## Synchronous Boost Converter with Voltage Detector

## General Description

The RT9276 is a synchronous boost converter, which is based on a fixed frequency Pulse-Width-Modulation (PWM) controller using a synchronous rectifier to obtain maximum efficiency. The converter provides a power supply solution for products powered by a variety of batteries such as single cell, dual cell alkaline, NiMH and NiCd battery. At light load currents, the converter enters power save mode to maintain a high efficiency over a wide load current range.

The output voltage can be programmed by an external resistor divider, or fixed at a certain voltage. Moreover, the converter can be disabled to minimize battery drain. During shutdown, the load is completely disconnected from the battery. The maximum peak current in the boost switch is limited to 2A for current limit.

For the RT9276, a low-EMI mode is implemented to reduce ringing of the inductor phase pin when the converter enters discontinuous conduction mode. Moreover, a voltage detector is built-in in the chip for low battery detection.

                50:5.0V
```

                    Note :
    Richtek products are :

- RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- Suitable for use in SnPb or Pb-free soldering processes.

## Features

- True Load Disconnection During Shutdown
- Internal Synchronous Rectifier
- Up to 96\% Efficiency
- Current Mode PWM Operation with Internal Compensation
- Low Start-Up Voltage
- Low Quiescent Current
- Internal Soft-Start Control
- Low Battery Comparator
- Low EMI Converter (Anti-Ringing)
- Power Save Mode for Improved Efficiency at Light Load Current
- Over Current Protection
- Short Circuit Protection
- Over Temperature Protection
- Over Voltage Protection
- Small WDFN-10L 3x3 Package
- RoHS Compliant and Halogen Free

## Applications

- All One-Cell, Two-Cell and Three-Cell Alkaline, NiCd, NiMH and Single-Cell Li Batteries
- Hand-Held Devices
- WLED Flash Light

Note 1. Stresses beyond those listed "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
Note 2. $\theta_{\mathrm{JA}}$ is measured at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ on a high effective thermal conductivity four-layer test board per JEDEC 51-7. $\theta_{\mathrm{Jc}}$ is measured at the exposed pad of the package.
Note 3. Devices are ESD sensitive. Handling precaution is recommended.
Note 4. The device is not guaranteed to function outside its operating conditions.

## Application Information

The RT9276 integrates a high efficiency synchronous stepup DC-DC converter and a low battery detector. To fully utilize its advantages, peripheral components should be appropriately selected. The following information provides detailed description of application.

## Inductor Selection

For a better efficiency in high switching frequency converter, the inductor selection has to use a proper core material such as ferrite core to reduce the core loss and choose low ESR wire to reduce copper loss. The most important point is to prevent core saturation when handling the maximum peak current. Using a shielded inductor can minimize radiated noise in sensitive applications. The maximum peak inductor current is the maximum input current plus half of the inductor ripple current. The calculated peak current has to be smaller than the current limitation in the electrical characteristics. A typical setting of the inductor ripple current is $20 \%$ to $40 \%$ of the maximum input current. If the selection is $40 \%$

$$
\begin{aligned}
\mathrm{I}_{\mathrm{PK}} & =\mathrm{I}_{\mathrm{IN}(\mathrm{MAX})}+\frac{1}{2} \mathrm{I}_{\mathrm{RIPPLE}}=1.2 \times \mathrm{I}_{\mathrm{IN}(\mathrm{MAX})} \\
& =1.2 \times\left[\frac{\mathrm{IOUT}^{\mathrm{MAX})} \times \mathrm{V}_{\mathrm{OUT}}}{\eta \times \mathrm{V}_{\mathrm{BAT}(\mathrm{MIN})}}\right]
\end{aligned}
$$

The minimum inductance value is derived from the following equation:
$\mathrm{L}=\frac{\eta \times \mathrm{I}_{\mathrm{IN}(\mathrm{MIN})}{ }^{2} \times\left[\mathrm{V}_{\mathrm{OUT}}-\mathrm{V}_{\mathrm{BAT}(\mathrm{MIN})}\right]}{0.4 \times \operatorname{loUT}(\mathrm{MAX}) \times \mathrm{V}_{\mathrm{OUT}^{2}} \times \mathrm{f}_{\mathrm{LX}}}$
Depending on the application, the recommended inductor value is between $2.2 \mu \mathrm{H}$ and $10 \mu \mathrm{H}$.

