

Automotive low drop voltage regulator

Datasheet - production data

Description

The L4993 is a monolithic integrated 5 V Voltage regulator with a low drop voltage at currents up to 150 mA. The output voltage regulating element consists in a p-channel MOS and the regulation is performed regardless of input voltage transients up to 40 V. The high precision of the output voltage is obtained with a pre-trimmed reference voltage. The L4993 is protected against short circuit and an over-temperature protection switches off the device in case of extremely high power dissipation. The L4993 watchdog is active when the Enable is high. State of the art features like reset and watchdog make this device particularly suitable to supply microprocessor systems in automotive applications.

Features

Max DC supply voltage	V_S	40 V
Max output voltage tolerance	ΔV_O	+/-2%
Max dropout voltage	V_{dp}	400 mV
Output current	I_O	150 mA
Quiescent current	I_{qn}	79 μA ⁽¹⁾

1. Typical value with watchdog disabled.

- AEC-Q100 qualified 
- Operating DC supply voltage range 5.6 V to 31 V
- Reset circuit sensing the output voltage down to 1 V
- Programmable reset pulse delay with external capacitor
- Watchdog
- Programmable watchdog timer with external
- Enable input for enabling/disabling the watchdog functionality
- Thermal shutdown and short circuit protection
- Wide temperature range ($T_j = -40^\circ C$ to $150^\circ C$)

2 Electrical specifications

2.1 Absolute maximum ratings

Stressing the device above the rating listed in [Table 3: Absolute maximum ratings](#) may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is not implied. Exposure to the conditions in the table below for extended periods may affect device reliability.

Table 3. Absolute maximum ratings

Symbol	Parameter	Value	Unit
V_{VSDC}	DC supply voltage	-0.3 to 40	V
I_{VSDC}	Input current	Internally limited	
V_{VO}	DC output voltage	-0.3 to 6 ⁽¹⁾	V
I_{VO}	DC output current	Internally limited	
V_{WI}	Watchdog input voltage	-0.3 to $V_{VO} + 0.3$	V
V_{OD}	Open drain output voltage	-0.3 to $V_{VO} + 0.3$	V
I_{OD}	Open drain output current	Internally limited	
V_{CR}	Reset delay voltage	-0.3 to $V_{VO} + 0.3$	V
V_{CW}	Watchdog delay voltage	-0.3 to $V_{VO} + 0.3$	V
V_{WEN}	Watchdog Enable input voltage	-0.3 to $V_{VO} + 0.3$	V
T_J	Junction temperature	-40 to 150	°C
V_{ESD}	ESD voltage level (HBM-MIL STD 883C)	±2	kV
V_{ESD}	ESD voltage level (CDM AEC-Q100-011)	750	V

1. Using the typical application schematic with $C_{out} = 10 \mu F$ and $I_{out} = 0 A$, when the regulator is switched-on, an overshoot exceeding 6 V could occur. This behavior does not impact the reliability of the regulator.

3 Application information

Figure 24. L4993 application schematic

Note: The input capacitor $C_s > 200 \text{ nF}$ is necessary for the smoothing of line disturbances. The output capacitor $C_{01} > 100 \text{ nF}$ is necessary for the stability of the regulation loop. In order to damp output voltage oscillations during high load current surges, it is recommended put an additional electrolytic capacitor $C_{02} > 10 \mu\text{F}$ at the output pin.

3.1 Voltage regulator

Voltage regulator uses a p-channel transistor as a regulating element. With this structure, very low dropout voltage at current up to 500 mA is obtained. The output voltage is regulated up to transient input supply voltage of 40 V. No functional interruption due to over-voltage pulses is generated. A short circuit protection to GND is provided. The voltage regulator watchdog functionality can be disabled by putting WEn low.

Figure 25. Behavior of output current versus regulated voltage Vo

3.2 Reset

The reset circuit supervises the output voltage V_o . The V_{o_th} reset threshold is defined with the internal reference voltage and a resistor output divider. If the output voltage becomes lower than V_{o_th} then Res goes low with a reaction time t_{rr} . The reset low signal is guaranteed for an output voltage V_o greater than 1 V.

When the output voltage becomes higher than V_{o_th} then Res goes high with a delay t_{rd} . This delay is obtained by an internal oscillator.

The oscillator period is given by:

$$T_{osc} = [(V_{rhth} - V_{rlth}) \times C_{tr}] / I_{cr} + [(V_{rhth} - V_{rlth}) \times C_{tr}] / I_{dr}$$

where:

- I_{cr} : is an internally generated charge current
- I_{dr} : is an internally generated discharge current
- V_{rhth} , V_{rlth} : are two voltages defined with the output voltage and a resistor output divider
- C_{tr} : is an external capacitance.

t_{rd} is given by:

$$t_{rd} = 512 \times T_{osc}$$

Reset is active when En is high.

Figure 26. Reset timing diagram

3.3 Watchdog

A connected microcontroller is monitored by the watchdog input W_i . If pulses are missing, the Reset output pin is set to low. The pulse sequence time can be set within a wide range with the external capacitor, C_{tw} . The watchdog circuit discharges the capacitor C_{tw} , with the constant current $I_{c wd}$. If the lower threshold V_{wlth} is reached, a watchdog reset is generated. To prevent this the microcontroller must generate a positive edge during the discharge of the capacitor before the voltage has reached the threshold V_{wlth} . In order to calculate the minimum time t , during which the micro-controller must output the positive edge, the following equation can be used:

$$(V_{whth} - V_{wlth}) \times C_{tw} = I_{c wd} \times t$$

Every W_i positive edge switches the current source from discharging to charging. The same happens when the lower threshold is reached. When the voltage reaches the upper threshold, V_{whth} , the current switches from charging to discharging. The result is a saw-tooth voltage at the watchdog timer capacitor C_{tw} .
