1. Supply current measurement is based on 0x93[2:0] = 6 setting. These bits should be set to 6 after power-on and resets. Lower settings will increase power consumption.
2. Crystal deviation is based on normal operation condition.
3. Compliance to datasheet limits is assured by one or more methods: production test, characterization and/or design.

# Video Decoder

## VIDEO DECODER OVERVIEW

The TW2964 is a low power NTSC/PAL video decoder chip that is designed for video surveillance applications. It consumes very low power in a typical composite input application. The available power down mode further reduces the power consumption. It uses the 1.0V for digital supply voltage and 3.3V for I/O and analog power. A single 27MHz crystal is all that needed to decode all analog video standards.

The video decoder decodes the base-band analog CVBS into digital 8-bit 4:2:2 YCbCr for output. It consists of analog front-end with input source selection, variable gain amplifier and analog-to-digital converters, Y/C separation circuit, multi-standard color decoder (PAL BGHI, PAL M, PAL N, combination PAL N, NTSC M, NTSC 4.43) and synchronization circuitry. The Y/C separation is done with high quality adaptive 4H (5-line) comb filter for reduced cross color and cross luminance. The advanced synchronization processing circuitry can produce stable pictures for non-standard signal as well as weak signal.

## Analog Front End

The analog front-end prepares and digitizes the AC coupled analog signal for further processing. Each channel has built-in anti-aliasing filter and 10-bit over-sampling ADCs. The characteristic of the filter is available in the filter curve section. The Y channel has additional 2-input multiplexer, and a variable gain amplifier for automatic gain control (AGC). It can support a maximum input voltage range of 1.4V without attenuation. Software selectable analog inputs allow two selectable composite video inputs.

## Sync Processor

The sync processor of TW2964 detects horizontal synchronization and vertical synchronization signals in the composite video or in the Y signal of an S-video or component signal. The processor contains a digital phase-locked-loop and decision logic to achieve reliable sync detection in stable signal as well as in unstable signals such as those from VCR fast forward or backward. It allows the sampling of the video signal in line-locked fashion.

## Y/C Separation

For NTSC and PAL standard signals, the luma/chroma separation can be done either by adaptive comb filtering or notch/band-pass filter combination. The default selection for NTSC/PAL is comb filter. The characteristics of the band-pass filter are shown in the filter curve section.

TW2964 employs high quality 4-H (5-line) adaptive comb filter to reduce artifacts like hanging dots and crawling dots. Due to the line buffer used in the comb filter, there is always two lines processing delay in the output images no matter what standard or filter option is chosen.

## Color Demodulation

The color demodulation of NTSC and PAL signal is done by first quadrature down mixing and then low-pass filtering. The low-pass filter characteristic can be selected for optimized transient color performance. For the PAL system, the PAL ID or the burst phase switching is identified to aid the PAL color demodulation.

The sub-carrier signal for use in the color demodulator is generated by direct digital synthesis PLL that locks onto the input sub-carrier reference (color burst). This arrangement allows any sub-standard of NTSC and PAL to be demodulated easily with single crystal frequency.

## AUTOMATIC CHROMA GAIN CONTROL

The Automatic Chroma Gain Control (ACC) compensates for reduced amplitudes caused by high-frequency loss in video signal. The range of ACC control is -6db to +26db.

## COLOR KILLER

For low color amplitude signals, black and white video or very noisy signals, the color will be suppressed or killed. The color killer uses the burst amplitude measurement as well as sub-carrier PLL status to switch-off the color.

## AUTOMATIC STANDARD DETECTION

The TW2964 has build-in automatic standard discrimination circuitry. The circuit uses burst-phase, burst-frequency and frame rate to identify NTSC or PAL color signals. The standards that can be identified are NTSC (M), NTSC (4.43), PAL (B, D, G, H, I), PAL (M), PAL (N), PAL (60) and SECAM. Each standard can be included or excluded in the standard recognition process by software control. The identified standard is indicated by the Standard Selection (SDT) register. Automatic standard detection can be overridden by software controlled standard selection. The SECAM standard can be recognized but not properly decoded.

