

Application Note: AN_SY8029

High Efficiency 2MHz, Dual 2A Synchronous Step Down Regulator

General Description

The SY8029 is a dual-output, high efficiency 2MHz synchronous step down DC-DC regulator IC, capable of delivering up to 2A output current each output channel. The SY8029 operates over a wide input voltage range from 2.5V to 5.5V and integrates main switch and synchronous switch with very low $R_{DS(ON)}$ to minimize the conduction loss.

Ordering Information

Ordering Number	Package type	Note
SY8029AIC	TSOT23-8	

Features

- Input range: 2.5V to 5.5V input voltage
- 2MHz switching frequency
- 180° out of phase operation
- Output current: 2A per channel
- Low Quiescent Current: <45uA for both channels
- Low $R_{DS(ON)}$ for internal switches (PFET/NFET): $125m\Omega/100m\Omega$
- Internal soft-start
- 100% dropout operation
- RoHS Compliant and Halogen Free
- Compact package: TSOT23-8

Applications

- SSD
- Cell Phones
- Digital Cameras
- PDAs
- Portable Media Players

Typical Applications

Note 1: Stresses beyond the "Absolute Maximum Ratings" may cause permanent damage to the device. These are for stress ratings. Functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may remain possibility to affect device reliability.

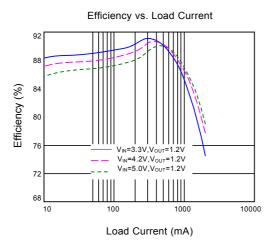

Note 2: θ JA is measured in the natural convection at $T_A = 25^{\circ}C$ on a low effective single layer thermal conductivity test board of JEDEC 51-3 thermal measurement standard.

Note 3: The device is not guaranteed to function outside its operating conditions.

Operation

The SY8029 is a dual-output, high efficiency 2MHz synchronous step down DC-DC regulator IC, capable of delivering up to 2A output current each output channel. The SY8029 operates over a wide input voltage range from 2.5V to 5.5V and integrate main switch and synchronous switch with very low $R_{DS(ON)}$ to minimize the conduction loss.

Applications Information

Because of the high integration in the SY8029 IC, the application circuit based on this regulator IC is rather simple. Only input capacitor C_{IN} , output capacitor C_{OUT} , output inductor L and feedback resistors (R1 and R2) need to be selected for the targeted applications specifications.

Feedback resistor dividers R1 and R2:

Choose R1 and R2 to program the proper output voltage. To minimize the power consumption under light loads, it is desirable to choose large resistance values for both R1 and R2. A value of between 100k and 1M is highly recommended for both resistors. If R2=120k is chosen, then R1 can be calculated to be: $r_{eff} = (V_{OUT} = 0.6 \text{ V}) \cdot (K2)$

$$\frac{(v_{\text{OUT}} - 0.6 \text{ V}) \cdot (\text{K2})}{0.6 \text{ V}}$$

Input capacitor C_{IN:}

This ripple current through input capacitor is calculated as:

$$I_{\text{CIN}_{\text{RMS}}} = I_{\text{OUT}} \times \sqrt{D(1-D)}$$

This formula has a maximum at $V_{IN}=2V_{OUT}$ condition, where $I_{CIN_RMS}=I_{OUT}/2$. This simple worst-case condition is commonly used for DC/DC design.

With the maximum load current at 2.0A. A typical X5R or better grade ceramic capacitor with 10V rating and greater than 10uF capacitance can handle this ripple current well. To minimize the potential noise problem, ceramic capacitor should be placed really close to the V_{IN} and GND pins. Care should be taken to minimize the loop area formed by C_{IN} , and V_{IN}/GND pins.

Output capacitor COUT:

The output capacitor is selected to handle the output ripple noise requirements. Both steady state ripple and transient requirements must be taken into consideration when selecting this capacitor. For the best performance, it is recommended to use X7R or better grade ceramic capacitor with 6V rating and greater than 10uF capacitance.

Output inductor L:

There are several considerations in choosing this inductor.

 Choose the inductance to provide the desired ripple current. It is suggested to choose the ripple current to be about 40% of the maximum output current. The inductance is calculated as: T Vout(1- Vout/VINMAX)

$$L = \frac{V_{OUT}(1 - V_{OUT}/V_{IN,MAX})}{F_{SW} \times I_{OUT,MAX \times 40\%}}$$

where Fsw is the switching frequency and Iout,max is the maximum load current.

