAN-associated registers. Refer to 25.1 “CAN SFRs” for details.

25.1 CAN SFRs

The CAN-associated registers are shown in Figures 25.2 to 25.11, 25.13, 25.14, 25.16 to 25.20, 25.22, and 25.24 to 25.30.

25.1.1 CAN0 Control Register (C0CTLR Register)

CAN0 Control Register



Symbol	Address	Reset Value
C0CTLR	47F41h-47F40h	0000 0000 0000 0101b

Bit Symbol	Bit Name	Function	RW
CANM	CAN Operating Mode Select Bit (1)	b1 b0 0 0 : CAN operation mode 0 1 : CAN reset mode 1 0 : CAN halt mode 1 1 : Do not use this combination	RW
SLPM	CAN Sleep Mode Bit (1, 2)	0: Other than CAN sleep mode 1: CAN sleep mode	RW
BOM	Bus-Off Recovery Mode Select Bit (3)	b4 b3 0 0 : Normal mode (ISO11898-1 compliant) 0 1: Entry to CAN halt mode automatically at bus-off entry 1 0 : Entry to CAN halt mode automatically at bus-off end 1 1 : Entry to CAN halt mode (during bus-off recovery period) by a program request	RW
RBOC	Forcible Return From Bus-Off Bit (4)	0: Nothing occurred 1: Forcible return from bus-off (5)	RW
— (b7-b6)	Reserved	Should be written with 0	RW
MBM	CAN Mailbox Mode Select Bit (3)	0: Normal mailbox mode 1: FIFO mailbox mode	RW
IDFM	ID Format Mode Select Bit (3)	b10b9 0 0 : Standard ID mode 0 1 : Extended ID mode 1 0 : Mixed ID mode 1 1 : Do not use this combination	RW
MLM	Message Lost Mode Select Bit (3)	0: Overwrite mode 1: Overrun mode	RW
TPM	Transmit Priority Mode Select Bit (3)	0: ID priority transmit mode 1: Mailbox number priority transmit mode	RW
TSRC	Time Stamp Counter Reset Bit (6)	0: Nothing occurred 1: Reset (5)	RW
TSPS	Time Stamp Prescaler Select Bit (3)	b15b14 0 0 : Every bit time 0 1 : Every 2-bit time 1 0 : Every 4-bit time 1 1 : Every 8-bit time	RW

Notes:
1. When bits CANM and SLPM are changed, check the C0STR register to ensure that the mode has been switched.
   Do not change bits CANM and SLPM until the mode has been switched.
2. Write to the SLPM bit in CAN reset mode or CAN halt mode.
   When rewriting the SLPM bit, set only this bit to 0 or 1.
3. Write to bits BOM, MBM, IDFM, MLM, TPM, and TSPS in CAN reset mode.
4. Set the RBOC bit to 1 in bus-off state.
5. Bits RBOC and TSRC are automatically set back to 0 after being set to 1. They are read as 0.
6. Set the TSRC bit to 1 in CAN operation mode.

Figure 25.2 C0CTLR Register

25.1.1.1 CANM Bit

The CANM bit selects one of the following modes for the CAN module: CAN operation mode, CAN reset mode, or CAN halt mode. Refer to 25.2 “Operating Mode” for detail.
CAN sleep mode is set by the SLPM bit.
Do not set the CANM bit to 11b.
When the CAN module enters CAN halt mode according to the setting of the BOM bit, the CANM bit is automatically set to 10b.

25.1.1.2 SLPM Bit

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode.
When this bit is set to 0, the CAN module exits CAN sleep mode.
Refer to 25.2 “Operating Mode” for detail.

25.1.1.3 BOM Bit

The BOM bit is used to select bus-off recovery mode.

When the BOM bit is 00b, the recovery from bus-off is compliant with ISO11898-1, i.e. the CAN module re-enters CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off.

When the BOM bit is 01b, as soon as the CAN module reaches the bus-off state, the CANM bit in the C0CTLR register is set to 10b (CAN halt mode) and the CAN module enters CAN halt mode. No bus-off recovery interrupt request is generated when recovering from bus-off and registers C0TECR and C0RECR are set to 00h.

When the BOM bit is 10b, the CANM bit is set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, i.e. after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off and registers C0TECR and C0RECR are set to 00h.

When the BOM bit is 11b, the CAN module enters CAN halt mode by setting the CANM bit to 10b while the CAN module is still in bus-off state. No bus-off recovery interrupt request is generated when recovering from bus-off and registers C0TECR and C0RECR are set to 00h. However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM bit is set to10b, a bus-off recovery interrupt request is generated.

If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM bit is 01b, or at bus-off end when the BOM bit is 10b), then the CPU request to enter CAN reset mode has higher priority.

25.1.1.4 RBOC Bit

When the RBOC bit is set to 1 (forcible return from bus-off) in bus-off state, the CAN module forcibly returns from the bus-off state. This bit is automatically set to 0. The error state changes from bus-off to error-active.

When the RBOC bit is set to 1, registers C0RECR and C0TECR are set to 00h and the BOST bit in the C0STR register is set to 0 (the CAN module is not in bus-off state). The other registers remain unchanged. No bus-off recovery interrupt request is generated by this recovery from the bus-off state.
Use the RBOC bit only when the BOM bit is 00b (normal mode).

25.1.1.5 MBM Bit

When the MBM bit is 0 (normal mailbox mode), mailboxes [0] to [31] are configured as transmit or receive mailboxes.
When this bit is 1 (FIFO mailbox mode), mailboxes [0] to [23] are configured as transmit or receive mailboxes. Mailboxes [24] to [27] are configured as a transmit FIFO and mailboxes [28] to [31] as a receive FIFO.
Transmit data is written into mailbox [24] (mailbox [24] is a window mailbox for the transmit FIFO).
Receive data is read from mailbox [28] (mailbox [28] is a window mailbox for the receive FIFO).
Table 25.3 lists the mailbox configuration.

Table 25.3 Mailbox Configuration

Mailbox	MBM = 0 (Normal Mailbox Mode)	MBM = 1 (1) (FIFO Mailbox Mode)
Mailboxes [0] to [23]	Normal mailbox	Normal mailbox
Mailboxes [24] to [27]		Transmit FIFO
Mailboxes [28] to [31]		Receive FIFO

Note:
1. When the MBM bit is set to 1, note the following:
   - Transmit FIFO is controlled by the C0TFCR register.
     The C0MCTLj register (j = 0 to 31) for mailboxes [24] to [27] is disabled.
     Registers C0MCTL24 to C0MCTL27 cannot be used.
   - Receive FIFO is controlled by the C0RFCR register.
     The C0MCTLj register for mailboxes [28] to [31] is disabled.
     Registers C0MCTL28 to C0MCTL31 cannot be used.
   - Refer to the C0MIER register about the FIFO interrupts.
   - The corresponding bits in the C0MKIVLR register for mailboxes [24] to [31] are disabled. Set 0 to these bits.
   - Transmit/receive FIFOs can be used for both data frames and remote frames.

25.1.1.6 IDFM Bit

The IDFM bit specifies the ID format.
When this bit is 00b, all mailboxes (including FIFO mailboxes) handle only standard IDs.
When this bit is 01b, all mailboxes (including FIFO mailboxes) handle only extended IDs.
When this bit is 10b, all mailboxes (including FIFO mailboxes) handle both standard IDs and extended IDs. Standard IDs or extended IDs are specified by using the IDE bit in the corresponding mailbox in normal mailbox mode. In FIFO mailbox mode, the IDE bit in the corresponding mailbox is used for mailboxes [0] to [23], the IDE bit in registers C0FIDCR0 and C0FIDCR1 is used for the receive FIFO, and the IDE bit in mailbox [24] is used for the transmit FIFO.
Do not set 11b to the IDFM bit.

25.1.1.7 MLM Bit

The MLM bit specifies the operation when a new message is captured in the unread mailbox.
Overwrite mode or overrun mode can be selected. All mailboxes (including the receive FIFO) are set to either overwrite mode or overrun mode.

When the MLM bit is 0, all mailboxes are set to overwrite mode and the new message is overwriting the old message.
When this bit is 1, all mailboxes are set to overrun mode and the new message is discarded.

25.1.1.8 TPM Bit

The TPM bit specifies the priority of modes when transmitting messages.
ID priority transmit mode or mailbox number transmit mode can be selected.
All mailboxes are set for either ID priority transmission or mailbox number priority transmission.

When the TPM bit is 0, ID priority transmit mode is selected and transmission priority complies with the CAN bus arbitration rule, as defined in the ISO 11898-1 Specifications. In ID priority transmit mode, mailboxes [0] to [31] (in normal mailbox mode), and mailboxes [0] to [23] (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.

Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a transmit FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.

When the TPM bit is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (mailboxes [0] to [23]).

25.1.1.9 TSRC Bit

The TSRC bit is used to reset the time stamp counter.
When this bit is set to 1, the C0TSR register is set to 0000h. It is automatically set to 0.

25.1.1.10 TSPS Bit

The TSPS bit selects the prescaler for the time stamp.
The reference clock for the time stamp can be selected from either 1-, 2-, 4- or 8-bit time periods.

25.1.2 CAN0 Clock Select Register (C0CLKR Register)

CAN0 Clock Select Register

b7	b6	b5	b4	b3	b2	b1	b0
0	X	X	0	0	X	0	

Symbol	Address	Reset Value
C0CLKR	47F47h	000X 0000b

Bit Symbol	Bit Name	Function	RW
CCLKS	CAN Clock Source Select Bit (1)	0: Peripheral bus clock 1: Main clock (2)	RW
— (b1)	Reserved	Should be written with 0	RW
— (b2)	No register bit; should be written with 0 and read as 0		—
— (b3)	Reserved	Should be written with 0	RW
— (b4)	Reserved	Should be written with 0 and read as undefined value	RW
— (b6-b5)	No register bits; should be written with 0 and read as 0		—
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. Write to the CCLKS bit in CAN reset mode.
2. To set the CCLKS bit to 1, the frequency of the peripheral bus clock should be equal to or higher than the frequency of the main clock.

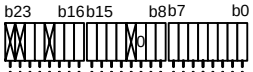
Figure 25.3 C0CLKR Register

25.1.2.1 CCLKS Bit

When the CCLKS bit is set to 0, the CAN clock source (fCAN) originates from the PLL.
When this bit is set to 1, the fCAN originates directly from the external XIN pin bypassing the PLL.

25.1.3 CAN0 Bit Configuration Register (C0BCR Register)

CAN0 Bit Configuration Register (1, 2)



Symbol	Address	Reset Value
C0BCR	47F46h-47F44h	00 0000h

Bit Symbol	Bit Name	Function	RW
BRP	Prescaler Division Ratio Set Bit (10 bits)	If the setting value is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1	RW
— (b10)	Reserved	Should be written with 0	RW
— (b11)	No register bit; should be written with 0 and read as 0		—
TSEG1	Time Segment 1 Control Bit	b15b14b13b12 0 0 0 0 : Do not use this combination 0 0 0 1 : Do not use this combination 0 0 1 0 : Do not use this combination 0 0 1 1 : 4 Tq 0 1 0 0 : 5 Tq 0 1 0 1 : 6 Tq 0 1 1 0 : 7 Tq 0 1 1 1 : 8 Tq 1 0 0 0 : 9 Tq 1 0 0 1 : 10 Tq 1 0 1 0 : 11 Tq 1 0 1 1 : 12 Tq 1 1 0 0 : 13 Tq 1 1 0 1 : 14 Tq 1 1 1 0 : 15 Tq 1 1 1 1 : 16 Tq	RW

— (b19)	No register bit; should be written with 0 and read as 0		—
SJW	Resynchronization Jump Width Control Bit	b21b20 0 0 : 1 Tq 0 1 : 2 Tq 1 0 : 3 Tq 1 1 : 4 Tq	RW
— (b23-b22)	No register bits; should be written with 0 and read as 0		—

Notes:
1. Set the C0BCR register before entering CAN halt mode from CAN reset mode or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset mode or CAN halt mode.
2. The C0BCR register consists of 24 bits. A 32-bit read/write access should be performed carefully not to rewrite the C0CLKR register.

Figure 25.4 C0BCR Register

Refer to 25.3 “CAN Communication Speed Configuration” about the bit timing configuration.

25.1.3.1 BRP Bit

The BRP bit is used to set the frequency of the CAN communication clock (fCANCLK).
The cycle of the fCANCLK is set to be 1 Time Quantum (Tq).

25.1.3.2 TSEG1 Bit

The TSEG1 bit is used to specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with the value of Tq.
A value from 4 to 16 time quanta can be set.

25.1.3.3 TSEG2 Bit

The TSEG2 bit is used to specify the length of phase buffer segment TSEG2 (PHASE_SEG2) with the value of Tq.
A value from 2 to 8 time quanta can be set.
Set the value smaller than that of the TSEG1 bit.

25.1.3.4 SJW Bit

The SJW bit is used to specify the resynchronization jump width with the value of Tq.
A value from 1 to 4 time quanta can be set.
Set the value smaller than or equal to that of the TSEG2 bit.

25.1.4 CAN0 Mask Register k (C0MKRk Register) (k = 0 to 7)

CAN0 Mask Register k (k = 0 to 7) (1)

Symbol	Address	Reset Value
C0MKR0, C0MKR1	47E03h-47E00h, 47E07h-47E04h	Undefined
C0MKR2, C0MKR3	47E0Bh-47E08h, 47E0Fh-47E0Ch	Undefined
C0MKR4, C0MKR5	47E13h-47E10h, 47E17h-47E14h	Undefined
C0MKR6, C0MKR7	47E1Bh-47E18h, 47E1Fh-47E1Ch	Undefined

Bit Symbol	Bit Name	Function	RW
EID	Extended ID Bit	0: Corresponding EID bit is not compared 1: Corresponding EID bit is compared	RW
SID	Standard ID Bit	0: Corresponding SID bit is not compared 1: Corresponding SID bit is compared	RW
— (b31-b29)	Reserved	Should be written with 0	RW

Note:
1. Write to registers C0MKR0 to C0MKR7 in CAN reset mode or CAN halt mode.

Figure 25.5 Registers C0MKR0 to C0MKR7

Refer to 25.5 “Acceptance Filtering and Masking Function” about the masking function in FIFO mailbox mode.

25.1.4.1 EID Bit

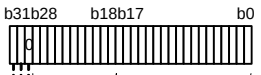
The EID bit is the filter mask bit corresponding to the CAN extended ID bit. This bit is used to receive extended ID messages.
When the EID bit is 0, the corresponding EID bit is not compared for the received ID and the mailbox ID.
When this bit is 1, the corresponding EID bit is compared for the received ID and the mailbox ID.

25.1.4.2 SID Bit

The SID bit is the filter mask bit corresponding to the CAN standard ID bit. This bit is used to receive both standard ID and extended ID messages.
When the SID bit is 0, the corresponding SID bit is not compared for the received ID and the mailbox ID.
When this bit is 1, the corresponding SID bit is compared for the received ID and the mailbox ID.

25.1.5 CAN0 FIFO Received ID Compare Register n (Registers C0FIDCR0 and C0FIDCR1) (n = 0, 1)

CAN0 FIFO Received ID Compare Register n (n = 0, 1) (1)



Symbol	Address	Reset Value
C0FIDCR0	47E23h-47E20h	Undefined
C0FIDCR1	47E27h-47E24h	Undefined

Bit Symbol	Bit Name	Function	RW
EID	Extended ID Bit	0: Corresponding EID bit is 0 1: Corresponding EID bit is 1	RW
SID	Standard ID Bit	0: Corresponding SID bit is 0 1: Corresponding SID bit is 1	RW
— (b29)	Reserved	Should be written with 0	RW
RTR	Remote Frame Request Bit	0: Data frame 1: Remote frame	RW
IDE	ID Extension Bit (2)	0: Standard ID 1: Extended ID	RW

Notes:
1. Write to registers C0FIDCR0 and C0FIDCR1 in CAN reset mode or CAN halt mode.
2. The IDE bit is enabled when the IDFM bit in the C0CTLR register is 10b (mixed ID mode). When the IDFM bit is either 00b (standard ID mode) or 01b (extended ID mode), the IDE bit should be written with 0.

Figure 25.6 Registers C0FIDCR0 and C0FIDCR1

Registers C0FIDCR0 and C0FIDCR1 are enabled when the MBM bit in the C0CTLR register is set to 1 (FIFO mailbox mode). Bits EID, SID, RTR, and IDE in registers C0MB28 to C0MB31 are disabled. Refer to 25.5 “Acceptance Filtering and Masking Function” about the usage of these registers.

25.1.5.1 EID Bit

The EID bit sets the extended ID of data frames and remote frames. This bit is used to receive extended ID messages.

25.1.5.2 SID Bit

The SID bit sets the standard ID of data frames and remote frames. This bit is used to receive both standard ID and extended ID messages.

25.1.5.3 RTR Bit

The RTR bit sets the specified frame format of data frames or remote frames.
This bit specifies the following operation:

- When both RTR bits in registers C0FIDCR0 and C0FIDCR1 are set to 0, only data frames can be received.
- When both RTR bits in registers C0FIDCR0 and C0FIDCR1 are set to 1, only remote frames can be received.
- When the RTR bits in registers C0FIDCR0 and C0FIDCR1 are set to 0 or 1 individually, both data frames and remote frames can be received.

25.1.5.4 IDE Bit

The IDE bit sets the ID format of standard ID or extended ID.
This bit is enabled when the IDFM bit in the C0CTLR register is 10b (mixed ID mode).
When the IDFM bit is 10b, the IDE bit specifies the following operation:

- When both IDE bits in registers C0FIDCR0 and C0FIDCR1 are set to 0, only standard ID frames can be received.
- When both IDE bits in registers C0FIDCR0 and C0FIDCR1 are set to 1, only extended ID frames can be received.
- When the IDE bits in registers C0FIDCR0 and C0FIDCR1 are set to 0 or 1 individually, both standard ID and extended ID frames can be received.

25.1.6 CAN0 Mask Invalid Register (C0MKIVLR Register)

CAN0 Mask Invalid Register (1)

Normal mailbox mode

b31 b0

Symbol: C0MKIVLR
Address: 47E2Bh-47E28h
Reset Value: Undefined

Bit Symbol	Bit Name	Function	RW
— (b31-b0)	Mask Invalid Bit	0: Mask valid 1: Mask invalid	RW

FIFO mailbox mode

b31 b24b23 b0

Bit Symbol	Bit Name	Function	RW
— (b23-b0)	Mask Invalid Bit	0: Mask valid 1: Mask invalid	RW
— (b31-b24)	Reserved	Should be written with 0	RW

Note:
1. Write to the C0MKIVLR register in CAN reset mode or CAN halt mode.

Figure 25.7 C0MKIVLR Register

Each bit corresponds to the mailbox with the same number. When each bit is 1, the acceptance mask for the mailbox corresponding to the bit number is disabled. In this case, a receiving message is stored into the mailbox only if its ID matches bits SID and EID in the C0MBj register (j = 0 to 31).

25.1.7 CAN0 Mailbox (C0MBj Register) (j = 0 to 31)

Table 25.4 lists the CAN0 mailbox memory mapping, and Table 25.5 lists the CAN data frame structure. The value after reset of CAN0 mailbox is undefined.

Table 25.4 CAN0 Mailbox Memory Mapping

Address	Message Content
CAN0	Memory Mapping
47C00h + j × 16 + 0	EID7 to EID0
47C00h + j × 16 + 1	EID15 to EID8

47C00h + j × 16 + 14	Time stamp lower byte
47C00h + j × 16 + 15	Time stamp upper byte

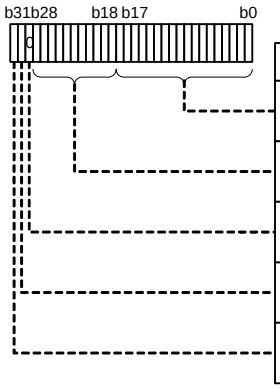
j: Mailbox number (j = 0 to 31)

Table 25.5 CAN Data Frame Structure

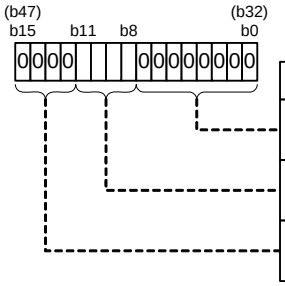
SID10 to SID6	SID5 to SID0	EID17 to EID16	EID15 to EID8	EID7 to EID0	DLC3 to DLC0	DATA0	DATA1	.....	DATA7

CAN0 Mailbox Register j (j = 0 to 31) (1)

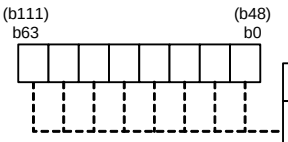
Symbol	Address (2)	Reset Value
C0MB0 to C0MB31	47C00h to 47DFFh	Undefined



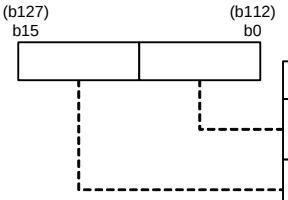
Bit Symbol	Bit Name	Function	RW
EID	Extended ID (3)	0: Corresponding EID bit is 0 1: Corresponding EID bit is 1	RW
SID	Standard ID	0: Corresponding SID bit is 0 1: Corresponding SID bit is 1	RW
— (b29)	Reserved	Should be written with 0	RW
RTR	Remote Frame Request Bit	0: Data frame 1: Remote frame	RW
IDE	ID Extension Bit (4)	0: Standard ID 1: Extended ID	RW



Bit Symbol	Bit Name	Setting Range	RW
— (b7-b0)	Reserved	Should be written with 0	RW
DLC	Data Length Code (5)	0h to Fh	RW
— (b15-b12)	Reserved	Should be written with 0	RW



Symbol	Name	Setting Range	RW
DATA0 to DATA7	Data Bytes 0 to 7 (5, 6)	00h to FFh	RW



Symbol	Name	Setting Range	RW
TSL	Time Stamp Lower Byte	00h to FFh	RW
TSH	Time Stamp Higher Byte	00h to FFh	RW

Notes:
1. Write to the C0MBj register only when the associated C0MCTLj register is 00h and the corresponding mailbox is not processing an abort request.
2. Refer to the memory mapping table for CAN0 mailbox on the previous page for detailed addresses.
3. If the mailbox has received a standard ID message, the EID bit in the mailbox is undefined.
4. The IDE bit is enabled when the IDFM bit in the C0CTLR register is 10b (mixed ID mode). When the IDFM bit is either 00b (standard ID mod) or 01b (extended ID mode), it should be written with 0.
5. If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.
6. If the mailbox has received a remote frame, the previous values of DATA0 to DATA7 in the mailbox are retained.

Figure 25.8 C0MBj Register

The previous value of each mailbox is retained unless a new message is received.

25.1.7.1 EID Bit

The EID bit sets the extended ID of data frames and remote frames. This bit is used to transmit or receive extended ID messages.

25.1.7.2 SID Bit

The SID bit sets the standard ID of data frames and remote frames. This bit is used to transmit or receive both standard ID and extended ID messages.

25.1.7.3 RTR Bit

The RTR bit sets the frame format of data frames or remote frames.
This bit specifies the following operation:

- Receive mailbox receives only frames with the format specified by the RTR bit.
- Transmit mailbox transmits according to the frame format specified by the RTR bit.
- Receive FIFO mailbox receives the data frame, remote frame, or both frames specified by the RTR bit in registers C0FIDCR0 and C0FIDCR1.
- Transmit FIFO mailbox transmits the data frame or remote frame specified by the RTR bit in the relevant transmitting message.

25.1.7.4 IDE Bit

The IDE bit sets the ID format of standard IDs or extended IDs.
This bit is enabled when the IDFM bit in the C0CTLR register is 10b (mixed ID mode).
When the IDFM bit is 10b, the IDE bit specifies the following operation:

- Receive mailbox receives only the ID format specified by the IDE bit.
- Transmit mailbox transmits according to the ID format specified by the IDE bit.
- Receive FIFO mailbox receives messages with the standard ID, extended ID, or both IDs specified by the IDE bit in registers C0FIDCR0 and C0FIDCR1.
- Transmit FIFO mailbox transmits messages with the standard ID or extended ID specified by the IDE bit in the relevant transmitting message.

25.1.7.5 DLC (Data Length Code)

The DLC is used to set the number of data bytes to be transmitted in a data frame. When data is requested using a remote frame, the number of data bytes to be requested is set.
When a data frame is received, the number of received data bytes is stored. When a remote frame is received, the number of requested data bytes is stored.
Table 25.6 lists the data length corresponding DLC.

Table 25.6 Data Length Corresponding DLC

DLC[3]	DLC[2]	DLC[1]	DLC[0]	Data Length
0	0	0	0	0 byte
0	0	0	1	1 byte
0	0	1	0	2 bytes
0	0	1	1	3 bytes
0	1	0	0	4 bytes
0	1	0	1	5 bytes
0	1	1	0	6 bytes
0	1	1	1	7 bytes
1	X	X	X	8 bytes

X: Any value

25.1.7.6 DATA0 to DATA7

DATA0 to DATA7 store the transmitted or received CAN message data. Transmission or reception starts from DATA0. The bit order on the CAN bus is MSB first, and transmission or reception starts from bit 7.

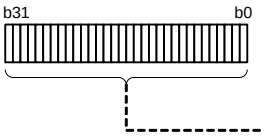
25.1.7.7 TSL and TSH

TSL and TSH store the counter value of the time stamp when received messages are stored in the mailbox.

25.1.8 CAN0 Mailbox Interrupt Enable Register (C0MIER Register)

CAN0 Mailbox Interrupt Enable Register (1, 2)

Normal mailbox mode



Symbol	Address	Reset Value
C0MIER	47E2Fh-47E2Ch	Undefined

Bit Symbol	Bit Name	Function	RW
— (b31-b0)	Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW

FIFO mailbox mode

Bit Symbol	Bit Name	Function	RW
— (b23-b0)	Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW
— (b24)	Transmit FIFO Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW
— (b25)	Transmit FIFO Interrupt Generation Timing Control Bit	Transmit FIFO interrupt request is generated 0: Every time transmission is completed 1: When transmit FIFO becomes empty due to completion of transmission	RW
— (b27-b26)	Reserved	Should be written with 0	RW
— (b28)	Receive FIFO Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW
— (b29)	Receive FIFO Interrupt Generation Timing Control Bit	Receive FIFO interrupt request is generated 0: Every time reception is completed 1: When receive FIFO becomes buffer warning by completion of reception (3)	RW
— (b31-b30)	Reserved	Should be written with 0	RW

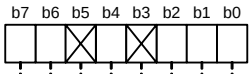
Notes:
1. Write to the C0MIER register only when the associated C0MCTLj register (j = 0 to 31) is 00h and the corresponding mailbox is not processing a transmission or reception abort request.
2. In FIFO mailbox mode, change the bits in the C0MIER register for the associated FIFO only when:
   - The TFE bit in the C0TFCR register is 0 and the TFEST bit is 1, and
   - The RFE bit in the C0RFCR register is 0 and the RFEST bit is 1.
3. No interrupt request is generated when the receive FIFO becomes buffer warning from full.

Figure 25.9 C0MIER Register

Interrupts can enabled individually for each mailbox.
In normal mailbox mode (bits 0 to 31) and in FIFO mailbox mode (bits 0 to 23), each bit corresponds to the mailbox with the same number. These bits enable or disable transmission/reception complete interrupts for the corresponding mailboxes.
In FIFO mailbox mode, bits 24, 25, 28, and 29 specify whether transmit/receive FIFO interrupts are enabled/disabled and timing when interrupt requests are generated.
“Buffer warning” indicates a state in which the third unread message is stored in the receive FIFO.

25.1.9 CAN0 Message Control Register j (C0MCTLj Register) (j = 0 to 31)

CAN0 Message Control Register j (j = 0 to 31) (1, 2)



Symbol	Address	Reset Value
C0MCTL0 to C0MCTL31	47F20h to 47F3Fh	00h

Bit Symbol	Bit Name	Function	RW
When the TRMREQ bit is 0 and the RECREQ bit is 1			
NEWDATA	Reception Complete Flag (3, 4)	0: No data has been received or 0 is written to the NEWDATA bit 1: A new message is being stored or has been stored to the mailbox	RW
INVALDATA	Reception-in-Progress Status Flag	0: Message valid 1: Message being updated	RO
MSGLOST	Message Lost Flag (3, 4)	0: Message is not overwritten or overrun 1: Message is overwritten or overrun	RW
When the TRMREQ bit is 1 and the RECREQ bit is 0			
SENTDATA	Transmission Complete Flag (3, 4)	0: Transmission is not completed (pending) 1: Transmission is completed (success)	RW
TRMACTIVE	Transmission-in-Progress Status Flag	0: Transmission is pending or transmission is not requested 1: From acceptance of transmission request to completion of transmission, or error/arbitration lost	RO
TRMABT	Transmission Abort Complete Flag (3, 4)	0: Transmission has started, transmission abort failed because transmission is completed, or transmission abort is not requested 1: Transmission abort is completed	RW
— (b3)	No register bit; should be written with 0 and read as 0		—
ONESHOT	One-shot Enable Bit (5)	0: One-shot reception or one-shot transmission disabled 1: One-shot reception or one-shot transmission enabled	RW
— (b5)	No register bit; should be written with 0 and read as 0		—
RECREQ	Receive Mailbox Set Bit (4, 6, 7)	0: Not configured for reception 1: Configured for reception	RW
TRMREQ	Transmit Mailbox Set Bit (4, 6)	0: Not configured for transmission 1: Configured for transmission	RW

Notes:
1. Write to the C0MCTLj register in CAN operation mode or CAN halt mode.
2. Do not use registers C0MCTL24 to C0MCTL31 in FIFO mailbox mode.
3. Write 0 only. Writing 1 has no effect.
4. When writing 0 to bits NEWDATA, SENTDATA, MSGLOST, TRMABT, RECREQ, and TRMREQ by a program, use the MOV instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.
5. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1. To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming it has been set to 0.
   To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1. To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message has been transmitted or aborted.
6. Do not set both the RECREQ and TRMREQ bits to 1.
7. When setting the RECREQ bit to 0, set bits MSGLOST, NEWDATA, RECREQ to 0 simultaneously.

Figure 25.10 C0MCTLj Register

25.1.9.1 NEWDATA Bit

The NEWDATA bit is set to 1 when a new message is being stored or has been stored to the mailbox.
The timing for setting this bit to 1 is simultaneous with the INVALDATA bit.
The NEWDATA bit is set to 0 by writing 0 by a program.
This bit is not be set to 0 by writing 0 by a program while the related INVALDATA bit is 1.

25.1.9.2 SENTDATA Bit

The SENTDATA bit is set to 1 when data transmission from the corresponding mailbox is completed.
This bit is set to 0 by writing 0 by a program.
To set the SENTDATA bit to 0, first set the TRMREQ bit to 0.
Bits SENTDATA and TRMREQ cannot be set to 0 simultaneously.
To transmit a new message from the corresponding mailbox, set the SENTDATA bit to 0.

25.1.9.3 INVALDATA Bit

After the completion of a message reception, the INVALDATA bit is set to 1 while the received message is being updated into the corresponding mailbox.
This bit is set to 0 immediately after the message has been stored. If the mailbox is read while this bit is 1, the data is undefined.

25.1.9.4 TRMACTIVE Bit

The TRMACTIVE bit is set to 1 when the corresponding mailbox of the CAN module begins transmitting a message.
This bit is set to 0 when the CAN module has lost CAN bus arbitration, a CAN bus error occurs, or data transmission is completed.

25.1.9.5 MSGLOST Bit

The MSGLOST bit is set to 1 when the mailbox is overwritten or overrun by a new received message while the NEWDATA bit is 1. The MSGLOST bit is set to 1 at the end of the 6th bit of EOF.
This bit is set to 0 by writing 0 by a program.
In both overwrite and overrun modes, this bit is not set to 0 by writing 0 by a program during five cycles of fCAN (CAN system clock) following the 6th bit of EOF.

25.1.9.6 TRMABT Bit

The TRMABT bit is set to 1 in the following cases:

- Following a transmission abort request, when the transmission abort is completed before starting transmission.
- Following a transmission abort request, when the CAN module detects CAN bus arbitration lost or a CAN bus error.
- In one-shot transmission mode (RECREQ bit = 0, TRMREQ bit = 1, and ONESHOT bit = 1), when the CAN module detects CAN bus arbitration lost or a CAN bus error.

The TRMABT bit is not set to 1 when data transmission is completed. In this case, the SENTDATA bit is set to 1.
The TRMABT bit is set to 0 by writing 0 by a program.

25.1.9.7 ONESHOT Bit

The ONESHOT bit can be used in the following two ways, receive mode and transmit mode:

(1) One-shot Receive Mode

When the ONESHOT bit is set to 1 in receive mode (RECREQ bit = 1 and TRMREQ bit = 0), the mailbox receives a message only one time. The mailbox does not behave as a receive mailbox after having received a message one time. The behavior of bits NEWDATA and INVALDATA is the same as in normal reception mode. In one-shot receive mode, the MSGLOST bit is not set to 1.
To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it has been set to 0.

(2) One-shot Transmit Mode

When the ONESHOT bit is set to 1 in transmit mode (RECREQ bit = 0 and TRMREQ bit = 1), the CAN module transmits a message only one time. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration lost occurs. When transmission is completed, the SENTDATA bit is set to 1. If transmission is not completed due to a CAN bus error or CAN bus arbitration lost, the TRMABT bit is set to 1.
Set the ONESHOT bit to 0 after the SENTDATA or TRMABT bit is set to 1.

25.1.9.8 RECREQ Bit

The RECREQ bit selects receive modes shown in Table 25.11.
When the RECREQ bit is set to 1, the corresponding mailbox is configured for reception of a data frame or a remote frame.
When this bit is set to 0, the corresponding mailbox is not configured for reception of a data frame or a remote frame.
Due to HW protection, the RECREQ bit cannot be set to 0 by writing 0 by a program during the following period:
HW protection is started
- from the acceptance filter procedure (the beginning of the CRC field)

HW protection is released
- for the mailbox that is specified to receive the incoming message, after the received data is stored into the mailbox or a CAN bus error occurs (i.e. a maximum period of HW protection is from the beginning of the CRC field to the end of the 7th bit of EOF)
- for the other mailboxes, after the acceptance filter procedure
- if no mailbox is specified to receive the message, after the acceptance filter procedure

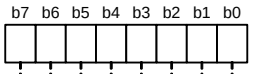
When setting the RECREQ bit to 1, do not set 1 to the TRMREQ bit.
To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set bits SENTDATA and TRMABT to 0 before changing to reception.

25.1.9.9 TRMREQ Bit

The TRMREQ bit selects transmit modes shown in Table 25.11.
When this bit is set to 1, the corresponding mailbox is configured for transmission of a data frame or a remote frame.
When this bit is set to 0, the corresponding mailbox is not configured for transmission of a data frame or a remote frame.
If the TRMREQ bit is changed from 1 to 0 to cancel the corresponding transmission request, either the TRMABT or SENTDATA bit is set to 1.
When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1.
To change the configuration of a mailbox from reception to transmission, first abort the reception and then set bits NEWDATA and MSGLOST to 0 before changing to transmission.

25.1.10 CAN0 Receive FIFO Control Register (C0RFCR Register)

CAN0 Receive FIFO Control Register (1)



Symbol	Address	Reset Value
C0RFCR	47F48h	1000 0000b

Bit Symbol	Bit Name	Function	RW
RFE	Receive FIFO Enable Bit (2)	0: Receive FIFO disabled 1: Receive FIFO enabled	RW
RFUST	Receive FIFO Unread Message Number Status Bit	b3 b2 b1 0 0 0 : No unread message 0 0 1 : 1 unread message 0 1 0 : 2 unread messages 0 1 1 : 3 unread messages 1 0 0 : 4 unread messages 1 0 1 : Reserved 1 1 0 : Reserved 1 1 1 : Reserved	RO
RFMLF	Receive FIFO Message Lost Flag (3)	0: No receive FIFO message lost has occurred 1: Receive FIFO message lost has occurred	RW
RFFST	Receive FIFO Full Status Bit	0: Receive FIFO is not full 1: Receive FIFO is full (4 unread messages)	RO
RFWST	Receive FIFO Buffer Warning Status Bit	0: Receive FIFO is not buffer warning 1: Receive FIFO is buffer warning (3 unread messages)	RO
RFEST	Receive FIFO Empty Status Bit	0: Unread message in receive FIFO 1: No unread message in receive FIFO	RO

Notes:
1. Write to the C0RFCR register in CAN operation mode or CAN halt mode.
2. When setting the RFE bit to 0, set the RFMLF bit to 0 as well.
3. Write 0 only. Writing 1 has no effect.

Figure 25.11 C0RFCR Register

25.1.10.1 RFE Bit

When the RFE bit is set to 1, the receive FIFO is enabled.
When this bit is set to 0, the receive FIFO is disabled for reception and becomes empty (RFEST bit = 1).
Do not set this bit to 1 in normal mailbox mode (MBM bit in the C0CTLR register = 0).
Due to HW protection, the RFE bit is not set to 0 by writing 0 by a program during the following period:
HW protection is started

- from the acceptance filter procedure (the beginning of the CRC field)

HW protection is released

- if the receive FIFO is specified to receive the incoming message, after the received data is stored into the receive FIFO or a CAN bus error occurs. (i.e. a maximum period of HW protection is from the beginning of the CRC field to the end of the 7th bit of EOF.)
- if the receive FIFO is not specified to receive the message, after the acceptance filter procedure.

25.1.10.2 RFUST Bit

The RFUST bit indicates the number of unread messages in the receive FIFO.
The value of this bit is initialized to 000b when the RFE bit is set to 0.

25.1.10.3 RFMLF Bit

The RFMLF bit is set to 1 (receive FIFO message lost has occurred) when the receive FIFO receives a new message and the receive FIFO is full. The timing for setting this bit to 1 is at the end of the 6th bit of EOF.
The RFMLF bit is set to 0 by writing 0 by a program.
In both overwrite and overrun modes, this bit cannot be set to 0 (receive FIFO message lost has not occurred) by writing 0 by a program due to HW protection during the five cycles of fCAN following the 6th bit of EOF, if the receive FIFO is full and determined to receive the message.

25.1.10.4 RFFST Bit

The RFFST bit is set to 1 (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. This bit is set to 0 (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. This bit is set to 0 when the RFE bit is 0.

25.1.10.5 RFWST Bit

The RFWST bit is set to 1 (receive FIFO is buffer warning) when the number of unread messages in the receive FIFO is 3. This bit is set to 0 (receive FIFO is not buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. This bit is set to 0 when the RFE bit is 0.

25.1.10.6 RFEST Bit

The RFEST bit is 1 (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is 0. This bit is set to 1 when the RFE bit is set to 0. The RFEST bit is set to 0 (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more.

Figure 25.12 shows the receive FIFO mailbox operation.