TW2964 supports all common video formats as shown in Table 3. The video decoder needs to be programmed appropriately for each of the composite video input formats.

## Component Processing

The TW2964 supports the brightness, contrast, color saturation and Hue adjustment for changing the video characteristic. The Cb and Cr gain can be adjusted independently for flexibility.

## SHARPNESS

The TW2964 also provides a sharpness control function through control registers. It provides the control up to +9db. The center frequency of the enhancement curve is selectable. A coring function is provided to prevent noise enhancement.

## COLOR TRANSIENT IMPROVEMENT

A programmable Color Transient Improvement circuit is provided to enhance the color bandwidth. Low level noise enhancement can be suppressed by a programmable coring logic. Overshoot and undershoot are also removed by special circuit to prevent false color generation at the color edge.

## VIDEO OUTPUT FORMAT

The TW2964 supports ITU-R BT.656 like format. All video data and timing signal of four channels are synchronous with the pins CLKPO or CLKNO output. Therefore, CLKPO or CLKNO can be connected to four channel interfaces for synchronizing data.

## CHANNEL ID

The channel ID can be inserted in the data stream using the CHID\_MD register. Two kinds of channel ID format can be supported. One is horizontal blanking code with channel ID and the other is ITU-R BT.656 sync code with channel ID. Each ITU-R BT.656 like data stream in 4x output data, 2x output data can have this Sync Code and Blanking Code. Table 4 shows this Channel ID format. Nibble data value **m** shows Video Decoder number to be output in this video stream.

## VIDEO LOSS OUTPUT

When NOVID\_656 register is set to 1, bit7 of Fourth byte of SAV/EAV code will be 0 when video signal is lost. This can be an optional set of 656 SAV/EAV code for no-video (video lost) specific application.

## ITU-R BT.656 LIKE FORMAT

In ITU-R BT.656 like format, SAV and EAV sequences are inserted into the data stream to indicate the active video time. It is noted that the number of active pixels per line is constant in this mode regardless of the actual incoming line length. The output timing is illustrated in Figure 2. The SAV and EAV sequences are shown in Table 5. An optional set of 656 SAV/EAV code sequence can be enabled to identify no-video status using the NOVID\_656 bit.

### TWO CHANNEL ITU-R BT.656 TIME-MULTIPLEXED FORMAT WITH 54/72MHZ

The TW2964 supports two channels ITU-R BT.656 like time-multiplexed format with x2(54MHz/72MHz) that is useful to security application requiring two channel outputs through one channel video port. The CHMDn register enables the dual ITU-R BT.656 like time-multiplexed format and the MAINCHn/SELCHn register selects channel output to be multiplexed with its own channel on each VD pins. To de-multiplex the time-multiplexed data in the back end chip, the channel ID can be inserted in the data stream using the CHID\_MD register. Two kinds of channel ID format can be supported. One is horizontal blanking code with channel ID and the other is ITU-R BT.656 sync code with channel ID. Figure 3 and Figure 4 illustrate VDn[7:0]/CLKPO/CLKNO pin timing with x2(72MHz/54MHz),x1(27MHz/36MHz) clock output mode.

### FOUR CHANNEL 960H TIME-DIVISION-MULTIPLEXED FORMAT WITH 108/144MHZ

Four channel of 960H/720H at 36MHz/27MHz video stream that are time-division-multiplexed at x4(144MHz/108MHz) data rate format is implemented in TW2964 for security surveillance application. In order to reduce pin counts (thus shrink chip size) on both decoder's digital output port and the input port of the back end compression Codec devices, TW2964 implements single 8-bit bus at 4 times the base band pixel clock rate of x1(36MHz/27MHz). While quadrupling the data rate on a single bus to meet the new requirement, individually, each channel data arrangement still retains the base band x1(36MHz/27MHz) ITU-R BT.656 like specification. For interface that can accept the new x4(144MHz/108MHz) clock bus, only one single clock at x4(144MHz/108MHz) is required. Embedded timing (SAV-EAV) code and Channel ID are inserted into each channel for de-multiplexing and separation of channel data.

