

# 1.1MHz, Precision, Rail-to-Rail I/O CMOS Operational Amplifier

## FEATURES

- **HIGH GAIN BANDWIDTH: 1.1MHz**
- **RAIL-TO-RAIL INPUT AND OUTPUT**  
 $\pm 0.5\text{mV Max } V_{os}$  (RS6331P, RS6332P)  
 $\pm 0.8\text{mV Max } V_{os}$  (RS6334P)
- **INPUT VOLTAGE RANGE: -0.1V to +5.6V**  
with  $V_s = 5.5\text{V}$
- **SUPPLY RANGE: +2.1V to +5.5V**
- **SPECIFIED UP TO +125°C**
- **Micro SIZE PACKAGES: SOT23-5, SOT353(SC70-5)**

## APPLICATIONS

- **SENSORS**
- **PHOTODIODE AMPLIFICATION**
- **ACTIVE FILTERS**
- **TEST EQUIPMENT**
- **DRIVING A/D CONVERTERS**

## DESCRIPTION

The RS6331P, RS6332P, RS6334P families of products offer low voltage operation and rail-to-rail input and output, as well as excellent speed/power consumption ratio, providing an excellent bandwidth (1.1MHz) and slew rate of 0.5V/us. The op-amps are unity gain stable and feature an ultra-low input bias current.

The RS6331P, RS6332P and RS6334P has lower offset, which is guaranteed not upper than  $\pm 0.5\text{mV}$  (RS6331P, RS6332P) /  $\pm 0.8\text{mV}$  (RS6334P) at 25°C with  $V_s = 5\text{V}$ ,  $V_{CM} = V_s/2$ .

The devices are ideal for sensor interfaces, active filters and portable applications. The RS6331P, RS6332P, RS6334P families of operational amplifiers are specified at the full temperature range of -40°C to +125°C under single supplies of 2.1V to 5.5V or dual power supplies of  $\pm 1.05\text{V}$  to  $\pm 2.75\text{V}$ .

## Detailed Description

### Overview

The RS633XP devices are unity-gain stable, dual and quad-channel op amps with low noise and distortion. The device consists of a low noise input stage with a folded cascade and a rail-to-rail output stage. This topology exhibits superior noise and distortion performance across a wide range of supply voltages that are not delivered by legacy commodity audio operational amplifiers.

### Phase Reversal Protection

The RS633XP family has internal phase-reversal protection. Many op amps exhibit phase reversal when the input is driven beyond the linear common-mode range. This condition is most often encountered in noninverting circuits when the input is driven beyond the specified common-mode voltage range, causing the output to reverse into the opposite rail. The input of the RS633XP prevents phase reversal with excessive common-mode voltage. Instead, the appropriate rail limits the output voltage. This performance is shown in figure 14

**Figure 14. Output Waveform Devoid of Phase Reversal During an Input Overdrive Condition**

### EMI Rejection Ratio (EMIRR)

The electromagnetic interference (EMI) rejection ratio, or EMIRR, describes the EMI immunity of operational amplifiers. An adverse effect that is common to many operational amplifiers is a change in the offset voltage as a result of RF signal rectification. An operational amplifier that is more efficient at rejecting this change in offset as a result of EMI has a higher EMIRR and is quantified by a decibel value. Measuring EMIRR can be performed in many ways, but this document provides the EMIRR IN+, which specifically describes the EMIRR performance when the RF signal is applied to the noninverting input pin of the operational amplifier. In general, only the noninverting input is tested for EMIRR for the following three reasons:

- Operational amplifier input pins are known to be the most sensitive to EMI, and typically rectify RF signals better than the supply or output pins.
- The noninverting and inverting operational amplifier inputs have symmetrical physical layouts and exhibit nearly matching EMIRR performance.
- EMIRR is easier to measure on noninverting pins than on other pins because the noninverting input pin can be isolated on a printed-circuit-board (PCB). This isolation allows the RF signal to be applied directly to the noninverting input pin with no complex interactions from other components or connecting PCB traces.

