

High efficiency, high-side switch with extended diagnostics and smart driving for capacitive loads

#### **Features**

- 8V to 60V operating supply voltage range
- Smart driving of capacitive load
- · Under-voltage lock-out
- V<sub>CC</sub> over-voltage protection
- Fast demagnetization of inductive loads
- · Overload and over-temperature protection
- · Case over-temperature protection
- · Overload event diagnostic pin
- Over-temperature event diagnostic pin
- Ground disconnection protection
- Designed to meet IEC 61000-4-2, IEC 61000-4-4, IEC 61000-4-5
- Package PowerSSO-24

### **Applications**

- · Programmable logic control
- Vending machines
- Industrial PC peripheral input/output
- Numerical control machines
- · General high-side switch applications

#### Product label

#### **Description**

The IPS1025H and IPS1025H-32 are single high-side switch ICs able to drive capacitive, resistive or inductive loads with one side connected to ground.

The very low  $R_{DS-ON}$  ( $\leq 25m\Omega$  up to  $T_J$  = 125°C) makes the IC suitable for the applications with up to 2.4A/ 5.6A steady state operating current.

The output channel is protected against junction over-temperature events by a junction temperature sensor, and a further temperature sensor is included to monitor case temperature, so the overheated output channel can only be turned back ON when the case temperature returns below the reset temperature.

The embedded overload protection circuit monitors the output current and, on triggering of the activation threshold ( $I_{PK}$ ), starts modulating the impedance of the output switch to limit the output current to  $I_{LIM}$ , for both IC and load protection.

The IC offers two different sets of activation threshold and limitation levels ( $I_{PKH}$ ,  $I_{LIMH}$  and  $I_{PKL}$ ,  $I_{LIML}$ ) for smart driving of capacitive loads (such as bulb lamps) and loads with initial peak current requirements.

The IC diagnostics is based on FLT<sub>1</sub> and FLT<sub>2</sub> pins (both current source); activated by respective overload or overtemperature events on the output channel.

### 7 Protections and diagnostic

The IC integrates several protections to help the design of robust applications.

### 7.1 Under-voltage lock-out

The IC is turned off if the voltage on  $V_{CC}$  pin falls below the turn-off threshold ( $V_{UVOFF}$ ). Normal operation restarts after  $V_{CC}$  exceeds the turn-on threshold ( $V_{UVON}$ ). Turn-on and turn-off thresholds are defined in Table 4.

### 7.2 Over-temperature

The device is protected against overheating in case of overload conditions. During the driving period (when the MCU is forcing the IN pin high), if the output is overloaded, the device suffers two different thermal stresses: one related to the junction temperature of each output channel, and the other related to the whole case temperature. The two thermal faults (Thermal Junction and Thermal Case) have different trigger thresholds:  $T_{JSD}$  and  $T_{CSD}$ , respectively.

Usually, in thermal stress conditions due to overload, the junction thermal shutdown is the first protection that is activated: the output channel (OUT) is turned off when its junction temperature  $(T_J)$  is higher than the activation threshold  $(T_{JSD})$  and turned back on when it falls below the reset threshold  $(T_{JR})$ . This behavior continues while overload on the output persists. When the thermal protection is active, the FLT<sub>1</sub> (current source) becomes active accordingly.

If the thermal protection is active and the temperature of the case  $(T_C)$  increases over the case protection threshold  $(T_{CSD})$ , then the thermal case protection is activated and the output is switched off until the junction temperature and case temperature fall below their respective reset thresholds  $(T_{CR})$  and  $T_{JR}$ . The FLT<sub>1</sub> pin is active even when thermal case events occur.

Figure 7 shows the thermal protection behavior, while Figure 8 and Section 7.2 show typical temperature trends and output vs. input state.