Figure 5 depicts the temporal arrangement of the video data in x4(144MHz/108MHz) data rate. Each channel is byte level time-division multiplexed (TDM). Main clock is x4(144MHz/108MHz) clock

## OUTPUT ENABLING ACT

After power-up, the TW2964 registers have the default values. After RSTB pin is asserted and released, all registers have the default values. After reset, the TW2964 data outputs are tri-stated. The OE register should be written after reset to enable outputs desired.

## VIDEO OUTPUT CHANNEL SELECTION

If CHMDn[1:0] in Reg0xCA is set to 0hex, MAINCHn[1:0] in Reg0xCD selects one number of Video Channels to be output on VDn[7:0] pin as Single Channel ITU-R BT.656 like Format output. If CHMDn[1:0] in Reg0xCA is set to 1hex, MAINCHn[1:0] in Reg0xCD and SELCHn[1:0] in Reg0xCC select two numbers of Video Channels to be output on VDn[7:0] pin as Two Channel ITU-R BT.656 like Time-multiplexed Format output. If CHMDn[1:0] in Reg0xCA is set to 2hex, Four Channel ITU-R BT.656 like x4 Time-multiplexed Format is output on VDn[7:0] pin.

## EXTRA SYNC OUTPUT

The additional timing information such as syncs and field flag are also supported through the MPP pins. The video output timing is illustrated in Figure 6 and Figure 7. TW2964 HS/VS/FLD output function is compatible to TW9907 Video decoder HSYNC/VS/FLD output function. Start of VS timing is controlled by VSHT register(V timing) and OVSDLY register(H timing). End of VS timing is controlled by OVSEND register(V Timing). Start of FLD timing is controlled by OFDLY register(V timing). Start of HS timing is controlled by HSBEGIN register and End of HS timing is controlled by HSEND register.

## Audio Codec

The audio codec in the TW2964 is composed of five audio Analog-to-Digital converters processing, one Digital-to-Analog converter, audio mixer, digital serial audio interface and audio detector shown as the Figure 8. The TW2964 can accept 5 analog audio signals and 1 digital serial audio data and produce 1 mixing analog audio signal and 2 digital serial audio data.

The level of analog audio input signal AIN1 ~ AIN5 can be adjusted respectively by internal programmable gain amplifiers that are defined via the AIGAIN1, AIGAIN2, AIGAIN3, AIGAIN4 and AIGAIN5 registers and then sampled by each Analog-to-Digital converters. The digital serial audio input data through the ACLKP, ASYNP and ADATP pins are used for playback function. To record audio data, the TW2964 provides the digital serial audio output via the ACLKR, ASYNR and ADATR pins.

The TW2964 can mix all of audio inputs including analog audio signal and digital audio data according to the predefined mixing ratio for each audio via the MIX\_RATIO1 ~ MIX\_RATIO5 and MIX\_RATIO6 registers. This mixing audio output can be provided through the analog and digital interfaces. The embedded audio Digital-to-Analog converter supports the analog mixing audio output whose level can be controlled by programmable gain amplifier via the AOGAIN register. The ADATM pin supports the digital mixing audio output and its digital serial audio timings are provided through the ACLKR and ASYNR pins that are shared with the digital serial audio record timing pins.

The main purpose of AIN5 is to make the standard I2S/DSP digital audio output on ADATM pin for special application. Usually, 4 AIN1/AIN2/AIN3/AIN4 audio data are only used on ADATR pin output.