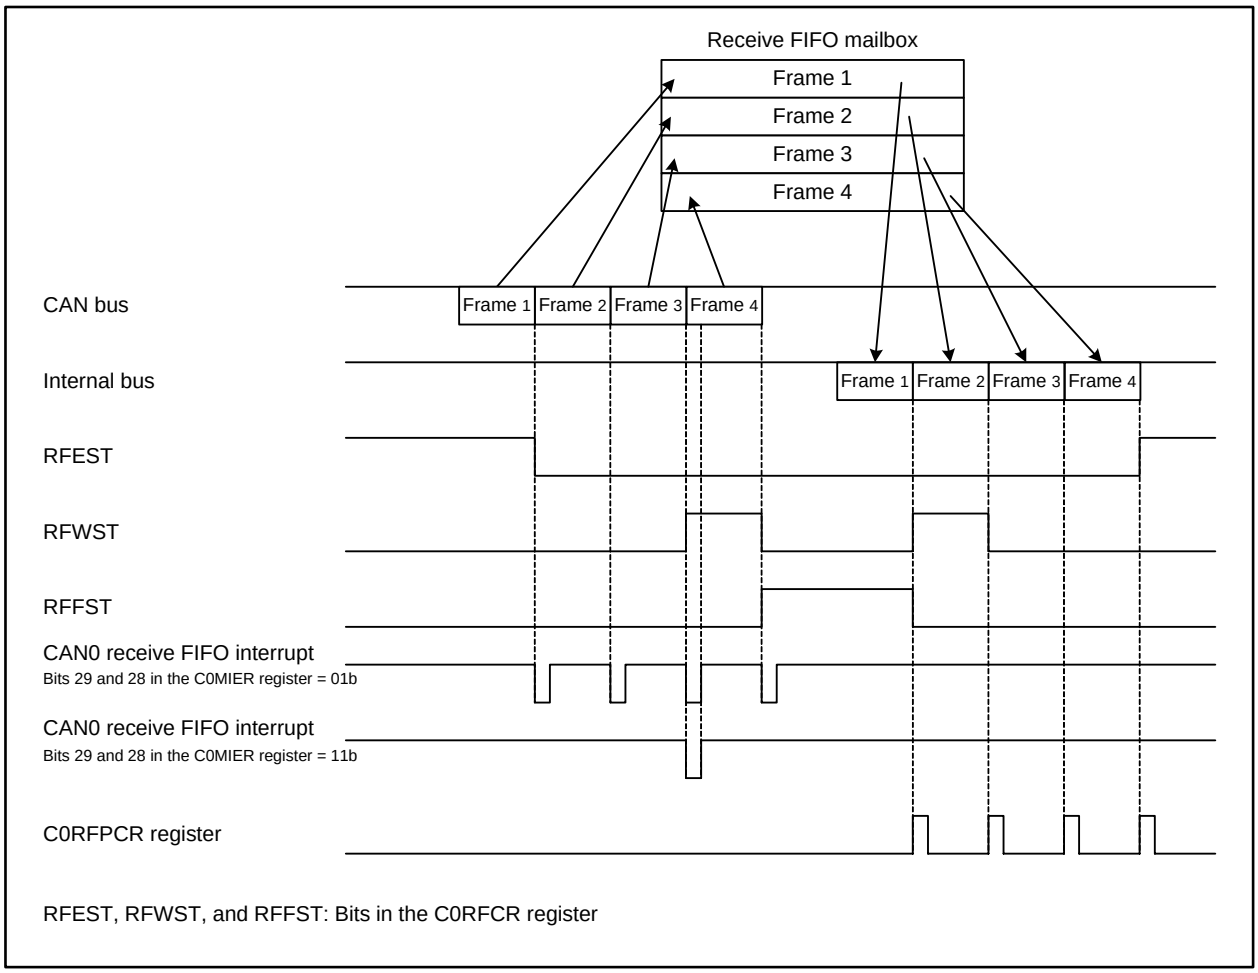


Figure 25.12 Receive FIFO Mailbox Operation (Bits 29 and 28 in C0MIER Register = 01b and 11b)

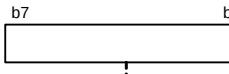
25.1.11 CAN0 Receive FIFO Pointer Control Register (C0RFPCR Register)

CAN0 Receive FIFO Pointer Control Register



Symbol	Address	Reset Value
C0RFPCR	47F49h	Undefined

Function	Setting Value	RW
The CPU-side pointer for the receive FIFO is incremented by writing FFh	FFh	WO

Figure 25.13 C0RFPCR Register

When the receive FIFO is not empty, write FFh to the C0RFPCR register by a program to increment the CPU-side pointer for the receive FIFO to the next mailbox location.
Do not write to the C0RFPCR register when the RFE bit in the C0RFCR register is 0 (receive FIFO disabled).
Both the CAN-side pointer and the CPU-side pointer are incremented when a new message is received and the RFFST bit is 1 (receive FIFO is full) in overwrite mode. When the RFMLF bit is 1 in this condition, the CPU-side pointer cannot be incremented by writing to the C0RFPCR register by a program.

25.1.12 CAN0 Transmit FIFO Control Register (C0TFCR Register)

CAN0 Transmit FIFO Control Register (1)

b7	b6	b5	b4	b3	b2	b1	b0
		0	X				

Symbol	Address	Reset Value
C0TFCR	47F4Ah	1000 0000b

TFUST	Transmit FIFO Unsent Message Number Status Bit	b3 b2 b1 0 0 0 : No unsent message 0 0 1 : 1 unsent message 0 1 0 : 2 unsent messages 0 1 1 : 3 unsent messages 1 0 0 : 4 unsent messages 1 0 1 : Reserved 1 1 0 : Reserved 1 1 1 : Reserved	RO
— (b4)	No register bit; should be written with 0 and read as 0		—
— (b5)	Reserved	Should be written with 0 and read as undefined value	RO
TFFST	Transmit FIFO Full Status Bit	0: Transmit FIFO is not full 1: Transmit FIFO is full (4 unsent messages)	RO
TFEST	Transmit FIFO Empty Status Bit	0: Unsent message in transmit FIFO 1: No unsent message in transmit FIFO	RO

Note:
1. Write to the C0TFCR register in CAN operation mode or CAN halt mode.

Figure 25.14 C0TFCR Register

25.1.12.1 TFE Bit

When the TFE bit is set to 1, the transmit FIFO is enabled.
When this bit is set to 0, the transmit FIFO becomes empty (TFEST bit = 1) and then unsent messages from the transmit FIFO are lost as described below:

- If a message from the transmit FIFO is not scheduled for the next transmission or during transmission.
- Following the completion of transmission, a CAN bus error, CAN bus arbitration lost, or entry to CAN halt mode if a message from the transmit FIFO is scheduled for the next transmission or already during transmission.

Before setting the TFE bit to set to 1 again, ensure that the TFEST bit has been set to 1.
After setting the TFE bit to 1, write transmit data into the C0MB24 register.
Do not set this bit to 1 in normal mailbox mode (MBM bit in the C0CTLR register = 0).

25.1.12.2 TFUST Bit

The TFUST bit indicates the number of unsent messages in the transmit FIFO.
After the TFE bit is set to 0, the value of the TFUST bit is initialized to 000b when transmission abort or transmission is completed.

25.1.12.3 TFFST Bit

The TFFST bit is set to 1 (transmit FIFO is full) when the number of unsent messages in the transmit FIFO is 4. This bit is set to 0 (transmit FIFO is not full) when the number of unsent messages in the transmit FIFO is less than 4. This bit is set to 0 when transmission from the transmit FIFO has been aborted.

25.1.12.4 TFEST Bit

The TFEST bit is set to 1 (no message in transmit FIFO) when the number of unsent messages in the transmit FIFO is 0. This bit is set to 1 when transmission from the transmit FIFO has been aborted.
The TFEST bit is set to 0 (message in transmit FIFO) when the number of unsent messages in the transmit FIFO is not 0.

Figure 25.15 shows the transmit FIFO mailbox operation.

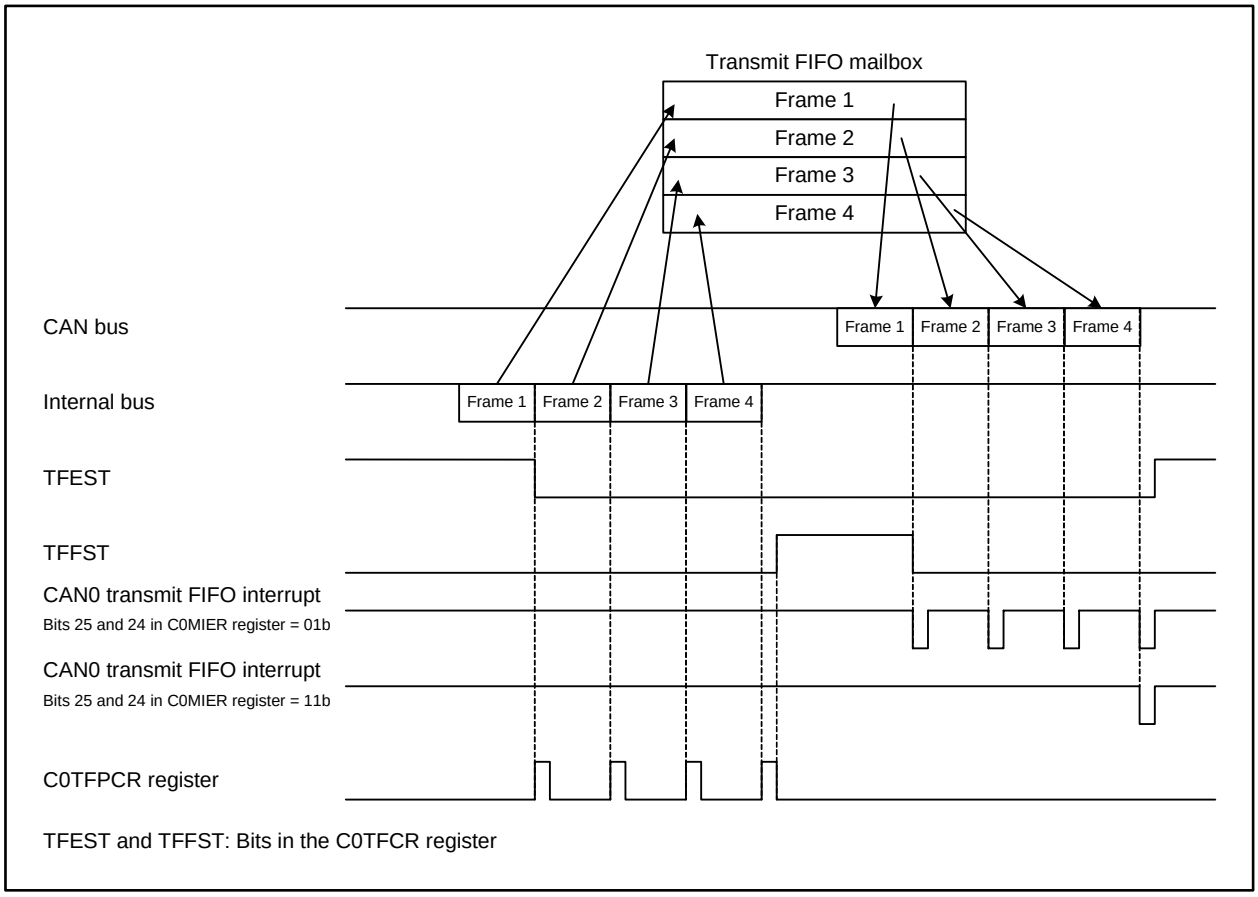

Figure 25.15 Transmit FIFO Mailbox Operation (Bits 25 and 24 in C0MIER Register = 01b and 11b)

EST	Error Status Flag	0: No error occurred 1: Error occurred	RO

Figure 25.17 C0STR Register

25.1.14.1 RSTST Bit

The RSTST bit is set to 1 when the CAN module is in CAN reset mode.
This bit is set to 0 when the CAN module is not in CAN reset mode.
Even when the state is changed from CAN reset mode to CAN sleep mode, the RSTST bit remains 1.

25.1.14.2 HLTST Bit

The HLTST bit is set to 1 when the CAN module is in CAN halt mode.
This bit is set to 0 when the CAN module is not in CAN halt mode.
Even when the state is changed from CAN halt mode to CAN sleep mode, the HLTST bit remains 1.

25.1.14.3 SLPST Bit

The SLPST bit is set to 1 when the CAN module is in CAN sleep mode.
This bit is set to 0 when the CAN module is not in CAN sleep mode.

25.1.14.4 EPST Bit

The EPST bit is set to 1 when the value of the C0TECR or C0RECR register exceeds 127 and the CAN module is in error-passive state ($128 \leq TEC < 256$ or $128 \leq REC < 256$). This bit is set to 0 when the CAN module is not in error-passive state.
TEC indicates the value of the transmit error counter (C0TECR register) and REC indicates the value of the receive error counter (C0RECR register).

25.1.14.5 BOST Bit

The BOST bit is set to 1 when the value of the C0TECR register exceeds 255 and the CAN module is in bus-off state ($TEC \geq 256$). This bit is set to 0 when the CAN module is not in bus-off state.

25.1.14.6 TRMST Bit

The TRMST bit is set to 1 when the CAN module performs as a transmitter node or is in bus-off state.
This bit is set to 0 when the CAN module performs as a receiver node or is in bus-idle state.

25.1.14.7 RECST Bit

The RECST bit is set to 1 when the CAN module performs as a receiver node.
This bit is set to 0 when the CAN module performs as a transmitter node or is in bus-idle state.

25.1.14.8 NDST Bit

The NDST bit is set to 1 when at least one NEWDATA bit in the C0MCTLj register (j = 0 to 31) is 1 regardless of the value of the C0MIER register.
The NDST bit is set to 0 when all NEWDATA bits are 0.

25.1.14.9 SDST Bit

The SDST bit is set to 1 when at least one SENTDATA bit in the C0MCTLj register (j = 0 to 31) is 1 regardless of the value of the C0MIER register.
The SDST bit is set to 0 when all SENTDATA bits are 0.

25.1.14.10 RFST Bit

The RFST bit is set to 1 when the receive FIFO is not empty.
This bit is set to 0 when the receive FIFO is empty.
This bit is set to 0 when normal mailbox mode is selected.

25.1.14.11 TFST Bit

The TFST bit is set to 1 when the transmit FIFO is not full.
This bit is set to 0 when the transmit FIFO is full.
This bit is set to 0 when normal mailbox mode is selected.

25.1.14.12 NMLST Bit

The NMLST bit is set to 1 when at least one MSGLOST bit in the C0MCTLj register is 1 regardless of the value of the C0MIER register.
The NMLST bit is set to 0 when all MSGLOST bits are 0.

25.1.14.13 FMLST Bit

The FMLST bit is set to 1 when the RFMLF bit in the C0RFCR register is 1 regardless of the value of the C0MIER register.
The FMLST bit is set to 0 when the RFMLF bit is 0.

25.1.14.14 TABST Bit

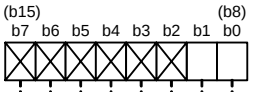
The TABST bit is set to 1 when at least one TRMABT bit in the C0MCTLj register is 1 regardless of the value of the C0MIER register.
The TABST bit is set to 0 when all TRMABT bits are 0.

25.1.14.15 EST Bit

The EST bit is 1 when at least one error is detected by the C0EIFR register regardless of the value of the C0EIER register.
This bit is set to 0 when no error is detected by the C0EIFR register.

25.1.15 CAN0 Mailbox Search Mode Register (C0MSMR Register)

CAN0 Mailbox Search Mode Register (1)



Symbol	Address	Reset Value

Note:
1. Write to the C0MSMR register in CAN operation mode or CAN halt mode.

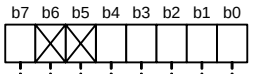
Figure 25.18 C0MSMR Register

25.1.15.1 MBSM Bit

The MBSM bit selects the search mode for the mailbox search function.
When this bit is 00b, receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA bit in the C0MCTLj register (j = 0 to 31) for the normal mailbox and the RFEST bit in the C0RFCR register.
When the MBSM bit is 01b, transmit mailbox search mode is selected. In this mode, the search target is the SENTDATA bit in the C0MCTLj register.
When the MBSM bit is 10b, message lost search mode is selected. In this mode, the search targets are the MSGLOST bit in the C0MCTLj register for the normal mailbox and the RFMLF bit in the C0RFCR register.
When the MBSM bit is 11b, channel search mode is selected. In this mode, the search target is the C0CSSR register. Refer to 25.1.17 “CAN0 Channel Search Support Register (C0CSSR Register)”.

25.1.16 CAN0 Mailbox Search Status Register (C0MSSR Register)

CAN0 Mailbox Search Status Register



Symbol	Address	Reset Value
C0MSSR	47F52h	1000 0000b

Bit Symbol	Bit Name	Function	RW
MBNST	Search Result Mailbox Number Status Bit	Output of search result in each search mode Output number: 0 to 31	RO
— (b6-b5)	No register bits; should be written with 0 and read as 0		—
SEST	Search Result Status Bit	0: Search result found 1: No search result	RO

Figure 25.19 C0MSSR Register

25.1.16.1 MBNST Bit

The MBNST bit outputs the smallest mailbox number that is searched in each mode of the C0MSMR register.
In receive mailbox, transmit mailbox, and message lost search modes, the value of the mailbox i.e.,the search result to be output, is updated as described below:

- When the NEWDATA, SENTDATA, or MSGLOST bit for the output mailbox is set to 0.
- When the NEWDATA, SENTDATA, or MSGLOST bit for a higher-priority mailbox is set to 1.

In receive mailbox search and message lost search modes, the receive FIFO (mailbox [28]) is output when the receive FIFO is not empty and there are no unread received messages or no lost messages in any of the normal mailboxes (mailboxes [0] to [23]).
In transmit mailbox search mode, the transmit FIFO (mailbox [24]) is not output.
Table 25.7 lists the behavior of MBNST bit in FIFO mailbox mode.

Table 25.7 Behavior of MBNST Bit in FIFO Mailbox Mode

MBSM Bit	Mailbox [24] (Transmit FIFO)	Mailbox [28] (Receive FIFO)
00b	Mailbox [24] is not output	Mailbox [28] is output when no NEWDATA bit for the normal mailbox is set to 1 and the receive FIFO is not empty
01b		Mailbox [28] is not output
10b		Mailbox [28] is output when no MSGLOST bit for the normal mailbox is set to 1 and the RFMLF bit is set to 1 in the receive FIFO
11b		Mailbox [28] is not output

In channel search mode, the MBNST bit outputs the corresponding channel number. After the C0MSSR register is read by a program, the next target channel number is output.

25.1.16.2 SEST Bit

The SEST bit is set to 1 when no corresponding mailbox is found after searching all mailboxes.
For example, in transmit mailbox search mode, the SEST bit is set to 1 when no SENTDATA bit for mailboxes is 1. The SEST bit is set to 0 when at lease one SENTDATA bit is 1.
When the SEST bit is 1, the value of the MBNST bit is undefined.

25.1.17 CAN0 Channel Search Support Register (C0CSSR Register)

CAN0 Channel Search Support Register (1, 2)

b7 b0

Symbol	Address	Reset Value
C0CSSR	47F51h	Undefined

Function	Setting Value	RW
When the value of the channel search is input, the channel number is output to the CiMSSR register	Channel value	RW

Notes:
1. Write to the C0CSSR register only when the MBSM bit in the C0MSMR register is 11b (channel search mode).
2. Write to the C0CSSR register in CAN operation mode and CAN halt mode.

Figure 25.20 C0CSSR Register

The bits in the C0CSSR register, which are set to 1, are encoded by an 8-to-3 priority encoder (the lower bit position, the higher priority) and output to the MBNST bits in the C0MSSR register.
The value of the C0MSSR register is updated whenever the C0MSSR register is read.
Figure 25.21 shows the write and read of registers C0CSSR and C0MSSR.

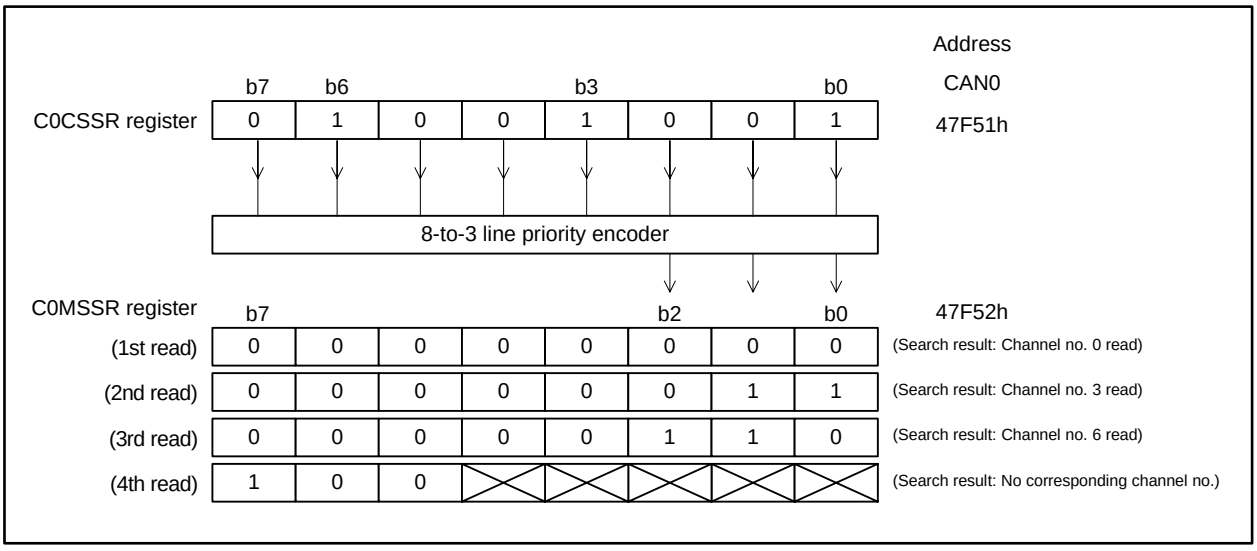


Figure 25.21 Write and Read of Registers C0CSSR and C0MSSR

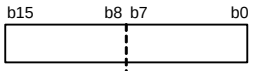
The value of the C0CSSR register is also updated whenever the C0MSSR register is read. When the C0CSSR register is read, the value before the 8-to-3 priority encoder conversion is read.

25.1.18 CAN0 Acceptance Filter Support Register (C0AFSR Register)

CAN0 Acceptance Filter Support Register (1)



Symbol	Address	Reset Value
C0AFSR	47F57h-47F56h	Undefined

Function	Setting Value	RW
After the standard ID of a received message is written, the value converted for data table search can be read	Standard ID/ converted value	RW

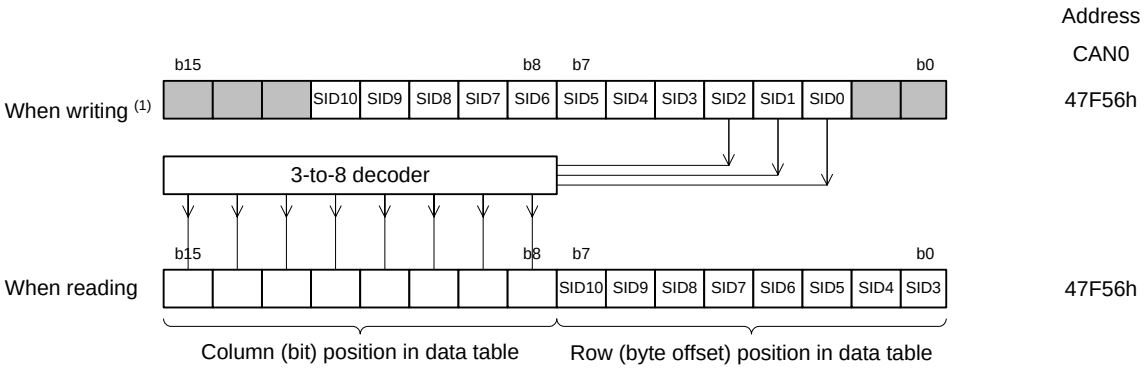
Note:
1. Write to the C0AFSR register in CAN operation mode or CAN halt mode.

Figure 25.22 C0AFSR Register

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) search. In the data table, all standard IDs created by the user are set to be valid/invalid in bit units. When the C0AFSR register is written with the 16-bit unit data including the SID bit in the C0MBj register (j = 0 to 31), in which a received ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.
The ASU is enabled in the following cases:

- When the ID to receive cannot be masked by the acceptance filter.
  Example) IDs to receive: 078h, 087h, 111h
- When there are too many IDs to receive and software filtering time is expected to be shortened.

Figure 25.23 shows the write and read of C0AFSR register.

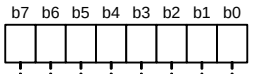


Note:
1. Write the same value as the 16-bit unit data including the SID bit in the C0MBj (j = 0 to 31) register.

Figure 25.23 Write and Read of C0AFSR Register

25.1.19 CAN0 Error Interrupt Enable Register (C0EIER Register)

CAN0 Error Interrupt Enable Register (1)



Symbol	Address	Reset Value
C0EIER	47F4Ch	00h

BORIE	Bus-Off Recovery Interrupt Enable Bit	0: Bus-off recovery interrupt disabled 1: Bus-off recovery interrupt enabled	RW
ORIE	Receive Overrun Interrupt Enable Bit	0: Receive overrun interrupt disabled 1: Receive overrun interrupt enabled	RW
OLIE	Overload Frame Transmit Interrupt Enable Bit	0: Overload frame transmit interrupt disabled 1: Overload frame transmit interrupt enabled	RW
BLIE	Bus Lock Interrupt Enable Bit	0: Bus lock interrupt disabled 1: Bus lock interrupt enabled	RW

Note:
1. Write to the C0EIER register in CAN reset mode.

Figure 25.24 C0EIER Register

The C0EIER register is used to set the error interrupt enabled/disabled individually for each error interrupt source in the C0EIFR register.

25.1.19.1 BEIE Bit

When the BEIE bit is 0, no error interrupt request is generated even if the BEIF bit in the C0EIFR register is set to 1.
When the BEIE bit is 1, an error interrupt request is generated if the BEIF bit is set to 1.

25.1.19.2 EWIE Bit

When the EWIE bit is 0, no error interrupt request is generated even if the EWIF bit in the C0EIFR register is set to 1.
When the EWIE bit is 1, an error interrupt request is generated if the EWIF bit is set to 1.

25.1.19.3 EPIE Bit

When the EPIE bit is 0, no error interrupt request is generated even if the EPIF bit in the C0EIFR register is set to 1.
When the EPIE bit is 1, an error interrupt request is generated if the EPIF bit is set to 1.

25.1.19.4 BOEIE Bit

When the BOEIE bit is 0, no error interrupt request is generated even if the BOEIF bit in the C0EIFR register is set to 1.
When the BOEIE bit is 1, an error interrupt request is generated if the BOEIF bit is set to 1.

25.1.19.5 BORIE Bit

When the BORIE bit is 0, an error interrupt request is not generated even if the BORIF bit in the C0EIFR register is set to 1.
When the BORIE bit is 1, an error interrupt request is generated if the BORIF bit is set to 1.

25.1.19.6 ORIE Bit

When the ORIE bit is 0, no error interrupt request is generated even if the ORIF bit in the C0EIFR register is set to 1.
When the ORIE bit is 1, an error interrupt request is generated if the ORIF bit is set to 1.

25.1.19.7 OLIE Bit

When the OLIE bit is 0, no error interrupt request is generated even if the OLIF bit in the C0EIFR register is set to 1.
When the OLIE bit is 1, an error interrupt request is generated if the OLIF bit is set to 1.

25.1.19.8 BLIE Bit

When the BLIE bit is 0, no error interrupt request is generated even if the BLIF bit in the C0EIFR register is set to 1.
When the BLIE bit is 1, an error interrupt request is generated if the BLIF bit is set to 1.

25.1.20 CAN0 Error Interrupt Factor Judge Register (C0EIFR Register)

CAN0 Error Interrupt Factor Judge Register (1)

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
C0EIFR	47F4Dh	00h

Bit Symbol	Bit Name	Function	RW
BEIF	Bus Error Detect Flag	0: No bus error detected 1: Bus error detected	RW
EWIF	Error Warning Detect Flag	0: No error warning detected 1: Error warning detected	RW
EPIF	Error Passive Detect Flag	0: No error passive detected 1: Error passive detected	RW
BOEIF	Bus-Off Entry Detect Flag	0: No bus-off entry detected 1: Bus-off entry detected	RW
BORIF	Bus-Off Recovery Detect Flag	0: No bus-off recovery detected 1: Bus-off recovery detected	RW
ORIF	Receive Overrun Detect Flag	0: No receive overrun detected 1: Receive overrun detected	RW
OLIF	Overload Frame Transmission Detect Flag	0: No overload frame transmission detected 1: Overload frame transmission detected	RW
BLIF	Bus Lock Detect Flag	0: No bus lock detected 1: Bus lock detected	RW

Note:
1. When writing 0 to these bits by a program, use the MOV instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 has no effect to these bit values.

Figure 25.25 C0EIFR Register

If an event corresponding to each bit occurs, the corresponding bit in the C0EIFR register is set to 1 regardless of the setting of the C0EIER register.
To set each bit to 0, write 0 by a program. If the set timing occurs simultaneously with the clear timing by the program, the bit becomes 1.

25.1.20.1 BEIF Bit

The BEIF bit is set to 1 when a bus error is detected.

25.1.20.2 EWIF Bit

The EWIF bit is set to 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95.
This bit is set to 1 only when the REC or TEC initially exceeds 95. Thus, if 0 is written to the EWIF bit by a program while the REC or TEC remains greater than 95, this bit is not set to 1 until the REC and the TEC go below 95 and then exceed 95 again.

25.1.20.3 EPIF Bit

The EPIF bit is set to 1 when the CAN error state becomes error-passive (the REC or TEC value exceeds 127).
This bit is set to 1 only when the REC or TEC initially exceeds 127. Thus, if 0 is written to the EPIF bit by a program while the REC or TEC remains greater than 127, this bit is not set to 1 until the REC and the TEC go below 127 and then exceed 127 again.

25.1.20.4 BOEIF Bit

The BOEIF bit is set to 1 when the CAN error state becomes bus-off (the TEC value exceeds 255).
This bit is also set to 1 when the BOM bit in the C0CTLR register is 01b (entry to CAN halt mode automatically at bus-off entry) and the CAN module becomes the bus-off state.

25.1.20.5 BORIF Bit

The BORIF bit is set to 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions:
(1) When the BOM bit in the C0CTLR register is 00b
(2) When the BOM bit is 10b
(3) When the BOM bit is 11b

The BORIF bit is not set to 1 if the CAN module recovers from the bus-off state in the following conditions:
(1) When the CANM bit in the C0CTLR register is set to 01b (CAN reset mode)
(2) When the RBOC bit in the C0CTLR register is set to 1 (forcible return from bus-off)
(3) When the BOM bit is 01b
(4) When the BOM bit is 11b and the CANM bit is set to 10b (CAN halt mode) before normal recovery occurs

Table 25.8 lists the behavior of bits BOEIF and BORIF according to BOM bit setting value.

Table 25.8 Behavior of Bits BOEIF and BORIF according to BOM Bit Setting Value

BOM Bit	BOEIF Bit	BORIF Bit
00b	Set to 1 on entry to the bus-off state.	Set to 1 on exit from the bus-off state.
01b		Do not set to 1.
10b		Set to 1 on exit from the bus-off state.
11b		Set to 1 if normal bus-off recovery occurs before the CANM bit is set to 10b (CAN halt mode).

25.1.20.6 ORIF Bit

The ORIF bit is set to 1 when a receive overrun occurs.
This bit is not to set to 1 in overwrite mode. In overwrite mode, a reception complete interrupt request is generated if an overwrite condition occurs and this bit is not set to 1.
In normal mailbox mode, if an overrun occurs in any of mailboxes [0] to [31] in overrun mode, this bit is set to 1.
In FIFO mailbox mode, if an overrun occurs in any of mailboxes [0] to [23] or the receive FIFO in overrun mode, this bit is set to 1.

25.1.20.7 OLIF Bit

The OLIF bit is set to 1 if the transmitting condition of an overload frame is detected when the CAN module performs transmission or reception.

25.1.20.8 BLIF Bit

The BLIF bit is set to 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode.

After the BLIF bit is set to 1, 32 consecutive dominant bits are detected again under either of the following conditions:

- After this bit is set to 0 from 1, recessive bits are detected.
- After this bit is set to 0 from 1, the CAN module enters CAN reset mode or CAN halt mode and then enters CAN operation mode again.

25.1.21 CAN0 Receive Error Count Register (C0RECR Register)

CAN0 Receive Error Count Register

b7 b0

Symbol	Address	Reset Value
C0RECR	47F4Eh	00h

Function	Counter Value	RW
Receive error count function The C0RECR register increments or decrements the counter value according to the error status of the CAN module during reception	00h to FFh (1)	RO

Note:
1. The value in bus-off state is undefined.

Figure 25.26 C0RECR Register

The C0RECR register indicates the value of the receive error counter.
Refer to the CAN Specifications (ISO11898-1) about the increment/decrement conditions of the receive error counter.

25.1.22 CAN0 Transmit Error Count Register (C0TECR Register)

CAN0 Transmit Error Count Register

b7 b0

Symbol	Address	Reset Value
C0TECR	47F4Fh	00h

Function	Counter Value	RW
Transmit error count function The C0TECR register increments or decrements the counter value according to the error status of the CAN module during transmission	00h to FFh (1)	RO

Note:
1. The value in bus-off state is undefined.

Figure 25.27 C0TECR Register

The C0TECR register indicates the value of the TEC error counter.
Refer to the CAN Specifications (ISO11898-1) about the increment/decrement conditions of the transmit error counter.

25.1.23 CAN0 Error Code Store Register (C0ECSR Register)

CAN0 Error Code Store Register

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
C0ECSR	47F50h	00h

Bit Symbol	Bit Name	Function	RW
SEF	Stuff Error Flag (1, 2)	0: No stuff error detected 1: Stuff error detected	RW
FEF	Form Error Flag (1, 2)	0: No form error detected 1: Form error detected	RW
AEF	ACK Error Flag (1, 2)	0: No ACK error detected 1: ACK error detected	RW
CEF	CRC Error Flag (1, 2)	0: No CRC error detected 1: CRC error detected	RW
BE1F	Bit Error (recessive) Flag (1, 2)	0: No bit error detected 1: Bit error (recessive) detected	RW
BE0F	Bit Error (dominant) Flag (1, 2)	0: No bit error detected 1: Bit error (dominant) detected	RW
ADEF	ACK Delimiter Error Bit (1, 2)	0: No ACK delimiter error detected 1: ACK delimiter error detected	RW
EDPM	Error Display Mode Select Bit (3)	0: Output of first detected error code 1:Output of accumulated error code (4)	RW

Notes:
1. Writing 1 has no effect to these bit values.
2. When writing 0 to bits SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF by a program, use the MOV instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.
3. Write to the EDPM bit in CAN reset mode or CAN halt mode.
4. If more than one error condition is detected simultaneously, all related bits are set to 1.

Figure 25.28 C0ECSR Register

The C0ECSR register can be used to monitor whether an error has occurred on the CAN bus. Refer to the CAN Specifications (ISO11898-1) to check the generation conditions of each error.
To set each bit except the EDPM bit to 0, write 0 by a program. If the timing at which each bit is set to 1 and the timing at which is written by a program are the same, the relevant bit is set to 1.

25.1.23.1 SEF Bit

The SEF bit is set to 1 when a stuff error is detected.

25.1.23.2 FEF Bit

The FEF bit is set to 1 when a form error is detected.

25.1.23.3 AEF Bit

The AEF bit is set to 1 when an ACK error is detected.

25.1.23.4 CEF Bit

The CEF bit is set to 1 when a CRC error is detected.

25.1.23.5 BE1F Bit

The BE1F bit is set to 1 when a recessive bit error is detected.

25.1.23.6 BE0F Bit

The BE0F bit is set to 1 when a dominant bit error is detected.

25.1.23.7 ADEF Bit

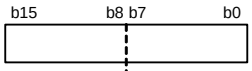
The ADEF bit is set to 1 when a form error is detected with the ACK delimiter during transmission.

25.1.23.8 EDPM Bit

The EDPM bit selects the output mode of the C0ECSR register.
When this bit is set to 0, the C0ECSR register outputs the first error code.
When this bit is set to 1, the C0ECSR register outputs the accumulated error code.

25.1.24 CAN0 Time Stamp Register (C0TSR Register)

CAN0 Time Stamp Register (1)



Symbol	Address	Reset Value
C0TSR	47F55h-47F54h	0000h

Function	Counter Value	RW
Free-running counter value for the time stamp function	0000h to FFFFh	RO

Note:
1. Read the C0TSR register in 16-bit units.

Figure 25.29 C0TSR Register

When the C0TSR register is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read.
The value of the time stamp counter reference clock is a multiple of 1 bit time, as configured by the TSPS bit in the C0CTLR register.
The time stamp counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode.
The time stamp counter value is stored to TSL and TSH in the C0MBj register (j = 0 to 31) when a received message is stored in a receive mailbox.

25.1.25 CAN0 Test Control Register (C0TCR Register)

CAN0 Test Control Register (1)

b7	b6	b5	b4	b3	b2	b1	b0
0	0	0	0	0			

Symbol	Address	Reset Value
C0TCR	47F58h	00h

Bit Symbol	Bit Name	Function	RW
TSTE	CAN Test Mode Enable Bit	0: CAN test mode disabled 1: CAN test mode enabled	RW
TSTM	CAN Test Mode Select Bit	b2 b1 0 0 : Other than CAN test mode 0 1 : Listen-only mode 1 0 : Self-test mode 0 (external loop back) 1 1 : Self-test mode 1 (internal loop back)	RW
— (b7-b3)	Reserved	Should be written with 0	RW

Note:
1. Write to the C0TCR register only in CAN halt mode.

Figure 25.30 C0TCR Register

25.1.25.1 TSTE Bit

When the TSTE bit is set to 0, CAN test mode is disabled.
When this bit is set to 1, CAN test mode is enabled.

25.1.25.2 TSTM Bit

The TSTM bit selects the CAN test mode.
The details of each CAN test mode is described below.

25.1.25.3 Listen-Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In listen-only mode, the CAN node is able to receive valid data frames and valid remote frames. It sends only recessive bits on the CAN bus and the protocol controller is not required to send the ACK bit, overload flag, or active error flag.
Listen-only mode can be used for baud rate detection.
Do not request transmission from any mailboxes in this mode.
Figure 25.31 shows the connection when listen-only mode is selected.

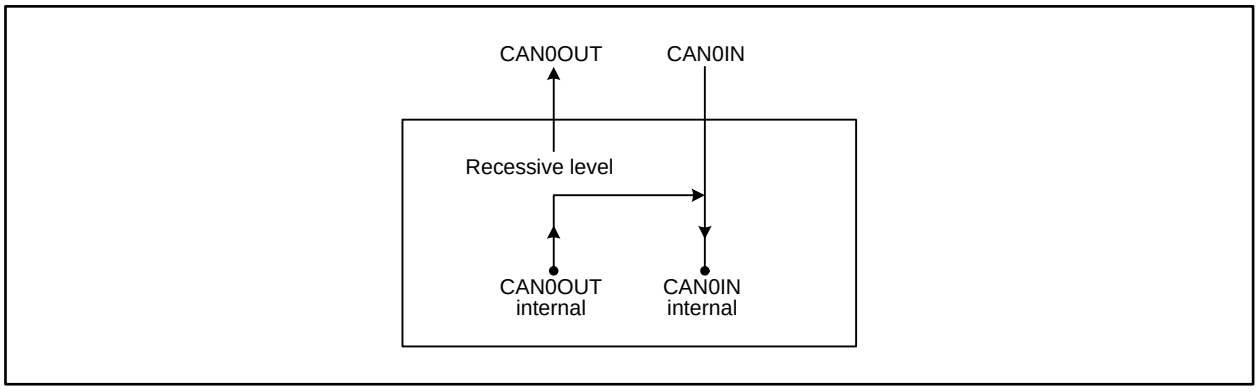


Figure 25.31 Connection when Listen-Only Mode is Selected

25.1.25.4 Self-Test Mode 0 (External Loop Back)

Self-test mode 0 is provided for CAN transceiver tests.
In this mode, the protocol controller treats its own transmitted messages as messages received via the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.
Connect the CAN0OUT/CAN0IN pins to the transceiver.
Figure 25.32 shows the connection when self-test mode 0 is selected.

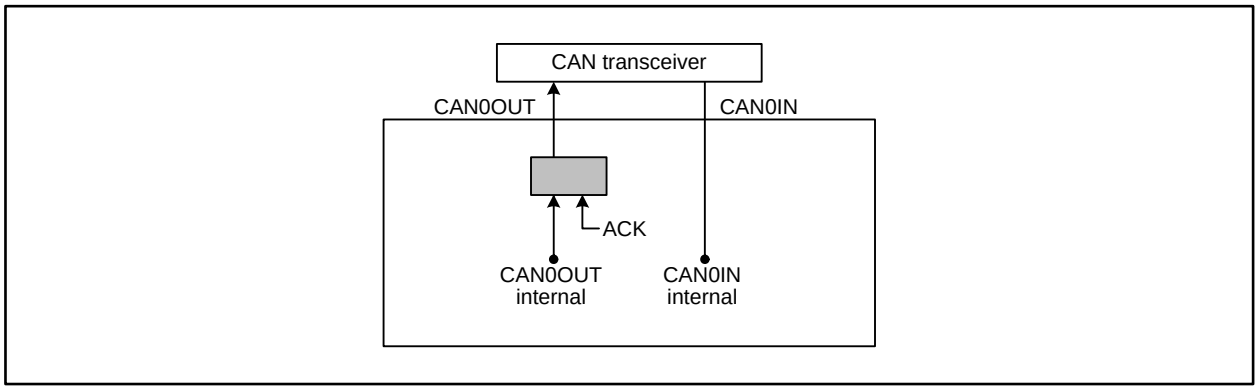

Figure 25.32 Connection when Self-Test Mode 0 is Selected

25.1.25.5 Self-Test Mode 1 (Internal Loop Back)

Self-test mode 1 is provided for self-test functions.