DS13780 - Rev 1 page 12/28

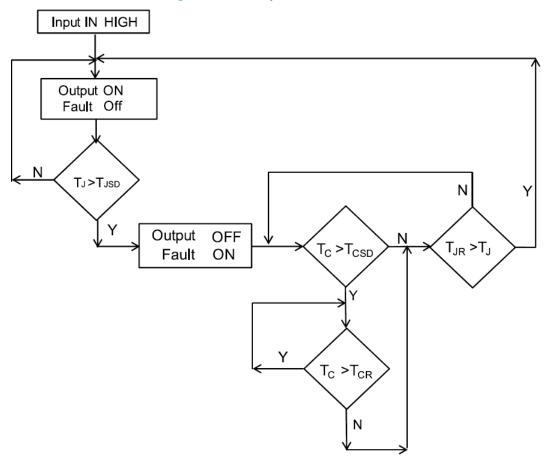

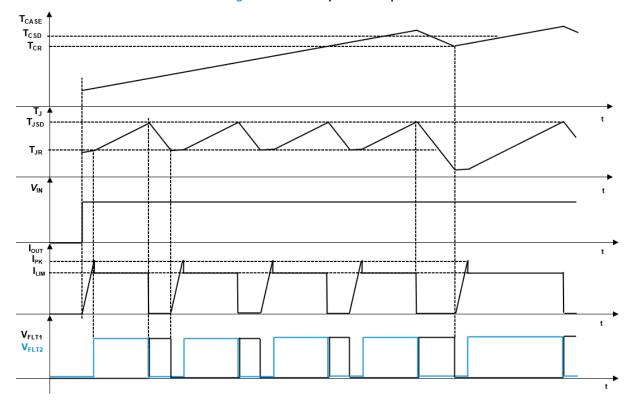

Figure 7. Thermal protection flowchart

DS13780 - Rev 1 page 13/28

#### 7.3 Overload

The IC integrates an overload protection circuit consisting of an output current sensing section and an output current limitation section.

When the output channel is ON, the sensing circuitry monitors the current supplied to the load: if the activation threshold ( $I_{PK}$ ) is triggered, then the current limitation control circuitry is activated to limit output current to the current limitation level ( $I_{LIM}$ ) and  $FLT_2$  pin is activated until the overload condition is removed.

See the following sections for details and Table 9 for specific activation thresholds and limitation levels. Note that while the output channel operates below its activation threshold, the power dissipation can be calculated by  $R_{ON} * I_{OUT}^2$ , but when the current limitation circuit is activated, power dissipation increases and can be calculated by  $V_{DS} * I_{OUT}$ , where  $V_{DS}$  is the voltage drop between the OUT and  $V_{CC}$  pins of the IC. In order to protect the IC against thermal stress, the over-temperature protection is always active and retains the highest priority.

#### 7.3.1 Overload protection with dual threshold

This case is activated when the pin  $I_{PD}$  is connected to GND by a capacitor ( $C_{PD}$ ) and the IC works with two activation thresholds  $I_{PKH}$  and  $I_{PKL}$ .

The  $I_{PKH}$  is active only in the limited time frame between the L-H transition of the IN signal and the  $D_{PK}$  delay defined by the following design rule:

$$D_{PK}[\mu s] = 215 \times CPD[nF]$$

The above design rule is valid in the range 470 pF  $\leq$  C<sub>PD</sub>  $\leq$  470 nF (see Table 9).

If the I<sub>PKH</sub> is triggered within the D<sub>PK</sub> time frame, then the output current is limited to I<sub>LIMH</sub>.

After D<sub>PK</sub> has elapsed, the IC operates with I<sub>PKL</sub> activation threshold and I<sub>LIML</sub> limitation level, respectively.

DS13780 - Rev 1 page 14/28

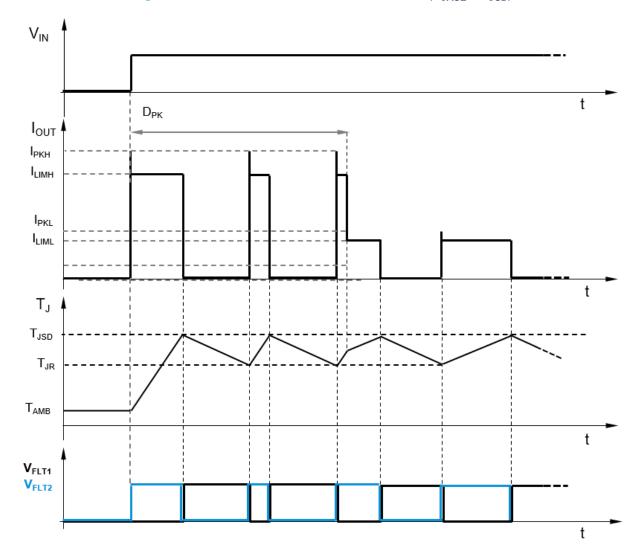

Figure 9. Short-circuit behavior with dual threshold ( $T_{CASE} < T_{CSD}$ )

#### 7.3.2 Overload protection with single (low) threshold

The user can set the activation threshold to  $I_{PKL}$  and the limitation level to  $I_{LIML}$  by connecting the  $I_{PD}$  pin to the IN pin with a 220 K $\Omega$  resistor.

