## 1 Features

■ FROM 3V TO 5.5V VCc RANGE

- MINIMUM OUTPUT VOLTAGE AS LOW AS 0.6 V

■ 1V TO 35V INPUT VOLTAGE RANGE

- CONSTANT ON TIME TOPOLOGY
- VERY FAST LOAD TRANSIENTS
- 0.6V, $\pm 1 \%$ VREF
- SELECTABLE SINKING MODE
- LOSSLESS CURRENT LIMIT, AVAILABLE ALSO IN SINKING MODE
■ REMOTE SENSING
- OVP,UVP LATCHED PROTECTIONS

■ 600 $\mu \mathrm{A}$ TYP QUIESCENT CURRENT
■ POWER GOOD AND OVP SIGNALS

- PULSE SKIPPING AT LIGTH LOADS

■ 94\% EFFICIENCY FROM 3.3V TO 2.5V

## 2 Applications

- NETWORKING
- DC/DC MODULES

■ DISTRIBUTED POWER

- MOBILE APPLICATIONS

■ CHIP SET, CPU, DSP AND MEMORIES SUPPLY

## 3 Description

The device is a high efficient solution for networking dc/dc modules and mobile applications compatible with 3.3 V bus and 5 V bus.
It's able to regulate an output voltage as low as 0.6 V . The constant on time topology assures fast load transient response. The embedded voltage feed-forward provides nearly constant switching frequency operation in spite of a wide input voltage range.
An integrator can be introduced in the control loop to reduce the static output voltage error.
The remote sensing improves the static and dynamic regulation, recovering the wires voltage drop.
Pulse skipping technique reduces power consumption at light loads. Drivers current capability allows output currents in excess of 20A.

Figure 4. Functional \& Block Diagram

## 4 DEVICE DESCRIPTION

### 4.1 Constant On Time PWM topology

Figure 5. Loop block schematic diagram

The device implements a Constant On Time control scheme, where the Ton is the high side MOSFET on time duration forced by the one-shot generator. The On Time is directly proportional to VSENSE pin voltage and inverse to OSC pin voltage as in Eq1:

$$
\begin{equation*}
\mathrm{T}_{\mathrm{ON}}=\mathrm{K}_{\mathrm{OSC}} \frac{\mathrm{~V}_{\mathrm{SENSE}}}{\mathrm{~V}_{\mathrm{OSC}}}+\tau \tag{1}
\end{equation*}
$$

where Kosc $=180 \mathrm{~ns}$ and $\tau$ is the internal propagation delay time (typ. 40ns). The system imposes in steady state a minimum On Time corresponding to $\mathrm{V}_{\text {OSC }}=1 \mathrm{~V}$. In fact if the $\mathrm{V}_{\text {OSC }}$ voltage increases above 1V the corresponding Ton will not decrease. Connecting the OSC pin to a voltage partition from Vin to GND, it allows a steady-state switching frequency Fsw independent of $\mathrm{V}_{\mathrm{IN}}$. It results:

$$
f_{\mathrm{SW}}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}} \frac{1}{\mathrm{~T}_{\mathrm{ON}}}=\frac{\alpha_{\mathrm{OSC}}}{\alpha_{\mathrm{OUT}}} \frac{1}{\mathrm{~K}_{\mathrm{OSC}}} \rightarrow \alpha_{\mathrm{OSC}}=\mathrm{f}_{\mathrm{SW}} \mathrm{~K}_{\mathrm{OSC}} \alpha_{\mathrm{OUT}} \text { (2) }
$$

where

$$
\begin{align*}
& \alpha_{\text {OSC }}=\frac{V_{\text {OSC }}}{V_{\text {IN }}}=\frac{R_{2}}{R_{2}+R_{1}}  \tag{3}\\
& \alpha_{\text {OUT }}=\frac{V_{\text {FB }}}{V_{\text {OUT }}}=\frac{R_{4}}{R_{3}+R_{4}} \tag{4}
\end{align*}
$$