FIGURE 8. BLOCK DIAGRAM OF AUDIO CODEC

## AUDIO CLOCK MASTER/SLAVE MODE

The TW2964 has two types of Audio Clock modes. If ACLKRMAS<sub>TER</sub> register is set to 1, fs audio sample date is processed from audio clock internal ACKG (Audio Clock Generator) generates. In this master mode, ACLKR/ASYNR pins are output mode. ASYNROEN register for ASYNR pin should be set to 0 (output enable mode). If ACLKRMAS<sub>TER</sub> register is set to 0, fs audio sample rate is processed from audio clock on ACLKR pin input. 256xfs, 320xfs or 384xfs audio clock should be connected to ACLKR pin from external master clock source in this slave mode. ASYNR pin can be input or output by external Audio clock master in slave mode. ASYNR signal should change per fs audio sample rate in both master and slave mode. AIN5MD and AFS384 register set up Audio fs mode by following table.

REGISTER		FS MODE
AIN5MD	AFS384	
0	0	256xfs
1	0	320xfs
0	1	384xfs

## AUDIO DETECTION

The TW2964 has an audio detector for individual 5 channels. There are 2 kinds of audio detection method defined by the ADET\_TH. One is the detection of absolute amplitude and the other is of differential amplitude. For both detection methods, the accumulating period is defined by the ADET\_FILT register and the detecting threshold value is defined by the ADET\_TH1 ~ ADET\_TH5 registers. The detection of differential amplitude is recommended for most use. The status for audio detection is read by the STATE\_AVDET register and it also makes the interrupt request through the IRQ pin with the combination of the status for video loss detection.

## MULTI-CHIP OPERATION

TW2964 can output 16 channel audio data on ACLKR/ASYNR/ADATR output simultaneously. Therefore, up to 4 chips should be connected on most Multi-Chip application cases. SMD register selects Audio cascade serial interface mode. If SMD register is set to 2, ALINKI pin is audio cascade serial input and ALINKO pin is audio cascade serial output mode.

Each stage chip can accept 5 analog audio signals so that four cascaded chips will be 16-channel audio controller as default {AFS384, AIN5MD} = 00. The first stage chip provides 16ch digital serial audio data for record. Even though the first stage chip has only 1 digital serial audio data pin ADATR for record, the TW2964 can generate 16 channel data simultaneously using multi-channel method. In addition, each stage chip can support 4 channel record outputs that are corresponding with analog audio inputs. This first stage chip can also output 16 channel mixing audio data by the digital serial audio data and analog audio signal. The first stage chip accepts the digital serial audio data for playback. The digital playback data can be converted to analog signal by Digital-to-Analog converter in the first stage chip.

Several Master/Slave mode configurations are available. Figure 9 is the most recommended and demanded system with Clock Master mode (ACLKRMAS<sub>TER</sub> = 1). Figure 10 is the most recommended system with Clock Slave Sync Slave mode (ACLKRMAS<sub>TER</sub>=0, ASYNROEN=1). Other system combinations are also available if application need different type specific system. Figure 9 and Figure 10 show the most typical system.

In the following FIGURES, Mix1-16-51-54/Pb1 means Mix output of AIN1-16, AIN51-54 and Playback1. AIN1-16-51-54/Pb1 means one selected Audio output in AIN1-16-51-54/Pb1.

If one of TW2964s uses {AFS384, AIN5MD} = 01 or {AFS384, AIN5MD} = 10, all other cascaded TW2964 chips must set up same {AFS384 AIN5MD} mode together.

In Multi-Chip Audio operation mode, one same Oscillator clock source need to be connected to all TW2964 XTI pins.

If special application needs 108MHz XTI input, the RSTB pin input control needs to be considered. RSTB input controlled by MPP4 or MPP3 GPO output is one of the solutions. Another way needs XTI/RSTB timing control, as shown in Figure 9. RSTB/XTI timing control is not required in 27MHz XTI mode.