This condition is equivalent to setting  $D_{PK} = 0 \mu s$ .

Note: Leaving I<sub>PD</sub> floating is equivalent to having an initial peak duration of 1 μs.

#### 7.3.3 Overload protection with single (high) threshold

The user can set the activation threshold to  $I_{PKH}$  and the limitation level to  $I_{LIMH}$  by connecting the  $I_{PD}$  pin to GND with a 10 K $\Omega$  resistor.

### 7.4 V<sub>CC</sub> disconnection protection

 $V_{CC}$  disconnection involves the disconnection of the module from the supply line. When this condition is detected, the output channel can be driven normally until the voltage on  $V_{CC}$  pin remains higher than the UVLO threshold.

In case of inductive load, if the  $V_{CC}$  is disconnected while the channel is active, the energy stored in the inductance is discharged through the power switch thanks to the integrated demagnetization circuit.

DS13780 - Rev 1 page 15/28

### 7.5 GND disconnection protection

GND disconnection is the disconnection of the module from the reference line. When this condition occurs, the output channel is turned off regardless of the input status.

When this event occurs, the IC continues working normally until the voltage between  $V_{CC}$  and GND pins of the IC results  $\geq V_{UVOFF}$ . The voltage on the GND pin of the IC rises up to the supply rail voltage level. In case of a GND disconnection event, a current ( $I_{LGND}$ ) flows through OUT pin.

For an inductive load, if the GND is disconnected while the output channel is active, the current flows through the power, which is activated by an active clamp as if the input had been deactivated.

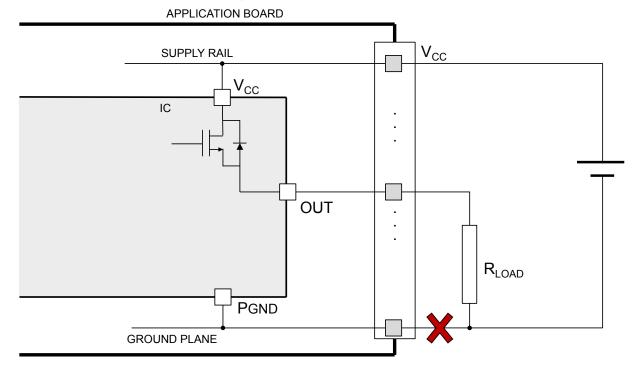

Figure 10. Ground disconnection

DS13780 - Rev 1 page 16/28

## 8 Active clamp

Active clamp is also known as Fast Demagnetization of inductive loads or Fast Current Decay. When a high-side driver turns off an inductance, an under-voltage on output is detected.

The OUT pin is pulled-down to  $V_{CC}$ - $V_{DEMAG}$ . The conduction state is modulated by an internal circuitry in order to keep the OUT pin voltage at  $\sim V_{DEMAG}$  until the load energy has been dissipated. The energy is dissipated in both IC internal switch and load resistance.

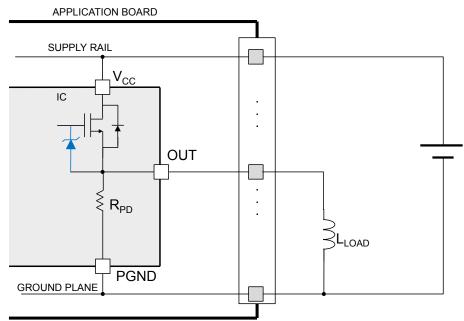

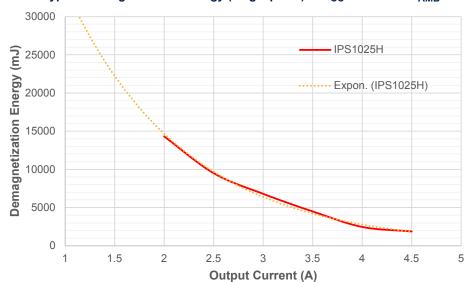

Figure 11. Active clamp equivalent principle schematic

DS13780 - Rev 1 page 17/28

## 9 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK packages, depending on their level of environmental compliance. ECOPACK specifications, grade definitions and product status are available at: www.st.com. ECOPACK is an ST trademark.