The above equations allow setting the frequency divider ratio $\alpha$ OSC once output voltage has been set; note that such equations hold only if $\mathrm{V}_{\mathrm{OSC}}<1 \mathrm{~V}$. Further the Eq2 shows how the system has a switching frequency ideally independent from the input voltage. The delay introduces a light dependence from $\mathrm{V}_{\text {IN }}$. A minimum Off-Time constraint of about 500ns is introduced in order to assure the boot capacitor charge and to
limit the switching frequency after a load transient as well as to mask PWM comparator output against noise and spikes.
The system has not an internal clock, because this is a hysteretic controller, so the turn on pulse will start if three conditions are met contemporarily: the FB pin voltage is lower than the reference voltage, the minimum off time is passed and the current limit comparator is not triggered (i.e. the inductor current is below the current limit value). The voltage at the OSC pin must range between 50 mV and 1 V to ensure the system linearity.

### 4.2 Closing the loop

The loop is closed connecting the output voltage (or the output divider middle point) to the FB pin. The FB pin is internally conncted to the comparator negative pin while the positive pin is connected to the reference voltage ( 0.6 V Typ.) as in Figure 5. When the FB goes lower than the reference voltage, the PWM comparator output goes high and sets the flip-flop output, turning on the high side MOSFET. This condition is latched to avoid noise. After the On-Time (calculated as described in the previous section) the system resets the flip-flop, turns off the high side MOSFET and turns on the low side MOSFET. For more details refers to the Figure 4.

The voltage drop along ground and supply metal paths connecting output capacitor to the load is a source of $D C$ error. Further the system regulates the output voltage valley value not the average, as shown in Figure 6. So, the voltage ripple on the output capacitor is a source of DC static error (well as the PCB traces). To compensate the DC errors, an integrator network must be introduced in the control loop, by connecting the output voltage to the INT pin through a capacitor and the FB pin to the INT pin directly as in Figure 7. The internal integrator amplifier with the external capacitor $\mathrm{C}_{\mathrm{INT} 1}$ introduces a DC pole in the control loop. $\mathrm{C}_{\mathrm{INT} 1}$ also provides an AC path for output ripple.

Figure 6. Valley regulation

The integrator amplifier generates a current, proportional to the DC errors, that increases the output capacitance voltage in order to compensate the total static error. A voltage clamp within the device forces anINT pin voltage range ( $\mathrm{V}_{\text {REF }}-50 \mathrm{mV}$, $\mathrm{V}_{\text {REF }}+150 \mathrm{mV}$ ). This is useful to avoid or smooth output voltage overshoot during a load transient. Also, this means that the integrator is capable of recovering output error due to ripple when its peak-to-peak amplitude is less than 150 mV in steady state.
In case the ripple amplitude is larger than 150 mV , a capacitor $\mathrm{C}_{\text {INT2 }}$ can be connected between INT pin and ground to reduce ripple amplitude at INT pin, otherwise the integrator will operate out of its linear range. Choose CINT1 according to the following equation:

$$
\begin{equation*}
\mathrm{C}_{\mathrm{INT} 1}=\frac{g_{\mathrm{INT}} \cdot \alpha_{\mathrm{OUT}}}{2 \cdot \pi \cdot \mathrm{~F}_{\mathrm{u}}} \tag{5}
\end{equation*}
$$

where $g_{\text {INT }}=50 \mu \mathrm{~s}$ is the integrator transconductance, $\alpha_{O U T}$ is the output divider ratio given from Eq4 and $\mathrm{Fu}^{\prime}$ is the close loop bandwidth. This equation holds if $\mathrm{C}_{\mathrm{INT} 2}$ is connected between INT pin and ground. $\mathrm{C}_{\mathrm{INT}}$ is given by:

$$
\begin{equation*}
\frac{\mathrm{C}_{\text {INT2 }}}{\mathrm{C}_{\text {INT1 }}}=\frac{\Delta \mathrm{V}_{\mathrm{OUT}}}{\Delta \mathrm{~V}_{\mathrm{INT}}} \tag{6}
\end{equation*}
$$

Where $\Delta \mathrm{V}_{\text {OUT }}$ is the output ripple and $\Delta \mathrm{V}_{\text {INT }}$ is the required ripple at the INT pin ( 100 mV typ).
Figure 7. Integrator loop block diagram