## Detailed Description (continued)

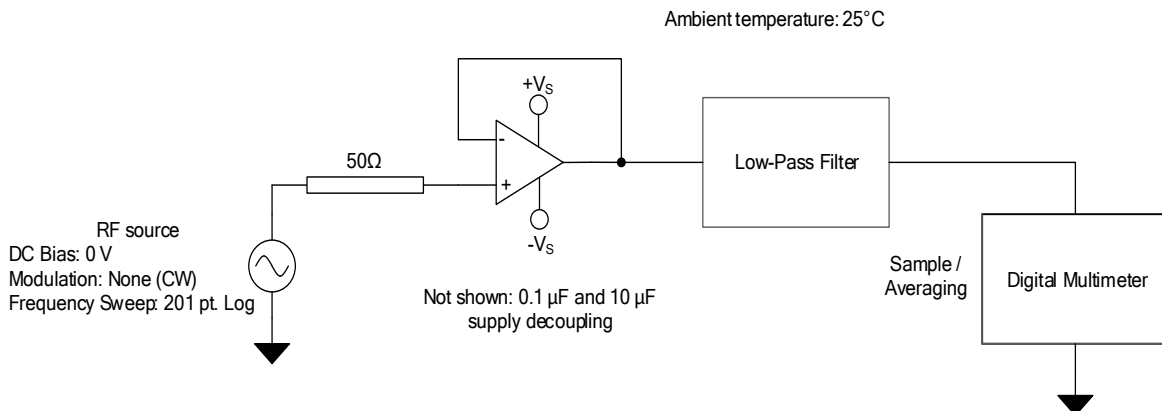

The EMIRR IN+ of the RS633XP is plotted versus frequency in Figure 15. If available, any dual and quad operational amplifier device versions have approximately identical EMIRR IN+ performance. The RS633XP unity-gain bandwidth is 1.1MHz. EMIRR performance below this frequency denotes interfering signals that fall within the operational amplifier bandwidth.

**Figure 15. RS633XP EMIRR vs Frequency**

## EMIRR IN+ Test Configuration

Figure 16 shows the circuit configuration for testing the EMIRR IN+. An RF source is connected to the operational amplifier noninverting input pin using a transmission line. The operational amplifier is configured in a unity-gain buffer topology with the output connected to a low-pass filter (LPF) and a digital multimeter (DMM). A large impedance mismatch at the operational amplifier input causes a voltage reflection; however, this effect is characterized and accounted for when determining the EMIRR IN+. The resulting dc offset voltage is sampled and measured by the multimeter. The LPF isolates the multimeter from residual RF signals that can interfere with multimeter accuracy.

**Figure 16. EMIRR IN+ Test Configuration Schematic**

## APPLICATION NOTES

The RS6331P, RS6332P, RS6334P are high precision, rail-to-rail operational amplifiers that can be run from a single-supply voltage 2.1V to 5.5V ( $\pm 1.05V$  to  $\pm 2.75V$ ). Supply voltages higher than 7V (absolute maximum) can permanently damage the amplifier. Rail-to-rail input and output swing significantly increases dynamic range, especially in low-supply applications. Good layout practice mandates use of a 0.1 $\mu F$  capacitor place closely across the supply pins.

### Typical Applications

#### 25-kHz Low-pass Filter

**Figure 17. 25-kHz Low-Pass Filter**

#### Design Requirements

Low-pass filters are commonly employed in signal processing applications to reduce noise and prevent aliasing. The RS633XP devices are ideally suited to construct high-speed, high-precision active filters. Figure 17 shows a second-order, low-pass filter commonly encountered in signal processing applications.

Use the following parameters for this design example:

- Gain = 5 V/V (inverting gain)
- Low-pass cutoff frequency = 25 kHz
- Second-order Chebyshev filter response with 3-dB gain peaking in the passband

#### Detailed Design Procedure

The infinite-gain multiple-feedback circuit for a low-pass network function is shown in Figure 17. Use Equation 1 to calculate the voltage transfer function.

$$\frac{\text{Output}}{\text{Input}}(s) = \frac{-1/R_1 R_3 C_2 C_5}{s^2 + (s/C_2) (1/R_1 + 1/R_3 + 1/R_4) + 1/R_3 R_4 C_2 C_5} \quad (1)$$

This circuit produces a signal inversion. For this circuit, the gain at dc and the low-pass cutoff frequency are calculated by Equation 2:

$$\text{Gain} = \frac{R_4}{R_1}$$

$$f_c = \frac{1}{2\pi} \sqrt{(1/R_3 R_4 C_2 C_5)} \quad (2)$$

#### Application Curve

**Figure 18. Low pass filter transfer function**

## LAYOUT GUIDELINS

Attention to good layout practices is always recommended. Keep traces short. When possible, use a PCB ground plane with surface-mount components placed as close to the device pins as possible. Place a 0.1uF capacitor closely across the supply pins.

These guidelines should be applied throughout the analog circuit to improve performance and provide benefits such as reducing the EMI susceptibility.