## SERIAL AUDIO INTERFACE

There are 3 kinds of digital serial audio interfaces in the TW2964; the first is a recording output, the second is a mixing output and the third is a playback input. These 3 digital serial audio interfaces follow a standard I2S or DSP interface as shown in Figure 13.

FIGURE 13. FIG13 TIMING CHART OF SERIAL AUDIO INTERFACE

### Playback Input

The serial interface using the ACLKP, ASYNP and ADATP pins accepts the digital serial audio data for the playback purpose. The ACLKP and ASYNP pins can be operated as master or slave mode. For master mode, these pins work as output pin and generate the standard audio clock and synchronizing signal. For slave mode, these pins are input mode and accept the standard audio clock and synchronizing signal. The ADATP pin is always input mode regardless of operating mode. One of audio data in left or right channel should be selected for playback audio by the PB\_LRSEL.

**Record Output**

To record audio data, the TW2964 provides the digital serial audio data through the ACLKR, ASYNR and ADATR pins. Sampling frequency comes from 256xfs, 320xfs or 384xfs audio system clock setting. Even though the standard I2S and DSP format can have only 2 audio data on left and right channel, the TW2964 can provide an extended I2S and DSP format which can have 16 channel audio data through ADATR pin. The R\_MULTCH defines the number of audio data to be recorded by the ADATR pin. ASYNR signal is always fs frequency rate. One ASYNR period is always equal to 256xACLKR clock length with AIN5MD=0. Figure 14 shows the digital serial audio data organization for multi-channel audio.

**FIGURE 14. TIMING CHART OF MULTI-CHANNEL AUDIO RECORD**

Table 7 shows the sequence of audio data to be recorded for each mode of the R\_MULTCH register. The sequences of 0 ~ F do not mean actual audio channel number but represent sequence only. The actual audio channel should be assigned to sequence 0 ~ F by the R\_SEQ\_0 ~ R\_SEQ\_F register. When the ADATM pin is used for record via the R\_ADATM register, the audio sequence of ADATM is also shown in Table 7.

**Mix Output**

The digital serial audio data on the ADATM pin has 2 different audio data, which are mixing audio, and playback audio. The mixing digital serial audio data is the same as analog mixing output. The sampling frequency, bit width and number of audio for the ADATM pin are same as the ADATR pin because the ACLKR and ASYNR pins are shared with the ADATR and ADATM pins.

## AUDIO CLOCK SLAVE MODE DATA OUTPUT TIMING

TW2964 always output ASYNR/ADATR/ADATM by ACLKR falling edge triggered timing. ADATR/ADATM output data are always changing at next ACLKR falling edge triggered timing after ASYNR signal changes. If ASYNR is output, ADATR/ADATM output are always fixed to one ACLKR falling edge timing. However, if ASYNR is input, ADATR/ADATM output timing changes by ASYNR input timing.

ASYNR is ACLKR falling edge triggered input/output

If ASYNR is input and ASYNR input is ACLKR falling edge triggered input as ASYNR input signal is changing after ACLKR falling edge, or if ASYNR is output, TW2964 output ADATR/ADATM by ACLKR falling edge triggered timing as shown in the following FIGURES. ASYNR signal is changing during ACLKR = 0. TW2964 output ADATR/ADATM data after next ACLKR falling edge triggered timing with more than half ACLKR clock delay.

ASYNR is ACLKR rising edge triggered input

If ASYNR is input and ASYNR input is ACLKR rising edge triggered input as ASYNR input signal is changing after ACLKR rising edge, TW2964 output ADATR/ADATM by ACLKR falling edge triggered timing as shown in the following FIGURES. ASYNR signal is changing during ACLKR = 1. TW2964 output ADATR/ADATM data after next ACLKR falling edge triggered timing with less than half ACLKR clock delay.

## ACLKP/ASYNP SLAVE MODE DATA INPUT TIMING

The following 8 data input timings are supported. ADATPDLY register needs to be set up according to the difference of ADATP data input timings. Data1 is only used as default. The MSB bit is the first input bit as default PBINSWAP = 0. If PBINSWAP = 1, LSB bit is the first input bit.