Respect to a traditional PWM controller, that has an internal oscillator setting the switching frequency, in a hysteretic system the frequency can change with some parameters. For example, while in a standard fixed switching frequency topology, the increase of the losses (increasing the output current, for example) generates a variation in the On Time and Off Time, in a fixed On Time topology, the increase of the losses generates only a variation on the Off Time, changing the switching frequency. In the device is implemented the voltage feedforward circuit that allows constant switching frequency during steady-sate operation and withinthe input range variation. Any way there are many factors affecting switching frequency accuracy in steady-state operation. Some of these are internal as dead times, which depends on high side MOSFET driver. Others related to the external components as high side MOSFET gate charge and gate resistance, voltage drops on supply and ground rails, low side and high side RDSON and inductor parasitic resistance.
During a positive load transient, (the output current increases), the converter switches at its maximum frequency (the period is TON+TOFFmin) to recover the output voltage drop. During a negative load transient, (the output current decreases), the device stops to switch (high side MOSFET remains off).

### 4.3 Transition from PWM to PFM/PSK

To achieve high efficiency at light load conditions, PFM mode is provided. The PFM mode differs from the PWM mode essentially for the off phase; the on phase is the same. In PFM after a On cycle the system turns-on the low side MOSFET until the inductor current goes down zero, when the zero-crossing comparator turns off the low side MOSFET. In PWM mode, after On cycle, the system keeps the low side MOSFET on until the next turnon cycle, so the energy stored in the output capacitor will flow through the low side MOSFET to ground. The PFM mode is naturally implemented in an hysteretic controller enabling the zero current comparator by enabling, in fact in PFM mode the system reads the output voltage with a comparator and then turns on the high side MOSFET when the output voltage goes down to reference value. The device works in discontinuous mode
at light load and in continuous mode at high load. The transition from PFM to PWM occurs when load current is around half the inductor current ripple. This threshold value depends on $\mathrm{V}_{\mathrm{IN}}, \mathrm{L}$, and $\mathrm{V}_{\mathrm{OUT}}$. Note that the higher the inductor value is, the smaller the threshold is. On the other hand, the bigger the inductor value is, the slower the transient response is. The PFM waveforms may appear more noisy and asynchronous than normal operation, but this is normal behaviour mainly due to the very low load. If the PFM is not compatible with the application it can be disabled connecting to $\mathrm{V}_{\mathrm{Cc}}$ the NOSKIP pin.

### 4.4 Softstart

After the device is turned on the SS pin voltage begins to increase and the system starts to switch. The softstart is realized by gradually increasing the current limit threshold to avoid output overvoltage. The active soft start range for the $\mathrm{V}_{S S}$ voltage (where the output current limit increase linearly) is from 0.6 V to 1 V . In this range an internal current source ( $5 \mu \mathrm{~A}$ Typ) charges the capacitor on the SS pin; the reference current (for the current limit comparator) forced through ILIM pin is proportional to SS pin voltage and it saturates at $5 \mu \mathrm{~A}$ (Typ.). When SS voltage is close to 1 V the maximum current limit is active. Output protections OVP \& UVP are disabled until the SS pin voltage reaches 1 V (see figure 8).

Once the SS pin voltage reaches the 1V value, the voltage on SS pin doesn't impact the system operation anymore. If the SHDN pin is turned on before the supplies, the power section must be turned on before the logic section. While if the supplies are applied with the SHND pin off, the start up sequence doesn't meter.

Figure 8. Soft -Start Diagram

Because the system implements the soft start by controlling the inductor current, the soft start capacitor should be selected based on of the output capacitance, the current limit and the soft start active range ( $\Delta \mathrm{V}_{\mathrm{SS}}$ ).

In order to select the softstart capacitor it must be imposed that the output voltage reaches the final value before the soft start voltage reaches the under voltage value (1V). After this UVP and OVP are enable.