In this mode, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CAN0OUT pin to the internal CAN0IN pin. The input value of the external CAN0IN pin is ignored. The external CAN0OUT pin outputs only recessive bits. The CAN0OUT/CAN0IN pins do not need to be connected to the CAN bus or any external device.

Figure 25.33 shows the connection when self-test mode 1 is selected.

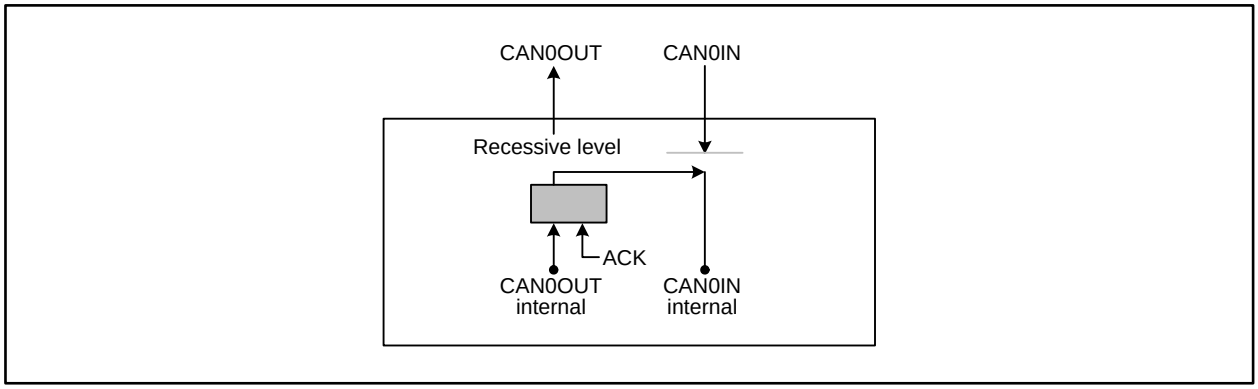

Figure 25.33 Connection when Self-Test Mode 1 is Selected

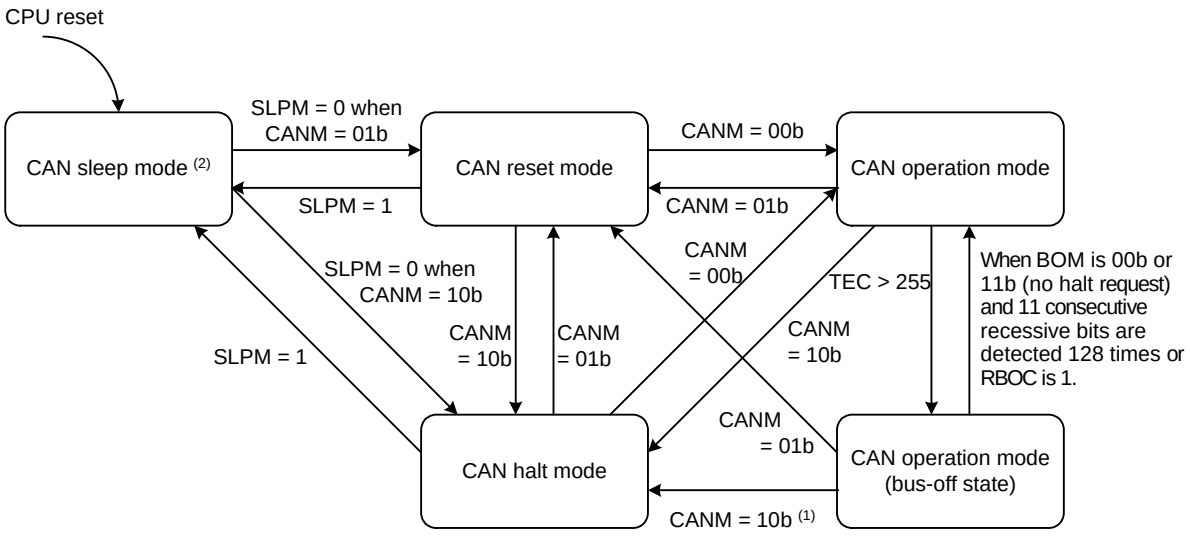
25.2 Operating Mode

The CAN module has the following four operating modes:

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 25.34 shows the transition between CAN operating modes.



CANM, SLPM, BOM, and RBOC: Bits in the C0CTLR register

Notes:

1. The transition timing from the bus-off state to CAN halt mode depends on the setting of the BOM bit.
   - When the BOM bit is 01b, the state transition timing is immediately after entering the bus-off state.
   - When the BOM bit is 10b, the state transition timing is at the end of the bus-off state.
   - When the BOM bit is 11b, the state transition timing is at the setting of the CANM bit to 10b (CAN halt mode).
2. Write only to the SLPM bit to exit/set CAN sleep mode.

Figure 25.34 Transition between CAN Operating Modes

25.2.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration.
When the CANM bit in the C0CTLR register is set to 01b, the CAN module enters CAN reset. Then the RSTST bit in the C0STR register is set to 1. Do not change the CANM bit until the RSTST bit is set to 1. Configure the C0BCR register before exiting CAN reset mode to any other modes.

The following registers are initialized to their reset values after entering CAN reset mode and their initialized values are retained during CAN reset mode:

- C0MCTLj register (j = 0 to 31)
- C0STR register (except bits SLPST and TFST)
- C0EIFR register
- C0RECR register
- C0TECR register
- C0TSR register
- C0MSSR register
- C0MSMR register
- C0RFCR register
- C0TFCR register
- C0TCR register
- C0ECSR register (except EDPM bit)

The previous values of the following registers are retained after entering CAN reset mode.

- C0CLKR register
- C0CTLR register
- C0STR register (bits SLPST and TFST)
- C0MIER register
- C0EIER register
- C0BCR register
- C0CSSR register
- C0ECSR register (EDPM bit only)
- C0MBj register
- Registers C0MKR0 to C0MKR7
- Registers C0FIDCR0 and C0FIDCR1
- C0MKIVLR register
- C0AFSR register
- C0RFPCR register
- C0TFPCR register

25.2.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.
When the CANM bit in the C0CTLR register is set to 10b, CAN halt mode is selected. Then the HLTST bit in the C0STR register is set to 1. Do not change the CANM bit until the HLTST bit is set to 1.
Refer to Table 25.9 “Operation in CAN Reset Mode and CAN Halt Mode” regarding the state transition conditions when transmitting or receiving.

All registers except bits RSTST, HLTST, and SLPST in the C0STR register remain unchanged when the CAN module enters CAN halt mode.
Do not change registers C0CLKR, C0CTLR (except bits CANM and SLPM,) and C0EIER in CAN halt mode. The C0BCR register can be changed in CAN halt mode only when listen-only mode is selected to use for automatic bit rate detection.

Table 25.9 Operation in CAN Reset Mode and CAN Halt Mode

Mode	Receiver	Transmitter	Bus-Off
CAN reset mode	CAN module enters CAN reset mode without waiting for the end of message reception.	CAN module enters CAN reset mode after waiting for the end of message transmission. (1, 4)	CAN module enters CAN reset mode without waiting for the end of bus-off recovery.
CAN halt mode	CAN module enters CAN halt mode after waiting for the end of message reception. (2, 3)	CAN module enters CAN halt mode after waiting for the end of message transmission. (1, 4)	[When the BOM bit is 00b] A halt request from a program will be acknowledged only after bus-off recovery. [When the BOM bit is 01b] CAN module enters automatically to CAN halt mode without waiting for the end of bus-off recovery (regardless of a halt request from a program). [When the BOM bit is 10b] CAN module enters automatically to CAN halt mode after waiting for the end of bus-off recovery (regardless of a halt request from a program). [When the BOM bit is 11b] CAN module enters CAN halt mode (without waiting for the end of bus-off recovery) if a halt is requested by a program during bus-off.

BOM bit: Bit in the C0CTLR register
Notes:
1. If several messages are requested to be transmitted, mode transition occurs after the completion of the first transmission. In a case that the CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.
2. If the CAN bus is locked at the dominant level, the program can detect this state by monitoring the BLIF bit in the C0EIFR register.
3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN mode transits to CAN halt mode.
4. If a CAN bus error or arbitration lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN mode transits to the requested CAN mode.

25.2.3 CAN Sleep Mode

CAN sleep mode is used for reducing current consumption by stopping the clock supply to the CAN module. After MCU hardware reset or software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in the C0CTLR register is set to 1, the CAN module enters CAN sleep mode. Then the SLPST bit in the C0STR register is set to 1. Do not change the value of the SLPM bit until the bit is set to 1. The other registers remain unchanged when the MCU enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any other registers (except the SLPM bit) during CAN sleep mode. Read operation is still allowed.
When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

25.2.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.
When the CANM bit in the C0CTLR register is set to 00b, the CAN module enters CAN operation mode. Then bits RSTST and HLTST in the C0STR register are set to 0. Do not change the value of the CANM bit until these bits are set to 0.

If 11 consecutive recessive bits are detected after entering CAN operation mode, the CAN module is in the following states:

- The CAN module becomes an active node on the network that enables transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module may be in one of the following three sub-modes, depending on the status of the CAN bus:

- Idle mode: Transmission or reception is not being performed.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module may receive its own message simultaneously when self-test mode 0 (TSTM bit in the C0TCR register = 10b) or self-test mode 1 (TSTM bit = 11b) is selected.

Figure 25.35 shows the sub mode in CAN operation mode.

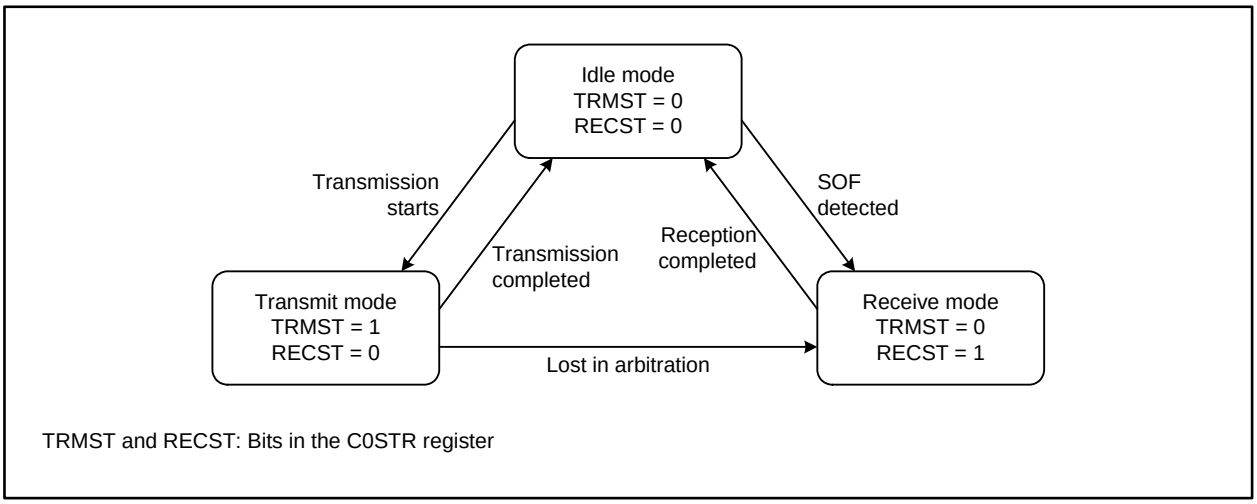


Figure 25.35 Sub Mode in CAN Operation Mode

25.2.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state according to the increment/decrement rules for the transmit/error counters in the CAN Specifications.
The following cases apply when recovering from the bus-off state. When the CAN module is in bus-off state, the values of the associated registers, except registers C0STR, C0EIFR, C0RECR, C0TECR and C0TSR, remain unchanged.

(1) When the BOM bit in the C0CTLR register is 00b (normal mode)

The CAN module enters the error-active state after it has completed the recovery from the bus-off state and CAN communication is enabled. The BORIF bit in the C0EIFR register is set to 1 (bus-off recovery detected) at this time.

(2) When the RBOC bit in the C0CTLR register is set to 1 (forcible return from bus-off)

The CAN module enters the error-active state when it is in bus-off state and the RBOC bit is set to 1. CAN communication is enabled again after 11 consecutive recessive bits are detected. The BORIF bit is not set to 1 at this time.

(3) When the BOM bit is 01b (entry to CAN halt mode automatically at bus-off entry)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF bit is not set to 1 at this time.

(4) When the BOM bit is 10b (entry to CAN halt mode automatically at bus-off end)

The CAN module enters CAN halt mode when it has completed the recovery from bus-off. The BORIF bit is set to 1 at this time.

(5) When the BOM bit is 11b (entry to CAN halt mode by a program) and the CANM bit in the C0CTLR register is set to 10b (CAN halt mode) during the bus-off state

The CAN module enters CAN halt mode when it is in bus-off state and the CANM bit is set to 10b (CAN halt mode). The BORIF bit is not set to 1 at this time.
If the CANM bit is not set to 10b during bus-off, the same behavior as (1) applies.

25.3 CAN Communication Speed Configuration

The following description explains about the CAN communication speed configuration.

25.3.1 CAN Clock Configuration

This group has a CAN clock selector.
The CAN clock can be configured by setting the CCLKS bit in the C0CLKR register and the BRP bit in the C0BCR register.
Figure 25.36 shows the block diagram of CAN clock generator.

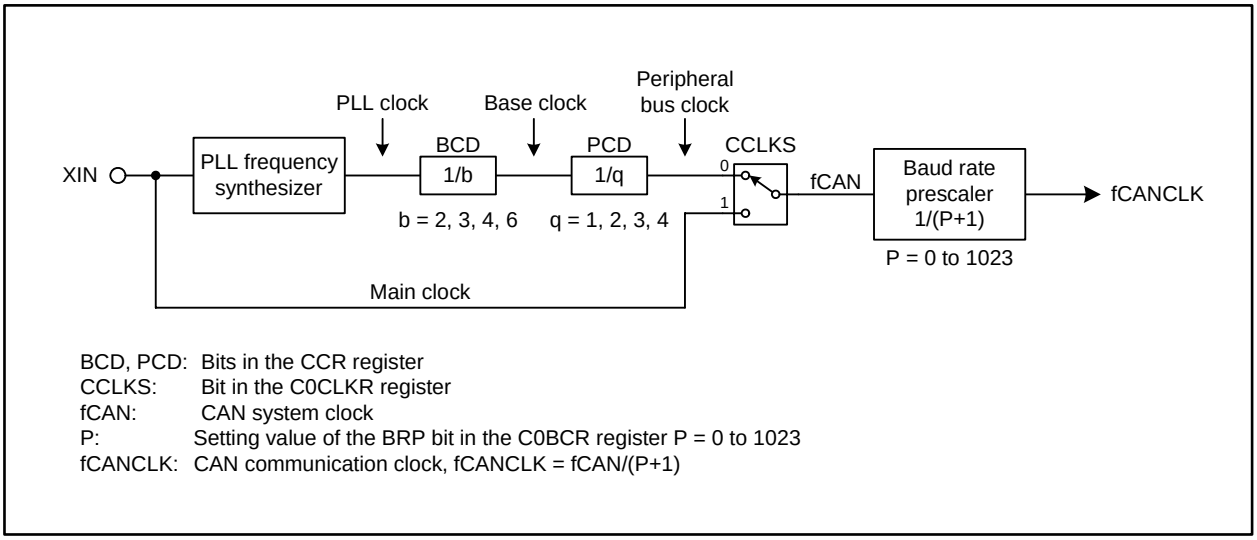

Figure 25.36 Block Diagram of CAN Clock Generator

25.3.2 Bit Timing Configuration

The bit time is a single bit time for transmitting/receiving a message and consists of the following three segments.
Figure 25.37 shows the bit timing.

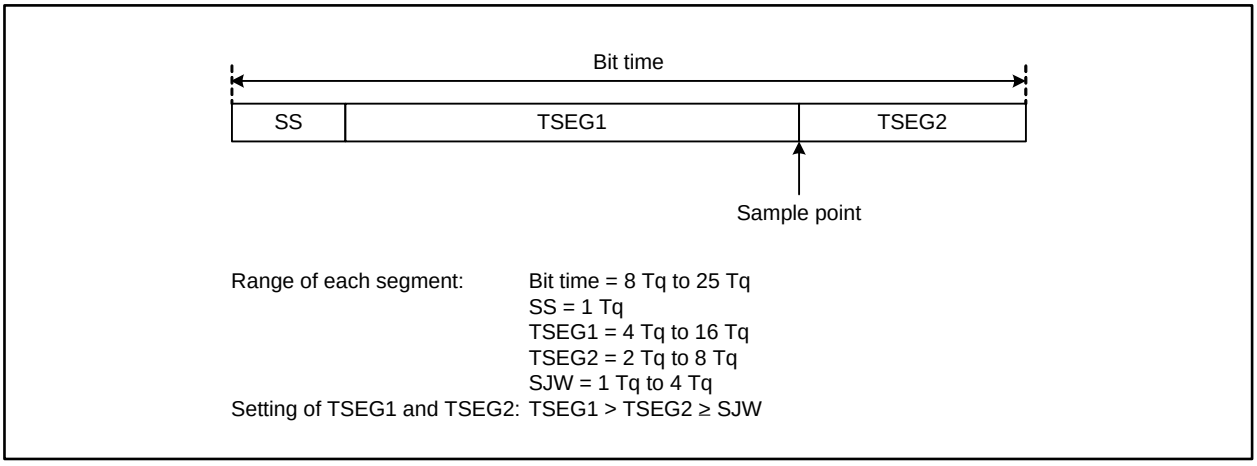

Figure 25.37 Bit Timing

25.3.3 Bit rate

The bit rate depends on the CAN clock (fCAN), the division value of the baud rate prescaler, and the number of Tq of one bit time.

$$\text{Bit rate[bps]} = \frac{fCAN}{\text{Baud rate prescaler division value}\ (1) \times \text{number of Tq of one bit time}} = \frac{fCANCLK}{\text{Number of Tq of one bit time}}$$

Note:
1. Division value of the baud rate prescaler = P + 1 (P = 0 to 1023)
   P: Setting value of the BRP bit in the C0BCR register

Table 25.10 lists bit rate examples.

Table 25.10 Bit Rate Examples

fCAN	32 MHz		24 MHz		20 MHz		16 MHz		8 MHz	
Bit Rate	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1
1 Mbps	8 Tq	4	8 Tq	3	10 Tq	2	8 Tq	2	8 Tq	1
	16 Tq	2			20 Tq	1	16 Tq	1

	10 Tq	96	10 Tq	72	10 Tq	60	10 Tq	48	10 Tq	24
	16 Tq	60	16 Tq	45	20 Tq	30	16 Tq	30	16 Tq	15
	20 Tq	48	20 Tq	36			20 Tq	24	20 Tq	12

25.4 Mailbox and Mask Register Structure

There are 32 mailboxes with the same structure.
Figure 25.38 shows the structure of C0MBj register (j = 0 to 31).

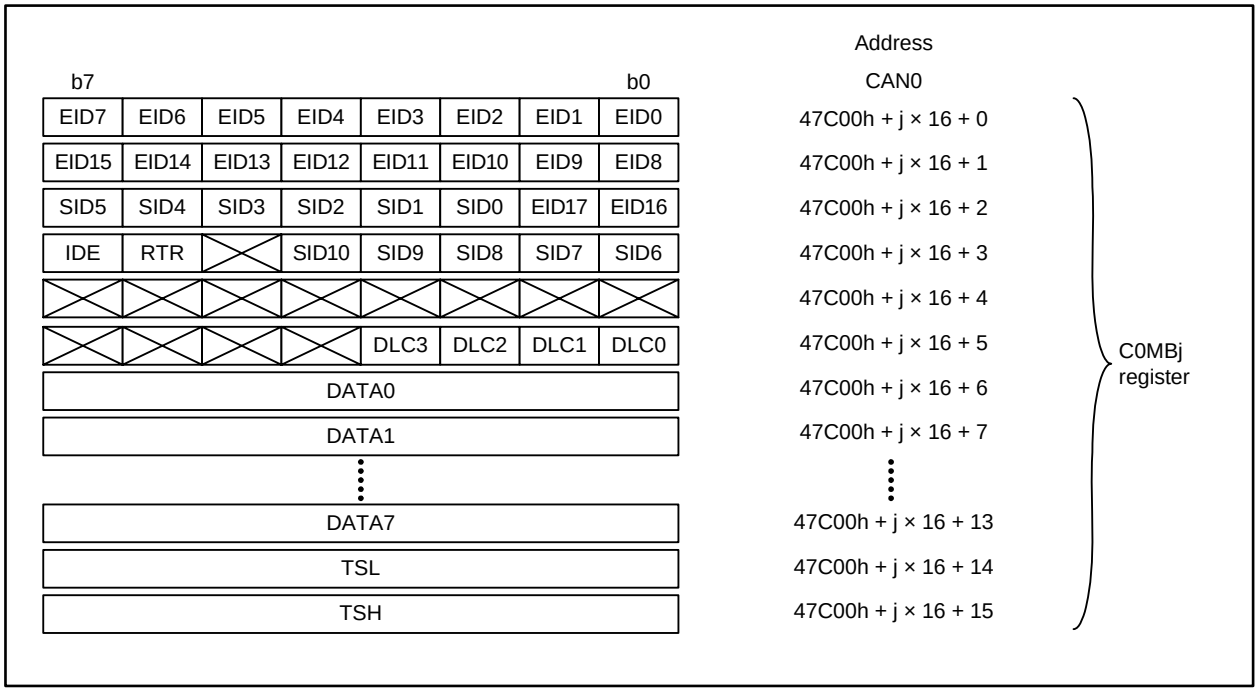

Figure 25.38 Structure of C0MBj Register (j = 0 to 31)

There are 8 mask registers with the same structure.
Figure 25.39 shows the structure of C0MKRk Register (k = 0 to 7).

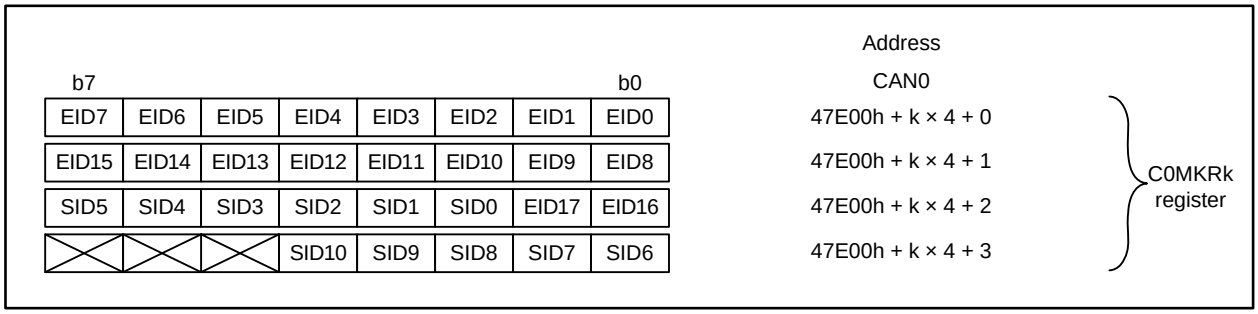

Figure 25.39 Structure of C0MKRk Register (k = 0 to 7)

There are 2 FIFO received ID compare registers with the same structure.
Figure 25.40 shows the structure of C0FIDCRn Register (n = 0, 1).

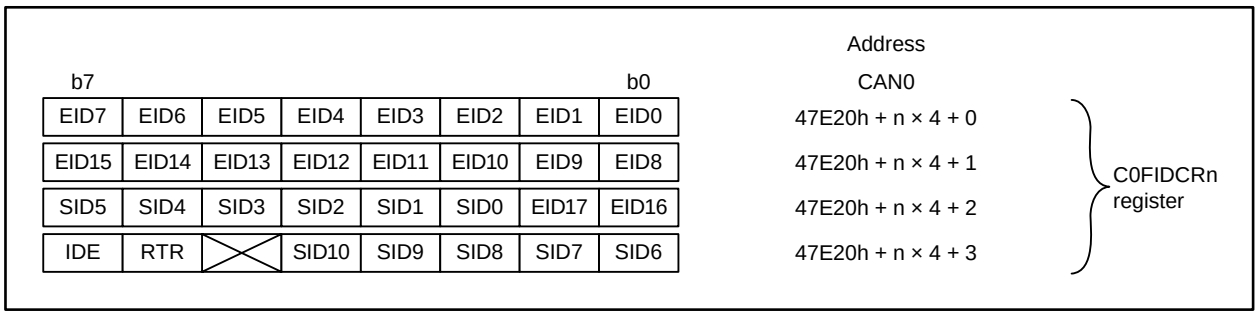

Figure 25.40 Structure of C0FIDCRn Register (n = 0, 1)

25.5 Acceptance Filtering and Masking Function

Acceptance filtering allows the user to receive messages with a specified range of multiple IDs for mailboxes.
Registers C0MKR0 to C0MKR7 can perform masking of the standard ID and the extended ID of 29 bits.

- The C0MKR0 register corresponds to mailboxes [0] to [3].
- The C0MKR1 register corresponds to mailboxes [4] to [7].
- The C0MKR2 register corresponds to mailboxes [8] to [11].
- The C0MKR3 register corresponds to mailboxes [12] to [15].
- The C0MKR4 register corresponds to mailboxes [16] to [19].
- The C0MKR5 register corresponds to mailboxes [20] to [23].
- The C0MKR6 register corresponds to mailboxes [24] to [27] in normal mailbox mode, and receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.
- The C0MKR7 register corresponds to mailboxes [28] to [31] in normal mailbox mode, and receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.

The C0MKIVLR register disables acceptance filtering individually for each mailbox.

The IDE bit in the C0MBj register (j = 0 to 31) is enabled when the IDFM bit in the C0CTLR register is 10b (mixed ID mode).
The RTR bit in the C0MBj register selects a data frame or a remote frame.

In FIFO mailbox mode, normal mailboxes (mailboxes [0] to [23]) use the single corresponding register among registers C0MKR0 to C0MKR5 for acceptance filtering. Receive FIFO mailboxes (mailboxes [28] to [31]) use two registers C0MKR6 and C0MKR7 for the acceptance filtering.
Also, the receive FIFO uses two registers C0FIDCR0 and C0FIDCR1 for ID comparison. Bits EID, SID, RTR, and IDE in registers C0MB28 to C0MB31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two ID-mask sets, two ranges of IDs can be received into the receive FIFO.
The C0MKIVLR register is disabled for the receive FIFO.

If both setting of standard ID and extended ID are set in the IDE bits in registers C0FIDCR0 and C0FIDCR1 individually, both ID formats are received.
If both setting of data frame and remote frame are set in the RTR bits in registers C0FIDCR0 and C0FIDCR1 individually, both data and remote frames are received.
When combination with two ranges of IDs is not necessary, set the same mask value and the same ID into both of the FIFO ID/mask register sets.

Figure 25.41 shows the correspondence of mask registers to mailboxes, and Figure 25.42 shows acceptance filtering.

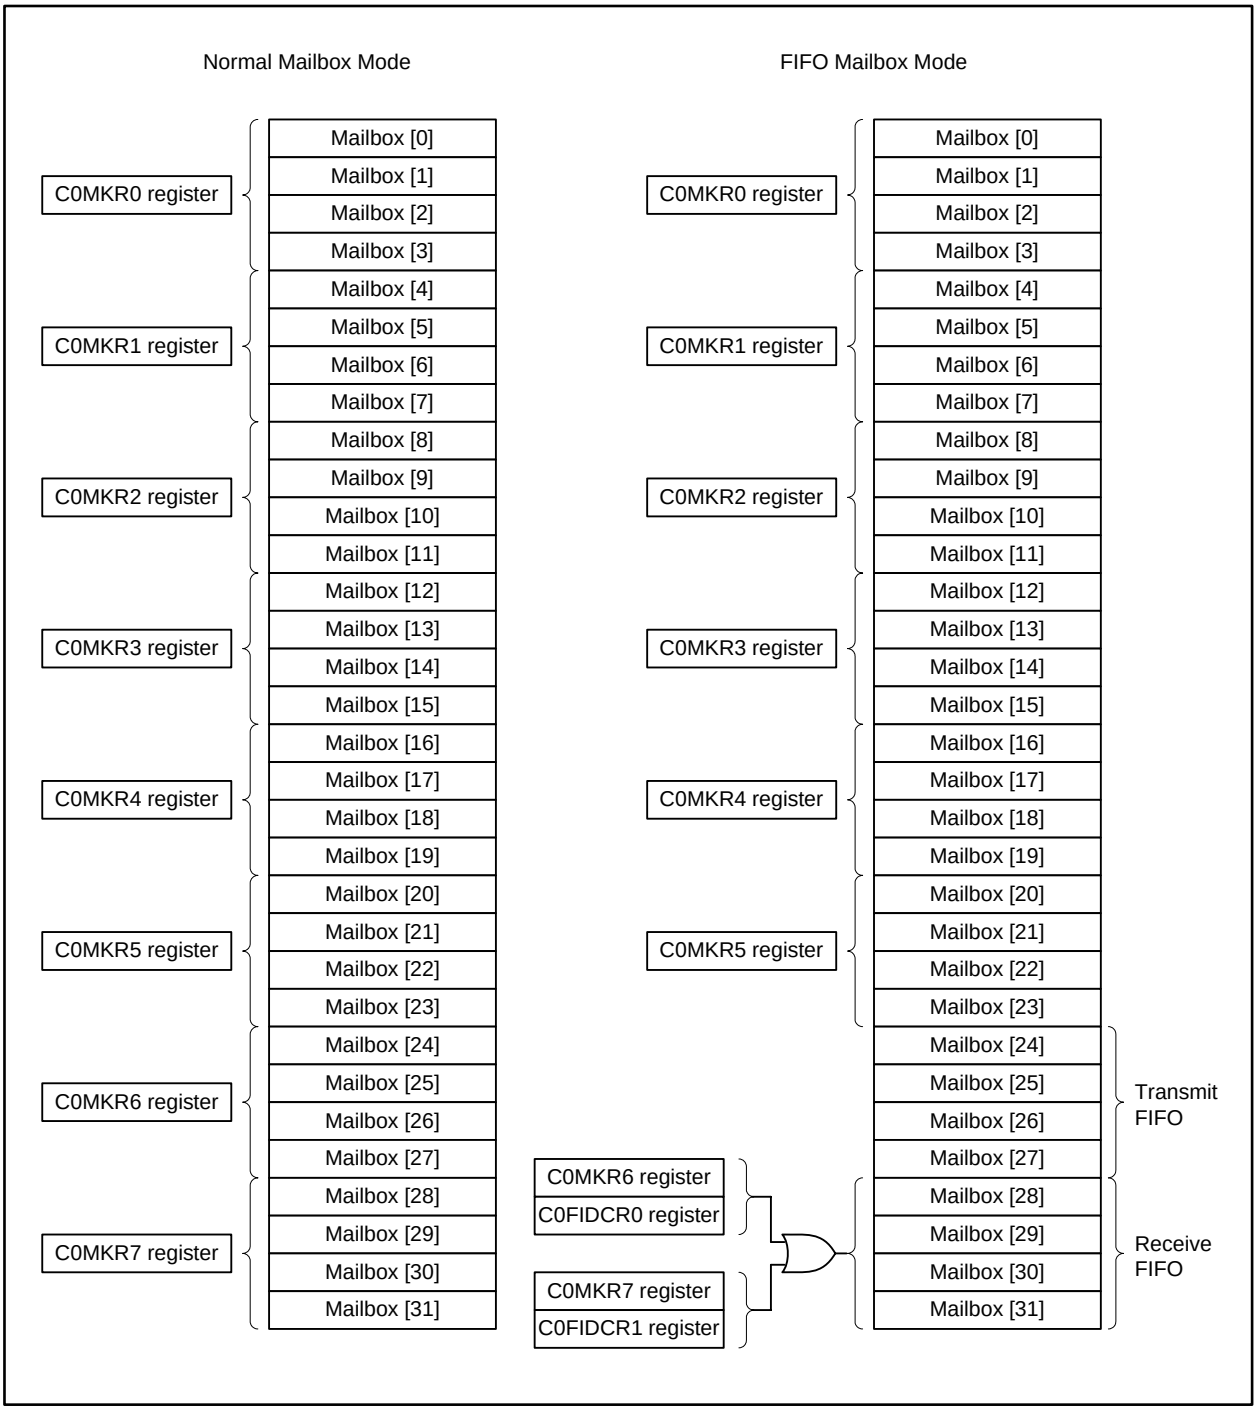

Figure 25.41 Correspondence of Mask Registers to Mailboxes

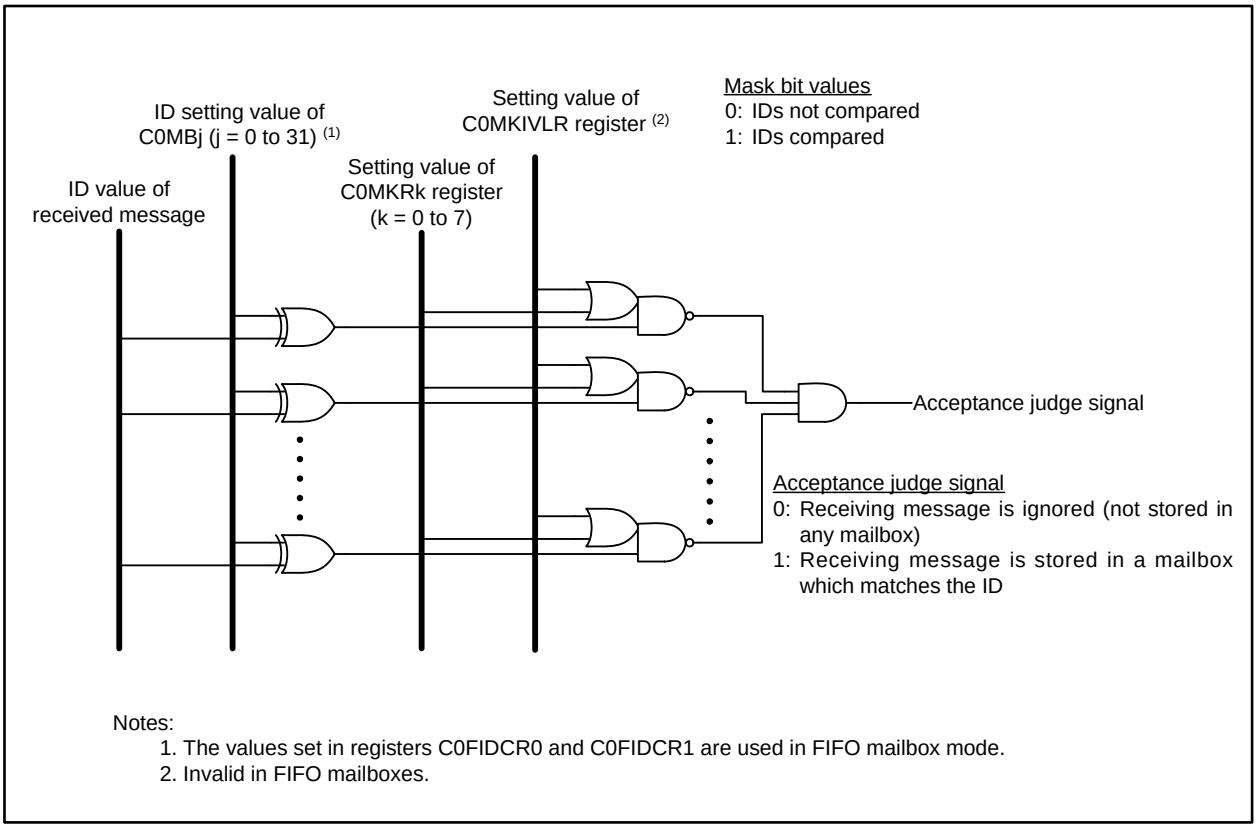

Figure 25.42 Acceptance Filtering

25.6 Reception and Transmission

Table 25.11 lists the CAN communication mode configuration.

Table 25.11 Configuration for CAN Reception Mode and Transmission Mode

TRMREQ	RECREQ	ONESHOT	Communication Mode of Mailbox
0	0	0	Mailbox disabled or transmission being aborted.
0	0	1	Configurable only when transmission or reception from a mailbox (programmed in one-shot mode) is aborted.
0	1	0	Configured as a receive mailbox for a data frame or a remote frame.
0	1	1	Configured as a one-shot receive mailbox for a data frame or a remote frame.
1	0	0	Configured as a transmit mailbox for a data frame or a remote frame.
1	0	1	Configured as a one-shot transmit mailbox for a data frame or a remote frame.
1	1	0	Do not set.
1	1	1	Do not set.

TRMREQ, RECREQ, ONESHOT: Bits in the C0MCTLj register (j = 0 to 31)

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, note the following:

(1) Before a mailbox is configured as a receive mailbox or a one-shot receive mailbox, set the C0MCTLj register (j = 0 to 31) to 00h.

(2) A received message is stored into the first mailbox that matches the condition according to the result of receive mode configuration and acceptance filtering. Upon deciding a mailbox which stores the received message, the mailbox with the smaller number has higher priority.

(3) In CAN operation mode, when a CAN module transmits a message whose ID matches with the ID/mask set of a mailbox configured to receive messages, the CAN module never receives the transmitted data. In self-test mode, however, the CAN module may receive its transmitted data. In this case, the CAN module sends an ACK.

When a mailbox is configured as a transmit mailbox or a one-shot transmit mailbox, note the following:

(1) Before a mailbox is configured as a transmit mailbox or one-shot transmit mailbox, ensure that the C0MCTLj register is 00h and that there is no pending abort process.

25.6.1 Reception

Figure 25.43 shows an operation example of data frame reception in overwrite mode.
This example shows the operation of overwriting the first message when the CAN module receives two consecutive CAN messages that matches the receiving conditions of the C0MCTL0 register.