ASYNP is ACLKP falling edge triggered input.

## AUDIO CLOCK GENERATION

TW2964 has built-in audio clock generator. The audio clock is digitally synthesized from the crystal clock input. The master audio clock frequency is programmable through ACKI register based following two equations.

$ACKI = \text{round} ( F_{AMCLK} / F_{27MHz} * 2^{23} )$ , it gives the Audio master Clock Nominal increment.

ACKI registers make audio\_source\_clock by 27MHz clock.

If MASCKMD=0,  $AMCLK = \text{audio\_source\_clock}$ . If MASCKMD=1,  $AMCLK = \text{audio\_source\_clock} / 2$ .

AMCLK is used as audio system clock and audio ADC clock in Master clock mode.

The following table provides setting example of some common used audio frequency assuming XTI clock frequency of 27MHz. If ACLKRMASMASTER register bit is set to 1, following AMCLK is used as audio system clock with MASCKMD inside TW2964.

ACPL=1(Loop open) should be used in TW2964 system.

### AUDIO CLOCK AUTO SETUP

If ACLKRMAS<sub>TER</sub> = 1 audio clock master mode is selected, and AFAUTO register is set to "1", TW2964 set up ACKI register by AFMD register value automatically. ACKI control input in ACKG module block is automatically set up to the required value by the condition of AFS384 and AFS384 register value.

AFAUTO	AFMD	ACKG MODULE ACKI CONTROL INPUT VALUE
1	0	8kHz mode value by each AFS384/AIN5MD case.
1	1	16kHz mode value by each AFS384/AIN5MD case.
1	2	32kHz mode value by each AFS384/AIN5MD case.
1	3	44.1kHz mode value by each AFS384/AIN5MD case.
1	4	48kHz mode value by each AFS384/AIN5MD case.

## Two-wire Serial Bus Interface

FIGURE 27. DEFINITION OF THE SERIAL BUS INTERFACE BUS START AND STOP

FIGURE 28. ONE COMPLETE REGISTER READ SEQUENCE VIA THE SERIAL BUS INTERFACE

FIGURE 29. ONE COMPLETE REGISTER WRITE SEQUENCE VIA THE SERIAL BUS INTERFACE

The two wire serial bus interface is used to allow an external micro-controller to write control data to, and read control or other information from the TW2964 registers. SCLK is the serial clock and SDAT is the data line. Both lines are pulled high by resistors connected to VDD0. ICs communicate on the bus by pulling SCLK and SDAT low through open drain outputs. In normal operation the master generates all clock pulses, but control of the SDAT line alternates back and forth between the master and the slave. For both read and write, each byte is transferred MSB first, and the data bit is valid whenever SCLK is high.

The TW2964 is operated as a bus slave device. It can be programmed to respond to one of two 7-bit slave device addresses by tying the SIAD[1:0] (Serial Interface Address) pins to either VDD00 or VSS (See below Table) through a pull-up or pull-down resistor. The SIAD[1:0] pins are multi-purpose pins and must not tied to supply voltage or ground directly. If the SIAD[1:0] pins are tied to VDD0, then the least significant 2-bit of the 7-bit address is a “11”. If the SIAD[1:0] pins are tied to VSS then the least significant 2-bit of the 7-bit address is a “00”. The most significant 5-bits are fixed. The 7-bit address field is concatenated with the read/write control bit to form the first byte transferred during a new transfer. If the read/write control bit is high the next byte will be read from the slave device. If it is low the next byte will be a write to the slave. When a bus master (the host microprocessor) drives SDAT from high to low, while SCLK is high, this is defined to be a start condition (See Figure 27). All slaves on the bus listen to determine when a start condition has been asserted.