## Input Capacitor Selection

For better input bypassing, low-ESR ceramic capacitors are recommended for performance. A $10 \mu \mathrm{~F}$ input capacitor is sufficient for most applications. For a lower output power requirement application, this value can be decreased

## Output Capacitor Selection

For lower output voltage ripple, low ESR ceramic capacitors are recommended. The tantalum capacitors can be used as well, but their ESR is bigger than ceramic capacitors. The output voltage ripple consists of two components:
one is the pulsating output ripple current which flows through the ESR, and the other is the capacitive ripple caused by charging and discharging.

$$
\begin{aligned}
& \mathrm{V}_{\text {RIPPLE }}=\mathrm{V}_{\text {RIPPLE }}(E S R)+\mathrm{V}_{\text {RIPPLE }}(\mathrm{C})
\end{aligned}
$$

## Output Voltage Setting

Referring to application circuit (Figure 1), the output voltage of the switching regulator ( $\mathrm{V}_{\text {OUT }}$ ) can be set with below equation :
$V_{\text {OUT }}=\left(1+\frac{\mathrm{R} 3}{\mathrm{R} 4}\right) \times \mathrm{V}_{\mathrm{FB}}$
where $\mathrm{V}_{\mathrm{FB}}=0.5 \mathrm{~V}$ (typ.)
When the input voltage is larger than output setting voltage 370 mV (typ.) the RT9276 will be in pre-charge mode. During pre-charge phase, the synchronous P-MOSFET is turned on until the output capacitor is charged to a value close to the input voltage minus 0.2 V . Then the converter is followed by PWM operation. The adaptive precharge current increases linearly to overcome the loading current in the pre-charge phase. If the loading current is larger than pre-charge current, the RT9276 will be in precharge mode until loading current is removed or reduced.

## Low Battery Voltage Detector

The low battery voltage detector is designed to monitor the battery voltage and to generate an error flag when the battery voltage drops below a user-set threshold voltage. The function is active only when the device is enabled. When the device is disabled, the LBO pin is in high impedance. The LBI threshold voltage is 0.5 V typically, with 10 mV hysteresis voltage. If the low-battery detection circuit is not used, the LBI pin should be connected to GND (or to $\mathrm{V}_{\mathrm{BAT}}$ ) and the LBO pin can be left unconnected. Do not let the LBI pin floating.

## Thermal Considerations

For continuous operation, do not exceed absolute maximum operation junction temperature. The maximum power dissipation depends on the thermal resistance of IC package, PCB layout, the rate of surroundings airflow and temperature difference between junction to ambient.

The maximum power dissipation can be calculated by following formula :
$P_{D(\text { MAX })}=\left(T_{J(M A X)}-T_{A}\right) / \theta_{J A}$
where $T_{J(M A X)}$ is the maximum operation junction temperature, $\mathrm{T}_{\mathrm{A}}$ is the ambient temperature and the $\theta_{\mathrm{JA}}$ is the junction to ambient thermal resistance.

For recommended operating conditions specification, the maximum junction temperature is $125^{\circ} \mathrm{C}$. The junction to ambient thermal resistance $\theta_{\mathrm{JA}}$ is layout dependent. For WDFN-10L $3 x 3$ package, the thermal resistance $\theta_{\mathrm{JA}}$ is $70^{\circ} \mathrm{C} / \mathrm{W}$ on a standard JEDEC 51-7 four- layer thermal test board. The maximum power dissipation at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ can be calculated by the following formula :
$P_{D(\text { MAX })}=\left(125^{\circ} \mathrm{C}-25^{\circ} \mathrm{C}\right) /\left(70^{\circ} \mathrm{C} / \mathrm{W}\right)=1.429 \mathrm{~W}$ for WDFN-10L $3 x 3$ packages

The maximum power dissipation depends on operating ambient temperature for fixed $\mathrm{T}_{\mathrm{J}(\mathrm{MAX})}$ and thermal resistance $\theta_{\mathrm{JA}}$. The Figure 5 of derating curves allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Figure 5. Derating Curve of Maximum Power Dissipation

## Layout Consideration

For best performance of the RT9276, the following layout guidelines must be strictly followed :

- Input and Output capacitors should be placed close to the IC and connected to ground plane to reduce noise coupling.
- The GND and Exposed Pad should be connected to a strong ground plane for heat sinking and noise protection.
- Keep the main current traces as short and wide as possible.
- Place the feedback components as close as possible to the IC and keep away from the noisy devices.