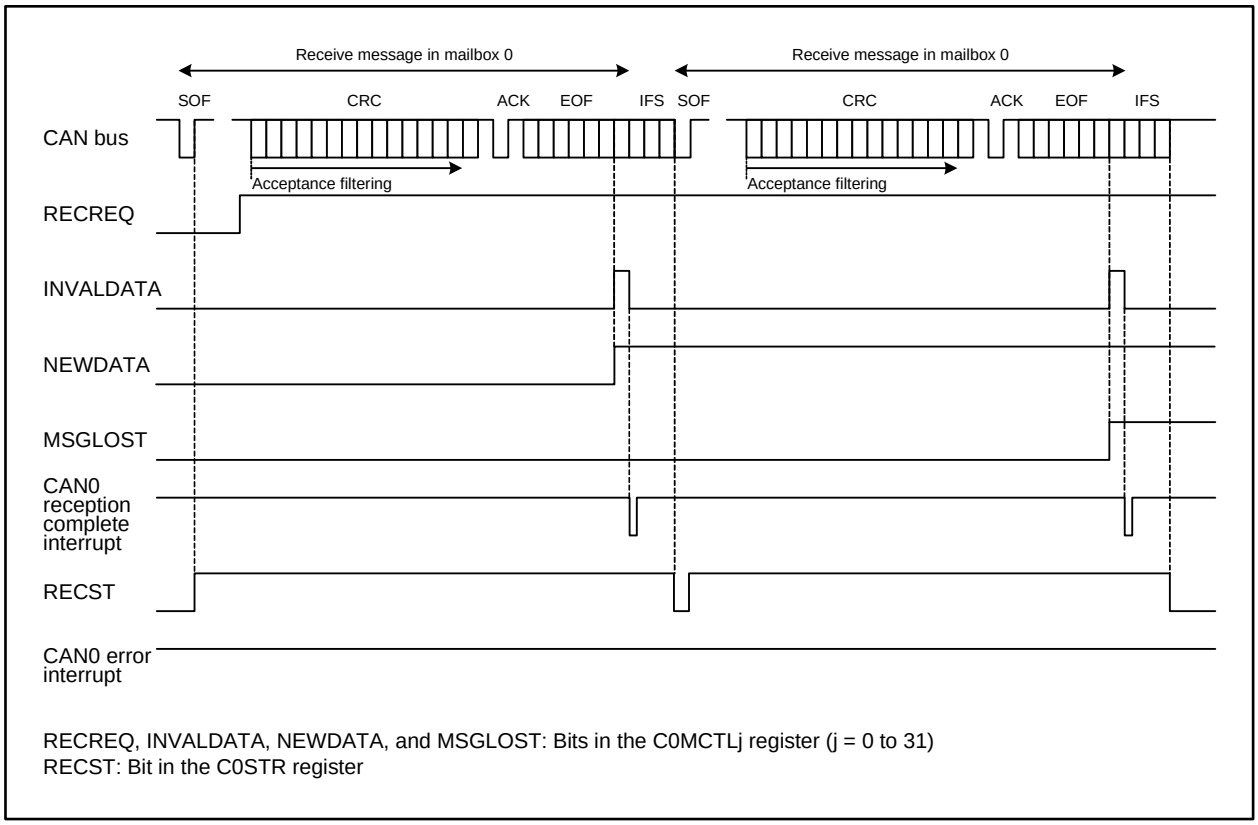

Figure 25.43 Operation Example of Data Frame Reception in Overwrite Mode

(1) When a SOF is detected on the CAN bus, the RECST bit in the C0STR register is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
(2) The acceptance filter procedure starts at the beginning of the CRC field to select the receive mailbox.
(3) After a message has been received, the NEWDATA bit in the C0MCTLj register (j = 0 to 31) for the receive mailbox is set to 1 (new data being updated/stored in the mailbox). The INVALDATA bit in the C0MCTLj register is set to 1 (message is being updated) at the same time, and then the INVALDATA bit is set to 0 (message valid) again after the complete message is transferred to the mailbox.
(4) When the interrupt enable bit in the C0MIER register for the receive mailbox is 1 (interrupt enabled), the CAN0 reception complete interrupt request is generated. This interrupt is generated when the INVALDATA bit is set to 0.
(5) After reading the message from the mailbox, the NEWDATA bit needs to be set to 0 by a program.
(6) In overwrite mode, if the next CAN message has been received into a mailbox whose NEWDATA bit is still set to 1, the MSGLOST bit in the C0MCTLj register is set to 1 (message has been overwritten). The new received message is transferred to the mailbox. The CAN0 reception complete interrupt request is generated the same as in (4).

Figure 25.44 shows the operational example of data frame reception in overrun mode.
This example shows the operation of overrunning the second message when the CAN module receives two consecutive CAN messages that matches the receiving conditions of the C0MCTL0 register.

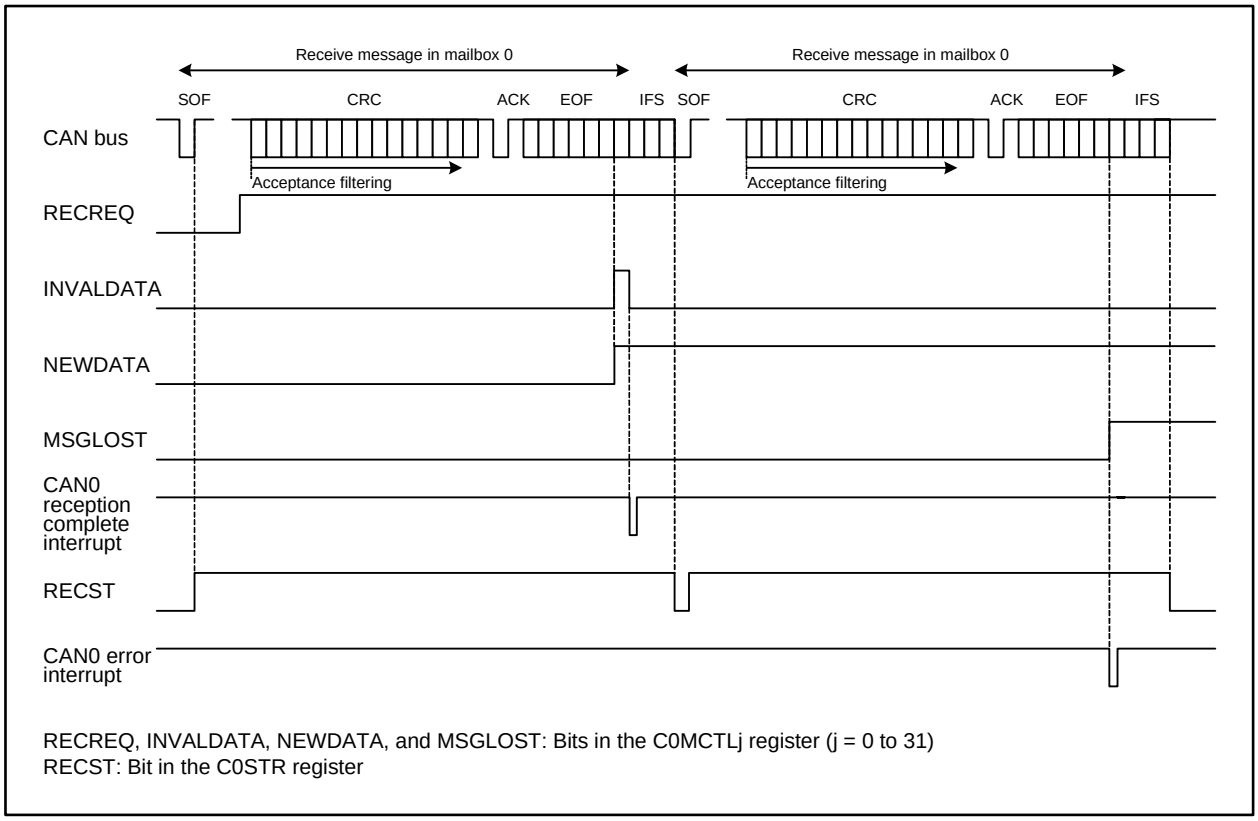

Figure 25.44 Operation Example of Data Frame Reception in Overrun Mode

(1) to (5) are the same as overwrite mode.

(6) In overrun mode, if the next message has been received before the NEWDATA bit is set to 0, the MSGLOST bit in the C0MCTLj register (j = 0 to 31) is set to 1 (message has been overrun). The new received message is discarded and a CAN0 error interrupt request is generated if the corresponding interrupt enable bit in the C0EIER register is set to 1 (interrupt enabled).

25.6.2 Transmission

Figure 25.45 shows an operation example of data frame transmission. This example shows the operation of transmitting messages that has been set in registers C0MCTL0 and C0MCTL1.

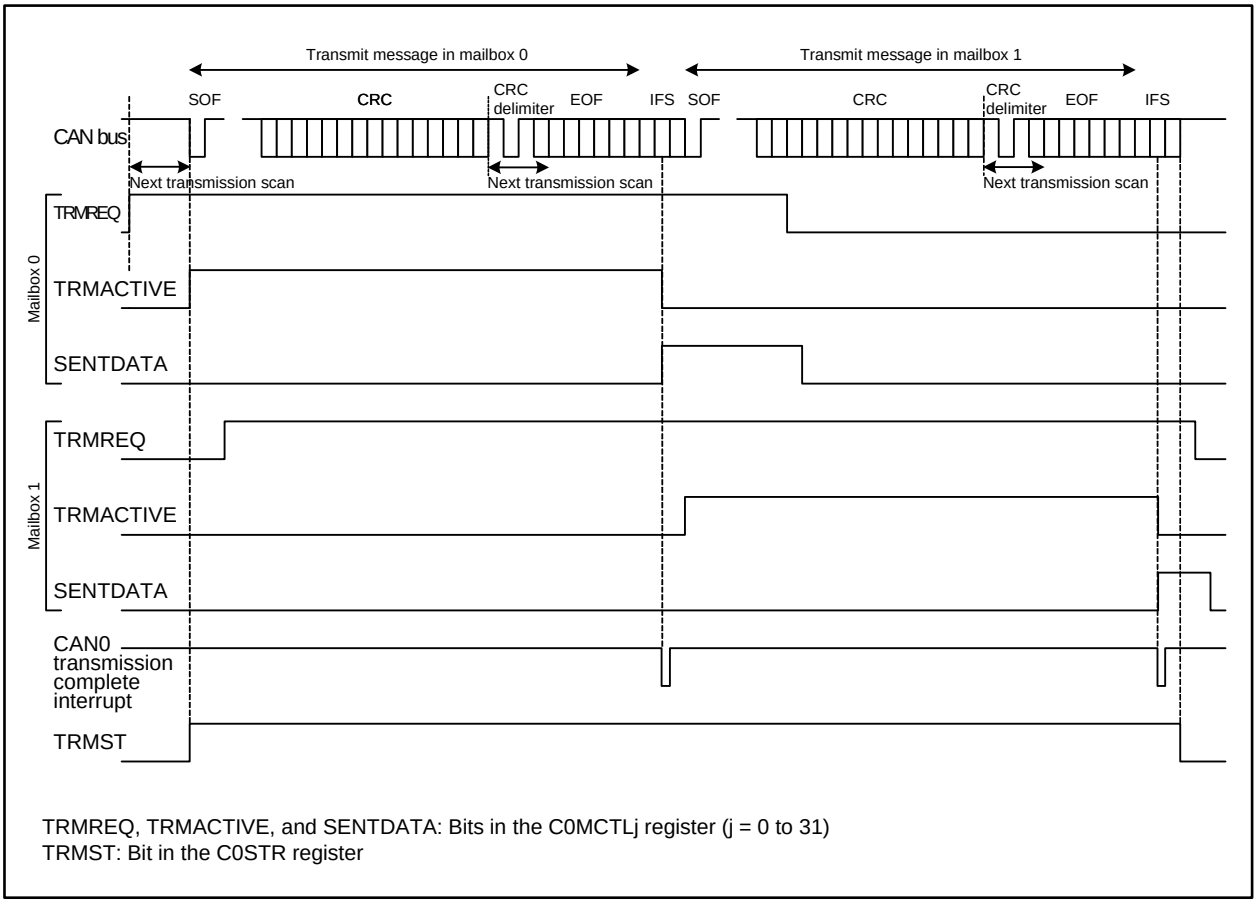

Figure 25.45 Operation Example of Data Frame Transmission

(1) When a TRMREQ bit in the C0MCTLj register (j = 0 to 31) is set to 1 (transmit mailbox) in bus-idle state, the mailbox scan procedure starts to decide the highest-priority mailbox for transmission. Once the transmit mailbox is decided, the TRMACTIVE bit in the C0MCTLj register is set to 1 (from when a transmission request is received until transmission is completed, or an error/arbitration lost has occurred), the TRMST bit in the C0STR register is set to 1 (transmission in progress), and the CAN module starts transmission. (1)

(2) If other TRMREQ bits are set, the transmission scan procedure starts with the CRC delimiter for the next transmission.

(3) If transmission is completed without losing arbitration, the SENTDATA bit in the C0MCTLj register is set to 1 (transmission completed) and the TRMACTIVE bit is set to 0 (transmission is pending, or no transmission request). If the interrupt enable bit in the C0MIER register is 1 (interrupt enabled), the CAN0 transmission complete interrupt request is generated.

(4) When requesting the next transmission from the same mailbox, set bits SENDTDATA and TRMREQ to 0, then set the TRMREQ bit to 1 after checking that bits SENDTDATA and TRMREQ have been set to 0.

Note:

1. If arbitration is lost after the CAN module starts transmission, the TRMACTIVE bit is set to 0. The transmission scan procedure is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following the loss of arbitration, the transmission scan procedure is performed again from the start of the error delimiter to search for the highest-priority transmit mailbox.

25.7 CAN Interrupt

The CAN module provides the following CAN interrupts:

- CAN0 wakeup interrupt
- CAN0 reception complete interrupt
- CAN0 transmission complete interrupt
- CAN0 receive FIFO interrupt
- CAN0 transmit FIFO interrupt
- CAN0 error interrupt

There are eight types of interrupt sources for the CAN0 error interrupts. These sources can be determined by checking the C0EIFR register.

- Bus error
- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery
- Receive overrun
- Overload frame transmission
- Bus lock

26. I/O Pins

Each pin of the MCU functions as a programmable I/O port, an I/O pin for internal peripheral functions, or a bus control pin. These functions can be switched by the function select registers or the processor mode registers. This chapter particularly addresses the function select registers. For the use as the bus control pin, refer to 7. “Processor Mode” and 9. “Bus”.
The pull-up resistors are enabled for every group of four pins. However, a pull-up resistor is separated from other peripheral functions even if it is enabled, when a pin functions as output pin or an analog I/O pin.
Figure 26.1 shows a block diagram of typical I/O pin.

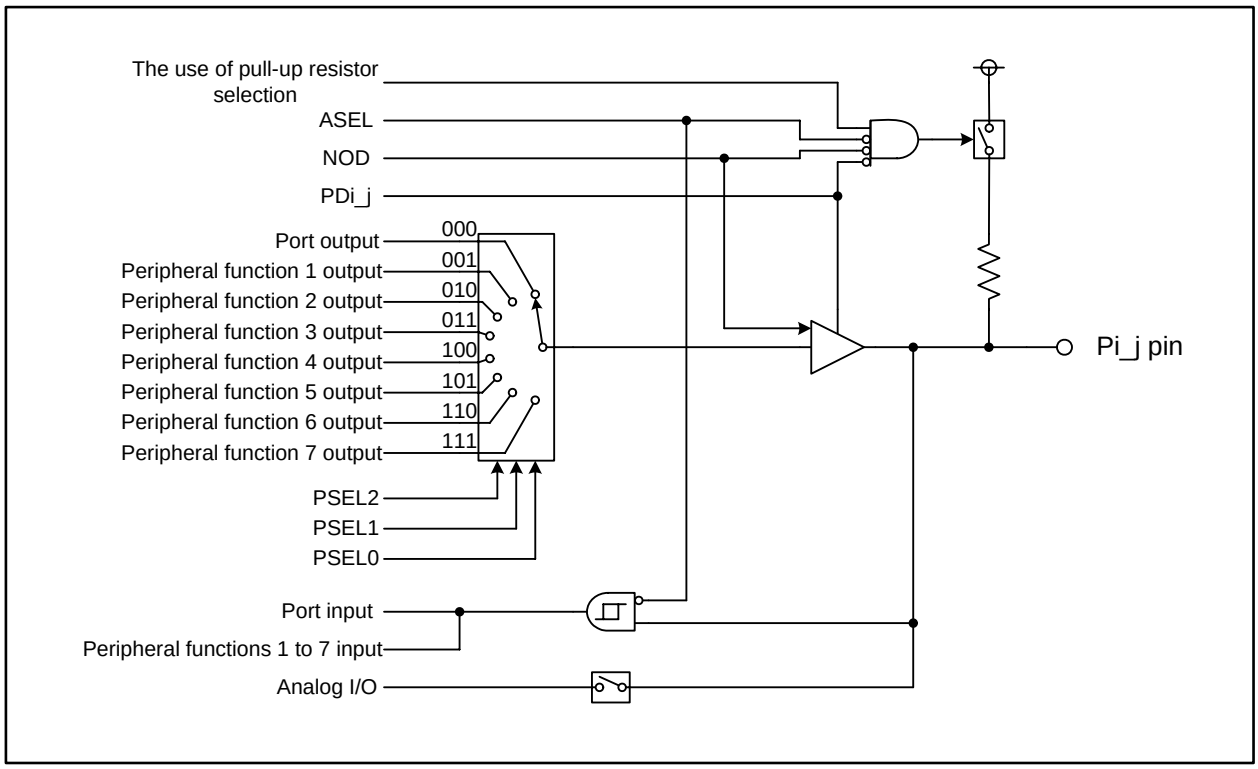

Figure 26.1 Typical I/O Pin Block Diagram (i = 0 to 15; j = 0 to 7)

The registers to control I/O pins are as follows: port Pi direction register (PDi register), output function select register and pull-up control register. The PDi register selects input or output state of pins. The output function select register which selects an output function consists of bits PSEL2 to PSEL0, NOD, and ASEL. Bits PSEL2 to PSEL0 are to select a function as programmable I/O or peripheral function output (except analog output). The NOD bit is to select the N-channel open drain output for a pin. The ASEL bit enables to prevent the increase in power consumption of input buffer due to an intermediate potential when a pin functions as an analog I/O pin. The pull-up control register enables/disables the pull-up resistors.
To use a pin as analog I/O pin, the PDi_j bit should be set to 0 (input) and bits PSEL2 to PSEL0 should be set to 000b and the ASEL bit should be set to 1.
The input-only port P8_5, which shares a pin with the $\overline{\text{NMI}}$ has neither bit 5 of the function select register nor the PDi register. The port P14_1 (or P9_1 in the 100-pin package) also functions as input-only port. Bit 1 of the function select register and the PDi register is assigned for reserved bit. The port P9 is protected from unexpected write accesses by the PRC2 bit in the PRCR register. (Refer to 10. “Protection”)

26.1 Port Pi Direction Register (PDi Register, i = 0 to 15)

The PDi register selects input or output state of pins. Each bit in this register corresponds to a respective pin.

In memory expansion mode or microprocessor mode, this register cannot control pins being used as the bus control pins (A0 to A23, D0 to D31, $\overline{CS0}$ to $\overline{CS3}$, WR/WR0, $\overline{BC0}$, BC1/WR1, BC2/WR2, BC3/WR3, $\overline{RD}$, CLKOUT/BCLK, $\overline{HLDA}$, $\overline{HOLD}$, ALE, and $\overline{RDY}$).

Figure 26.2 shows the PDi register.

No register bit is provided for the P8_5. For the P14_1 (or P9_1 in the 100-pin package), a reserved bit is provided.

The PD9 register is protected from unexpected write accesses by setting the PRC2 bit in the PRCR register. (Refer to 10. “Protection”)

Port Pi Direction Register (i = 0 to 15) (1)

PDi_6	Port Pi_6 Direction Bit (2)	0: Input port 1: Output port	RW
PDi_7	Port Pi_7 Direction Bit (2)	0: Input port 1: Output port	RW

Notes:
1. In memory expansion mode or microprocessor mode, the PDi register cannot control pins being used as bus control pins (A0 to A23, D0 to D31, $\overline{CS0}$ to $\overline{CS3}$, $\overline{WR/WR0}$, $\overline{BC0}$, $\overline{BC1/WR1}$, $\overline{BC2/WR2}$, $\overline{BC3}$ $\overline{WR3}$, $\overline{RD}$, CLKOUT/BCLK, $\overline{HLDA}$, $\overline{HOLD}$, ALE, and $\overline{RDY}$).
2. The PD8_5 bit in the PD8 register, bits PD11_5 to PD11_7 in the PD11 register, the PD14_7 bit in the PD14 register are unavailable on this MCU. These bits should be written with 0 and read as undefined value.
3. The PD9 register should be written immediately after the instruction to set the PRC2 bit in the PRC2 register to 1 (write enabled). Any interrupt or DMA transfer should not be generated between these two instructions.
4. Bits PD9_0 to PD9_2 in the PD9 register in the 100-pin package and PD14_0 to PD14_2 in the PD14 register in the 144-pin package are reserved. These bits should be written with 0.
5. In the 100-pin package, enabled bits in registers PD11 to PD15 should be written with 1 (output port).

Figure 26.2 Registers PD0 to PD15

26.2 Output Function Select Register

This register selects an output function of either the programmable I/O port or a peripheral function if these two functions share a pin. Regarding input function, every connected peripheral functions obtain input signals irrespective of this register setting.

The output function select register consists of bits PSEL2 to PSEL0, NOD, and ASEL. Bits PSEL2 to PSEL0 select a function as programmable I/O or peripheral function output (except analog output). The NOD bit is to select the N-channel open drain output. The ASEL bit enables to prevent the increase in power consumption due to an intermediate potential generated when a pin functions as an analog I/O pin. Table 26.1 shows the peripheral functions assigned for each combination of bits PSEL2 to PSEL0 and Figure 26.3 to Figure 26.19 show the function select registers.

Note that ports P8_5 and P14_1 (or P9_1 in the 100-pin package) (input only) have no output function select registers.

The P9_iS register is protected from unexpected write accesses by setting the PRC2 bit in the PRCR register (Refer to 10. “Protection”)

Figure 26.9 Registers P6_0S to P6_7S

The port P6_i (i = 0 to 7) shares a pin with the serial interface (UART0 and UART1) and the intelligent I/O group 2 (IIO2).
To use as an output pin, the PD6_i bit should be set to 1 (Port P6_i functions as output port) and a function should be selected according to the Figure 26.9. To use as an input pin, the PD6_i bit should be set to 0 (Port P6_i functions as input port).
Ports P6_0 to P6_7 are 5 V tolerant inputs. To use as an I/O pin with 5 V tolerant input enabled, the NOD bit should be set to 1.

Figure 26.10 Registers P7_0S to P7_7S

The port P7_i (i=0 to 7) shares a pin with the timer, the three-phase motor control, the serial interface (UART2, UART5, and UART8), the multi-master I2C-bus interface (MMI2C), the intelligent I/O groups 1 and 2 (IIO1 and IIO2), and the CAN module.

To use as an output pin, the PD7_i bit should be set to 1 (Port P7_i functions as output port) and a function should be selected according to the Figure 26.10. To use as an input pin, the PD7_i bit should be set to 0 (Port P7_i functions as input port).

Ports P7_0 to P7_7 are 5 V tolerant inputs. To use as an I/O pin with 5 V tolerant input enabled, the NOD bit should be set to 1.

Figure 26.13 Registers P9_3S to P9_7S (100-pin package)

The port P9_i (i = 0 to 7) shares a pin with the serial interface (UART3 and UART4) and the intelligent I/O group 2 (IIO2). In particular, the port P9_i (i = 3 to 6) also shares a pin with the A/D converter I/O (ANEX0 and ANEX1) pin and the D/A converter output pin.

To use as the A/D converter pin or the D/A converter pin, the P9_iS register should be set to 80h and the PD9_i bit should be set to 0 (Port P9_i functions as input port) irrespective of the input/output state.

To use as an output pin of functions other than the A/D converter or the D/A converter, the PD9_i bit should be set to 1 (Port P9_i functions as output port) and a function should be selected according to the Figure 26.12. To use as an input pin of functions other than the A/D converter or the D/A converter, the PD9_i bit should be set to 0 (Port P9_i functions as input port).

When the NOD bit is set to 1, the corresponding pin functions as an N-channel open drain output.

2. Do not use this combination.

Figure 26.19 Registers P15_0S to P15_7S

The port P15_i (i = 0 to 7) shares a pin with the serial interface (UART6 and UART7), the intelligent I/O group 0 (IIO0), and the AN15_i input pin for the A/D converter.
To use as an output pin, the PD15_i bit should be set to 1 (Port P15_i functions as output port) and a function should be selected according to the Figure 26.19. To use as an input pin (except for the A/D converter), the PD15_i bit should be set to 0 (Port P15_i functions as input port). To use as an input pin for the A/D converter, the P15_iS register should be set to 80h and the PD15_i bit should be set to 0.
To use as an N-channel open drain output, the NOD bit should be set to 1.

26.3 Input Function Select Register

When a peripheral function input is assigned to multiple pins, this register selects which input pin should be connected to the peripheral function.
Figure 26.20 to Figure 26.23 show the input function select registers.

Figure 26.23 IFS3 Register

26.4 Pull-up Control Registers 0 to 4 (Registers PUR0 to PUR4)

Figure 26.24 to Figure 26.28 show registers PUR0 to PUR4.

These registers enable/disable the pull-up resistors for every group of four pins. To enable the pull-up resistors, the corresponding bits in registers PUR0 to PUR4 should be set to 1 (pull-up resistor enabled) and the respective bits in the direction register should be set to 0 (input).

In memory expansion mode or microprocessor mode, the pull-up control bits for ports P0 to P5, and P11 to P13 running as the bus control pins, should be set to 0 (pull-up resistor disabled). The pull-up resistors are enable for ports P0, P1, and P11 to P13 when these pins function as input ports in these modes.

Pull-Up Control Register 0 (1)

b7	b6	b5	b4	b3	b2	b1	b0

Symbol	Address	Reset Value
PUR0	03F0h	0000 0000b

Bit Symbol	Bit Name	Function	RW
PU00	P0_0 to P0_3 Pull-Up Control Bit	Control pull-up setting for corresponding ports 0: Pull-up resistor disabled 1: Pull-up resistor enabled	RW
PU01	P0_4 to P0_7 Pull-Up Control Bit		RW
PU02	P1_0 to P1_3 Pull-Up Control Bit		RW
PU03	P1_4 to P1_7 Pull-Up Control Bit		RW
PU04	P2_0 to P2_3 Pull-Up Control Bit		RW
PU05	P2_4 to P2_7 Pull-Up Control Bit		RW
PU06	P3_0 to P3_3 Pull-Up Control Bit		RW
PU07	P3_4 to P3_7 Pull-Up Control Bit		RW

Note:
1. In memory expansion mode or microprocessor mode, each bit of the PUR0 register should be set to 0 since ports P0 to P3 are used as the bus control pins. However, the pull-up resistors are enabled for ports P0 and P1 when these pins function as I/O ports with 8-bit bus or multiplexed bus format.

— (b7-b4)	No register bits; should be written with 0 and read as undefined value		—

Note:
1. This register should be set to 00h in the 100-pin package.

Figure 26.28 PUR4 Register

26.5 Port Control Register (PCR Register)

Figure 26.29 shows the PCR register.

This register selects an output mode for the port P1 between push-pull output and pseudo-N-channel open drain output. When the PCR0 bit is set to 1, the P-channel transistor in the output buffer is turned off. Note that the port P1 cannot be a perfect open drain output due to remaining parasitic diode. The absolute maximum rating of the input voltage is, therefore, from -0.3 V to VCC + 0.3 V (Refer to Figure 26.30).

In memory expansion mode or microprocessor mode, when the port P1 is used for the data bus, the PCR0 bit should be set to 0. However, when the port P1 is used as the programmable I/O port or an I/O pin for the peripheral functions, the output mode can be selected using the PCR0 bit even in these operating modes.

Port Control Register

b7 b6 b5 b4 b3 b2 b1 b0

Symbol	Address	Reset Value
PCR	03FFh	0XXX XXX0b

Bit Symbol	Bit Name	Function	RW
PCR0	Port P1 Output Format Control Bit (1)	0: Push-pull output 1: Pseudo-N-channel open drain output (2)	RW
— (b6-b1)	No register bits; should be written with 0 and read as undefined value		—
PCE	Ports P9_0, P9_2, P11 to P15 Enable Bit (3)	0: Ports P9_0, P9_2, P11 to P15 disabled 1: Ports P9_0, P9_2, P11 to P15 enabled	RW

Notes:
1. In memory expansion mode or microprocessor mode, this bit should be set to 0 since the port P1 is used for the data bus. However, when it is used as the I/O port or an I/O pin for the peripheral functions, the PCR0 bit can select an output format between push-pull output and pseudo-N-channel open drain output.
2. This function is designated not to make the port P1 a full open drain but to turn off the P-channel transistor in the CMOS output buffer. Therefore, the absolute maximum rating of the input voltage is from -0.3 V to VCC + 0.3 V.
3. This bit should not be set to 1 in the 100-pin package.

Figure 26.29 PCR Register

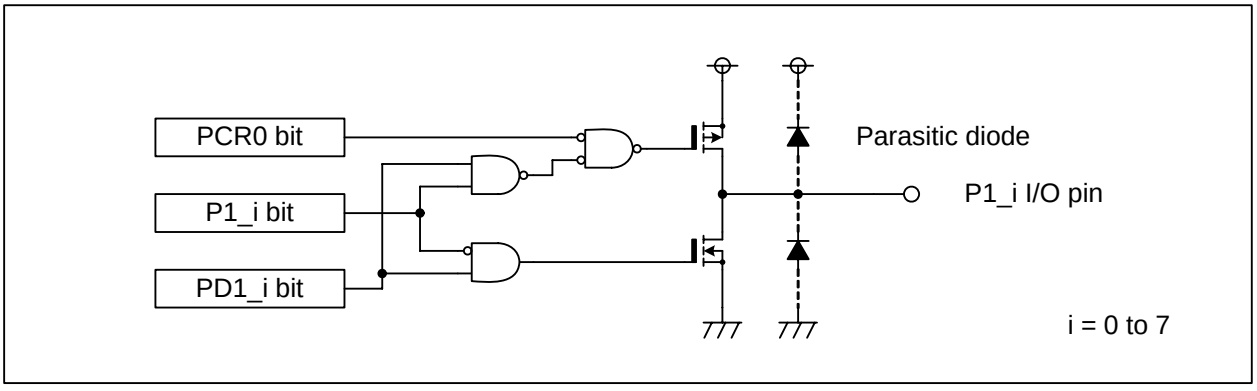

Figure 26.30 Port P1 Output Buffer Configuration

26.6 How To Configure Unused Pins

Table 26.2, Table 26.3, and Figure 26.32 show configuring examples of unused pins on the board.

Table 26.2 Unused Pin Configuration in Single-chip Mode (1)

Pin Name	Setting
Ports P0 to P15 (excluding ports P8_5, and P9_1 (in the 100-pin package) or P14_1 (in the 144-pin package)) (2, 3, 4)	Configure as input ports so that each pin is connected to VSS via its own resistor (5); or configure as output ports to leave the pins open
P9_1 (in the 100-pin package)	Connect the pin to VSS via a resistor (5)
P14_1 (in the 144-pin package)	Connect the pin to VSS via a resistor (5)
XOUT (6)	Leave pin open
$\overline{\text{NMI}}$ (P8_5)	Connect the pin to VCC via a resistor (5)
AVCC	Connect the pin to VCC
AVSS, VREF	Connect the pin to VSS
NSD	Connect the pin to VCC via a resistor of 1 to 4.7 kΩ

Notes:

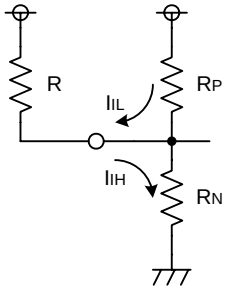
1. Unused pins should be wired as closely as possible to the MCU (within 2 cm).
2. When configuring the pins as output ports to leave them open, note that the ports as inputs remain unchanged from when the reset is released until the mode transition is completed. During this transition, the power current may increase due to an undefined voltage level of the pins. In addition, the contents of the direction register may change because of noise or program runaway caused by the noise. To avoid these situations, reconfigure the direction register regularly by software, which may achieve the higher program reliability.
3. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only.
4. In the 100-pin package, set FFh to the following addresses: 03D7h, 03DAh, 03DBh, 03DEh, and 03DFh.
5. The resistance value appropriate to the system should be designated. The range from 10 to 100 kΩ is recommended.
6. The setting is applicable when an external clock is applied to the XIN pin

Table 26.3 Unused Pin Configuration in Memory Expansion Mode or Microprocessor Mode (1)

Pin Name	Setting
Ports P1 and P6 to P15 (excluding ports P8_5, and P9_1 (in the 100-pin package) or P14_1 (in the 144-pin package)) (2, 3, 4)	Configure as input ports so that each pin is connected to VSS via its own resistor (5); or configure as output ports to leave the pins open
P9_1 (in the 100-pin package)	Connect the pin to VSS via a resistor (5)
P14_1 (in the 144-pin package)	Connect the pin to VSS via a resistor (5)
$\overline{BC0}$ to $\overline{BC3}$, $\overline{WR0}$ to $\overline{WR3}$, ALE, $\overline{HLDA}$, XOUT (6), BCLK	Leave pins open
$\overline{HOLD}$, $\overline{RDY}$	Connect the pins to VCC via a resistor (5)
$\overline{NMI}$(P8_5)	Connect the pin to VCC via a resistor (5)
AVCC	Connect the pin to VCC
AVSS, VREF	Connect the pins to VSS
NSD	Connect the pin to VCC via a resistor of 1 to 4.7 kΩ

Notes:
1. Unused pins should be wired as closely as possible to the MCU (within 2 cm).
2. In case of entering output mode to leave pins open, the ports remain input mode from when the reset is released until the ports become output mode. During this input mode, the power current may increase due to undefined voltage level of the pin. In addition to that, the contents of direction register may change because of noise which may lead to the out of control of program. Consequently, the higher program reliability may depend on the regular reconfiguration of the direction register by software.
3. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only.
4. In the 100-pin package, set FFh to the following addresses: 03D7h, 03DAh, 03DBh, 03DEh, and 03DFh.
5. The resistance value appropriate to the system should be designated. The range from 10 to 100 kΩ is recommended.
6. The setting is applicable when an external clock is applied to the XIN pin.

Pull-up/pull-down resistors



The figure shows the equivalent circuit of an input pin.
The equivalent input resistors (R_P and R_N) are calculated using input power current (I_{IL} and I_{IH}).

(Example) When VCC = 5.0 V, $I_{IH} = I_{IL}$ = 5 µA,

$$R_P = R_N = \frac{5.0}{5 \times 10^{-6}} = 1\ M\Omega$$

Since the voltage (V_{IH}) defined as high is more than 0.8 VCC, the resistance value R should satisfy the following expression:

$$R // R_P : R_N = 0.2 : 0.8$$

That is,

$$R = \frac{2R_PR_N}{8R_P - 2R_N}$$

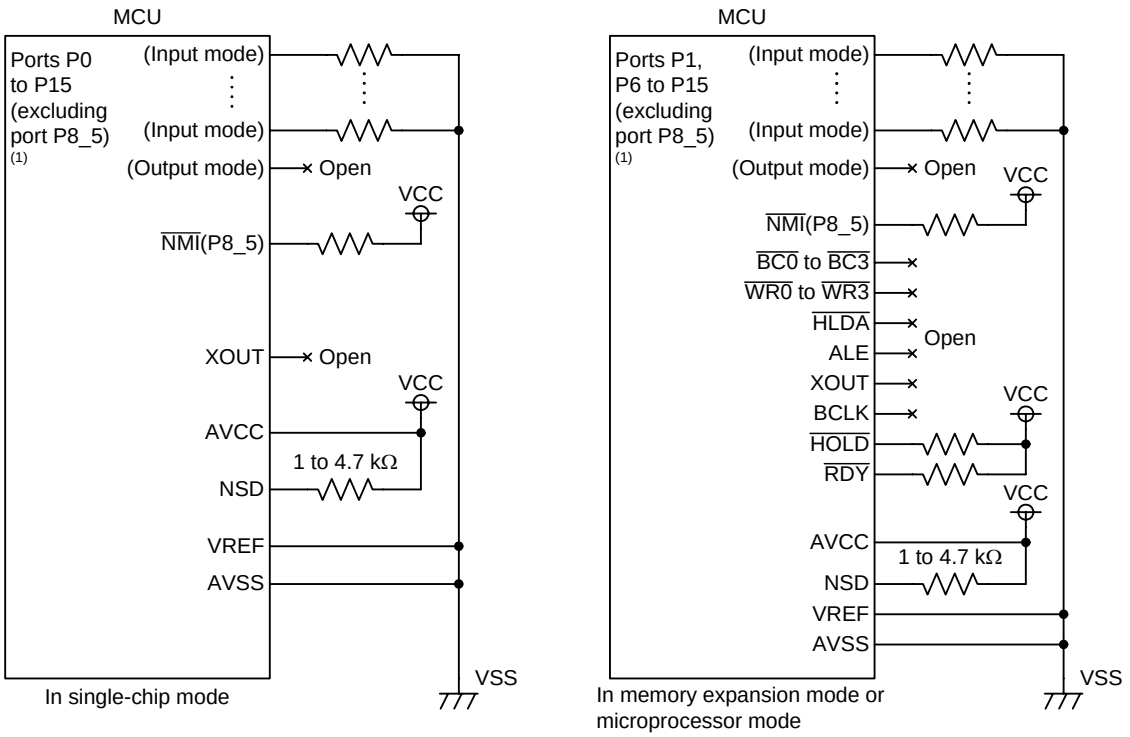
Specifically,

(Example) When VCC = 5.0 V, $I_{IH} = I_{IL}$ = 5 µA,

$$R = \frac{2 \times 10^6 \times 10^6}{8 \times 10^6 - 2 \times 10^6} = 333333$$

The maximum pull-up resistor R is approx. 330 kΩ.
The actual resistance value is the calculated value with some margins.

Figure 26.31 Pull-up/Pull-down Resistors



Note:
1. Ports P11 to P15 are in the 144-pin package only.

Figure 26.32 Unused Pin Configuration

27. Flash Memory

27.1 Overview

Rewrite operation to the flash memory can be performed in the following three modes: CPU rewrite mode, standard serial I/O mode, and parallel I/O mode.
Table 27.1 lists specifications of the flash memory and Table 27.2 shows the overview of each rewrite mode.

Table 27.1 Flash Memory Specifications

Item	Specification
Rewrite modes	CPU rewrite mode, standard serial I/O mode, parallel I/O mode
Structure	Block architecture. Refer to Figure 27.1
Program operation	8-byte basis
Erase operation	1-block basis
Program/erase controlled by	Software commands
Protection types	Lock bit protect, ROM code protect, ID code protect
Software commands	9 commands

Table 27.2 Flash Memory Rewrite Mode Overview

Rewrite Mode	CPU Rewrite Mode	Standard Serial I/O Mode	Parallel I/O Mode
Function	CPU executes a software command to rewrite the flash memory EW0 mode: Rewritable in areas other than the on-chip flash memory EW1 mode: Rewritable in areas other than specified blocks to be rewritten	A dedicated serial programmer rewrites the flash memory Standard serial I/O mode 1: Synchronous serial I/O selected Standard serial I/O mode 2: UART selected	A dedicated parallel programmer rewrites the flash memory
CPU operating mode	Single-chip mode, Memory expansion mode (EW0 mode)	Standard serial I/O mode	Parallel I/O mode
Programmer	—	Serial programmer	Parallel programmer
On-board rewriting	Supported	Supported	Not supported

Figure 27.1 shows the on-chip flash memory structure.
The on-chip flash memory contains program area to store user programs, and data area/data flash to store the result of user programs. The program area consists of blocks 0 to 17, and data area/data flash consists of blocks A and B.
Each block can be individually protected (locked) from programing or erasing by setting the lock bit.