After a start condition, all slave devices listen for their device addresses. The host then sends a byte consisting of the 7-bit slave device ID and the R/W bit. This is shown in Figure 28. (For the TW2964, the next byte is normally the index to the TW2964 registers and is a write to the TW2964 therefore the first R/W bit is normally low.)

After transmitting the device address and the R/W bit, the master must release the SDAT line while holding SCLK low, and wait for an acknowledgement from the slave. If the address matches the device address of a slave, the slave will respond by driving the SDAT line low to acknowledge the condition. The master will then continue with the next 8-bit transfer. If no device on the bus responds, the master transmits a stop condition and ends the cycle. Notice that a successful transfer always includes nine clock pulses.

To write to the internal register of the TW2964, the master sends another 8-bits of data, the TW2964 loads this to the register pointed by the internal index register. The TW2964 will acknowledge the 8-bit data transfer and automatically increment the index in preparation for the next data. The master can do multiple writes to the TW2964 if they are in ascending sequential order. After each 8-bit transfer, the TW2964 will acknowledge the receipt of the 8-bits with an acknowledge pulse. To end all transfers to the TW2964 the host will issue a stop condition.

SERIAL BUS INTERFACE 7-BIT SLAVE ADDRESS							READ/WRITE BIT
0	1	0	1	0	SIAD[1]	SIAD[0]	1=Read 0=Write

A TW2964 read cycle has two phases. The first phase is a write to the internal index register. The second phase is the read from the data register. (See FIGURE 28). The host initiates the first phase by sending the start condition. It then sends the slave device ID together with a 0 in the R/W bit position. The index is then sent followed by either a stop condition or a second start condition. The second phase starts with the second start condition. The master then resends the same slave device ID with a 1 in the R/W bit position to indicate a read. The slave will transfer the contents of the desired register. The master remains in control of the clock. After transferring eight bits, the slave releases and the master takes control of the SDAT line and acknowledges the receipt of data to the slave. To terminate the last transfer the master will issue a negative acknowledge (SDAT is left high during a clock pulse) and issue a stop condition.

### Interrupt Interface

The TW2964 provides the interrupt request function using an IRQ pin so that the host does not need to waste much resource to detect video or audio signal from TW2964. To use interrupt request function, the interrupt request should be enabled by the IRQENA and polarity of the IRQ pin should be selected by the IRQPOL. In addition, each channel of video and audio detection should be enabled by the AVDET\_ENA. Then, the interrupt mode should be defined by the VDET\_MODE and ADET\_MODE that control the time to request interrupt and set the status register AVDET\_STATE. Figure 30 shows operation of interrupt when the VDET\_MODE and/or ADET\_MODE are 2 and 3. The IRQ pin is cleared automatically by reading the AVDET\_STATE. When the VDET\_MODE and/or ADET\_MODE are 1 or 2, the status register AVDET\_STATE will also be cleared automatically by reading AVDET\_STATE. However, when the VDET\_MODE and/or ADET\_MODE are 3, the status register AVDET\_STATE will not be cleared automatically, but has the same value as actual status of video and audio detection flag.

## Clock PLL

The TW2964 has built-in clock PLL. It generates 108MHz clock and 144MHz clock from 27MHz input reference clock.

## XTI Clock Input

If XTI input needs special x2(54MHz or 72MHz),x4(108MHz or 144MHz) frequency, {MPP2,MPP1} pin pull-down setting during RSTB = 0 period support up to 400kbps two wire serial bus speed at all x1/x2/x4 XTI input mode.

MPP2	MPP1	SYSTEM CLOCK OF TWO WIRE SERIAL BUS INTERFACE	REQUIRED XTI INPUT FREQUENCY
NC	NC	XTI	X1(27MHz or 36MHz)
NC	Pull-down	XTI/2	X2(54MHz or 72MHz)
Pull-down	NC	XTI/4	X4(108MHz or 144MHz)

Some normal functions are not available when XTI=27MHz is not used.