The SY8029 regulator IC is quite tolerant of different ripple current amplitude. Consequently, the final choice of inductance can be slightly off the calculation value without significantly impacting the performance.

2) The saturation current rating of the inductor must be selected to be greater than the peak inductor current under full load conditions.
 Journal Journal Tournal Control VIN, MAX

2 ·Fsw·L

3) The DCR of the inductor and the core loss at the switching frequency must be low enough to achieve the desired efficiency requirement. It is desirable to choose an inductor with DCR<50mohm to achieve a good overall efficiency.

Load Transient Considerations:

The SY8029 regulator IC integrates the compensation components to achieve good stability and fast transient responses. In some applications, adding a 22pF ceramic cap in parallel with R1 may further speed up the load transient responses and is thus recommended for applications with large load transient step requirements.

Layout Design:

The layout design of SY8029 regulator is relatively simple. For the best efficiency and minimum noise problems, we should place the following components close to the IC: C_{IN} , L, R_H and R_L .

1) It is desirable to maximize the PCB copper area connecting to GND pin to achieve the best thermal and noise performance. If the board space allowed, a ground plane is highly desirable. Reasonable vias are

suggested to be placed underneath the ground pad to enhance the soldering quality and thermal performance.

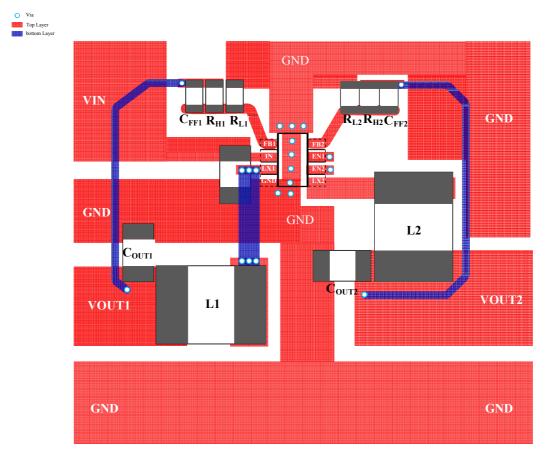

2) Input cap must be close to Pins IN and GND. The loop area formed by input cap, IN, GND must be minimized.

3) The PCB copper area associated with LX pin must be minimized to avoid the potential noise problem. For the smallest loop area of C_{IN} , IN and GND, LX pin copper can pour area on internal or bottom layer.

AN_SY8029

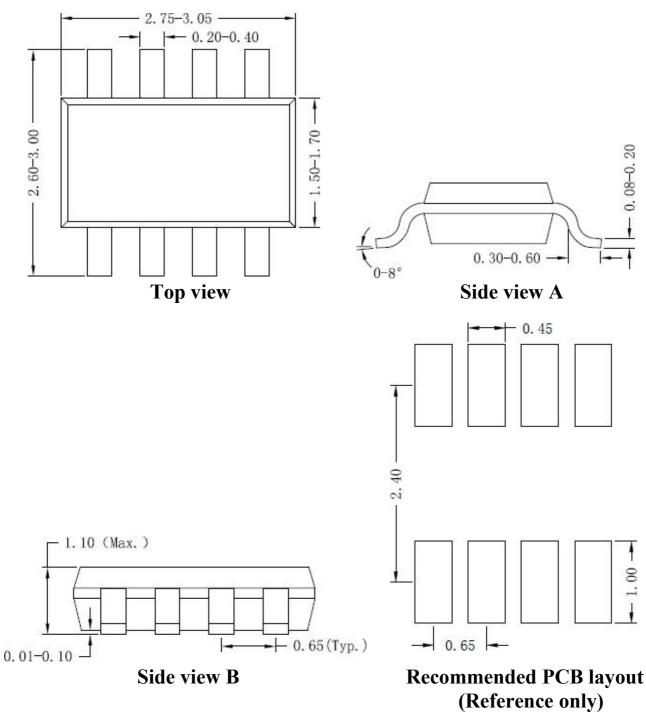

4) The components R_H and R_L , and the trace connecting to the FB pin must NOT be adjacent to the LX net on the PCB layout to avoid the noise problem.

5) If the system chip interfacing with the EN pin has a high impedance state at shutdown mode and the IN pin is connected directly to a power source such as a Li-Ion battery, it is desirable to add a pull down 1Mohm resistor between the EN and GND pins to prevent the noise from falsely turning on the regulator at shutdown mode.
