

3A, 1MHz, 6V CMCOT Synchronous Step-Down Converter

General Description

The RT5797A is a high efficiency synchronous stepdown DC-DC converter. Its input voltage range is from 2.7V to 6V and provides an adjustable regulated output voltage from 0.6V to 3.4V while delivering up to 3A of output current.

The internal synchronous low on-resistance power switches increase efficiency and eliminate the need for an external Schottky diode. The Current Mode Constant-On-time (CMCOT) operation with internal compensation allows the transient response to be optimized over a wide range of loads and output capacitors. The RT5797A is available in the WDFN-8L 2x2 and WDFN-8SL 2x2 packages.

Ordering Information

Note:

Richtek products are:

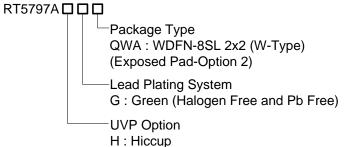

- ▶ RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- ▶ Suitable for use in SnPb or Pb-free soldering processes.

Features

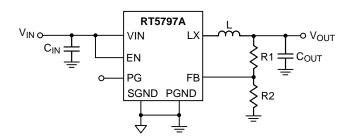

- Efficiency Up to 95%
- $R_{DS(ON)}$ 100m Ω HS / 70m Ω LS
- V_{IN} Range 2.7V to 6V
- V_{REF} 0.6V with ±1% Accuracy at 25°C
- CMCOT[™] Control Loop Design for Best Transient Response, Robust Loop Stability with Low-ESR (MLCC) C_{OUT}
- Soft-Start 1.2ms
- Power Saving in Light Load

Applications

- STB, Cable Modem, & xDSL Platforms
- LCD TV Power Supply & Metering Platforms
- General Purpose Point of Load (POL)

Simplified Application Circuit

Functional Pin Description

Pin No.		
WDFN-8L 2x2 WDFN-8SL 2x2	Pin Name	Pin Function
1	FB	Feedback voltage input. An external resistor divider from the output to GND, tapped to the FB pin, sets the output voltage.
2	PG	Power good indicator. The output of this pin is an open-drain with external pull-up resistor. PG is pulled up when the FB voltage is within 90%, otherwise it is LOW.
3	VIN	Supply voltage input. The RT5797A operates from a 2.7V to 6V input.
4, 9 (Exposed Pad)	PGND	Power ground. The exposed pad must be soldered to a large PCB and connected to PGND for maximum power dissipation.
5	NC	No internal connection.
6	LX	Switch node.
7	EN	Enable control input.
8	SGND	Signal GND.

Functional Block Diagram

Operation

The RT5797A is a synchronous low voltage step-down converter that can support the input voltage range from 2.7V to 6V and the output current can be up to 3A. The RT5797A uses a constant on-time, current mode architecture. In normal operation, the high side P-MOSFET is turned on when the switch controller is set by the comparator and is turned off when the Ton comparator resets the switch controller.

Low side MOSFET peak current is measured by internal RSENSE. The error amplifier EA adjusts COMP voltage by comparing the feedback signal (V_{FB}) from the output voltage with the internal 0.6V reference. When the load current increases, it causes a drop in the feedback voltage relative to the reference, then the COMP voltage rises to allow higher inductor current to match the load current.

UV Comparator

If the feedback voltage (VFB) is lower than threshold voltage 0.2V, the UV comparator's output will go high and the switch controller will turn off the high side MOSFET. The output under voltage protection is designed to operate in Hiccup mode for the RT5797AH, Latch mode for the RT5797AL.

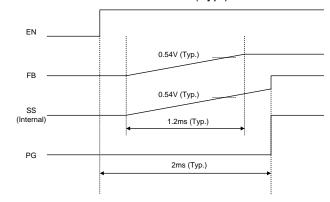

Soft-Start (SS)

An internal current source charges an internal capacitor to build the soft-start ramp voltage. The V_{FB} voltage will

track the internal ramp voltage during soft-start interval. The typical soft-start time is 1.2ms.

PGOOD Comparator

When the feedback voltage (V_{FB}) is higher than threshold voltage 0.54V and the internal soft-start function has been finished, the PGOOD open drain output will be high impedance. The internal PG MOSFET is typical 100Ω . The PGOOD signal delay time is defined from EN high to the internal soft-start function end which is about 2ms (Typ.).

Enable Comparator

A logic-high enables the converter; a logic-low forces the IC into shutdown mode.

Over-Current Protection (OCP)

The RT5797A provides over-current protection by detecting low side MOSFET valley inductor current. If

Copyright © 2021 Richtek Technology Corporation. All rights reserved.

the sensed valley inductor current is over the current limit threshold (3.7A typ.), the OCP will be triggered. When OCP is tripped, the RT5797A will keep the over current threshold level then cause the UV protection.