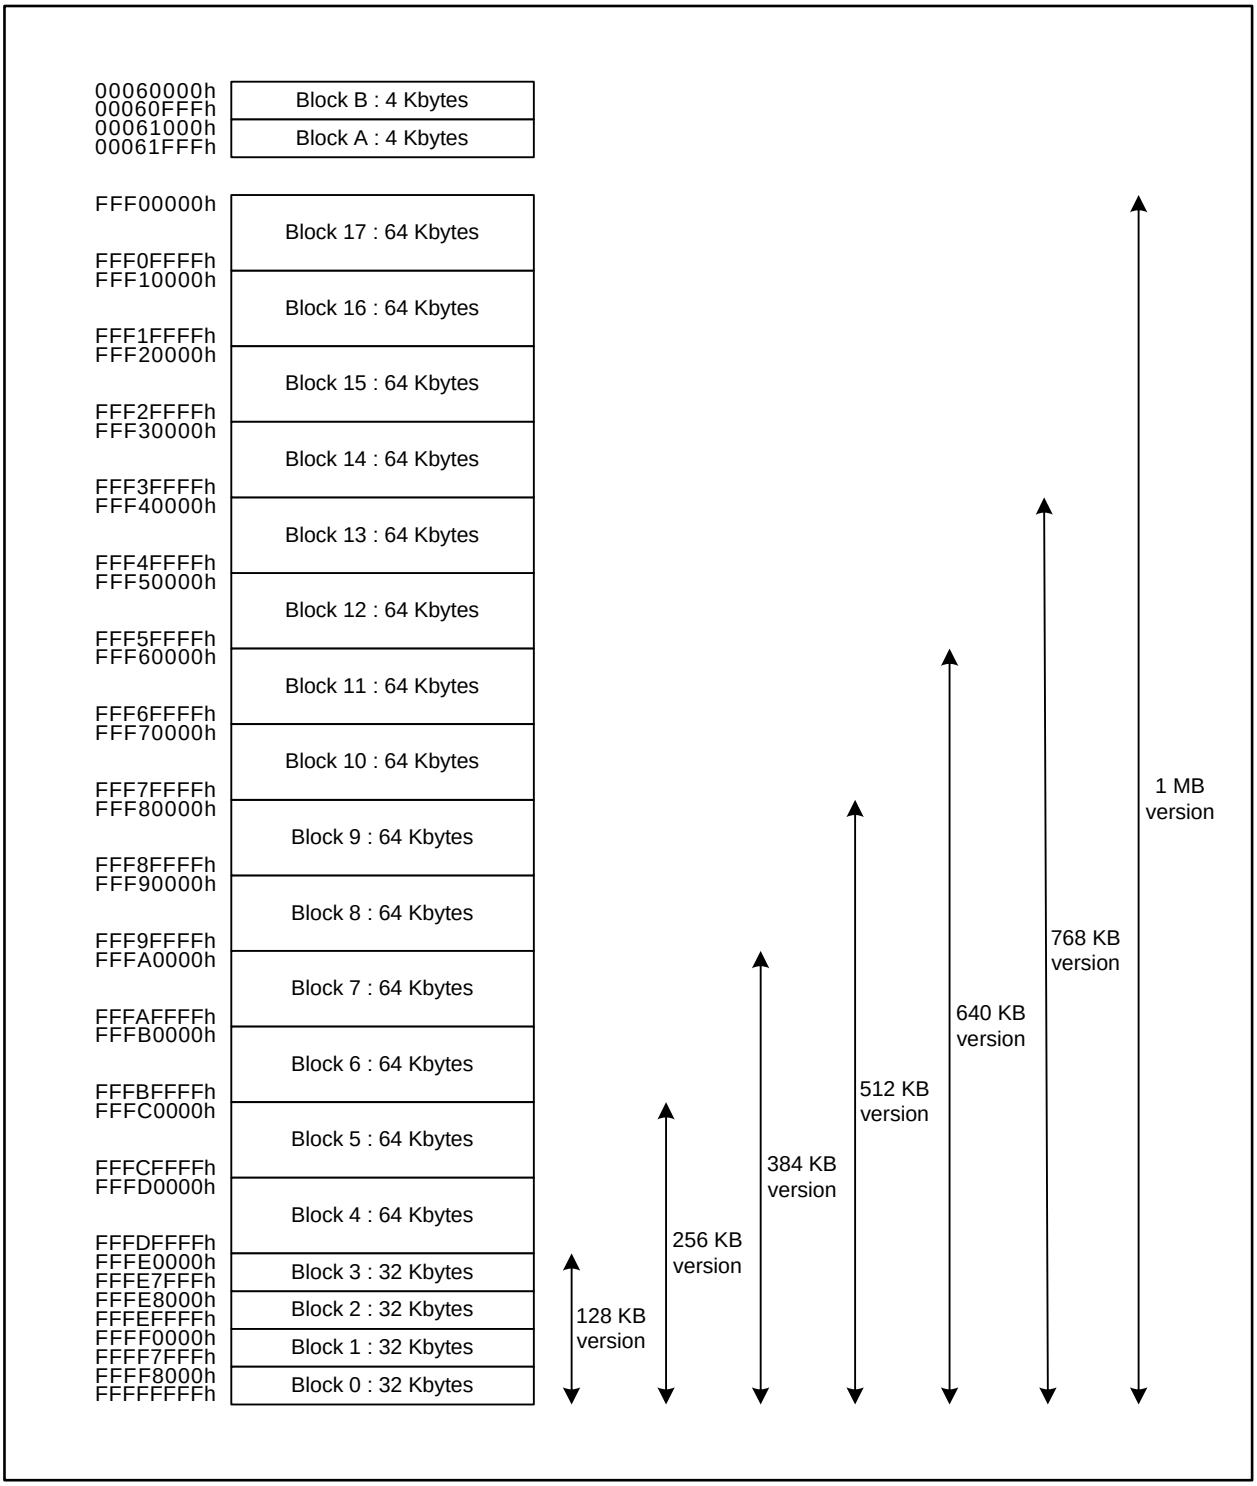


Figure 27.1 Embedded Flash Memory Block Diagram

27.2 Flash Memory Protection

There are three types of protections as shown in Table 27.3. Lock bit protection is intended to prevent accidental program or erase by program runaway. ROM code protection and ID code protection are intended to prevent read or write by a third party.

Table 27.3 Protection Types and Characteristics

Protection Type	Lock Bit Protection	ROM Code Protection	ID Code Protection
Operations to be protected	Erase, write	Read, write	Read, erase, write
Protection available in	CPU rewrite mode Standard serial I/O mode Parallel I/O mode	Parallel I/O mode	Standard serial I/O mode
Protection available for	Individual blocks	The whole flash memory	The whole flash memory
Protection activated by	Setting 0 to the lock bit of block to be protected	Setting 0 to any protect bit of blocks	Writing the program which has set an ID code to specified address
Protection deactivated by	Setting the LBD bit in the FMR register to 1 (lock bit protection disabled). Or, by erasing the blocks whose lock bits are set to 0 to permanently deactivate the protection	Erasing all blocks whose protect bits are set to 0	Inputting a proper ID code to the serial programmer

27.2.1 Lock Bit Protection

This protection is available in all three rewrite modes. When the lock bit protection is activated, all the blocks whose lock bits are set to 0 (locked) are protected against programming and erasing.
To set the lock bit to 0, the lock bit program command must be issued.
To temporarily deactivate the protection of all protected blocks, disable the lock bit protection itself by setting the LBD bit in the FMR1 register to 1 (lock bit protection disabled). To permanently deactivate the protection of a protected block, erase the respective block to set the lock bit to 1 (unlocked).

27.2.2 ROM Code Protection

This protection is available only in parallel I/O mode. When the ROM code protection is activated, the whole flash memory is protected against reading and writing.
To deactivate the protection, erase all the blocks whose protect bits are set to 0 (protected).
Each block has two protect bits. Setting any protect bit to 0 by a software command activates the protection for the whole flash memory. Table 27.4 lists protect bit addresses.

Table 27.4 Protect Bit Addresses

Block	Protect Bit 0	Protect Bit 1
Block B	00060100h	00060300h
Block A	00061100h	00061300h
Block 17	FFF00100h	FFF00300h
Block 16	FFF10100h	FFF10300h
Block 15	FFF20100h	FFF20300h
Block 14	FFF30100h	FFF30300h
Block 13	FFF40100h	FFF40300h
Block 12	FFF50100h	FFF50300h
Block 11	FFF60100h	FFF60300h
Block 10	FFF70100h	FFF70300h
Block 9	FFF80100h	FFF80300h
Block 8	FFF90100h	FFF90300h
Block 7	FFFA0100h	FFFA0300h
Block 6	FFFB0100h	FFFB0300h
Block 5	FFFC0100h	FFFC0300h
Block 4	FFFD0100h	FFFD0300h
Block 3	FFFE0100h	FFFE0300h
Block 2	FFFE8100h	FFFE8300h
Block 1	FFFF0100h	FFFF0300h
Block 0	FFFF8100h	FFFF8300h

27.2.3 ID Code Protection

This protection is available only in standard serial I/O mode. When the ID code protection is activated, a command sent from the serial programmer is accepted only if the 7-byte ID code sent from the serial programmer is identical to the ID code programmed in the flash memory. However, if the reset vector is FFFFFFFFh, the ID code check is skipped because the flash memory is considered as “erase completed”. When the reset vector is FFFFFFFFh and the ROM code protection is activated, only the block erase command is accepted.

The ID codes sent from the serial programmer are consecutively numbered as ID1, ID2, ..., and ID7. On the other hand, the ID codes programmed in the flash memory, also numbered as ID1, ID2, ..., and ID7, are respectively assigned for addresses FFFFFFE8h, FFFFFFE9h, ..., and FFFFFFEEh as shown in Figure 27.2. The ID code protection is activated when a program which has an ID code set in the corresponding address is written to the flash memory.

In the high speed version (64 MHz version), the following two ASCII code combinations are specified as reserved ID codes: “ALeRASE” and “Protect”. Refer to Table 27.5, 27.2.4 “Forcible Erase Function”, and 27.2.5 “Standard Serial I/O Mode Disable Function” for details.

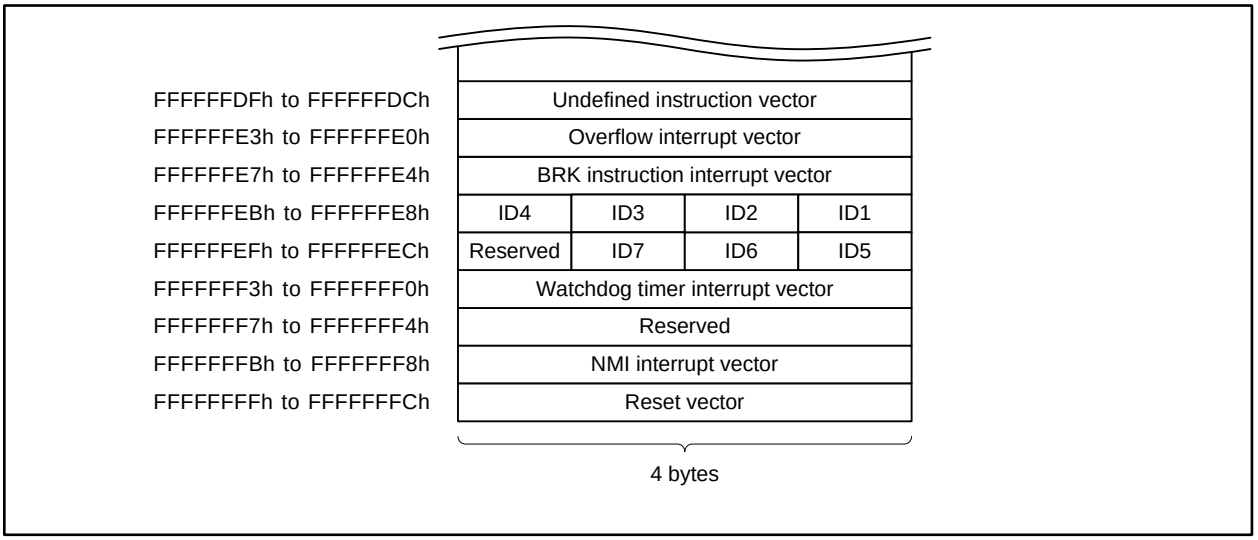

Figure 27.2 Addresses for ID Code Stored

Table 27.5 Reserved ID Codes

ID Code		ID1	ID2	ID3	ID4	ID5	ID6	ID7
ALeRASE	Glyph	A	L	e	R	A	S	E
	ASCII code	41h	4Ch	65h	52h	41h	53h	45h
Protect	Glyph	P	r	o	t	e	c	t
	ASCII code	50h	72h	6Fh	74h	65h	63h	74h

27.2.4 Forcible Erase Function

The forcible erase function is available in standard serial I/O mode in the high speed version (64 MHz version). It is not available in the normal speed version (50 MHz version). With this function, all blocks of the flash memory are forcibly erased when ID codes sent from the serial programmer matches the ASCII code corresponding to the following sequential ASCII-glyphs: “A”, “L”, “e”, “R”, “A”, “S”, and “E”. However, the function is ignored when the ROM code protection is activated and ID codes other than “ALeRASE” are programmed in the flash memory.

Table 27.6 Operational Conditions for Forcible Erase Function

ID Codes Sent From the Serial Programmer	ID Codes Programmed in the Flash Memory	ROM Code Protection	Function
“ALeRASE”	“ALeRASE”	—	Erase all blocks of the flash memory
	Any codes other than “ALeRASE” or ”Protect”	Inactivated	
		Activated	Check ID codes (resulted in unmatched codes)
Any codes other than “ALeRASE”	“ALeRASE”	—	Check ID codes (resulted in unmatched codes)
	Any codes other than “ALeRASE” or ”Protect”	—	Check ID codes

27.2.5 Standard Serial I/O Mode Disable Function

The standard serial I/O mode disable function is available in the high speed version (64 MHz version) It is not available in the normal speed version (50 MHz version). With the standard serial I/O mode disable function, the flash memory in standard serial I/O mode is inaccessible from the CPU when ID code programmed in the flash memory are ASCII codes corresponding to the following sequential ASCII-glyphs: “P”, “r”, “o”, “t”, “e”, “c”, and “t”.

When the ROM code protection is activated and ID codes corresponding to “Protect” are programmed, the serial programmer cannot deactivate the ROM code protection. In this case, the flash memory is not accessible from the outside of MCU other than to delete the flash memory with parallel programmer.

27.3 CPU Rewrite Mode

In CPU rewrite mode, CPU executes software commands to rewrite the flash memory. The CPU accesses the flash memory not via the CPU buses but via the dedicated flash memory rewrite buses (refer to Figure 27.3).

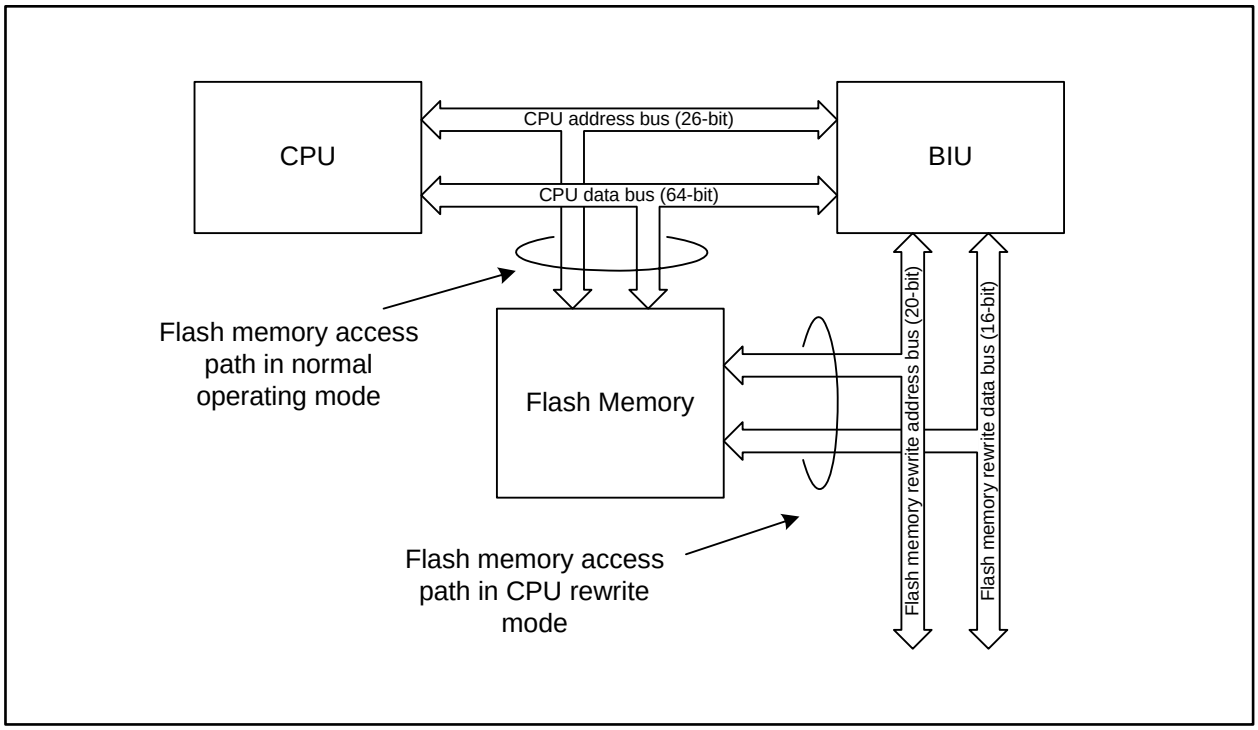

Figure 27.3 Flash Memory Access Path in CPU Rewrite Mode

Bus setting for flash memory rewrite should be performed by the FEBC0 and/or FEBC3 registers. Refer to 27.3.2 “Flash Memory Rewrite Bus Timing” and 28. “Electrical Characteristics” for the appropriate bus setting. Note that registers FEBC0 and FEBC3 share respective addresses with registers EBC0 and EBC3, that is, a rewrite of these registers affects the external bus setting. Set the EBC0 and/or EBC3 registers again after rewriting the FEBC0 and/or FEBC3 registers.

The CPU rewrite mode contains two sub modes: EW0 mode and EW1 mode as shown in Table 27.7.

Table 27.7 Modes EW0 and EW1

Item	EW0 Mode	EW1 Mode
CPU operating modes	Single-chip mode Memory expansion mode (1)	Single-chip mode
Rewrite program executable spaces	Spaces other than the on-chip flash memory	Internal spaces other than specified blocks to be rewritten, internal RAM
Restriction on software command	None	• Do not execute either the program command or the block erase command for blocks where the rewrite control programs are written to • Do not execute the enter read status register mode command • Execute the enter read lock bit status mode command in RAM • Execute the enter read protect bit status mode command in RAM
Mode after program/ erase operation	Read status register mode	Read array mode
CPU state during program/erase operation	Operating	In a hold state (I/O ports maintain the state before the command was executed)
Flash memory state detection by	• Reading the FMSR0 register by a program • Executing the enter read status register mode command to read data	• Reading the FMSR0 register by a program
Other restrictions	None	• Disable interrupts (except NMI) and DMA transfer during program/erase operation

Note:
1. The $\overline{CS0}$ space and $\overline{CS3}$ space are conditionally available in memory expansion mode. Refer to 27.3.1 “CPU Operating Mode and Flash Memory Rewrite” for details.

To select CPU rewrite mode, the FEW bit in the FMCR register should be set to 1. Then, EW0 mode/EW1 mode can be selected by setting the EWM bit in the FMR0 register.
Registers FMCR and FMR0 are protected by registers PRR and FPR0, respectively.
Figure 27.4 to Figure 27.12 show associated registers.

Figure 27.12 FBPM2 Register

27.3.1 CPU Operating Mode and Flash Memory Rewrite

To rewrite the flash memory, the bus setting using by the FEBC0 and/or FEBC3 registers is required. For exclusive use of single-chip mode, the FEBC3 register is not used. In this mode, do not change the reset value 00h of registers CB01, CB12, and CB23. The bus setting for both program area and data area can be performed by the FEBC0 register.

In other cases than the above, when the CPU operation is performed in memory expansion mode more than once, set registers CB01, CB12, and CB23 according to each setting range as shown in Table 27.8. The bus setting for program area and data area can be respectively performed by the FEBC0 register and FEBC3 register.

Note that registers FEBC0 and FEBC3 in memory expansion mode share respective addresses with registers EBC0 and EBC3, that is, when the FEBCi register (i = 0, 3) is set for the flash memory rewrite, the setting value for EBCi register is accordingly changed. This may cause external devices allocated for $\overline{CS0}$ space and/or $\overline{CS3}$ space in CPU rewrite mode to become inaccessible.

Table 27.8 lists the details of bus setting for the flash memory rewrite in each CPU operating mode.

Table 27.8 CPU Operating Mode and Flash Memory Rewrite

Item	CPU Operating Mode	
	Single-chip mode	Memory expansion mode
CB01 register	Hold the reset value 00h	Setting range: 04h to F8h Set an value higher than that for the CB12 register
CB12 register	Hold the reset value 00h	Setting range: 03h to F7h Set an value higher than that for the CB23 register and lower than that for the CB01 register
CB23 register	Hold the reset value 00h	Setting range: 02h to F6h Set an value lower than that for the CB12 register
Bus setting for program area	FEBC0 register	FEBC0 register
Bus setting for data area	FEBC0 register	FEBC3 register
State of $\overline{CS0}$ space and $\overline{CS3}$ space after the FEBCi register is set	N/A	• Separate bus format • 16-bit bus width • $\overline{RDY}$ ignored
Restrictions for the use of $\overline{CS0}$ space and $\overline{CS3}$ space	None	• $\overline{HOLD}$ is ignored • In CPU rewrite mode, external devices become inaccessible to data with the bus format set for $\overline{CS0}$ space and/or $\overline{CS3}$ space as multiplexed bus • The change of bus timing may cause external devices in $\overline{CS0}$ space and/or $\overline{CS3}$ space to become inaccessible

27.3.2 Flash Memory Rewrite Bus Timing

As mentioned in 27.3.1, the bus setting for the flash memory rewrite is performed by using the FEBC0 and/or FEBC3 registers. This section specifically describes the setting of registers FEBC0 and FEBC3. The reference clock is the base clock set using bits BCD1 and BCD0 in the CCR register. Time duration including tsu, tw, tc and th are specified by base clock cycles.

Table 27.9 to Table 27.11 show the correlation of read cycle and setting of following bits: MPY1, MPY0, and FWR4 to FWR0, according to respective peripheral bus clock divide ratio. Table 27.12 to Table 27.14 show the correlation of write cycle and setting of following bits: MPY1, MPY0, FSUW1, FSUW0, FWW1, and FWW0. Associated read/write timings are respectively illustrated in Figure 27.13 and Figure 27.14.

Read/write cycle timing is selected from these tables below to meet the timing requirements in CPU rewrite mode described in the electrical characteristics.

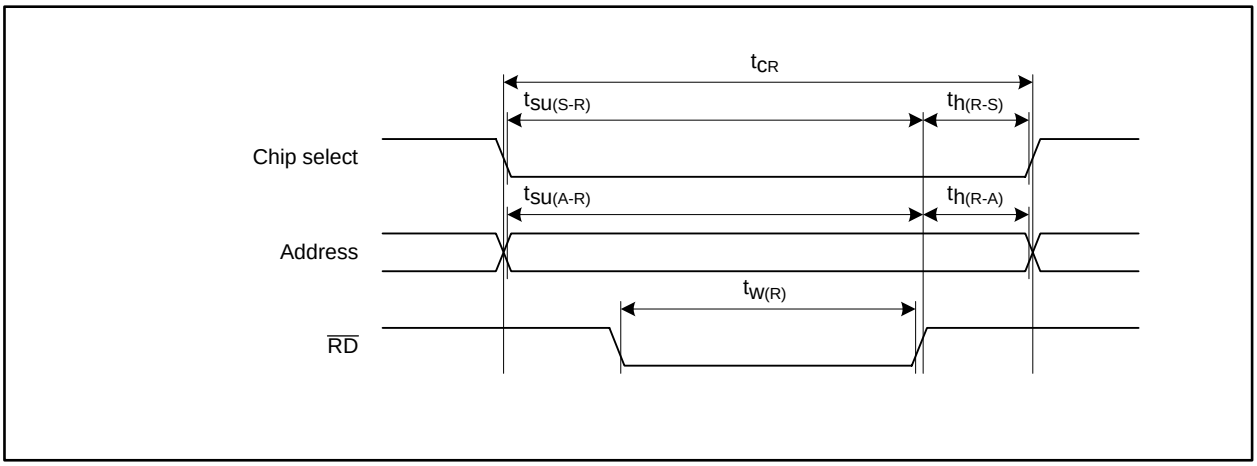

Figure 27.13 Read Timing

Table 27.9 The Read Cycle and Bit Settings: MPY1, MPY0, and FWR4 to FWR0, When Peripheral Bus Clock is Divided by 2 (unit: cycles)

27.3.3 Software Commands

In CPU rewrite mode, software commands enable to rewrite or erase the flash memory. A write of command and read of data should be performed in 16-bit units.
Table 27.15 lists the software commands.

Table 27.15 Software Commands

Command	First Command Cycle		Second Command Cycle	
	Address	Data	Address	Data
Enter read array mode	FFFFF800h	00FFh	—	—
Enter read status register mode (1)	FFFFF800h	0070h	—	—
Clear status register	FFFFF800h	0050h	—	—
Program (2)	FFFFF800h	0043h	WA	WD
Block erase	FFFFF800h	0020h	BA	00D0h
Lock bit program	FFFFF800h	0077h	BA	00D0h
Read lock bit status	FFFFF800h	0071h	BA	00D0h
Enter read lock bit status mode (3)	FFFFF800h	0071h	—	—
Protect bit program	FFFFF800h	0067h	PBA	00D0h
Enter read protect bit status mode (3)	FFFFF800h	0061h	—	—

WA: Even address to be written
WD: 16-bit data to be written
BA: An even address within a specific block
PBA: Protect bit address (Refer to Table 27.4)

Notes:
1. This command cannot be executed in EW1 mode.
2. A set of command consists of five words from the first command to the fifth. The program is performed in 64-bit (four-word) unit. The higher 29 bits of the address WA should be fixed and the lower three bits of respective commands from the second to fifth should be set to 000b, 010b, 100b, and 110b for the addresses 0h, 2h, 4h, and 6h, or 8h, Ah, Ch, and Eh.
3. This command should be executed in RAM.

27.3.4 Mode Transition

CPU rewrite mode supports four flash memory operating modes:

- Read array mode
- Read status register mode
- Read lock bit status mode
- Read protect bit status mode

When reading the flash memory in these modes, the content of memory, the content of status register, the state of lock bit of read block, and the state of protect bit are respectively read. The details are listed in Table 27.16 to Table 27.18.

Table 27.16 Status Register

Bit	Bit Symbol	Bit Name	Definition	
			0	1
b15-b8	—	Disabled bit	—	—
b7	SR7	Sequencer status	BUSY	READY
b6	—	Reserved bit	—	—
b5	SR5	Erase status	Successfully completed	Error
b4	SR4	Program status	Successfully completed	Error
b3	—	Reserved bit	—	—
b2	—	Reserved bit	—	—
b1	—	Reserved bit	—	—
b0	—	Reserved bit	—	—

Table 27.17 Lock Bit Status

Bit	Bit Symbol	Bit Name	Definition	
			0	1
b15-b7	—	Disabled bit	—	—
b6	LBS	Lock bit status	Locked	Unlocked
b5-b0	—	Disabled bit	—	—

Table 27.18 Protect Bit Status

Bit	Bit Symbol	Bit Name	Definition	
			0	1
b15-b7	—	Disabled bit	—	—
b6	PBS	Protect bit status	Protected	Unprotected
b5-b0	—	Disabled bit	—	—

In these operating modes, a program or erase operation can be performed by software commands. After the operation is completed, the flash memory module automatically enters read array mode (in EW1 mode) or read status register mode (in EW0 mode).

27.3.5 How to Issue Software Commands

This section describes how to issue the software commands.
These commands should be issued while the RDY bit in the FMSR0 register is 1 (ready).

27.3.5.1 Enter Read Array Mode Command

This command is executed to enter read array mode.
When 00FFh is written to address FFFFF800h, the flash memory enters read array mode. In this mode, data stored to a given address in memory can be read.
In EW1 mode, the flash memory is always in read array mode.

27.3.5.2 Enter Read Status Register Mode

This command is executed to enter read status register mode.
When 0070h is written to address FFFFF800h, data of the status register is read in any address of the flash memory.
Do not execute this command in EW1 mode.

27.3.5.3 Clear Status Register

This command is executed to reset the status register in the flash memory.
When 0050h is written to address FFFFF800h, bits SR5 and SR4 in the status register become 0 (successfully completed) (Refer to Table 27.16). Consequently, bits EERR and WERR in the FMSR0 register become 0 (no errors).

27.3.5.4 Program Command

This command is executed to program the flash memory in eight-byte (four-word) unit.
To start automatic programming (program and program-verify operation), write 0043h to address FFFFF800h, then write data to addresses 8n + 0 to 8n + 6. Verify that the FCA bit in the FMR0 register is 0 just before executing the final command.
To monitor the automatic program operation, read the RDY bit in the FMSR0 register. This bit indicates 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.
The operation result can be verified by the WERR bit in the FMSR0 register (Refer to 27.3.6 “Status Check”).
Do not write additional data to the address already programmed.

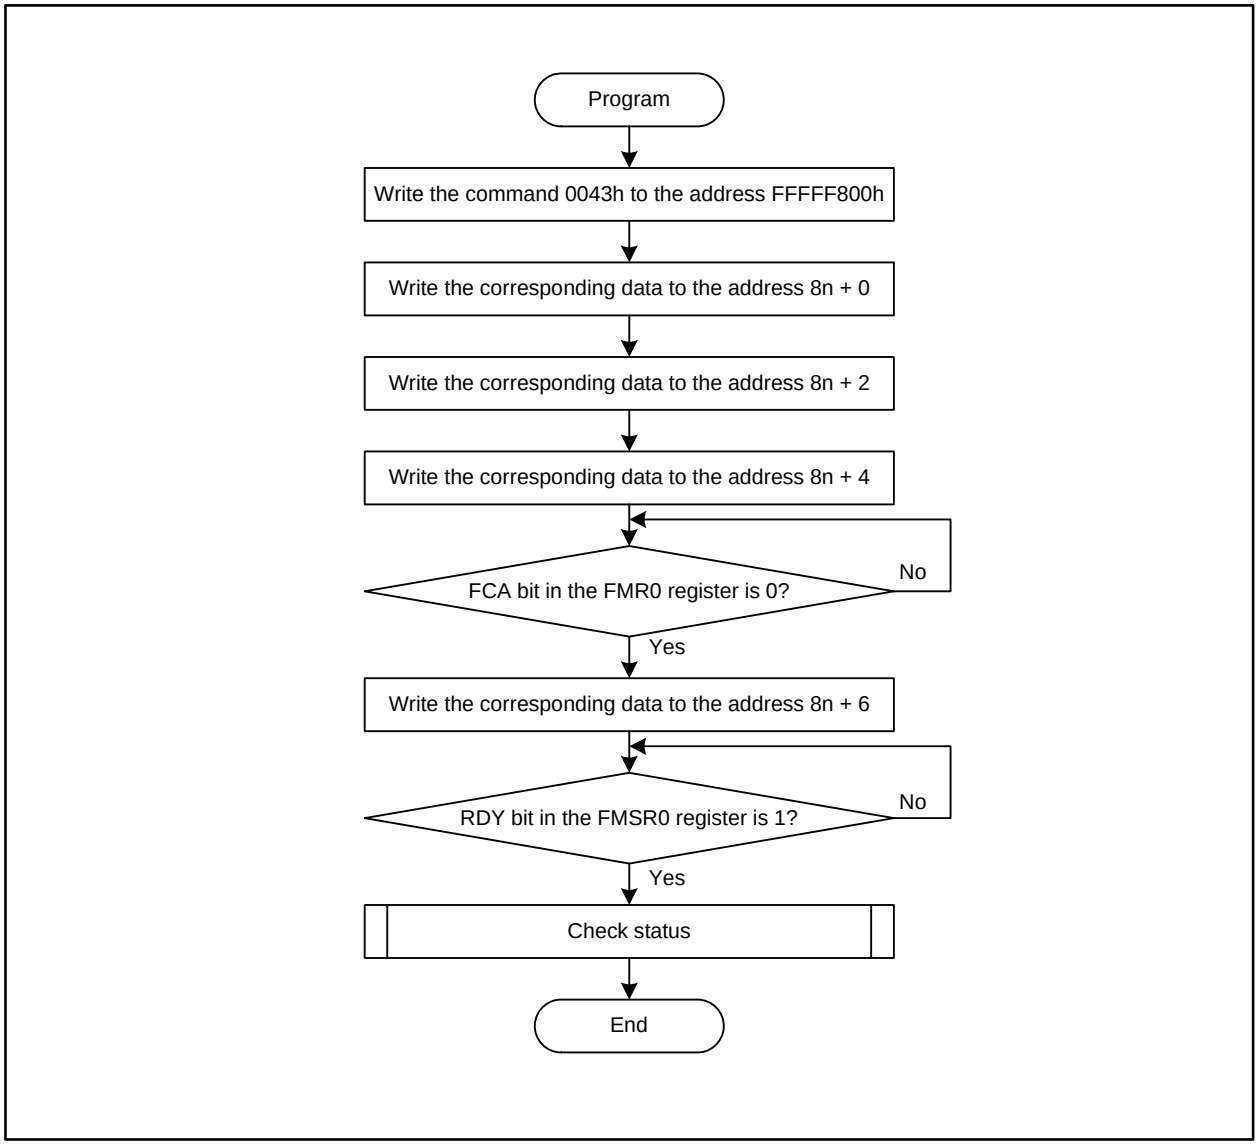

Figure 27.15 Program Command Flow

27.3.5.5 Block Erase Command

This command is executed to erase a specified block in the flash memory.
To start automatic erasing of the specified block (erase and erase-verify operation), write 0020h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, then write 00D0h to an even address of the corresponding block.
To monitor the automatic erase operation, read the RDY bit in the FMSR0 register. This bit indicates 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.
The operation result can be verified by the EERR bit in the FMSR0 register (Refer to 27.3.6 “Status Check”).

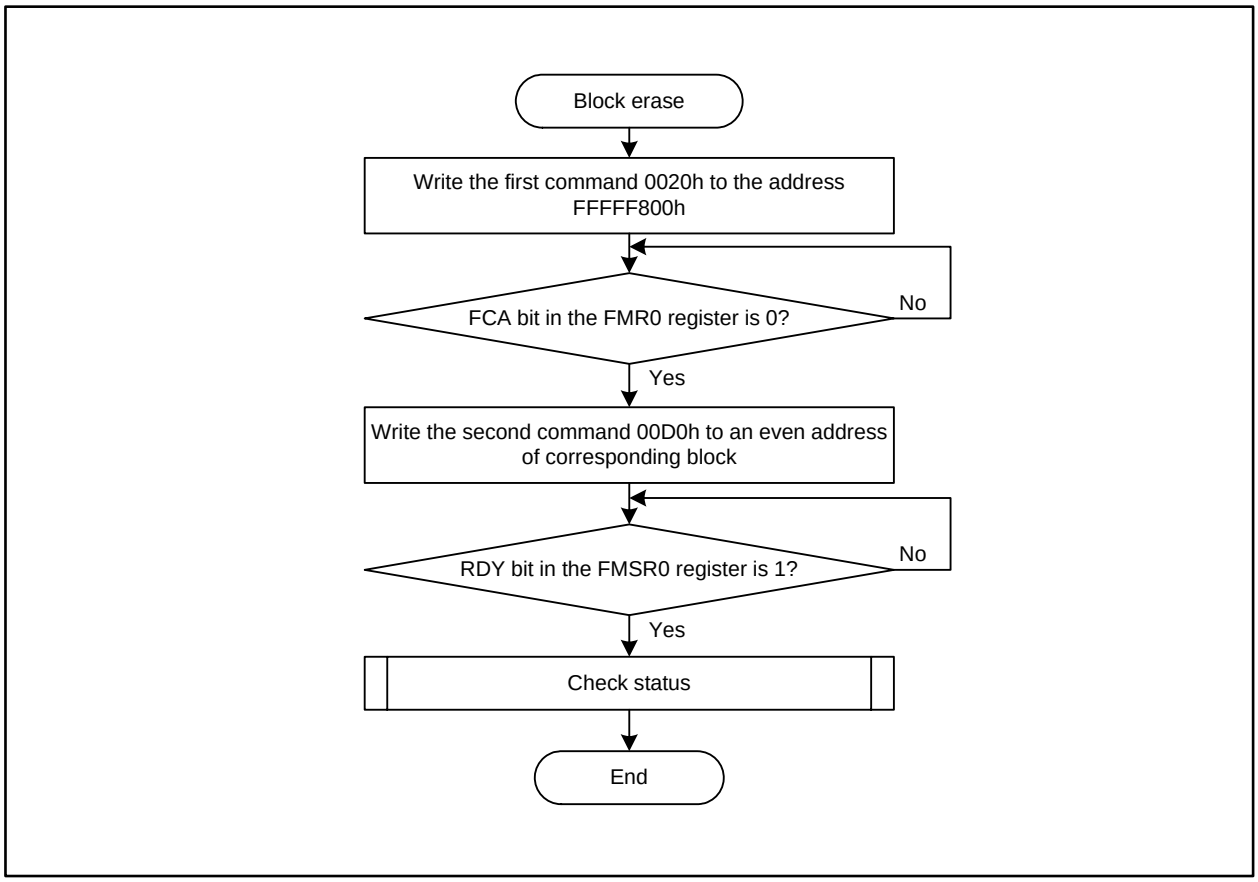

Figure 27.16 Block Erase Command Flow

27.3.5.6 Lock Bit Program Command

This command is executed to lock a specified block in the flash memory.
To lock the block, write 0077h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, then write 00D0h to an even address of the corresponding block. Then the lock bit of the block becomes 0 (locked).
To monitor the lock bit program, read the RDY bit in the FMSR0 register. This bit indicates 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.
The state of lock bit can be verified by the read lock bit status command if the LBM bit in the FMR0 register is 1 (read by the LBS bit) (Refer to 27.3.5.7 “Read Lock Bit Status Command”). If the LBM bit is 0 (read via data bus), enter read lock bit status mode (Refer to 27.3.5.8 “Enter Read Lock Bit Status Mode Command”).

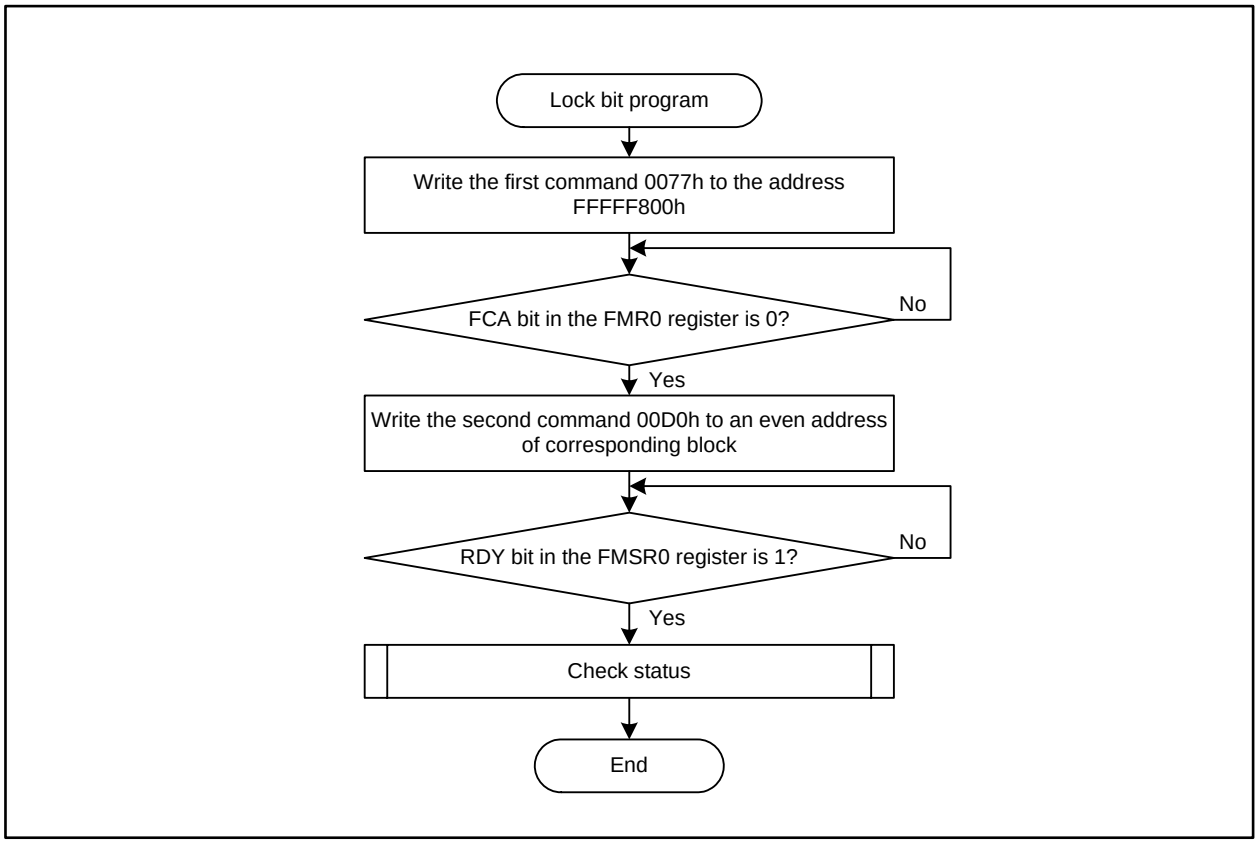

Figure 27.17 Lock Bit Program Command Flow

27.3.5.7 Read Lock Bit Status Command

This command is executed to verify if a specified block in the flash memory is locked. This command is available when the LBM bit in the FMR0 register is 1 (read by the LBS bit).
To read the LBS bit from the FMR0 register, write 0071h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, then write 00D0h to an even address of the corresponding block.
Read the LBS bit after the RDY bit in the FMSR0 register becomes 1 (ready).