Thermal Shutdown (OTP)

The device implements an internal thermal shutdown function when the junction temperature exceeds 150°C. The thermal shutdown forces the device to stop switching when the junction temperature exceeds the thermal shutdown threshold. Once the die temperature decreases below the hysteresis of 20°C, the device reinstates the power up sequence.

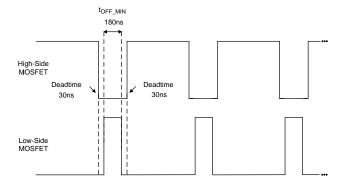

Maximum Duty Cycle

The maximum duty cycle (70%, min.) can be calculated by minimum off time (180ns, max.), dead time (60ns, max.) and switching frequency (1.2MHz, max.).

$$D_{MAX} = 1 - (t_{OFF_MIN} + t_{D}) x f_{SW}$$

Where $t_{\text{OFF_MIN}}$ is minimum off time, t_{D} is dead time and f_{SW} is switching frequency.

If input voltage and output voltage are closed, RT5797A operates at high duty cycle. Once the operational duty cycle is larger than the maximum duty cycle (70%, min.), RT5797A keeps minimum off time (180ns, max.) and deadtime (60ns, max.), then the output voltage starts to drop. The input voltage at which the devices enter dropout changes depending on the input voltage, output voltage, switching frequency, load current, and the efficiency of the design.

- Note 1. Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
- Note 2. θJA is measured under natural convection (still air) at TA = 25°C with the component mounted on a high effective-thermalconductivity four-layer test board on a JEDEC 51-7 thermal measurement standard.
- Note 3. Devices are ESD sensitive. Handling precaution recommended.
- Note 4. The device is not guaranteed to function outside its operating conditions.
- Note 5. Guaranteed by design.

Application Information

The RT5797A is a single-phase step-down converter. It provides single feedback loop constant on-time, current mode control with fast transient response. An internal 0.6V reference allows the output voltage to be precisely regulated for low output voltage applications. A fixed switching frequency (1MHz) oscillator and internal compensation are integrated to minimize external component count. Protection features include over current protection, under voltage protection and over temperature protection.

Output Voltage Setting

Connect a resistive voltage divider at the FB between VouT and GND to adjust the output voltage. The output voltage is set according to the following equation:

$$V_{OUT} = V_{REF} \times \left(1 + \frac{R1}{R2}\right)$$

where V_{REF} is the feedback reference voltage 0.6V (typ.).

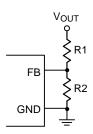

Figure 1. Setting VouT with a Voltage Divider

Chip Enable and Disable

The EN pin allows for power sequencing between the controller bias voltage and another voltage rail. The RT5797A remains in shutdown if the EN pin is lower than 400mV. When the EN pin rises above the V_{EN} trip point, the RT5797A begins a new initialization and soft-start cycle.

Enable disable falling time slew rate should be large than $1mV/\mu s$.

Internal Soft-Start

The RT5797A provides an internal soft-start function to prevent large inrush current and output voltage overshoot when the converter starts up. The soft-start (SS) automatically begins once the chip is enabled.

During soft-start, the internal soft-start capacitor becomes charged and generates a linear ramping up voltage across the capacitor. This voltage clamps the voltage at the FB pin, causing PWM pulse width to increase slowly and in turn reduce the input surge current. The internal 0.6V reference takes over the loop control once the internal ramping-up voltage becomes higher than 0.6V.

Over-Voltage Protection (OVP)

The RT5797AL provide Over-Voltage Protection function when output voltage over 120%. The IC will be into Latch-off mode.

UVLO Protection

The RT5797A has input Under-Voltage Lockout protection (UVLO). If the input voltage exceeds the UVLO rising threshold voltage (2.25V typ.), the converter resets and prepares the PWM for operation. If the input voltage falls below the UVLO falling threshold voltage during normal operation, the device will stop switching. The UVLO rising and falling threshold voltage has a hysteresis to prevent noise-caused reset.

Input Capacitor Selection

High quality ceramic input decoupling capacitor, such as X5R or X7R, with values greater than $22\mu F$ are recommended for the input capacitor. The X5R and X7R ceramic capacitors are usually selected for power regulator capacitors because the dielectric material has less capacitance variation and more temperature stability.

Voltage rating and current rating are the key parameters when selecting an input capacitor. Generally, selecting an input capacitor with voltage rating 1.5 times greater than the maximum input voltage is a conservatively safe design.

The input capacitor is used to supply the input RMS current, which can be approximately calculated using the following equation:

$$I_{IN_RMS} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)}$$

Copyright © 2021 Richtek Technology Corporation. All rights reserved.

The next step is selecting a proper capacitor for RMS current rating. One good design uses more than one capacitor with low equivalent series resistance (ESR) in parallel to form a capacitor bank.