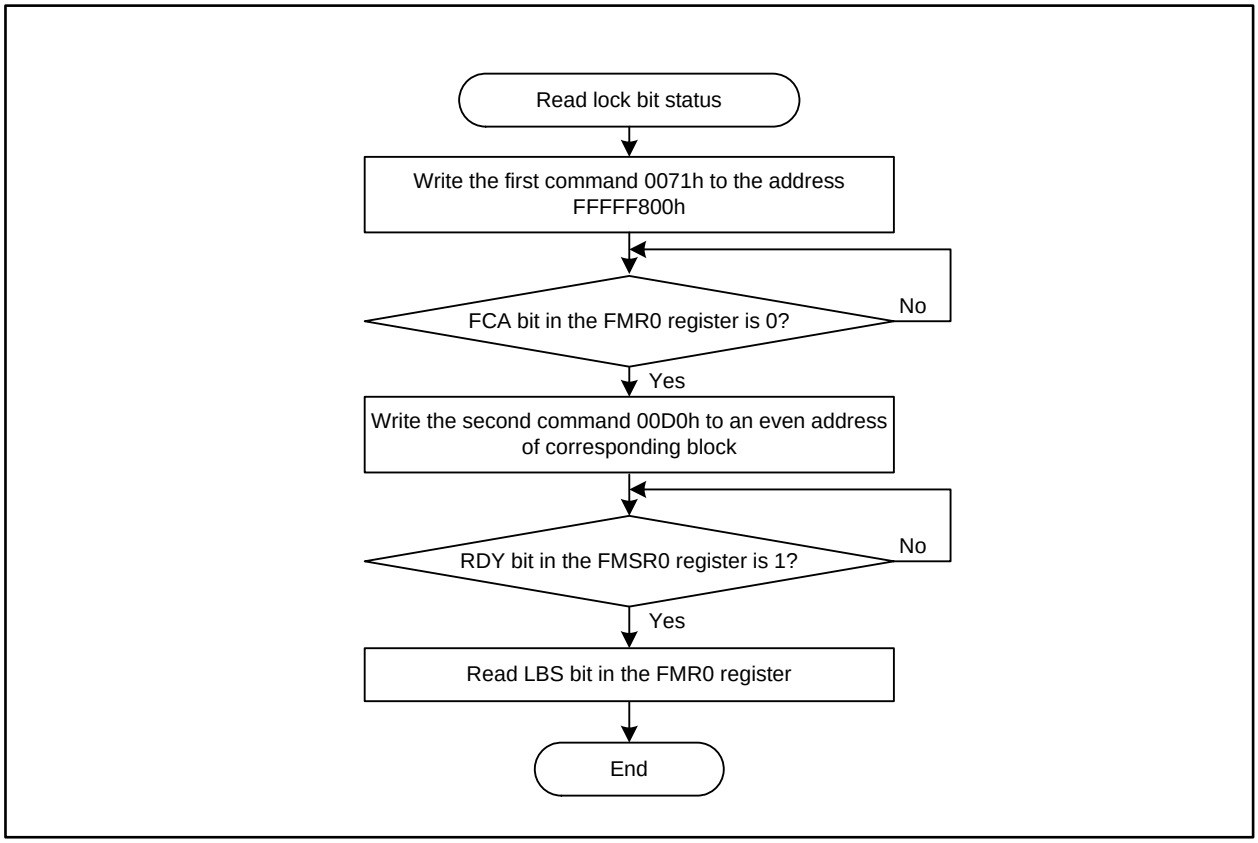

Figure 27.18 Read Lock Bit Status Command Flow

27.3.5.8 Enter Read Lock Bit Status Mode Command

This command is executed to enter read lock bit status mode. This command is enabled when the LBM bit in the FMR0 register is 0 (read via data bus).
To read the lock bit status of the read block, write 0071h to address FFFFF800h (Refer to Table 27.17).
The status is read in any address of the flash memory.
Execute this command in RAM.

27.3.5.9 Protect Bit Program Command

This command is executed to protect a block specified in the flash memory. ROM code protection is enabled by setting any protect bit of blocks to 0.

To program the protect bit of the designated block to 0 (protected), write 0067h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, then write 00D0h to the protect bit of the corresponding block (Refer to Table 27.4).

To monitor the protect bit program, read the RDY bit in the FMSR0 register. This bit shows 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.

To verify the state of protect bit, enter read protect bit status mode (Refer to 27.3.5.10 “Enter Read Protect Bit Status Mode Command”), then read the flash memory.

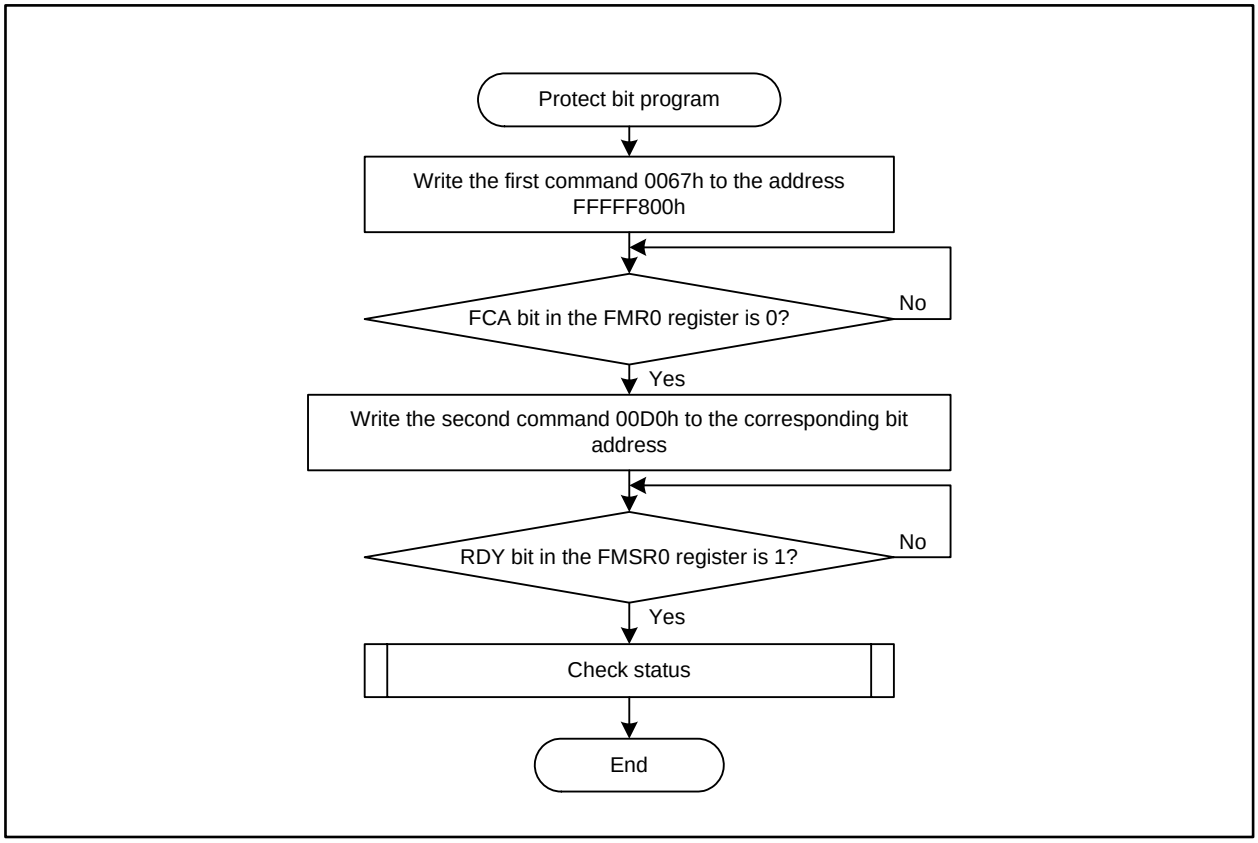

Figure 27.19 Protect Bit Program Command Flow

27.3.5.10 Enter Read Protect Bit Status Mode Command

This command is executed to enter read protect bit status mode.

To read the protect bit status of the read block, write 0061h to address FFFFF800h (Refer to Table 27.18). The status is read from any address of the flash memory.

Execute this command in RAM.

27.3.6 Status Check

To verify if a software command is successfully executed, read EERR or WERR bit in the FMSR0 register, or SR5 or SR4 bit in the status register.
Table 27.19 lists status and errors indicated by these bits and Figure 27.20 shows the flow of status check.

Table 27.19 Status and Errors

FMSR0 register (Status register)		Error	Causes for Error
EERR bit (SR5 bit)	WERR bit (SR4 bit)		
1	1	Command sequence error	• Data other than 00D0h or 00FFh (command to cancel) was written as the last command of two commands • An unavailable address was specified by an address specifying command
1	0	Erase error	• A locked block was tried to erase • Corresponding block was not erased properly
0	1	Program error	• A locked block was tried to program • Data was not programmed properly • Lock bit was not programmed properly • Protect bit was not programmed properly
0	0	No error	

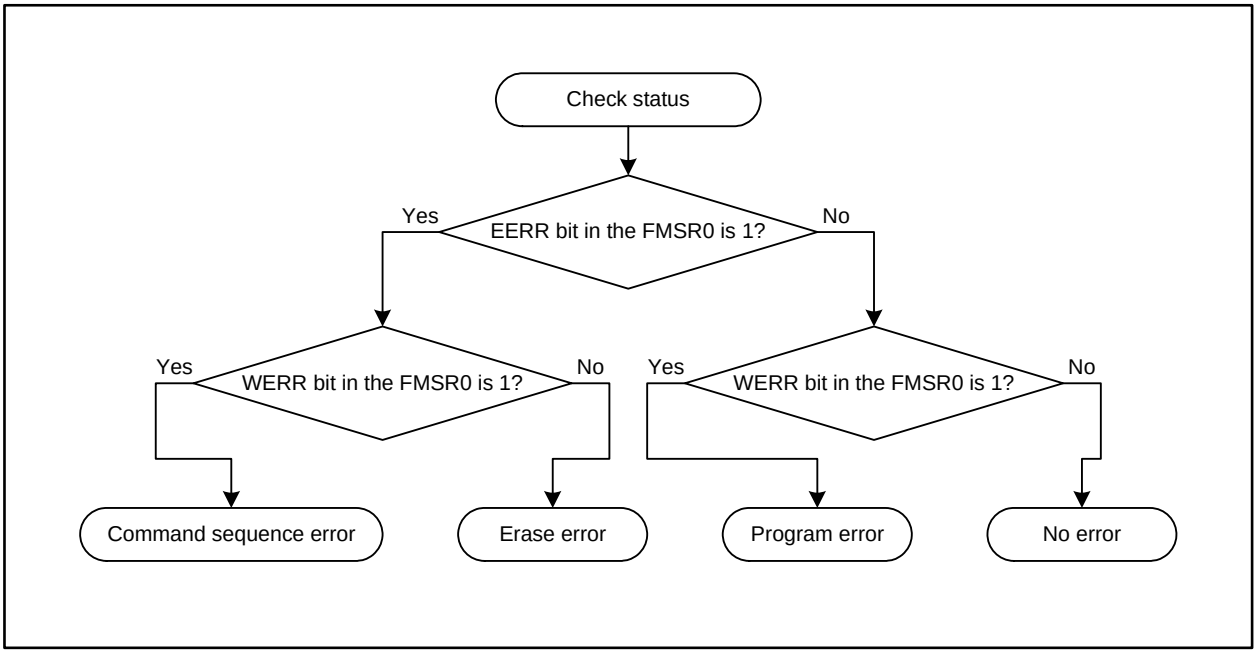

Figure 27.20 Status Check Flow

When an error occurs, execute clear status register command, then handle the error properly.
If erase errors or program errors occur frequently even though the program is correct, the corresponding block may be disabled.

27.4 Standard Serial I/O Mode

In standard serial I/O mode, the serial programmer supporting the R32C/117 Group can be used to rewrite the flash memory, while the MCU is mounted on a board.
For further information on the serial programmer, please contact your serial programmer manufacturer and refer to the user's manual included with your serial programmer for instructions.
This mode provides two types of transmit/receive mode: Standard serial I/O mode 1 which uses synchronous serial interface and standard serial I/O mode 2 which uses UART as shown in Table 27.20.

Table 27.20 Standard Serial I/O Mode Specifications

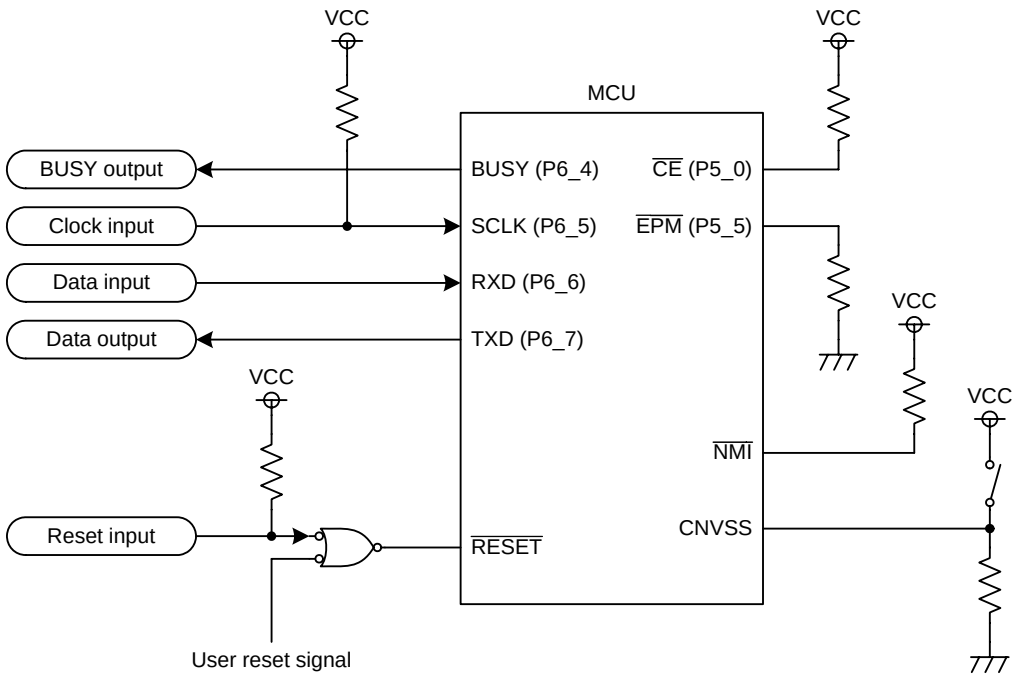
Item		Standard Serial I/O Mode 1	Standard Serial I/O Mode 2
Transmit/receive mode		Synchronous serial I/O	UART
Transmit/receive bit rate		High	Low
Serial interface to be used		UART1	UART1
Pin setting	CNVSS	High	High
	$\overline{CE}$ (P5_0)	High	High
	$\overline{EPM}$ (P5_5)	Low	Low
	SCLK (P6_5)	In reset: Low In transmission/reception: Transmit/receive clock	In reset: Low In transmission/reception: Unused
Pin function	BUSY (P6_4)	BUSY signal	Monitor to check program operation
	RXD (P6_6)	Serial data input	Serial data input
	TXD (P6_7)	Serial data output	Serial data output

Table 27.21 lists the pin definitions and functions in standard serial I/O mode. Figure 27.21 and Figure 27.22 show examples of a circuit application in standard serial I/O modes 1 and 2, respectively. Refer to the user's manual of your serial programmer to handle pins controlled by the serial programmer.

Table 27.21 Pin Definitions and Functions in Standard Serial I/O Mode

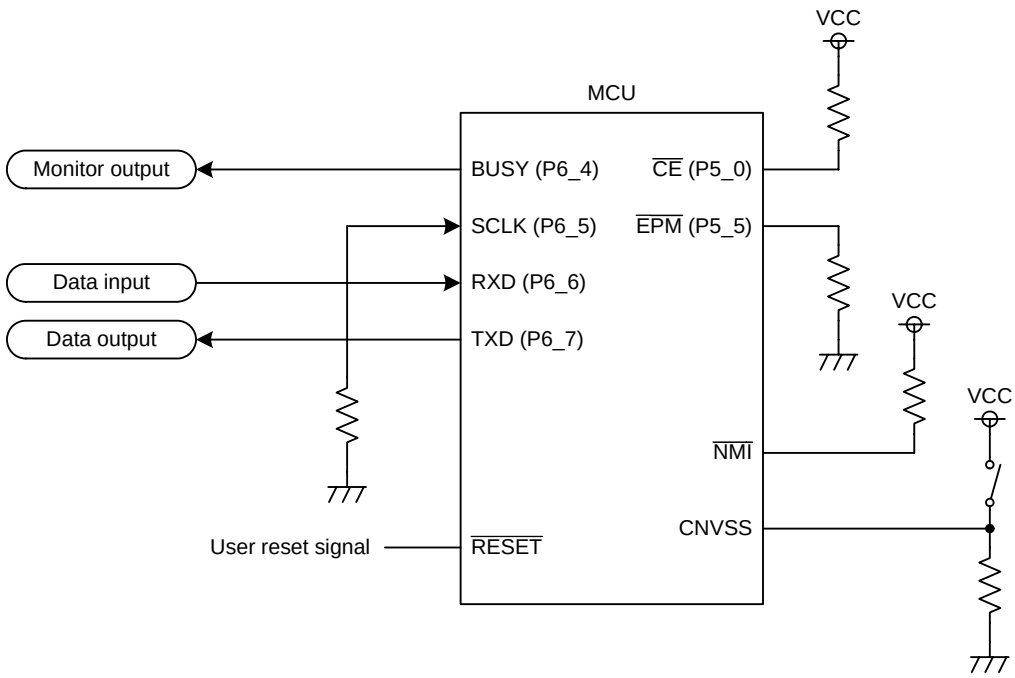
Symbol	Function	I/O	Description
VCC, VSS	Power supply input	I	Applicable as follows: VCC = guaranteed voltage for program/ erase operation, VSS = 0 V
VDC1, VDC0	Connecting pins for decoupling capacitor	—	A decoupling capacitor for internal voltage should be connected between VDC0 and VDC1
CNVSS	CNVSS	I	This pin should be connected to VCC via a resistor
$\overline{\text{RESET}}$	Reset input	I	Reset input pin. While the $\overline{\text{RESET}}$ pin is driven low, a clock of 20 cycles or more should be input at the XIN pin
XIN	Main clock input	I	A ceramic resonator or a crystal oscillator should be connected between pins XIN and XOUT. An external clock should be input at the XIN while leaving the XOUT open
XOUT	Main clock output	O	
NSD	Debug port	I/O	This pin should be connected to VCC via a resistor of 1 to 4.7 kΩ
AVCC, AVSS	Analog power supply	I	AVCC and AVSS should be connected to VCC and VSS, respectively
VREF	Reference voltage input	I	Reference voltage input for the A/D converter and D/A converter
P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7	Input port	I	High or low should be input, or the ports should be left open
P5_0	$\overline{\text{CE}}$ input	I	High should be input
P5_1 to P5_4	Input port	I	High or low should be input, or the ports should be left open
P5_5	$\overline{\text{EPM}}$ input	I	Low should be input
P5_6, P5_7, P6_0 to P6_3	Input port	I	High or low should be input, or the ports should be left open
P6_4	BUSY output	O	Standard serial I/O mode 1: BUSY output pin Standard serial I/O mode 2: Program operation monitor
P6_5	SCLK input	I	Standard serial I/O mode 1: Serial clock input pin Standard serial I/O mode 2: Low should be input
P6_6	Data input RXD	I	Serial data input pin
P6_7	Data output TXD	O	Serial data output pin
P7_0 to P7_7, P8_0 to P8_4	Input port	I	High or low should be input, or the ports should be left open
P8_5	$\overline{\text{NMI}}$ input	I	This pin should be connected to VCC via a resistor
P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7 (1)	Input port	I	High or low should be input, or the ports should be left open

Note:
1. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only.



Notes:
1. Control pins and external circuitry vary with the serial programmer. Refer to the user's manual included with the serial programmer.
2. In this example, a selector controls the voltage applied to the CNVSS pin to switch between in single-chip mode and in standard serial I/O mode 1.
3. If the user reset signal becomes low while the MCU is communicating with the serial programmer, the connection between the user reset signal and the $\overline{\text{RESET}}$ pin by, for example, a jumper selector.

Figure 27.21 Circuit Application in Standard Serial I/O Mode 1



Notes:
1. Control pins and external circuitry vary with the serial programmer. Refer to the user's manual included with the serial programmer.
2. In this example, a selector controls the voltage applied to the CNVSS pin to switch between in single-chip mode and in standard serial I/O mode 2.
3. If the user reset signal becomes low while the MCU is communicating with the serial programmer, the connection between the user reset signal and the $\overline{\text{RESET}}$ pin by, for example, a jumper selector.

Figure 27.22 Circuit Application in Standard Serial I/O Mode 2

27.5 Parallel I/O mode

In parallel I/O mode, the parallel programmer supporting the R32C/117 Group can be used to rewrite the flash memory.

For further information on the parallel programmer, please contact your parallel programmer manufacturer and refer to the user's manual included with your parallel programmer for instructions.

27.6 Notes on Flash Memory Rewriting

27.6.1 Note on Power Supply

- Keep the supply voltage constant within the range specified in the electrical characteristics while a rewrite operation on flash memory is in progress. If the supply voltage becomes beyond the guaranteed value, the device cannot be guaranteed.

27.6.2 Note on Hardware Reset

- Do not perform a hardware reset while a rewrite operation on flash memory is in progress.

27.6.3 Note on Flash Memory Protection

- If an ID code written in an assigned address has an error, any read/write operation of flash memory in standard serial I/O mode is disabled.

27.6.4 Notes on Programming

- Do not set the FEW bit in the FMCR register to 1 (CPU rewrite mode) in low speed mode or low power mode.
- Four software commands of program, block erase, lock bit program, and protect bit program are interrupted by an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt. If any of the software commands above is interrupted, erase the corresponding block and then execute the same command again. If the block erase command is interrupted, values of lock bits and protect bits become undefined. Therefore, disable the lock bit, and then execute the block erase command again.

27.6.5 Notes on Interrupts

- EW0 mode
  - To use interrupts assigned to the relocatable vector table, the vector table should be addressed in RAM space.
  - If either of an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt is generated, the flash memory module automatically enters read array mode. Therefore these interrupts are enabled even during a rewrite operation. On the other hand, the rewrite operation in progress is aborted by the interrupt and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.
  - Instructions BRK, INTO, and UND, which refer to data on the flash memory, are unavailable in this mode.

- EW1 mode
  - Interrupts assigned to the relocatable vector table should not be accepted during a program or block erase operation.
  - The watchdog timer interrupt should not be generated, either.
  - If either of an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt is generated, the flash memory module automatically enters read array mode. Therefore this interrupt is enabled even during a rewrite operation. On the other hand, the rewrite operation in progress is aborted by the interrupt and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the EWM bit in the FMR0 register to 1 (set as EW1 mode) and the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.

27.6.6 Notes on Rewrite Control Program

- EW0 mode
  - If the supply voltage lowers during the rewrite operation of blocks having the rewrite control program, the rewrite control program may not be successfully rewritten, then the rewrite operation itself may not be performed. In this case perform the rewrite operation by serial programmer or parallel programmer.

- EW1 mode
  - Do not rewrite blocks having the rewrite control program.

27.6.7 Notes on Number of Programming/Erasure and Software Command Execution Time

- According to the increase of program/erase operation, the four software commands: program, block erase, lock bit program, and protect bit program require more time to be executed. If the number of programming/erasure exceeds the minimum endurance value specified in the electrical characteristics, it may take unpredictable time to execute the software commands. The waiting time for the execution of software commands should be set much longer than the execution time specified in the electrical characteristics.

27.6.8 Other Notes

- The required time to perform the program or erase operation specified in the electrical characteristics can be guaranteed within the minimum values of programming/erasure endurance specified in the same table. Even if the number of programming/erasure exceeds the minimum endurance value, the program or erase operation may be unguaranteedly performed.
- Chips repeatedly programmed and erased for debugging are not allowed to be used for commercial products.

28. Electrical Characteristics

Table 28.1 Absolute Maximum Ratings (1)

Symbol	Characteristic		Condition	Value	Unit
V_{CC}	Supply voltage		$V_{CC} = AV_{CC}$	-0.3 to 6.0	V
AV_{CC}	Analog supply voltage		$V_{CC} = AV_{CC}$	-0.3 to 6.0	V
V_I	Input voltage	XIN, $\overline{RESET}$, CNVSS, NSD, V_{REF}, P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P5_0 to P5_3, P8_4 to P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7 (2)		-0.3 to V_{CC} + 0.3	V
		P4_0 to P4_7, P5_4 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_3		-0.3 to 6.0	V
V_O	Output voltage	XOUT, P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7 (2)		-0.3 to V_{CC} + 0.3	V
P_d	Power consumption		T_a = 25°C	500	mW
—	Operating temperature range			-40 to 85	°C
T_{stg}	Storage temperature range			-65 to 150	°C

Notes:
1. Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only. Port P9_1 is designated as input pin in the 100-pin package.

Table 28.2 Operating Conditions (1/5) (1)

Symbol	Characteristic			Value			Unit
				Min.	Typ.	Max.	
V_{CC}	Digital supply voltage			3.0	5.0	5.5	V
AV_{CC}	Analog supply voltage				V_{CC}		V
V_{REF}	Reference voltage			3.0		V_{CC}	V
V_{SS}	Digital ground voltage				0		V
AV_{SS}	Analog ground voltage				0		V
dV_{CC}/dt	V_{CC} ramp up rate (V_{CC} < 2.0 V)			0.05			V/ms
V_{IH}	High level input voltage	XIN, $\overline{\text{RESET}}$, CNVSS, NSD, P2_0 to P2_7, P3_0 to P3_7, P5_0 to P5_3, P8_4 to P8_7 (2), P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P14_1, P14_3 to P14_6, P15_0 to P15_7 (3)		0.8 × V_{CC}		V_{CC}	V
		P4_0 to P4_7, P5_4 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_3		0.8 × V_{CC}		6.0	V
		P0_0 to P0_7, P1_0 to P1_7, P12_0 to P12_7, P13_0 to P13_7 (3)	in single-chip mode	0.8 × V_{CC}		V_{CC}	V
			in memory expansion mode or microprocessor mode	0.5 × V_{CC}		V_{CC}	V
V_{IL}	Low level input voltage	XIN, $\overline{\text{RESET}}$, CNVSS, NSD, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_7 (2), P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P14_1, P14_3 to P14_6, P15_0 to P15_7 (3)		0		0.2 × V_{CC}	V
		P0_0 to P0_7, P1_0 to P1_7, P12_0 to P12_7, P13_0 to P13_7 (3)	in single-chip mode	0		0.2 × V_{CC}	V
			in memory expansion mode or microprocessor mode	0		0.16 × V_{CC}	V
T_{opr}	Operating temperature range	N version		-20		85	°C
		D version		-40		85	°C
		P version		-40		85	°C

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. V_{IH} and V_{IL} for P8_7 are specified for P8_7 as a programmable port. These values are not applicable to P8_7 as XCIN.
3. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only. Port P9_1 is designated as input pin in the 100-pin package.

Table 28.3 Operating Conditions (2/5)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) (1)

Symbol	Characteristic		Value (2)			Unit
			Min.	Typ.	Max.	
C_{VDC}	Decoupling capacitance for voltage regulator	Inter-pin voltage: 1.5 V	2.4		10.0	µF

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. This value should be satisfied with due consideration of every condition as follows: operating temperature, DC bias, aging, etc.

Table 28.4 Operating Conditions (3/5)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) (1)

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
$I_{OH(peak)}$	High level peak output current (2)	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7 (3)			-10.0	mA
$I_{OH(avg)}$	High level average output current (4)	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7 (3)			-5.0	mA
$I_{OL(peak)}$	Low level peak output current (2)	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7 (3)			10.0	mA
$I_{OL(avg)}$	Low level average output current (4)	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7 (3)			5.0	mA

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. The following conditions should be satisfied:
   - The sum of $I_{OL(peak)}$ of ports P0, P1, P2, P8_6, P8_7, P9, P10, P11, P14, and P15 is 80 mA or less.
   - The sum of $I_{OL(peak)}$ of ports P3, P4, P5, P6, P7, P8_0 to P8_4, P12, and P13 is 80 mA or less.
   - The sum of $I_{OH(peak)}$ of ports P0, P1, P2, and P11 is -40 mA or less.
   - The sum of $I_{OH(peak)}$ of ports P8_6, P8_7, P9, P10, P14, and P15 is -40 mA or less.
   - The sum of $I_{OH(peak)}$ of ports P3, P4, P5, P12, and P13 is -40 mA or less.
   - The sum of $I_{OH(peak)}$ of ports P6, P7, and P8_0 to P8_4 is -40 mA or less.
3. Ports P9_0, P9_2, and P11 to P15 are available in the 144-pin package only. Port P9_1 is designated as input pin in the 100-pin package.
4. Average value within 100 ms.

Table 28.5 Operating Conditions (4/5)

(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) (1)

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
$f_{(XIN)}$	Main clock oscillator frequency		4		16	MHz
$f_{(XRef)}$	Reference clock frequency		2		4	MHz
$f_{(PLL)}$	PLL clock oscillator frequency		96		128	MHz
$f_{(Base)}$	Base clock frequency	High speed			64	MHz
		Normal speed			50	MHz
$t_{c(Base)}$	Base clock cycle time	High speed	15.625			ns
		Normal speed	20			ns
$f_{(CPU)}$	CPU operating frequency	High speed			64	MHz
		Normal speed			50	MHz
$t_{c(CPU)}$	CPU clock cycle time	High speed	15.625			ns
		Normal speed	20			ns
$f_{(BCLK)}$	Peripheral bus clock operating frequency	High speed			32	MHz
		Normal speed			25	MHz
$t_{c(BCLK)}$	Peripheral bus clock cycle time	High speed	31.25			ns
		Normal speed	40			ns
$f_{(PER)}$	Peripheral clock source frequency				32	MHz
$f_{(XCIN)}$	Sub clock oscillator frequency			32.768	62.5	kHz

Note:
1. The device is operationally guaranteed under these operating conditions.

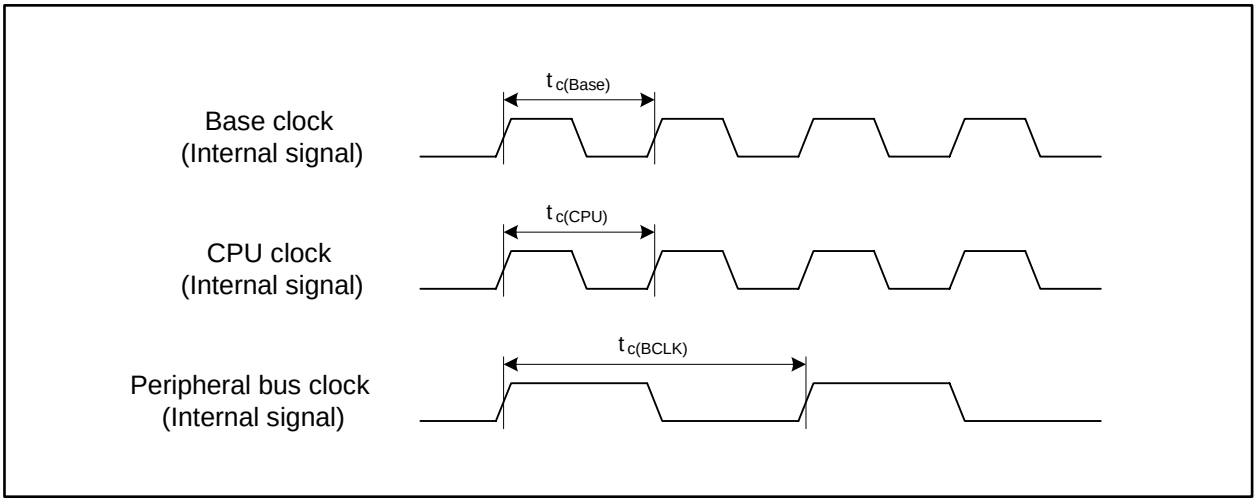


Figure 28.1 Clock Cycle Time

Table 28.6 Operating Conditions (5/5)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) (1)

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
$V_{r(VCC)}$	Allowable ripple voltage	V_{CC} = 5.0 V			0.5	Vp-p
		V_{CC} = 3.0 V			0.3	Vp-p
$dV_{r(VCC)}/dt$	Ripple voltage gradient	V_{CC} = 5.0 V			±0.3	V/ms
		V_{CC} = 3.0 V			±0.3	V/ms
$f_{r(VCC)}$	Allowable ripple frequency				10	kHz

Note:
1. The device is operationally guaranteed under these operating conditions.

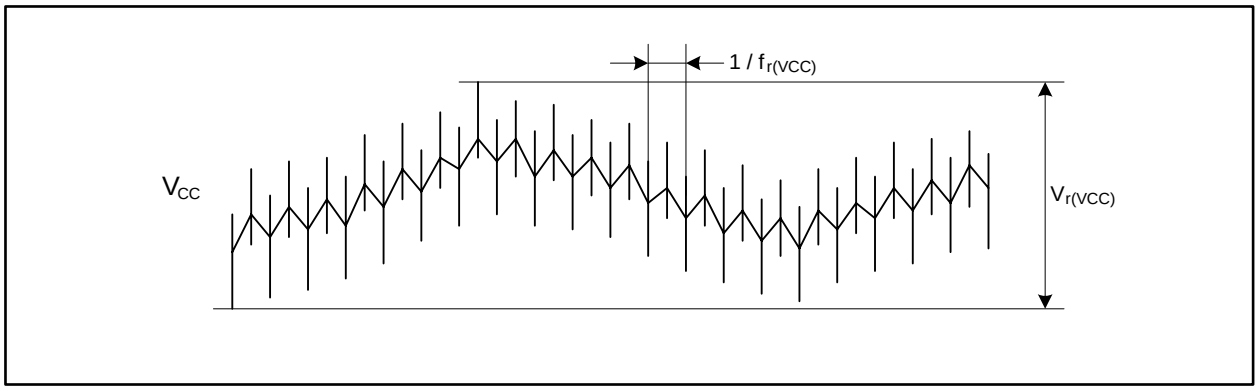

Figure 28.2 Ripple Waveform

(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and Ta = T_{opr}, unless otherwise noted)

Symbol	Characteristic	Measurement condition	Value			Unit
			Min.	Typ.	Max.	
V_{RDR}	RAM data retention voltage	in stop mode	2.0			V

Table 28.8 Flash Memory Electrical Characteristics
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and Ta = T_{opr}, unless otherwise noted)

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
—	Programming and erasure endurance of flash memory (1)	Program area	1000			times
		Data area	10000			times
—	4-word program time	Program area		150	900	µs
		Data area		300	1700	µs
—	Lock bit-program time	Program area		70	500	µs
		Data area		140	1000	µs
—	Block erasure time	4 Kbyte block		0.12	3.0	s
		32 Kbyte block		0.17	3.0	s
		64 Kbyte block		0.20	3.0	s
—	Data retention (2)	T_a = 55°C (3)	10			years

Notes:
1. Program/erase definition
   This value represents the number of erasures per block.
   If the flash memory is programmed/erased n times, each block can be erased n times.
   i.e. If 4-word write is performed in 512 different addresses in the block A of 4 Kbyte and then the block is erased, it is considered the programming/erasure is performed just once.
   However a write in the same address more than once for one erasure is disabled (overwrite disabled).
2. The data retention time includes the periods when the supply voltage is not applied and no clock is provided.
3. Please contact a Renesas Electronics sales office regarding data retention time other than the above.

Table 28.9 Power Supply Circuit Timing Characteristics (V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and $T_a = T_{opr}$, unless otherwise noted)

Symbol	Characteristic	Measurement condition	Value			Unit
			Min.	Typ.	Max.	
$t_{d(P-R)}$	Internal power supply start-up stabilization time after the main power supply is turned on				2	ms

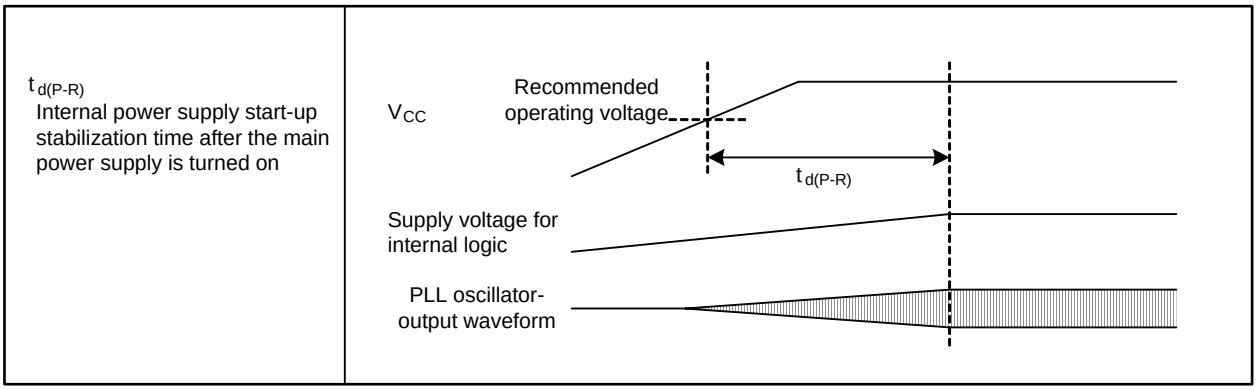

Figure 28.3 Power Supply Circuit Timing

V_{CC} = 5 V

Timing Requirements (V_{CC} = 4.2 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

Table 28.34 Multi-master I²C-bus Interface

Symbol	Characteristic	Value				Unit
		Standard-mode		Fast-mode		
		Min.	Max.	Min.	Max.	
$t_{w(SCLH)}$	MSCL input high level pulse width	600		600		ns
$t_{w(SCLL)}$	MSCL input low level pulse width	600		600		ns
$t_{r(SCL)}$	MSCL input rise time		1000		300	ns
$t_{f(SCL)}$	MSCL input fall time		300		300	ns
$t_{r(SDA)}$	MSDA input rise time		1000		300	ns
$t_{f(SDA)}$	MSDA input fall time		300		300	ns
$t_{h(SDA-SCL)S}$	MSCL high level hold time after start condition/restart condition	(1)		$2 \times t_{c(\phi IIC)} + 40$		ns
$t_{su(SCL-SDA)P}$	MSCL high level setup time for restart condition/stop condition	(1)		$2 \times t_{c(\phi IIC)} + 40$		ns
$t_{w(SDAH)P}$	MSDA high level pulse width after stop condition	(1)		$4 \times t_{c(\phi IIC)} + 40$		ns
$t_{su(SDA-SCL)}$	MSDA input setup time	100		100		ns
$t_{h(SCL-SDA)}$	MSDA input hold time	0		0		ns

Note:

1. The value is calculated by the following formulas based on a value SSC set by bits SSC4 to SSC0 in the I2CSSCR register:

   $t_{h(SDA-SCL)S} = SSC \div 2 \times t_{c(\phi IIC)} + 40$ [ns]

   $t_{su(SCL-SDA)P} = (SSC \div 2 + 1) \times t_{c(\phi IIC)} + 40$ [ns]

   $t_{w(SDAH)P} = (SSC + 1) \times t_{c(\phi IIC)} + 40$ [ns]

V_{CC} = 5 V

Switching Characteristics (V_{CC} = 4.2 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

Table 28.35 External Bus Timing (Separate bus)

Symbol	Characteristic	Measurement condition	Value		Unit
			Min.	Max.	
$t_{su(S-R)}$	Chip-select setup time for read	Refer to Figure 28.6	(1)		ns
$t_{h(R-S)}$	Chip-select hold time after read		$t_{c(Base)}$ - 15		ns
$t_{su(A-R)}$	Address setup time for read		(1)		ns
$t_{h(R-A)}$	Address hold time after read		$t_{c(Base)}$ - 15		ns
$t_{W(R)}$	Read pulse width		(1)		ns
$t_{su(S-W)}$	Chip-select setup time for write		(1)		ns
$t_{h(W-S)}$	Chip-select hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{su(A-W)}$	Address setup time for write		(1)		ns
$t_{h(W-A)}$	Address hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{W(W)}$	Write pulse width		(1)		ns
$t_{su(D-W)}$	Data setup time for write		(1)		ns
$t_{h(W-D)}$	Data hold time after write		0		ns

Note:

1. The value is calculated by the following formulas based on the base clock cycles ($t_{c(Base)}$) and respective cycles of Tsu(A-R), Tw(R), Tsu(A-W), and Tw(W) set by registers EBC0 to EBC3. If the calculation results in a negative value, modify the value to be set. For details on how to set values, refer to 9.3.5 “External Bus Timing”.

   $t_{su(S-R)} = t_{su(A-R)}$ = Tsu(A-R) × $t_{c(Base)}$ - 15 [ns]

   $t_{W(R)}$ = Tw(R) × $t_{c(Base)}$ - 10 [ns]

   $t_{su(S-W)} = t_{su(A-W)}$ = Tsu(A-W) × $t_{c(Base)}$ - 15 [ns]

   $t_{W(W)} = t_{su(D-W)}$ = Tw(W) × $t_{c(Base)}$ - 10 [ns]

V_{CC} = 5 V

Switching Characteristics (V_{CC} = 4.2 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

Table 28.36 External Bus Timing (Multiplexed bus)

Symbol	Characteristic	Measurement condition	Value		Unit
			Min.	Max.	
$t_{su(S-ALE)}$	Chip-select setup time for ALE	Refer to Figure 28.6	(1)		ns
$t_{h(R-S)}$	Chip-select hold time after read		1.5 × $t_{c(Base)}$ - 15		ns
$t_{su(A-ALE)}$	Address setup time for ALE		(1)		ns
$t_{h(ALE-A)}$	Address hold time after ALE		0.5 × $t_{c(Base)}$ - 5		ns
$t_{h(R-A)}$	Address hold time after read		1.5 × $t_{c(Base)}$ - 15		ns
$t_{d(ALE-R)}$	ALE-read delay time		0.5 × $t_{c(Base)}$ - 5	0.5 × $t_{c(Base)}$ + 10	ns
$t_{w(ALE)}$	ALE pulse width		(1)		ns
$t_{dis(R-A)}$	Address disable time after read			8	ns
$t_{w(R)}$	Read pulse width		(1)		ns
$t_{h(W-S)}$	Chip-select hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{h(W-A)}$	Address hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{d(ALE-W)}$	ALE-write delay time		0.5 × $t_{c(Base)}$ - 5	0.5 × $t_{c(Base)}$ + 10	ns
$t_{w(W)}$	Write pulse width		(1)		ns
$t_{su(D-W)}$	Data setup time for write		(1)		ns
$t_{h(W-D)}$	Data hold time after write		0.5 × $t_{c(Base)}$		ns

Note:

1. The value is calculated by the following formulas based on the base clock cycles ($t_{c(Base)}$) and respective cycles of Tsu(A-R), Tw(R), Tsu(A-W), and Tw(W) set by registers EBC0 to EBC3. If the calculation results in a negative value, modify the value to be set. For details on how to set values, refer to 9.3.5 “External Bus Timing”.

   $t_{su(S-ALE)}$ = $t_{su(A-ALE)}$ = $t_{w(ALE)}$ = (Tsu(A-R) - 0.5) × $t_{c(Base)}$ -15 [ns]

   $t_{w(R)}$ = Tw(R) × $t_{c(Base)}$ -10 [ns]

   $t_{w(W)}$ = $t_{su(D-W)}$ = Tw(W) × $t_{c(Base)}$ -10 [ns]

V_{CC} = 5 V

Switching Characteristics (V_{CC} = 4.2 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

V_{CC} = 3.3 V

Timing Requirements (V_{CC} = 3.0 to 3.6 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

Table 28.60 Multi-master I²C-bus Interface

Symbol	Characteristic	Value				Unit
		Standard-mode		Fast-mode		
		Min.	Max.	Min.	Max.	
$t_{w(SCLH)}$	MSCL input high level pulse width	600		600		ns
$t_{w(SCLL)}$	MSCL input low level pulse width	600		600		ns
$t_{r(SCL)}$	MSCL input rise time		1000		300	ns
$t_{f(SCL)}$	MSCL input fall time		300		300	ns
$t_{r(SDA)}$	MSDA input rise time		1000		300	ns
$t_{f(SDA)}$	MSDA input fall time		300		300	ns
$t_{h(SDA-SCL)S}$	MSCL high level hold time after start condition/restart condition	(1)		$2 \times t_{c(\phi IIC)} + 40$		ns
$t_{su(SCL-SDA)P}$	MSCL high level setup time for restart condition/stop condition	(1)		$2 \times t_{c(\phi IIC)} + 40$		ns
$t_{w(SDAH)P}$	MSDA high level pulse width after stop condition	(1)		$4 \times t_{c(\phi IIC)} + 40$		ns
$t_{su(SDA-SCL)}$	MSDA input setup time	100		100		ns
$t_{h(SCL-SDA)}$	MSDA input hold time	0		0		ns

Note:

1. The value is calculated by the following formulas based on a value SSC set by bits SSC4 to SSC0 in the I2CSSCR register:

   $t_{h(SDA-SCL)S} = SSC \div 2 \times t_{c(\phi IIC)} + 40$ [ns]

   $t_{su(SCL-SDA)P} = (SSC \div 2 + 1) \times t_{c(\phi IIC)} + 40$ [ns]

   $t_{w(SDAH)P} = (SSC + 1) \times t_{c(\phi IIC)} + 40$ [ns]

V_{CC} = 3.3 V

Switching Characteristics (V_{CC} = 3.0 to 3.6 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

Table 28.61 External Bus Timing (Separate bus)

Symbol	Characteristic	Measurement condition	Value		Unit
			Min.	Max.	
$t_{su(S-R)}$	Chip-select setup time for read	Refer to Figure 28.6	(1)		ns
$t_{h(R-S)}$	Chip-select hold time after read		$t_{c(Base)}$ - 15		ns
$t_{su(A-R)}$	Address setup time for read		(1)		ns
$t_{h(R-A)}$	Address hold time after read		$t_{c(Base)}$ - 15		ns
$t_{w(R)}$	Read pulse width		(1)		ns
$t_{su(S-W)}$	Chip-select setup time for write		(1)		ns
$t_{h(W-S)}$	Chip-select hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{su(A-W)}$	Address setup time for write		(1)		ns
$t_{h(W-A)}$	Address hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{w(W)}$	Write pulse width		(1)		ns
$t_{su(D-W)}$	Data setup time for write		(1)		ns
$t_{h(W-D)}$	Data hold time after write		0		ns

Note:

1. The value is calculated by the following formulas based on the base clock cycles ($t_{c(Base)}$) and respective cycles of Tsu(A-R), Tw(R), Tsu(A-W), and Tw(W) set by registers EBC0 to EBC3. If the calculation results in a negative value, modify the value to be set. For details on how to set values, refer to 9.3.5 “External Bus Timing”.

   $t_{su(S-R)} = t_{su(A-R)}$ = Tsu(A-R) × $t_{c(Base)}$ - 15 [ns]

   $t_{w(R)}$ = Tw(R) × $t_{c(Base)}$ - 10 [ns]

   $t_{su(S-W)} = t_{su(A-W)}$ = Tsu(A-W) × $t_{c(Base)}$ - 15 [ns]

   $t_{w(W)} = t_{su(D-W)}$ = Tw(W) × $t_{c(Base)}$ - 10 [ns]

V_{CC} = 3.3 V

Switching Characteristics (V_{CC} = 3.0 to 3.6 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted)

Table 28.62 External Bus Timing (Multiplexed bus)

Symbol	Characteristic	Measurement condition	Value		Unit
			Min.	Max.	
$t_{su(S-ALE)}$	Chip-select setup time for ALE	Refer to Figure 28.6	(1)		ns
$t_{h(R-S)}$	Chip-select hold time after read		1.5 × $t_{c(Base)}$ - 15		ns
$t_{su(A-ALE)}$	Address setup time for ALE		(1)		ns
$t_{h(ALE-A)}$	Address hold time after ALE		0.5 × $t_{c(Base)}$ - 5		ns
$t_{h(R-A)}$	Address hold time after read		1.5 × $t_{c(Base)}$ - 15		ns
$t_{d(ALE-R)}$	ALE-read delay time		0.5 × $t_{c(Base)}$ - 5	0.5 × $t_{c(Base)}$ + 10	ns
$t_{W(ALE)}$	ALE pulse width		(1)		ns
$t_{dis(R-A)}$	Address disable time after read			8	ns
$t_{w(R)}$	Read pulse width		(1)		ns
$t_{h(W-S)}$	Chip-select hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{h(W-A)}$	Address hold time after write		1.5 × $t_{c(Base)}$ - 15		ns
$t_{d(ALE-W)}$	ALE-write delay time		0.5 × $t_{c(Base)}$ - 5	0.5 × $t_{c(Base)}$ + 10	ns
$t_{w(W)}$	Write pulse width		(1)		ns
$t_{su(D-W)}$	Data setup time for write		(1)		ns
$t_{h(W-D)}$	Data hold time after write		0.5 × $t_{c(Base)}$		ns

Note:

1. The value is calculated by the following formulas based on the base clock cycles ($t_{c(Base)}$) and respective cycles of Tsu(A-R), Tw(R), Tsu(A-W), and Tw(W) set by registers EBC0 to EBC3. If the calculation results in a negative value, modify the value to be set. For details on how to set values, refer to 9.3.5 “External Bus Timing”.

   $t_{su(S-ALE)}$ = $t_{su(A-ALE)}$ = (Tsu(A-R) - 0.5) × $t_{c(Base)}$ -15 [ns]

   $t_{w(ALE)}$ = (Tsu(A-R) - 0.5) × $t_{c(Base)}$ - 20 [ns]

   $t_{w(R)}$ = Tw(R) × $t_{c(Base)}$ -10 [ns]

   $t_{w(W)}$ = $t_{su(D-W)}$ = Tw(W) × $t_{c(Base)}$ -10 [ns]

29. Usage Notes

29.1 Notes on Board Designing

29.1.1 Power Supply Pins

The board should be designed so that there is no potential difference between pins with the same name. Note the following points:

- Connect all VSS pins to an identical GND. The traces for the pins should be as wide as physically possible so that the same voltage can be applied to every VSS pin.
- Connect all VCC pins to an identical power supply. The traces for the pins should be as wide as physically possible so that the same voltage can be applied to every VCC pin.

Insert a capacitor between each VCC pin and the VSS pin to ensure the noise tolerance. The capacitor should be beneficially effective at high/low frequencies and should have around 0.1 µF of capacitance. The traces for the capacitor and the power supply pins should be short and wide as much as physically possible.

29.1.2 Supply Voltage

The device is operationally guaranteed under operating conditions specified in electrical characteristics.

Drive the $\overline{\text{RESET}}$ pin low before the supply voltage becomes lower than the recommended value.

29.2 Notes on Register Setting

29.2.1 Registers with Write-only Bits

Table 29.1 lists registers containing write-only bits. For the setting of these registers, read-modify-write instructions listed in Table 29.2 cannot be used since each of these instructions reads the value of an address, modifies the value, and writes to the same address. To set a new value by modifying the previous one, write the previous value into RAM as well as to the register, change the contents of the RAM and then transfer the new value to the register by the MOV instruction.

Table 29.1 Registers with Write-only Bit(s)

Module	Register	Symbol	Address(es)
Watchdog timer	Watchdog timer start register	WDTS	04404Eh
Timer A	Timer A0 register (1)	TA0	0347h-0346h
	Timer A1 register (1)	TA1	0349h-0348h
	Timer A2 register (1)	TA2	034Bh-034Ah
	Timer A3 register (1)	TA3	034Dh-034Ch
	Timer A4 register (1)	TA4	034Fh-034Eh
	Increment/decrement counting select register	UDF	0344h
Three-phase motor control timers	Timer B2 interrupt generating frequency set counter	ICTB2	030Dh
	Timer A1-1 register	TA11	0303h-0302h
	Timer A2-1 register	TA21	0305h-0304h
	Timer A4-1 register	TA41	0307h-0306h
	Dead time timer	DTT	030Ch
Serial interface	UART0 bit rate register	U0BRG	0369h
	UART1 bit rate register	U1BRG	02E9h
	UART2 bit rate register	U2BRG	0339h
	UART3 bit rate register	U3BRG	0329h
	UART4 bit rate register	U4BRG	02F9h
	UART5 bit rate register	U5BRG	01C9h
	UART6 bit rate register	U6BRG	01D9h
	UART7 bit rate register	U7BRG	01E1h
	UART8 bit rate register	U8BRG	01E9h
	UART0 transmit buffer register	U0TB	036Bh-036Ah
	UART1 transmit buffer register	U1TB	02EBh-02EAh
	UART2 transmit buffer register	U2TB	033Bh-033Ah
	UART3 transmit buffer register	U3TB	032Bh-032Ah
	UART4 transmit buffer register	U4TB	02FBh-02FAh
	UART5 transmit buffer register	U5TB	01CBh-01CAh
	UART6 transmit buffer register	U6TB	01DBh-01DAh
	UART7 transmit buffer register	U7TB	01E3h-01E2h
	UART8 transmit buffer register	U8TB	01EBh-01EAh
Intelligent I/O	Group 2 SIO transmit buffer register	G2TB	016Dh-016Ch
CAN module	CAN0 receive FIFO pointer control register	C0RFPCR	047F49h
	CAN0 transmit FIFO pointer control register	C0TFPCR	047F4Bh

Note:
1. The register has write-only bits in one-shot timer mode and pulse-width modulation mode.

Table 29.2 Read-Modify-Write Instructions

Function	Mnemonic
Transfer	MOV*Dir*
Bit processing	BCLR, BM*Cnd*, BNOT, BSET, BTSTC, and BTSTS
Shifting	ROLC, RORC, ROT, SHA, and SHL
Arithmetic operation	ABS, ADC, ADCF, ADD, ADSF, DEC, DIV, DIVU, DIVX, EXTS, EXTZ, INC, MUL, MULU, NEG, SBB, and SUB
Decimal operation	DADC, DADD, DSBB, and DSUB
Floating-point operation	ADDF, DIVF, MULF, and SUBF
Logical operation	AND, NOT, OR, and XOR

29.3 Notes on Clock Generator

29.3.1 Sub Clock

29.3.1.1 Oscillation Parameter Matching

The constant matching of sub clock oscillator should be evaluated in both cases when the drive power is high and low.
Contact your oscillator manufacturer for details on the oscillation circuit constant matching.

29.3.2 Power Control

Do not switch the base clock source until the oscillation of the clock to be used has stabilized. However, this does not apply to the on-chip oscillator since the on-chip oscillator starts running immediately after the CM31 bit in the CM3 register is set to 1.
To switch the base clock source from PLL clock to a low speed clock, that is, to set the BCS bit in the CCR register to 1, use either the MOV.L or OR.L instruction.

- Program example in assembly language

```
OR.L    #80h, 0004h
```

- Program example in C language

```
asm("OR.L  #80h, 0004h");
```

29.3.2.1 Stop Mode

- To exit stop mode by reset, apply a low signal to $\overline{\text{RESET}}$ pin until a main clock oscillation stabilizes.

29.3.2.2 Suggestions to Power Saving

The followings are suggestions to reduce power consumption when programming or designing systems.

- I/O pins:
  If inputs are floating, both transistors may be conducting. Set unassigned pins to input mode and connect each of them to VSS via a resistor, or set them to output mode and leave them open.
- A/D converter:
  When the A/D conversion is not performed, set the VCUT bit in the AD0CON1 register to 0 (VREF disconnected). To perform the A/D conversion, set the VCUT bit to 1 (VREF connected) and wait 1 µs or more for the operation.
- D/A converter:
  When the D/A conversion is not performed, set the DAiE bit in the DACON register (i = 0, 1) to 0 (output disabled) and the DAi register to 00h.
- Peripheral clock stop:
  When entering wait mode, power consumption can be reduced by setting the CM02 bit in the CM0 register to 1 to stop peripheral clock source. However, the fC32 does not stop by the CM02 bit setting.

29.4 Notes on Bus

29.4.1 Notes on System Designing

When the flash memory rewrite is performed in CPU rewrite mode using memory expansion mode, the use of $\overline{CS0}$ space and $\overline{CS3}$ space has the following restrictions:

- If the FEBC0 and/or FEBC3 registers are set in CPU rewrite mode, the bus format for the corresponding space functions as separate bus. Any external devices connected in multiplexed bus format become inaccessible.
- If the FEBC0 and/or FEBC3 registers are set in CPU rewrite mode, the bus timing for the corresponding space changes. This may cause external devices to become inaccessible depending on the register settings.

Devices required to be accessed in CPU rewrite mode should be allocated in $\overline{CS1}$ space and/or $\overline{CS2}$ space.

29.4.2 Notes on Register Settings

29.4.2.1 Chip Select Boundary Select Registers

When not using memory expansion mode, do not change values after a reset for registers CB01, CB12, and CB23.
When the CPU operation is performed in memory expansion mode more than once, set a value within the specified range to all of these registers irrespective of the use of them.

29.4.2.2 External Bus Control Registers

Registers EBC0 and EBC3 share respective addresses with registers FEBC0 and FEBC3. If the FEBC0 and/or FEBC3 registers are set while the flash memory is being rewritten, set the EBC0 and/or EBC3 registers again after rewriting the flash memory.

29.5 Notes on Interrupts

29.5.1 ISP Setting

The interrupt stack pointer (ISP) is initialized to 00000000h after a reset. Set a value to the ISP before an interrupt is accepted, otherwise the program may go out of control. A multiple of 4 should be set to the ISP, which enables faster interrupt sequence due to less memory access.
For the use of NMI, in particular, since this interrupt cannot be disabled, the PM24 bit in the PM2 register should be set to 1 (NMI enabled) after the ISP is set at the beginning of program.

29.5.2 NMI

- The NMI cannot be disabled once the PM24 bit in the PM2 register is set to 1 (NMI enabled). This bit setting should be done only for the use of NMI.

- When the PM24 bit in the PM2 register is set to 1 (NMI enabled), the P8_5 bit in the P8 register is enabled just for monitoring the $\overline{\text{NMI}}$ pin state. It is not enabled as a general port.

29.5.3 External Interrupt

- The input signal to the $\overline{\text{INTi}}$ pin (i = 0 to 8) requires the pulse width specified by the electrical characteristics. If a pulse width is narrower than the specification, the external interrupt may not be accepted.

- When the effective level and/or edge of $\overline{\text{INTi}}$ pin (i = 0 to 8) are/is changed by the following bits: bits POL and/or LVS in the INTiIC register, the IFSR0i bit (i = 0 to 5) in the IFSR0 register, and/or the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register, the corresponding IR bit may become 1 (interrupt requested). When setting the above mentioned bits, preset bits ILVL2 to ILVL0 in the INTiIC register to 000b (interrupt disabled). After setting the above mentioned bits, set the corresponding IR bit to 0 (no interrupt requested), then set bits ILVL2 to ILVL0.

- The interrupt input signals to pins $\overline{\text{INT6}}$ to $\overline{\text{INT8}}$ are also connected to bits INT6R to INT8R in registers IIO9IR to IIO11IR. Therefore, these input signals, when assigned to the intelligent I/O, can be used as a source for exiting wait mode or stop mode. Note that these signals are enabled only on the falling edge and not affected by the following bit settings: bits POL and LVS in the INTiIC register (i = 0 to 8), IFSR0i bit (i = 0 to 5) in the IFSR0 register, and the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register.

29.6 Notes on DMAC

29.6.1 DMAC-associated Register Settings

- Set the DMAC-associated registers while bits MDi1 and MDi0 (i = 0 to 3) in the DMDi register are 00b (DMA transfer disabled). Then, set bits MDi1 and MDi0 to 01b (single transfer) or 11b (repeat transfer) at the end of the setup procedure. This procedure is also applied to rewriting bits UDAi, USAi, and BWi1 and BWi0 in the DMDi register.

- In case the DMAC-associated registers are to be rewritten while DMA transfer is enabled, disable the peripheral function as DMA request source so that no DMA transfer request is generated, then set bits MDi1 and MDi0 in the DMDi register of the corresponding channel to 00b (DMA transfer disabled).

- Once a DMA transfer request is accepted, DMA transfer cannot be disabled even if setting bits MDi1 and MDi0 in the DMDi register to 00b (DMA transfer disabled). Do not change the settings of any DMAC-associated registers other than bits MDi1 and MDi0 until the DMA transfer is completed.

- Wait six or more peripheral bus clocks to set bits MDi1 and MDi0 in the DMDi register to 01b (single transfer) or 11b (repeat transfer) after setting registers DMiSL and DMiSL2.

29.6.2 Read from DMAC-associated Registers

- To sequentially read respective registers DMiSL and DMiSL2, follow the reading order as below:
  DM0SL, DM1SL, DM2SL, and DM3SL
  DM0SL2, DM1SL2, DM2SL2, and DM3SL2

29.7 Notes on Timers

29.7.1 Timer A and Timer B

All timers are stopped after a reset. To restart timers, configure parameters such as operating mode, count source, and counter value, then set the TAiS bit (i = 0 to 4) or TBjS bit (j = 0 to 5) in the TABSR or TBSR register to 1 (count starts).

The following registers and bits should be set while the TAiS bit or TBjS bit is 0 (count stops):

- Registers TAiMR and TBjMR
- The UDF register
- Bits TAZIE, TA0TGL, and TA0TGH in the ONSF register
- The TRGSR register

29.7.2 Timer A

29.7.2.1 Timer Mode

- While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

29.7.2.2 Event Counter Mode

- While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read if the timer counter underflows or 0000h if overflows while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

29.7.2.3 One-shot Timer Mode

- If the TAiS bit in the TABSR register is set to 0 (count stops) while the timer counter is running, the following operations are performed:
  - The timer counter stops and the setting value of the TAi register is reloaded.
  - A low signal is output at the TAiOUT pin.
  - The IR bit in the TAiIC register becomes 1 (interrupts requested) after one CPU clock cycle.

- One-shot timer is operated by an internal count source. When the trigger is an input to the TAiIN pin, the signal is output with a maximum of one count source clock delay after a trigger input to the TAiIN pin.

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt, set the IR bit to 0 after one of the settings below is done:
  - Select one-shot timer mode after a reset.
  - Switch the operating mode from timer mode to one-shot timer mode.
  - Switch the operating mode from event counter mode to one-shot timer mode.

- If a retrigger occurs while counting, the timer counter decrements by one, reloads the setting value of the TAi register, and then continues counting. To generate a retrigger while counting, wait one or more count source cycles after the last trigger is generated.

- When an external trigger input is selected to start counting in timer A one-shot mode, do not provide an external retrigger for 300 ns before the timer counter reaches 0000h. Otherwise, it may stop counting.

29.7.2.4 Pulse-width Modulation Mode

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt (i = 0 to 4), set the IR bit to 0 after one of the settings below is done:
  - Select pulse-width modulation mode after a reset.
  - Switch the operating mode from timer mode to pulse-width modulation mode.
  - Switch the operating mode from event counter mode to pulse-width modulation mode.

- If the TAiS bit in the TABSR register is set to 0 (count stops) while PWM pulse is output, the following operations are performed:
  - The timer counter stops.
  - The output level at the TAiOUT pin changes from high to low. The IR bit becomes 1.
  - When a low signal is output at the TAiOUT pin, it remains unchanged. The IR bit does not change, either.

29.7.3 Timer B

29.7.3.1 Timer Mode and Event Counter Mode

- While the timer counter is running, the TBj register (j = 0 to 5) indicates a counter value at any given time. However, FFFFh is read while reloading is in progress. A set value is read if the TBj register is set while the timer counter is stopped.

29.7.3.2 Pulse Period/Pulse-width Measure Mode

- To set the MR3 bit in the TBjMR register to 0 (no overflow), wait one or more count source cycles to write to the TBjMR register after the MR3 bit becomes 1 (overflow), while the TBjS bit is set to 1 (count starts).

- Use the IR bit in the TBjIC register to detect overflow. The MR3 bit is used only to determine an interrupt request source within the interrupt handler.

- The counter value is undefined when the timer counter starts. Therefore, the timer counter may overflow before a pulse to be measured is applied on the initial valid edge and cause a timer Bj interrupt request to be generated.

- When the pulse to be measured is applied on the initial valid edge after the timer counter starts, an undefined value is transferred to the reload register. At this time, the timer Bj interrupt request is not generated.

- The IR bit may become 1 (interrupt requested) by changing bits MR1 and MR0 in the TBjMR register after the timer counter starts. However, if the same value is rewritten to bits MR1 and MR0, the IR bit is not changed.

- Pulse width is repeatedly measured in pulse-width measure mode. Whether the measurement result is high-level width or not is determined by a program.

- If an overflow occurs simultaneously when a pulse is applied on the valid edge, this pulse is not recognized since an interrupt request is generated only once. Do not let an overflow occur in pulse period measure mode.

- In pulse-width measure mode, determine whether an interrupt source is a pulse applied on the valid edge or an overflow by reading the port level in the TBj interrupt handler.

29.8 Notes on Three-phase Motor Control Timers

29.8.1 Shutdown

- When a low signal is applied to the $\overline{\text{NMI}}$ pin with the bit settings below, pins TA1OUT, TA2OUT, and TA4OUT become high-impedance: the PM24 bit in the PM2 register is 1 (NMI enabled), the INV02 bit in the INVC0 register is 1 (the three-phase motor control timers used) and the INV03 bit is 1 (the three-phase motor control timer output enabled).

29.8.2 Register setting

- Do not write to the TAi1 register (i = 1, 2, 4) in the timing that timer B2 underflows. Before writing to the TAi1 register, read the TB2 register to verify that sufficient time is left until timer B2 underflows. Then, immediately write to the TAi1 register so that no interrupt handler is performed during this write procedure. If the TB2 register indicates little time is left until the underflow, write to the TAi1 register after timer B2 underflows.

29.9 Notes on Serial Interface

29.9.1 Changing the UiBRG Register (i = 0 to 8)

- Set the UiBRG register after setting bits CLK1 and CLK0 in the UiC0 register. When these bits are changed, the UiBRG register must be set again.
- If a clock is input immediately after the UiBRG register is set to 00h, the counter reaches FFh. In this case, it requires an extra 256 clocks to reload 00h into the register. Once the 00h is reloaded, the counter performs the operation without dividing the count source according to the setting.

29.9.2 Synchronous Serial Interface Mode

29.9.2.1 Selecting an External Clock

- If an external clock is selected, the following conditions must be met while the external clock is held high when the CKPOL bit in the UiC0 register (i = 0 to 8) is set to 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge), or while the external clock is held low when the CKPOL bit is set to 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge):
  - The TE bit in the UiC1 register is set to 1 (transmission enabled).
  - The RE bit in the UiC1 register is set to 1 (reception enabled). This bit setting is not required in transmit operation only.
  - The TI bit in the UiC1 register is set to 0 (data held in the UiTB register).

29.9.2.2 Receive Operation

- In synchronous serial interface mode, the transmit/receive clock is controlled by the transmit control circuit. Set the UARTi-associated registers (i = 0 to 8) for a transmit operation, even if the MCU is used only for receive operation. Dummy data is output from the TXDi pin while receiving if the TXDi pin is set to output mode.

- If data is received continuously, an overrun error occurs when the RI bit in the UiC1 register is 1 (data held in the UiRB register) and the seventh bit of the next data is received in the UARTi receive shift register. Then, the OER bit in the UiRB register becomes 1 (overrun error occurred). In this case, the UiRB register becomes undefined. If an overrun error occurs, the IR bit in the SiRIC register is not changed to 1.

29.9.3 Special Mode 1 (I^2C Mode)

- To generate a start condition, stop condition, or restart condition, set the STSPSEL bit in the UiSMR4 register (i = 0 to 6) to 0. Then, wait a half or more clock cycles of the transmit/receive clock to change the respective condition generate bit (the STAREQ, RSTAREQ, or STPREQ bit) from 0 to 1.

29.9.4 Reset Procedure on Communication Error

- Operations which result in communication errors such as rewritting function select registers during transmission/reception should not be performed. Follow the procedure below to reset the internal circuit once the communication error occurs in the following cases: when the operation above is performed by a receiver or transmitter or when a bit slip is caused by noise.

A. Synchronous Serial Interface Mode

(1) Set the TE bit in the UiC1 register (i = 0 to 8) to 0 (transmission disabled) and the RE bit to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 001b (synchronous serial interface mode).
(4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

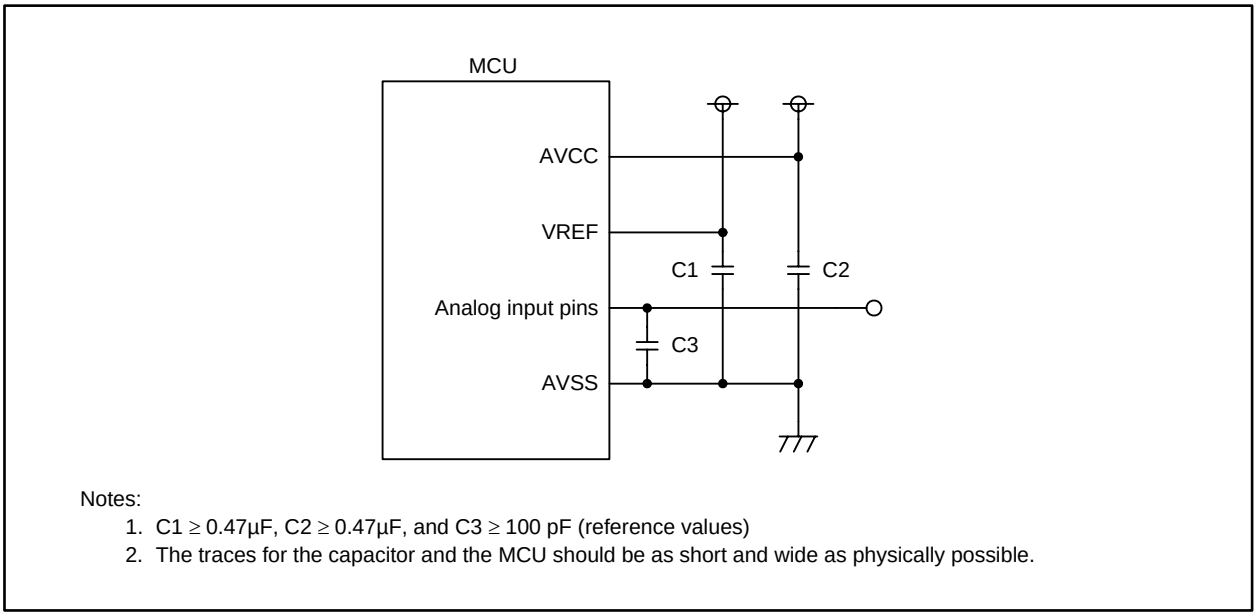
B. UART Mode

(1) Set the TE bit in the UiC1 register to 0 (transmittion disabled) and the RE bit to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 100b (UART mode, 7-bit character length), 101b (UART mode, 8-bit character length), or 110b (UART mode, 9-bit character length).
(4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

29.10 Notes on A/D Converter

29.10.1 Notes on Designing Boards

- Three capacitors should be respectively placed between the AVSS pin and such pins as AVCC, VREF, and analog inputs (AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, and AN15_0 to AN15_7) to avoid error operations caused by noise or latchup, and to reduce conversion errors. Figure 29.1 shows an example of pin configuration for A/D converter.



Notes:
1. C1 ≥ 0.47µF, C2 ≥ 0.47µF, and C3 ≥ 100 pF (reference values)
2. The traces for the capacitor and the MCU should be as short and wide as physically possible.

Figure 29.1 Pin Configuration for A/D Converter

- Do not use any of the four pins AN_4 to AN_7 for analog input if the key input interrupt is to be used. Otherwise, a key input interrupt request occurs when the A/D input voltage becomes VIL or lower.

- When AVCC = VREF = VCC, A/D input voltage for pins AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1 should be VCC or lower.

29.10.2 Notes on Programming

- The following registers should be written while the A/D conversion is stopped, that is, before a trigger occurs: AD0CON0 (except the ADST bit), AD0CON1, AD0CON2, AD0CON3, and AD0CON4.

- If the VCUT bit in the AD0CON1 register is switched from 0 (VREF connected) to 1 (VREF disconnected), the A/D conversion should be started after 1 µs or more. Set the VCUT bit to 0 when A/D conversion is not used to reduce power consumption.

- Set the port direction bit for the pin to be used as an analog input pin to 0 (input). Set the ASEL bit of the corresponding port function select register to 1 (the port is used as A/D input).

- If the TRG bit in the AD0CON0 register is set to 1 (external trigger or hardware trigger is selected), set the corresponding port direction bit (PD9_7 bit) for the $\overline{\text{ADTRG}}$ pin to 0 (input).

- The ϕAD frequency should be 16 MHz or below when VCC is 4.2 to 5.5 V, and 10 MHz or below when VCC is 3.0 to 4.2 V. It should be 1 MHz or above if the sample and hold function is enabled. If not, it should be 250 kHz or above.

- If A/D operating mode (bits MD1 and MD0 in the AD0CON0 register or the MD2 bit in the AD0CON1 register) has been changed, re-select analog input pins by using bits CH2 to CH0 in the AD0CON0 register or bits SCAN1 and SCAN0 in the AD0CON1 register.

- If the AD0i register (i = 0 to 7) is read when the A/D converted result is stored to the register, the stored value may have an error. Read the AD0i register after the A/D conversion has been completed.
  In one-shot mode or single sweep mode, read the respective AD0i register after the IR bit in the AD0IC register has become 1 (interrupt requested).
  In repeat mode, repeat sweep mode 0, or repeat sweep mode 1, an interrupt request can be generated each time when an A/D conversion has been completed if the DUS bit in the AD0CON3 register is set to 1 (DMAC operating mode enabled). Similar to the other modes above, read the AD00 register after the IR bit in the AD0IC register has become 1 (interrupt requested).

- If the A/D conversion in progress is halted by setting the ADST bit in the AD0CON0 register to 0, the converted result is undefined. In addition, the unconverted AD0i register may also become undefined. Consequently, the AD0i register should not be used just after A/D conversion is halted.

- The external trigger cannot be used in DMAC operating mode. When the DMAC is configured to transfer converted results, do not read the AD0i register by a program.

- If, in single sweep mode, the A/D conversion in progress is halted by setting the ADST bit in the AD0CON0 register to 0 (A/D conversion is stopped), an interrupt request may be generated even though the sweep is not completed. To halt the A/D conversion, first disable interrupts, then set the ADST bit to 0.

29.11 Notes on Flash Memory Rewriting

29.11.1 Note on Power Supply

- Keep the supply voltage constant within the range specified in the electrical characteristics while a rewrite operation on flash memory is in progress. If the supply voltage becomes beyond the guaranteed value, the device cannot be guaranteed.

29.11.2 Note on Hardware Reset

- Do not perform a hardware reset while a rewrite operation on flash memory is in progress.

29.11.3 Note on Flash Memory Protection

- If an ID code written in an assigned address has an error, any read/write operation of flash memory in standard serial I/O mode is disabled.

29.11.4 Notes on Programming

- Do not set the FEW bit in the FMCR register to 1 (CPU rewrite mode) in low speed mode or low power mode.
- Four software commands of program, block erase, lock bit program, and protect bit program are interrupted by an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt. If any of the software commands above is interrupted, erase the corresponding block and then execute the same command again. If the block erase command is interrupted, values of lock bits and protect bits become undefined. Therefore, disable the lock bit, and then execute the block erase command again.

29.11.5 Notes on Interrupts

- EW0 mode
  - To use interrupts assigned to the relocatable vector table, the vector table should be addressed in RAM space.
  - If either of an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt is generated, the flash memory module automatically enters read array mode. Therefore these interrupts are enabled even during a rewrite operation. On the other hand, the rewrite operation in progress is aborted by the interrupt and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.
  - Instructions BRK, INTO, and UND, which refer to data on the flash memory, are unavailable in this mode.

- EW1 mode
  - Interrupts assigned to the relocatable vector table should not be accepted during a program or block erase operation.
  - The watchdog timer interrupt should not be generated, either.
  - If either of an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt is generated, the flash memory module automatically enters read array mode. Therefore this interrupt is enabled even during a rewrite operation. On the other hand, the rewrite operation in progress is aborted by the interrupt and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the EWM bit in the FMR0 register to 1 (set as EW1 mode) and the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.

29.11.6 Notes on Rewrite Control Program

- EW0 mode
  - If the supply voltage lowers during the rewrite operation of blocks having the rewrite control program, the rewrite control program may not be successfully rewritten, then the rewrite operation itself may not be performed. In this case perform the rewrite operation by serial programmer or parallel programmer.

- EW1 mode
  - Do not rewrite blocks having the rewrite control program.

29.11.7 Notes on Number of Programming/Erasure and Software Command Execution Time

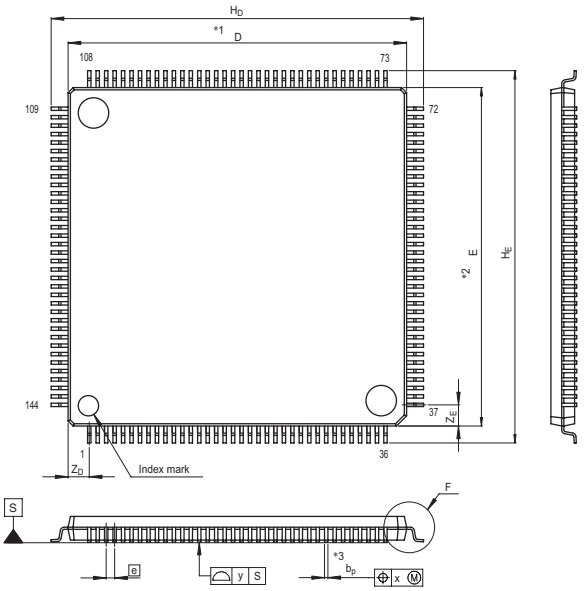
- According to the increase of program/erase operation, the four software commands: program, block erase, lock bit program, and protect bit program require more time to be executed. If the number of programming/erasure exceeds the minimum endurance value specified in the electrical characteristics, it may take unpredictable time to execute the software commands. The waiting time for the execution of software commands should be set much longer than the execution time specified in the electrical characteristics.

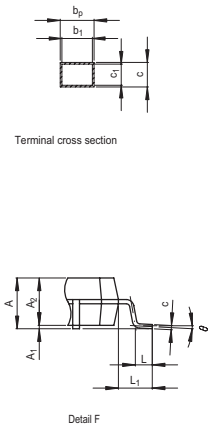
29.11.8 Other Notes

- The required time to perform the program or erase operation specified in the electrical characteristics can be guaranteed within the minimum values of programming/erasure endurance specified in the same table. Even if the number of programming/erasure exceeds the minimum endurance value, the program or erase operation may be unguaranteedly performed.
- Chips repeatedly programmed and erased for debugging are not allowed to be used for commercial products.

Appendix 1. Package Dimensions

JEITA Package Code	RENESAS Code	Previous Code	MASS[Typ.]
P-LQFP144-20x20-0.50	PLQP0144KA-A	144P6Q-A / FP-144L / FP-144LV	1.2g





NOTE)
1. DIMENSIONS "*1" AND "*2" DO NOT INCLUDE MOLD FLASH.
2. DIMENSION "*3" DOES NOT INCLUDE TRIM OFFSET.