The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be approximately calculated using the following equation:

$$\Delta V_{IN} = \frac{I_{OUT(MAX)}}{C_{IN} \times f_{SW}} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)$$

Output Capacitor Selection

The output capacitor and the inductor form a low pass filter in the Buck topology. In steady state condition, the ripple current flowing into/out of the capacitor results in ripple voltage. The output voltage ripple (V_{P-P}) can be calculated by the following equation:

$$V_{P_P} = LIR \times I_{LOAD(MAX)} \times \left(ESR + \frac{1}{8 \times C_{OUT} \times f_{SW}}\right)$$

When load transient occurs, the output capacitor supplies the load current before the controller can respond. Therefore, the ESR will dominate the output voltage sag during load transient. The output voltage undershoot (V_{SAG}) can be calculated by the following equation :

$$V_{SAG} = \Delta I_{LOAD} \times ESR$$

For a given output voltage sag specification, the ESR value can be determined.

Another parameter that has influence on the output voltage sag is the equivalent series inductance (ESL). The rapid change in load current results in di/dt during transient. Therefore, the ESL contributes to part of the voltage sag. Using a capacitor with low ESL can obtain better transient performance. Generally, using several capacitors connected in parallel can have better transient performance than using a single capacitor for the same total ESR.

Inductor Selection

The switching frequency (on-time) and operating point (% ripple or LIR) determine the inductor value as shown below:

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{f_{SW} \times LIR \times I_{LOAD(MAX)} \times V_{IN}}$$

where LIR is the ratio of the peak-to-peak ripple current to the average inductor current.

Find a low loss inductor having the lowest possible DC resistance that fits in the allotted dimensions. The core must be large enough not to saturate at the peak inductor current (IPEAK):

$$I_{PEAK} = I_{LOAD(MAX)} + \left(\frac{LIR}{2} \times I_{LOAD(MAX)}\right)$$

The calculation above serves as a general reference. To further improve transient response, the output inductor can be further reduced. This relation should be considered along with the selection of the output capacitor.

Inductor saturation current should be chosen over IC's current limit.

Thermal Considerations

The junction temperature should never exceed the absolute maximum junction temperature $T_{J(MAX)}$, listed under Absolute Maximum Ratings, to avoid permanent damage to the device. The maximum allowable power dissipation depends on the thermal resistance of the IC package, the PCB layout, the rate of surrounding airflow, and the difference between the junction and ambient temperatures. The maximum power dissipation can be calculated using the following formula :

$$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$$

where $T_{J(MAX)}$ is the maximum junction temperature, T_A is the ambient temperature, and θ_{JA} is the junction-to-ambient thermal resistance.

For continuous operation, the maximum operating junction temperature indicated under Recommended Operating Conditions is 125°C. The junction-to-ambient thermal resistance, θ_{JA} , is highly package dependent. For a WDFN-8L 2x2 package, the thermal resistance, θ_{JA} , is 45.5°C $\!\!\!/\!\!\!/\!\!\!/$ W on a standard JEDEC 51-7 high effective-thermal-conductivity four-layer test board. For a WDFN-8SL 2x2 package, the thermal resistance, θ_{JA} , is 45.6°C $\!\!\!/\!\!\!\!/\!\!\!/\!\!\!\!/$ W on a standard JEDEC 51-7 high effective-thermal-conductivity four-layer test board. The maximum power dissipation at $T_A=25$ °C can be calculated as below :

 $P_{D(MAX)} = (125^{\circ}C - 25^{\circ}C) / (45.5^{\circ}C /W) = 2.19W$ for a WDFN-8L 2x2 package.

 $P_{D(MAX)} = (125^{\circ}C - 25^{\circ}C) / (45.6^{\circ}C /W) = 2.19W$ for a WDFN-8SL 2x2 package.

The maximum power dissipation depends on the operating ambient temperature for the fixed $T_{J(MAX)}$ and the thermal resistance, θ_{JA} . The derating curve in allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

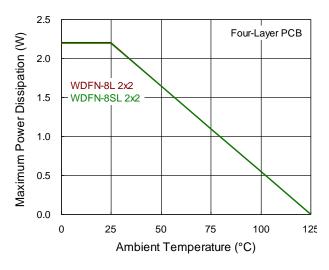

Figure 2. Derating Curve of Maximum Power

Dissipation

Layout Considerations

For best performance of the RT5797A, the following layout guidelines must be strictly followed.

- ▶ Input capacitor must be placed as close to the IC as possible.
- ► LX should be connected to inductor by wide and short trace. Keep sensitive components away from this trace.
- Keep every trace connected to pin as wide as possible for improving thermal dissipation.
- ► The feedback components must be connected as close to the device as possible. Keep sensitive component away.
- ▶ Via can help to reduce power trace and improve thermal dissipation.

The feedback components must be connected as close to the device as possible. Keep sensitive component away.