Reference Symbol	Dimension in Millimeters		
	Min	Nom	Max

Revision History	R32C/117 Group User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
0.62	Apr 08, 2009	—	Initial release
1.00	Nov 24, 2009	—	Second edition released
		—	This manual in general • Changed the following expressions: "start/stop condition", to "start condition/stop condition" (under Chapters 4, 11, 13, 18, and 24); "Pins/ports/bits/registers xxx, xxx, and xxx are provided in the xx-pin package", to "Pins/ports/bits/registers xxx, xxx, and xxx are available in the xx-pin package" (under Chapters 5, 9, 15, 16, 19, 23, 26, and 28); "reset operation", to "reset" (under Chapters 4, 7-9, 11, 12, 25, and 27) • Modified the following descriptions: "multimaster I^2C-bus interface", to "multi-master I^2C-bus interface" (under Chapters 1 and 26); "This register should be rewritten after (the xxx bit in) the xxx register is set to 1/AAh/00b ((re)write enabled).", to "Set (the xxx bit in) the xxx register to 1/AAh/00b (write enabled) before rewriting this register." (under Chapters 6, 8, 9, 13, 18, 24, and 27)
			About This Manual
		—	• Corrected typos "Hardware Manual" and "characteristics)" in **1. Purpose and Target User**, to "Hardware" and "characteristics", respectively • Made major text modifications to **2. Numbers and Symbols** • Revised the illustration in **3. Registers**
			Chapter 1. Overview
		1	• Modified description for **1.1.1**
		2, 4	• Modified description for "External Bus Expansion" in **Tables 1.1 and 1.3**; Moved this unit below "Clock"
		3, 5	• Modified description for "Flash memory" in **Tables 1.2 and 1.4**
		5	• Modified the position of note symbol (1) in **Table 1.4** • Modified description "32-slot message buffer" for "CAN Module" in **Table 1.4**, to "32 mailboxes"
		6	• Completed all "under development" products in **Table 1.5**
		9, 14	• Corrected a typo "R5_3" for pin No. 62 in **Figure 1.3** and for pin No. 41 in **Figure 1.4**, to "P5_3"
			Chapter 2. CPU
		25	• Modified the second sentence of **2.1.8.8** descriptively
			Chapter 4. SFRs
		28	• Changed hexadecimal format of reset values for registers CCR and FMCR in **Table 4.1**, to binary
		37	• Changed reset values "XXXX XXXXb" and "XXXX 000Xb" for registers U7RB and U8RB in **Table 4.10**, to "XXXXh"
		38	• Changed expression of register name "Xi Register Yi Register" (i = 0 to 15) and register symbol "XiR, YiR" in **Table 4.11**, to "Xi Register/ Yi Register" and "XiR/YiR", respectively
		66	• Changed reset value for C0CLKR in **Table 4.39** from "00h", to "000X 0000b"

Rev.	Date	Description	
		Page	Summary
			Chapter 5. Resets
		71	• Corrected a typo "pultiple" in line 2 of **5.4**, to "multiple"
			Chapter 6. Power Management
		—	• Made minor text modifications to this chapter
			Chapter 7. Processor Mode
		—	• Made minor text modification to this chapter
			Chapter 8. Clock
		—	• Made minor text modifications to this chapter
		93	• Added "in the PLC1 register" to "SEO bit" in **Figure 8.13**
		93, 94	• Added description to Note 1 for registers PLC0 and PLC1 in **Figures 8.14 and 8.15**, respectively
		94, 97, 98	• Deleted description associated with frequency from line 14 below **Figure 8.15**, line 2 of **8.3**, and line 2 of **8.4**
		101-103	• Added description for the following bits: BCS, CM04, CM05, CM10, CM20, CM30, and CM31, to **Figures 8.17 to 8.19**
		105	• Added description for procedure (6) to **8.7.2.2**
		107	• Added I^2C-bus interface interrupt and I^2C-bus line interrupt to **Table 8.6**
		109	• Moved previous Table 8.7 with one sentence above the table to 8.7.3.3 as **Table 8.8**
			• Added I^2C-bus line interrupt to **Table 8.8**
			Chapter 9. Bus
		—	• Made minor text modifications to this chapter
		112	• Deleted description for frequency and Note 1 in **Figure 9.1**; Modified description for peripheral data bus "16-bit", to "16-/32-bit"
		113	• Modified peripheral bus width in line 1 of **9.2**, from "16-bit width" to "16-/32-bit width"
			• Deleted description for 00b of PRD4 to PRD0 and PWR4 to PWR0 in **Figure 9.2**
		116	• Modified description for setting the P5_7B bit to 0 in **Figure 9.5**: "Output $\overline{RDY}$ from P5_7", to "$\overline{RDY}$ input pin"
		134	• Deleted "(i = 0 to 3)" from **Figure 9.17**
			Chapter 10. Protection
		—	• Made minor text modifications to this chapter
		137	• Added "I2CMR" as a protected register for PRC1 bit, to **Table 10.1 and Figure 10.1**; Changed the order of registers for PRC1 and PRC2
		138	• Deleted "(i = 0 to 7)" from the title of **Table 10.2**
			Chapter 11. Interrupts
		—	• Made minor text modifications to this chapter
		145-148	• Added details to "Reference" in **Tables 11.2 to 11.5**
		146	• Changed expression "Multi-master I^2C-bus interface" in Note 3 of **Table 11.3** to "I^2C-bus interface"
		158	• Modified "Bits RLVL02 to RLVL00" and "Bits RLVL12 to RLVL10" in **Figure 11.8**, to "Bits RLVL2 to RLVL0 in the RIPL1 register" and "Bits RLVL2 to RLVL0 in the RIPL2 register", respectively

Rev.	Date	Description	
		Page	Summary
		160	• Modified Note 1 for **11.11** descriptively
		162	• Moved "(i = 0 to 11)" in **Figure 11.12** to the title
		163, 164	• Modified the following register names: "Intelligent I/O Interrupt Request Register" in **Figure 11.13**, and "Intelligent I/O Interrupt Enable Register" in **Figure 11.14**, to "Intelligent I/O Interrupt Request Register i (i = 0 to 11)", and "Intelligent I/O Interrupt Enable Register i (i = 0 to 11)", respectively • Changed variables "i"s, "j"s, and "k"s for description of bits in **Figures 11.13 and 11.14**, to "x"s, "y"s, and "z"s, respectively; Added expression "channel", to descriptions for BTxR, TMxyR, POxyR, IEzR, BTxE, TMxyE, POxyE, and IEzE
			Chapter 12. Watchdog Timer
		—	• Revised this chapter entirely • Modified description "bus clock"s, to "peripheral bus clock"s
			Chapter 13. DMAC
		—	• Changed the following principle expressions: "transfer unit" to "transfer size", "destination address" to "addressing mode", "fixed" to "non-incrementing addressing", "forward" to "incrementing addressing"
		170	• Modified the following description: "registers DMiSL and DMiSL2" in line 3 of the paragraph above **Figure 13.2**, to "the DMiSL register, and in bits DSEL24 to DSEL20 in the DMiSL2 register"
		172	• Changed the following expressions in **Table 13.2**: "Multi-master I^2C-bus interface interrupt" to "I^2C-bus interface interrupt", "Multi-master I^2C-bus line interrupt" to "I^2C-bus line interrupt", and "Multi-master I^2C-bus interface" in Note 4 to "I^2C-bus interface"
		173	• Modified description "the INTiIC register, IFSR0 register)" in Note 1 of **Table 13.3**, to "the INTiIC register and the IFSR1 register)"
		174	• Changed bit names USAi and UDAi for DMDi register in **Figure 13.4** and their function descriptively • Deleted the second sentence of Note 2 for DMDi register in **Figure 13.4**; Added Note 3 • Modified description for Note 2 in **Figure 13.5**; Deleted Note 3
		182	• Modified description "channel i" in line 1 of the first bullet point of **13.4.1**, to "the DMDi register"; Added one sentence to the same bullet point; Deleted whole description of the second and third bullet points; Added two new paragraphs
			Chapter 14. DMAC II
		—	• Revised this chapter entirely • Changed the following principle expressions: "transfer data" to "transfer type", "transfer data unit" to "transfer size", "transfer space" to "transfer memory space", "transfer direction" to "addressing mode", "fixed address" to "non-incrementing/constant address", "forward address" to "incrementing address", "end-of-transfer interrupt" to "DMA II transfer complete interrupt", "transfer source address" to "source addressing", and "transfer destination address" to "destination addressing"

Rev.	Date	Description	
		Page	Summary
		183	• Corrected a typo "64 Kbyte-space" in **Table 14.1**, to "64-Mbyte space" • Modified description "The relocatable vector table" in the forth bullet point of **14.1**, to "The relocatable vector"
		187	• Modified description for MOD in **Figure 14.3**; Divided the figure into two according to the MULT bit setting; Modified function of b14 to b8 from "No register bits", to "Reserved"
		188	• Moved and modified description below previous Figure 14.5, to lines 7 to 10 of **14.2**
		190	• Modified description "CADR1 to CADR0" in **Figure 14.4**, to "CADR"; Changed "(1)", "(2)", and "(3)", to "(a)", "(b)", and "(c)", respectively • Modified description "IADR1 and IADR0" in line 2 of **14.6** (previous 14.4.5), to "IADR" • Moved a sentence from previous 14.5, to lines 5 and 6 of **14.6**
		191	• Modified formulas in **Figure 14.5**
			Chapter 16. Timers
		195	• Corrected the following typos: "TTA0TGL" and "TAiGH and TAiGL" in **Figure 16.1**, to "TA0TGL" and "TAiTGH and TAiTGL", respectively
		197	• Corrected a typo "TBiS bit" in **Figure 16.3**, to "TAiS"
		212	• Corrected a typo "FEh" as value of m for "8-bit PWM" in **Table 16.5**, to "FFh"
		213	• Modified reset value for TAiMR register in **Figure 16.16** from "0000 000b" to "0000 0000b"
		215	• Changed expression "TBiS bit" in **Figure 16.19**, to "TBiS"
		216	• Changed description for Note 1 of TBiMR in **Figure 16.21** descriptively
		227	• Deleted "(j = 0 to 5)" from the eighth bullet point of **16.3.3.2**
			Chapter 17. Three-phase Motor Control Timers
		—	• Made minor text modifications to the this chapter
		229	• Added description "P3_2 to P3_7" to paragraph below "Inverse control" unit in **Figure 17.1**
		230	• Modified the expression of Note 8 for INVC0 in **Figure 17.2** descriptively
		236	• Modified reset value for TB2MR in **Figure 17.8**
		243	• Corrected a typo "TA4-1 register" in **Figure 17.17**, to "TA41 register"
			Chapter 18. Serial Interface
		—	• Made minor text modifications to the this chapter
		250	• Modified expression "7 (, 8, and 9)-bit transfer data" for "Function" of UiMR register in **Figure 18.4**, to "7(, 8, and 9)-bit character length"
		256	• Modified "SCL pin" for SWC bit of UiSMR2 in **Figure 18.11**, to "SCLi pin"
		257	• Modified description "To set the SS" in Note 2 for UiSMR3 register in **Figure 18.12**, to "To use the SS function"; Corrected a typo "UiCO register" in Note 2, to "UiC0 register"
		258	• Modified description for the SWC9 bit of UiSMR4 in **Figure 18.13**

Rev.	Date	Description	
		Page	Summary
		259	• Deleted description "and read as undefined value" from "Function" of b15-b9 for UiTB register in **Figure 18.15**
		263	• Modified description "(i = 0 to 6)" for "Transmit/receive clock" in **Table 18.2**, to "(i = 0 to 8)"
		269	• Deleted a ")" from description for Note 1 in **Figure 18.23**
		271	• Modified expressions "1 stop bit" and "2 stop bits" in the first bullet point of "Error detection" in **Table 18.5**, to "1 stop bit length" and "2 stop bit length", descriptively
		277	• Deleted "(i = 0 to 8)" from "B" of **18.2.2**
		283	• Modified the following descriptions in **Table 18.11**: "UART transmit/ UART receive interrupt" in "IICM2 = 1", to "Transmit/receive interrupt"; "the Pi_jS register (i, j = 0 to 7) if the I/O port is selected)" in "Default output value at the SDAi pin", to "the Port Pi register (i = 0 to 7) if the I/O port is selected by output function select registers)"
		285	• Modified description "UART transmit/UART receive interrupt" in (3) of **Figure 18.32**, to "transmit/receive interrupt"
		293	• Corrected a typo "$\overline{SS}$ pin" in title of **Figure 18.37**, to "$\overline{SSi}$ pin"
		296	• Deleted whole description from the third bullet point of **18.5.2.2**
			Chapter 19. A/D Converter
		—	• Made minor text modifications to the this chapter
		302, 304	• Modified Notes 2 to 4 for AD0CON2 in **Figure 19.4** and AD0CON4 in **Figure 19.6** descriptively
		312	• Modified description "AD0j register" in line 3 of **19.2.1**, to "AD0i register"
		317	• Deleted "(j = 0 to 7)" from the eighth bullet point of **19.3.2**
			Chapter 20. X-Y Conversion
		—	• Made minor text modifications to the this chapter
			Chapter 23. Intelligent I/O
		—	• Made minor text modifications to the this chapter
		328-330	• Moved "(j = 0 to 7)" in **Figures 23.1 to 23.3** to respective figure titles
		328	• Added description for BT0R to **Figure 23.1**
		329	• Added description for BT1R to **Figure 23.2**
		330	• Added description for bits BT2R, PO2jR, IE0R to IE2R, SIO2TR, and SIO2RR to **Figure 23.3**; Deleted note symbol "(3)"
		348	• Changed "IIOi_j pin function" in **Table 23.4**, to "IIOi_j input pin function"; Moved "(j = 0 to 7)" for "Trigger input polarity", to the table title
		349	• Moved "(j = 0 to 7; k = 6, 7)" below **Table 23.5** to the title
		349, 350	• Moved "(j = 0 to 7)" in **Figures 23.22 and 23.23** to the titles
		351	• Moved "(j = 6, 7)" in **Figure 23.24** to the title
		352	• Moved "(j = 0 to 7)" below **Table 23.6** to the title
		353, 355, 357, 358	• Added "(or OUTC2_j pin for Group 2)" after "IIOi_j pin", to respective line 1 of **23.3.1**, **23.3.2**, and **23.3.3** and description for "Specification" in **Tables 23.7 to 23.9**

Rev.	Date	Description	
		Page	Summary
		353, 355, 358	• Modified "IIOi_j pin function" in "Item" in **Table 23.7**, and "IIOi_j pin function (output)" in "Item" in **Tables 23.8 and 23.9**, to "IIOi_j output pin (or OUTC2_j pin for Group 2) function"
		360	• Modified description "G2PO0 register" for "Output waveform" in **Table 23.10**, to "G2POj register (j = 0 to 7)"
		361	• Corrected following typos: "fBTi" in **Figure 23.28**, to "fBT2"; "G2POCR register", to "G2POCRj register"
		363	• Added description "in the G2RTP register" to "RTPj bit" in **Figure 23.30**
			Chapter 24. Multi-master I^2C-bus Interface
		—	• Made minor text modifications to the this chapter
		382	• Modified description "SCL/SDA Interrupt"s for bits SIP and SIS in **Figure 24.8**, to "I^2Cbus-line Interrupt"
		383	• Modified description "(b2-b3)" for I2CCR1 register in **Figure 24.9**, to "(b3-b2)"
		386	• Modified description "(b5)" for I2CCR2 register in **Figure 24.11**, to "(b6)"
		392	• Modified description "b2 b1 b0" for bits CLK2 to CLK0 in **Figure 24.14**, to "b3 b2 b1"
			• Modified description below **Figure 24.14 and 24.1.9.1**
			Chapter 25. CAN Module
		—	• Made minor text modifications to the this chapter
		407	• Modified description "XIN" in **Figure 25.1**, to "Main clock"
		413	• Modified read value of b4 for C0CLKR in **Figure 25.3**, to be as undefined
		414	• Added description "from CAN reset mode" to Note 1 for C0BCR in **Figure 25.4**
			• Corrected a typo "(b23-22)" for C0BCR register in **Figure 25.4**, to "(b23-b22)"
		416, 417	• Modified function of b31 to b29 for C0MKRk in **Figure 25.5** and b29 for C0FIDCRn in **Figure 25.6**, to "Reserved"
		417	• Deleted description "and read as 0" from Note 2 for C0FIDCRn in **Figure 25.6**
		421	• Modified function of b29, b39 to b32, and b47 to b44 for C0MBj in **Figure 25.8**, to "Reserved; Changed description for Note 2; Deleted description "and read as 0" from Note 4
		423	• Changed expression "-"s in **Table 25.6**, to "X"s
		425	• Modified Note 4 for C0MCTLj register in **Figure 25.10** descriptively
		428	• Deleted description of a maximum delay from lines 7 to 8 of **25.1.9.9**
		433	• Modified description for **25.1.12.2**
		442	• Modified description for Note 2 of C0CSSR in **Figure 25.20**
			• Modified "0"s for b3 and b4 of 4th read in **Figure 25.21**, to "X"s
		443	• Modified description for Note 1 of C0AFSR in **Figure 25.22**
		449, 450	• Deleted "(8 bits)" from "Function" for C0RECR in **Figure 25.26** and C0TECR in **Figure 25.27**
		457	• Modified description of Note 2 for **Figure 25.34**

Rev.	Date	Description	
		Page	Summary
		463	• Deleted description of BRP from **Figure 25.36**
		464	• Deleted description "division value of the" for fCAN from line 1 of **25.3.3**
		474	• Moved description for "CAN0 wake-up interrupt" in **25.7**, to an upper line
			Chapter 26. I/O Pins
		—	• Made minor text modifications to the this chapter
		477	• Added "b" to binary form in **Table 26.1**
		479	• Changed "IIO0_i output" and "IIO1_i output" in "Function" of P1_iS register in **Figure 26.4**, to "IIO0 output" and "IIO1 output", respectively
		484, 490	• Modified description "b7-b3" for P6_iS in **Figure 26.9** and P11_iS in **Figure 26.15**, to "b7"
		487	• Modified bit symbol for b6 of registers P9_3S to P9_0S in **Figure 26.12**, to be exclusively as NOD
		490	• Modified the explanation about the usage of an N-channel open drain output in the paragraphs below **Figure 26.15**
		496	• Modified expression "TAiIN input" in Note 1 for IFS0 in **Figure 26.20**, to "TAiIN"
		499	• Modified description for IFS30 and IFS31 in **Figure 26.23** from "port P9", to "port P6/port P9"
			Chapter 27. Flash Memory
		—	• Revised this chapter entirely • Changed expressions "write" and "rewrite", to "program" when this word is used in combination with "erase"
		507	• Revised **Table 27.1**
		517	• Corrected a typo "(b7-4)" for FMR1 register in **Figure 27.8**, to "(b7-b4)"
		519	• Corrected address and "Function" of BP15 bit in **Figure 27.12**
		526	• Corrected a typo "b5-0" in **Tables 27.15 and 27.16**, to "b5-b0"
		533	• Modified expression "Status/Error" in **Table 27.17**, to "Error"
		538	• Modified description for the third bullet point of EW1 mode in **27.6.5**
			Chapter 28. Electrical Characteristics
		—	• Made minor text modifications to the this chapter
		543	• Corrected a typo "pots" in line 2 of Note 2 for **Table 28.4**, to "ports"
		548	• Changed the order of description of trec(STOP) and trec(WAIT) in **Table 28.13 and Figure 28.4**
		558, 571	• Changed the minimum value for "$t_{w(ADH)}$" in **Tables 28.31 and 28.57** from "$2/\phi_{AD}$", to "$3/\phi_{AD}$"
		559, 562, 572, 575	• Newly Added characteristics for multi-master I^2C-bus to **Tables 28.34, 28.39, 28.40, 28.60, 28.65, and 28.66**
		561, 574	• Modified "Characteristics" for $t_{su(S-ALE)}$ in **Tables 28.36 and 28.62**, from "Chip-select hold time for ALE" to "Chip-select setup time for ALE"
		562, 575	• Modified "Characteristics" for $t_{h(C-Q)}$ in **Tables 28.37 and 28.63**, from "TXDi hold time" to "TXDi output hold time"

Rev.	Date	Description	
		Page	Summary
		562, 575	• Added "Measurement condition" to **Tables 28.38 and 28.64**
		568	• Corrected typos "$t_{w(H)}$," "$t_{w(L)}$", "t_r", and "t_f" in **Table 28.46**, to "$t_{w(XH)}$", "$t_{w(XL)}$", "$t_{r(X)}$", and "$t_{f(X)}$", respectively
		580	• Newly Added timing diagram for multi-master I²C-bus to **Figure 28.11**
			Chapter 29. Usage Notes
		—	• Made minor text modifications to the this chapter
		587	• Modified description "channel i" in line 1 of the first bullet point of **29.6.1**, to "the DMDi register"; Added one sentence to the same bullet point; Deleted whole description of the second and third bullet points; Added two new paragraphs
		590	• Deleted "(j = 0 to 5)" from the eighth bullet point of **29.7.3.2**
		592	• Deleted whole description from the third bullet point of **29.9.2.2**
		594	• Deleted "(i = 0 to 7)" from the eighth bullet point of **29.10.2**
		595	• Modified description for the third bullet point of EW1 mode in **29.11.5**
1.10	Sep 08, 2010	—	Third edition released
			This manual in general
		—	• Applied new Renesas templates and formats to the manual • Changed company name to "Renesas Electronics Corporation" and changed related descriptions due to business merger of Renesas Technology Corporation and NEC Electronics Corporation (under Chapters 1, 7, 18, 23, and 28) • Added specifications of 64 MHz version • Added "128 KB/20 KB" and "256 KB/20 KB" for ROM/RAM capacity • Modified expressions "version N", "version D", and "version P" to "N version", "D version", and "P version", respectively (under Chapters 1 and 28)
			Chapter 1. Overview
		—	• Modified wording and enhanced description in this chapter
		3, 5	• Deleted Note 1 from **Tables 1.2 and 1.4**
		9	• Deleted Note 4 from **Figure 1.2**
		19	• Modified expression "fC" in description for "Clock output" in **Table 1.14** to "low speed clocks"
		23	• Modified the following descriptions in "Pin names" in **Table 1.18**: "P14_1" to "P14_1, P14_3", and "P14_3 to P14_6" to "P14_4 to P14_6"
			Chapter 4. SFRs
		30, 53	• Modified expressions "I²C-Bus" and "I²C Bus" in **Tables 4.2 and 4.25** to "I²C-bus"
		34, 37	• Changed register name "Group i Timer Measurement Prescaler Register" in **Tables 4.6 and 4.9** to "Group i Time Measurement Prescaler Register"
		36	• Modified expression "IE Bus" in **Table 4.8** to "IEBus"
		39	• Modified expression "XY Control Register" in **Table 4.11** to "X-Y Control Register"

Rev.	Date	Description	
		Page	Summary
		41	• Changed register name "UART2 Transmission/Receive Mode Register" in **Table 4.13** to "UART2 Transmit/Receive Mode Register"; Changed hexadecimal format of reset values for registers TABSR, ONSF, and TRGSR to binary
		43	• Modified reset value "X00X X000b" of the AD0CON2 register in **Table 4.15** to "XX0X X000b"
		52	• Changed register name "External Interrupt Source Select Register i" in **Table 4.24** to "External Interrupt Request Source Select Register i"
		53	• Modified reset values for registers I2CSSCR, I2CCR1, I2CCR2, I2CSR, and I2CMR in **Table 4.25**; Changed register name "I2C Bus START Condition/STOP Condition Control Register" to "I2C-bus START and STOP Conditions Control Register"
		67	• Modified register names "CAN0 Reception Error Count Register" and "CAN0 Transmission Error Count Register" in **Table 4.39** to "CAN0 Receive Error Count Register" and "CAN0 Transmit Error Count Register", respectively
			Chapter 5. Resets
		68	• Changed expression "operating level" in (2) of B in **5.1** to "operating voltage"
			Chapter 6. Power Management
		—	• Made minor text modifications to this chapter
			Chapter 7. Processor Mode
		—	• Modified wording and enhanced description in this chapter
		80	• Corrected address "44044h" of PM0 in **Figure 7.1** to "40044h"
		81	• Deleted "00008000h" and "FFF80000h" from **Figure 7.2**
			Chapter 8. Clock Generator
		—	• Made minor text modifications to this chapter
		83	• Modified expression "fC" for CLKOUT in **Figure 8.1** to "Low speed clock"; Modified "low speed clock" associated items
		84	• Deleted the last sentence from Note 2 in **Figure 8.2**; Modified Note 6
		85	• Modified expression "fC" in "Function" of bits CM01 and CM00 in **Figure 8.3** to "a low speed clock"; Added Note 8
		86	• Modified bit name "PLL Clock Oscillator Stop Bit" in **Figure 8.4** to "PLL Oscillator Stop Bit"; Added Note 4
		87	• Added description "and the BCS bit in the CCR register to 0 (PLL clock selected)" to Note 1 in **Figure 8.6**
		89	• Changed explanations for bits CM05 and CM10 in Note 3 of **Figure 8.9**; Added Note 5
		90	• Added the second sentence to Note 1 in **Figure 8.10**
		94	• Modified the following descriptions for the SEO bit in **Figure 8.15**: "Self-Oscillation Mode Setting Bit" to "Self-Oscillating Setting Bit", "PLL mode" to "PLL lock-in", and "Self-oscillation mode" to "Self-oscillating"

Rev.	Date	Description	
		Page	Summary
		97	• Added description "the main clock oscillator should be stopped from resuming (set the CM05 bit in the CM0 register to 1) or" to the second paragraph in **8.2.1**
		99	• Modified expressions "fC" in **8.6** and "fC" in **Tables 8.3 and 8.4** to "low speed clocks" and "low speed clock", respectively
		100	• Revised the entire paragraph of **8.7**
		101	• Added explanation for each mode to (1) to (5) in **8.7.1**; Changed the following expressions: "peripheral clock source" to "peripheral clocks", and "The PLL clock or the main clock" to "fAD, f1, f8, f32, and f2n"
		102	• Added description for **Figures 8.17 to 8.19** to **8.7.1**
		103-105	• Moved **Figures 8.17 to 8.19** from **8.7** to **8.7.1**; Explained "main clock stop" and "CM05 = 1" separately; Added explanation for the SEO bit
		103	• Corrected a typo "f(XPLL)" in the third row of **Figure 8.17** to "f(PLL)"; Deleted Note 4
		104	• Deleted Note 3 in **Figure 8.18**
		105	• Corrected "CM31 = 1" in the first row and "CM10 = 0" in the second row of **Figure 8.19** to "CM31 = 0" and "CM10 = 1", respectively; Deleted Note 3
		106	• Changed expression "Before executing WAIT instruction" in **8.7.2.2** to "Steps before entering wait mode"; Changed steps before entering wait mode
		107, 110	• Modified expression "fC" in **Tables 8.5 and 8.7** to "a low speed clock"
		107	• Modified description in **8.7.2.4**
		108	• Added Note 1 to **Table 8.6**
		109	• Changed the first sentence in **8.7.3**
			• Changed expression "Before entering stop mode" in **8.7.3.1** to "Steps before entering stop mode"; Changed steps before entering stop mode
		110	• Modified the first sentence in **8.7.3.3**
			• Added the usage condition for "External interrupt" to **Table 8.8**
			Chapter 9. Bus
		117, 118	• Deleted Note 2 from **Figures 9.4 to 9.6**
		124	• Added EXMPX bit values to the bus format row in **Table 9.2**; Modified function of P4_0 to P4_3 for memory expansion mode to "I/O ports" only
		132	• Added period of address becoming undefined to "(1) 8-bit data bus" in **Figure 9.15**; Added Note 2
			Chapter 10. Protection
		—	• Modified subchapter titles

Rev.	Date	Description	
		Page	Summary
			Chapter 11. Interrupts
		—	• Made minor text modifications to this chapter
		159	• Deleted "Bits RLVL2 to RLVL0 in the RIPL2 register" and associated signal lines from **Figure 11.8**; Changed expression "DMAC II" to "DMA II transfer complete"
		164	• Changed description for b0 in **Figure 11.13**; Modified Note 3
		166	• Revised the third bullet point of description in **11.14.3**
			Chapter 12. Watchdog Timer
		168	• Added Note 1 to **Figure 12.2**
			Chapter 13. DMAC
		—	• Made minor text modifications to this chapter
		183	• Modified description "peripheral clocks" in the fourth bullet point of 13.4.1 to "peripheral bus clocks"
			Chapter 14. DMAC II
		189	• Modified the following addresses in **14.3.1**: "001FFFFFh" to "01FFFFFFh", "00200000h" to "02000000h", and "00000000h" to "FE000000h"
			Chapter 16. Timers
		—	• Made minor text modifications to this chapter
		197	• Separated signal for overflow or underflow from interrupt signal in **Figure 16.2**
			Chapter 17. Three-phase Motor Control Timers
		232	• Changed "Timer A" in the Function column of the INV13 bit in **Figure 17.3** to "Timer A1"
		237	• Changed functions of bits MR2 and MR3 in **Figure 17.8**
		238	• Changed function of the PWCON bit in **Figure 17.9**
		244	• Modified explanation for the bit setting of Case 1 in **Figure 17.17**
		246	• Changed the order of descriptions for bits INV02 and INV03 in **17.6.1**
			• Modified "overflow" in **17.6.2** to "underflow"
			Chapter 18. Serial Interface
		—	• Made minor text modifications to this chapter
		251	• Deleted "I^2C mode" from "Function" of bits SMD2 to SMD0 in **Figure 18.4**
		259, 287	• Corrected typos "STARREQ" in Note 3 in **Figure 18.13 and 18.3.2** to "STAREQ"
		274	• Modified "SUM0" in "Bits" of the UiRB register **Table 18.7** to "SUM"
		279, 280	• Changed expression "Transmit/receive clock" in **Figures 18.29 and 18.30** to "CLKi"
		297	• Moved description in the fourth dash in **18.5.2.1** to the second dash
		298	• Added **18.5.4** "Reset Procedure on Communication Error"
			Chapter 19. A/D Converter
		—	• Made minor text modifications to this chapter
			• Changed expressions "A/D conversion result" and "A/D conversion results" to "A/D converted result" and "A/D converted results", respectively

Rev.	Date	Description	
		Page	Summary
		305	• Changed Note 5 in **Figure 19.5**
		306	• Changed Notes 1, 3, and 4 in **Figure 19.7**
		307-313	• Changed description in "Specification" for "Start conditions" and "Reading of A/D converted result" in **Tables 19.2 to 19.8**
		319	• Modified description in the ninth bullet of **19.3.2**
			Chapter 21. CRC Calculator
		322	• Corrected a typo "CRC_CCITT" in line 2 of **21. CRC Calculator** to "CRC-CCITT"
			Chapter 22. X-Y Conversion
		325, 326	• Changed figure titles "XiR Register" and "YjR Register" for Figures 22.2 and 22.3 to "Registers X0R to X15R" and "Registers Y0R to Y15R", respectively; Changed preposition "to" in between addresses to "-"
			Chapter 23. Intelligent I/O
		—	• Made minor text modifications to this chapter
		330, 331	• Modified descriptions "Request from the $\overline{\text{INT0}}$ pin" in **Figure 23.1** and "Request from the $\overline{\text{INT1}}$ pin" in **Figure 23.2** to "Request from the $\overline{\text{INT0}}$ pin or the $\overline{\text{INT1}}$ pin"
		332	• Corrected the following typos in **Figure 23.3**: "IE_IN" to "IEIN", "IE_OUT" to "IEOUT", "ISRxD2" to "ISRXD2", and "ISTxD2" to "ISTXD2"
		335	• Changed expression "$\overline{\text{INTi}}$ pin" in **Figure 23.6** to "$\overline{\text{INT0}}$/$\overline{\text{INT1}}$ pin"; Changed Note 3
		337	• Corrected a typo "bits BT0S to BT3S" in (2) of Note 1 in **Figure 23.8** to "bits BT0S to BT2S"
		341	• Corrected a typo "ISTxD2" in **Figure 23.13** to "ISTXD2"
		344	• Changed description in the second bullet of "Specification" for "Reset conditions" in **Table 23.2**
		345	• Changed expression "$\overline{\text{INTi}}$ pin" in **Figure 23.18** to "$\overline{\text{INT0}}$/$\overline{\text{INT1}}$ pin"; Moved "i = 0 to 2" to the title
		347, 348	• Moved "(i = 0, 1)" to the title of **Figures 23.19 and 23.20**
		362	• Corrected a typo "00h to 3FFh" in **Table 23.10** to "000h to 3FFh"
		368	• Deleted Note 1 from **23.4**
		370	• Changed "ISTxD" and "ISRxD" in **Figure 23.36** to "ISTXD2" and "ISRXD2", respectively
		374	• Corrected a typo "ISRX2" in **Table 23.15** to "ISRXD2"
			Chapter 24. Multi-master I^2C-bus Interface
		—	• Modified wording and enhanced description in this chapter • Modified expression "general call" to "general call address" • Modified expression "flag" to "bit" when it is used with bit symbols • Modified expressions "standard-mode" and "fast-mode" to "Standard-mode" and "Fast-mode", respectively • Modified expression "set to" for the RST bit in the I2CCCR0 register to "written with"

Rev.	Date	Description	
		Page	Summary
		—	• Modified expressions "START condition and STOP condition" and "START condition or STOP condition" to "START and STOP conditions" and "START or STOP condition", respectively
		376	• Modified description for "Timeout detector" in **Table 24.1**
		377	• Modified "Bus is busy detector" in **Table 24.2** to "Bus busy detector"; Modified specifications of "Slave-address match detector" and "Arbitration lost detector"
		378	• Modified description in the Function column in **Figure 24.2**
		380	• Changed bit name "Transmit/Receive Bit Number Set Bit" in **Figure 24.5** to "Transmit/Receive Bit Length Setting Bit"
		381	• Modified expression "slave address data" in line 2 of **24.1.3.3** to "slave address"
			• Modified expression "I^2C reset signal" in **Figure 24.6** to "I^2C-bus interface reset signal"
		382	• Modified "ACKCLK bit" in line 2 of **24.1.4** to "ACKD bit"
			• Corrected descriptions "below 100 kHz" and "below 400 kHz" in Note 1 of **Table 24.3** to "100 kHz or less" and "400 kHz or less", respectively
		383	• Corrected a typo "ϕIIO" in line 2 of **24.1.4.2** to "ϕIIC"
			• Modified expressions "MSDA pin level" in line 4 of **24.1.4.3 and Table 24.4** and "MSDA Pin Levels" for table title of Table 24.4 to "MSDA pin state" and "MSDA Pin States", respectively
		384	• Changed expressions "I^2C Bus-line" in **Figure 24.8** and "I^2C bus line" in **24.1.5.2 and 24.1.5.3** to "I^2C-bus line"
		385	• Moved "(2)" from "Function" to "Bit Name" in **Figure 24.9**; Changed expression "1-bit instruction" to "bit processing instruction" in Note 1; Switched Notes 2 and 3
		387	• Corrected a typo "SDO" in line 3 of **26.1.6.3** to "SDAO"
		388	• Changed symbol "/" in function description of bits ICK4 to ICK2 in **Figure 24.11** to "divided-by-"
		389	• Modified setting value of TOSEL bit in **24.1.7.3**
		390	• Moved "(1)" to "(3)" from "Function" to "Bit Name" in **Figure 24.13**; Added "(1)" to "Function"
		391	• Deleted explanation in parentheses in line 1 of **24.1.8.2**
			• Modified description in Line 3 and 4 of **24.1.8.4**
		392	• Modified "R/W bit" in Line 6 of **24.1.8.7** to "R/$\overline{W}$ bit"
		393	• Modified description "lost byte of data" in the second bullet point of **24.1.8.8** to "corresponding byte"
		397	• Modified "(I^2C-bus interface enabled)" in line 5 of the second paragraph below **Figure 24.18** to "(I^2C-bus interface disabled)"
		398, 399	• Modified expression "VIIC" in **Figures 24.19 and 24.22** to "ϕIIC"
		399	• Modified expression "high period of MSCL" in lines 4 to 5 in the first paragraph of **24.5** to "high period of MSCL pin"
		400	• Changed "Standard Clock Mode" and "Fast Clock Mode" in **Table 24.10** to "Standard-mode" and "Fast-mode"; Changed parameter "BBSY flag setting time" to "BBSY bit set/reset time"

Rev.	Date	Description	
		Page	Summary
		401	• Changed parameter "Successful receive interrupt" for I2CCR1 register in **Table 24.12** to "Successful data receive interrupt"
		403	• Modified description "For (A) to (C) in the figure, see A to C" in **24.6.2** to "For (A) to (D) in the figure, see A to D"
		404	• Modified description for I2CCCR register in **24.7.1**
		405	• Modified expression "Bits to be zero" in **Figures 24.25 and 24.26** to "Bits to be reset"
			• Modified "TRX bit" in **Figure 24.27** to "TRS bit"; Modified the following expressions: "Bits to be zero" to "Bits to be reset", and "Bit to be zero" to "Bit to be set"; Modified description of TRS bit
		406	• Modified "By a program" in **Figure 24.28** to "Software wait"
			Chapter 25. CAN Module
		—	• Made minor text modifications to this chapter
			• Changed expression "8/3 encoder" to "8-to-3 priority encoder"
		407	• Modified description "Table 25.1 lists" in line 5 of **25** to "Table 25.1 and Table 25.2 list"
		419	• Changed Note 2 in **Figure 25.6**
		423	• Changed description "Setting Value" in **Figure 25.8** to "Setting Range"; Changed Note 4
		427	• Modified register name "CANi Message Control Register" in **25.1.9** to "CANi Message Control Register j"
		430	• Modified Note 2 in **Figure 25.11**
		436	• Corrected a typo "CiTFPCR register" in line 3 of **25.1.13** to "CiTFCR register"
		443	• Modified description in line 3 of **25.1.17**
		444	• Changed expression "3/8 decoder" in **Figure 25.23** to "3-to-8 decoder"
		452	•Moved "(4)" from "Bit Name" to "Function" in **Figure 25.28**
		462	•Corrected a typo "CiSTR register" in the fourth paragraph of **25.2.4** to "CiTCR register"
			Chapter 26. I/O Pins
		—	• Made minor text modifications to this chapter
		486	• Added "(MMI2C)" to line 2 below **Figure 26.10**
		489	• Modified reset value "0XXX X000b" of P9_3S in **Figure 26.13** to "00XX X000b"; Modified description for b6
			• Modified bit symbol "PD_9i" in line 4 of the third paragraph below **Figure 26.13** to "PD9_i"
		492	• Modified reset values "0XXX X000b" of P12_0S to P12_3S in **Figure 26.16** to "X0XX X000b"; Modified description for b7 to b3
		497	• Changed description "1: Port P7/port P9" in "Function" of the IFS01 bit in **Figure 26.20** to "1: Port P9"
		502	• Corrected a typo "P9_1 to P9_3 Pull-Up Control Bit" in "Bit Name" of the PU26 bit in **Figure 26.26** to "P9_0 to P9_3 Pull-Up Control Bit"
		503	• Corrected a typo "P14_1 to P14_3 Pull-Up Control Bit" in "Bit Name" of the PU26 bit in **Figure 26.28** to "P14_1 and P14_3 Pull-Up Control Bit"

Rev.	Date	Description	
		Page	Summary
		505, 506	• Added description "P9_0, P9_2, and" to Note 3 of **Tables 26.2 and 26.3**
			Chapter 27. Flash Memory
		—	• Made minor text modifications to this chapter
			• Added forcible erase function and standard serial I/O mode disable function for high speed version (64 MHz version)
		510	• Deleted description "erase" from "ROM Code Protection" of "Operations to be protected" in **Table 27.3**; Added description "erase" to "ID Code Protection" of "Operations to be protected"; Deleted description "by using the serial programmer" from "ROM Code Protection" of "Protection deactivated by"
			• Deleted description "use the serial programmer to" from the second paragraph of **27.2.2**
		511	• Corrected a typo "FFFFFE8h" in line 9 of **27.2.3** to "FFFFFFE8h"
		515	• Changed the following descriptions in **Table 27.7**: "the program or the block erase command" to "the program command or the block erase command", and "read status register command" and "ready status register command" to "enter read status register mode"
			• Modified figure number "Figure 27.11" in the last line below **Table 27.7** to "Figure 27.12"
		523, 525	• Changed the following descriptions in **Figures 27.13 and 27.14**: "$\overline{CS0}$" and "$\overline{CS0}$ to $\overline{CS3}$" to "Chip select", and "A23 to A0, $\overline{BC0}$ to $\overline{BC3}$" to "Address"
			Chapter 28. Electrical Characteristics
		—	• Made minor text modifications to this chapter
			• Added electrical characteristics of 64 MHz version
			• Changed expression "input clock period" to "input clock cycle time"
		551	• Changed the following descriptions in **Figure 28.5**: "$\overline{CS0}$" and "$\overline{CS0}$ to $\overline{CS3}$" to "Chip select", and "A23 to A0, $\overline{BC0}$ to $\overline{BC3}$" to "Address"
		552, 553, 565, 566	• Changed values of $f_{(CPU)}$ under the titles of **Tables 28.15, 28.16, 28.41, and 28.42**
		555, 568	• Changed values of $f_{(BCLK)}$ under the titles of **Tables 28.18 and 28.44**
			Chapter 29. Usage Notes
		—	• Made minor text modifications to this chapter
		588	• Revised the third bullet point of description in **29.5.3**
		593	• Changed the order of descriptions for bits INV02 and INV03 in **29.8.1**
			• Modified "overflow" in **29.8.2** to "underflow"
		594	• Moved description in the fourth dash in **29.9.2.1** to the second dash
		595	• Added **29.9.4** "Reset Procedure on Communication Error"
		597	• Modified description in the ninth bullet of **29.10.2**
			Appendix 1. Package Dimensions
		600	• Added a seating plane to the drawing of package dimension