The time necessary to charge the SS capacitor up to 1 V is given by:

$$
\begin{equation*}
\mathrm{T}_{S S}\left(\mathrm{C}_{\mathrm{SS}}\right)=\frac{1 \mathrm{~V}}{\mathrm{ISS}} \cdot \mathrm{C}_{\mathrm{SS}} \tag{7}
\end{equation*}
$$

In order to calculate the output voltage chargin time it should be considered that the inductor current function can be supposed linear function of the time.

$$
\begin{equation*}
I_{L}\left(t, C_{S S}\right)=\frac{\left(R_{\text {ilim }} / R_{d s o n} \cdot K_{I L I M} \cdot I_{S S} \cdot t\right)}{\left(\Delta V_{S S} \cdot C_{S S}\right)} \tag{8}
\end{equation*}
$$

so considering zero the output load the output voltage is given by:

$$
\begin{equation*}
V_{\text {out }}\left(t, C_{S S}\right)=\frac{Q\left(t, C_{S S}\right)}{C_{\text {out }}}=\frac{\left(R_{\text {ilim }} / R_{\text {dson }} \cdot K_{I L I M} \cdot I_{S S} \cdot t^{2}\right)}{\left(C_{\text {out }} \cdot \Delta V_{S S} \cdot C_{S S} \cdot 2\right)} \tag{9}
\end{equation*}
$$

indicating with $\mathrm{V}_{\text {out }}$ the final value, the output charging time can be estimated as:

$$
\begin{equation*}
\mathrm{V}_{\text {out }}\left(\mathrm{C}_{\mathrm{SS}}\right)=\left[\frac{\left(\mathrm{V}_{\text {out }} \cdot \mathrm{C}_{\text {out }} \cdot \Delta \mathrm{V}_{\text {SS }} \cdot \mathrm{C}_{\text {SS }} \cdot 2\right)}{\left(\mathrm{R}_{\text {ilim }} / \mathrm{R}_{\text {dson }} \cdot \mathrm{K}_{\text {ILIM }} \cdot \mathrm{I}_{\text {SS }}\right)}\right]^{0.5} \tag{10}
\end{equation*}
$$

the minimum $\mathrm{C}_{S S}$ value is given imposing this condition:

$$
\begin{equation*}
\mathrm{T}_{\text {out }}=\mathrm{T}_{\mathrm{ss}} \tag{11}
\end{equation*}
$$

### 4.5 Current limit

The current limit comparator senses the inductor current through the low side MOSFET RDSON drop and compares this value with the ILIM pin voltage value. While the current is above the current limit value, the control inhibits the high side MOSFET Turn On.
To properly set the current limit threshold, it should be noted that this is a valley current limit. The Average current depends on the inductor value, $\mathrm{V}_{\mathrm{IN}} \mathrm{V}_{\text {OUT }}$ and switching frequency.
The average output current in current limit is given by:

$$
\mathrm{I}_{\mathrm{OUT}}^{\mathrm{CL}}, ~=\mathrm{I}_{\max \text { valley }}+\frac{\Delta \mathrm{I}}{2}(12)
$$

Thus, to set the current threshold, choose RILIM according to the following equation:

$$
\begin{equation*}
I_{\text {max valley }}=\frac{R_{I L i m}}{R d s_{o n}} \cdot \mathrm{~K}_{\mathrm{ILIM}} \tag{13}
\end{equation*}
$$

In overcurrent conditions the system keeps the current constant until the output voltage meets the undervoltage threshold. The negative valley current limit, for the sink mode, is set automatically at the same value of the positive valley current limit. The average negative current limit differs from the positive average current limit by the ripple current; this difference is due to the valley control technique.
The current limit system accuracy is function of the precision of the resistance connected to the ILIM pin and the low side MOSFET RDSON accuracy. Moreover the voltage on ILIM pin must range between 10 mV and 1 V to ensure the system linearity.

Figure 9. Current limit schematic

### 4.6 Protection and fault

The load protection is realized by using the VSENSE pin. Both OVP and UVP are latched, and the fault condition is indicated by the PGOOD and the OVP pins. If the output voltage is between the $89 \%$ (typ.) and $110 \%$ (typ) of the regulated value, PGOOD is high. If a hard overvoltage or an undervoltage occurs, the device is latched: low side MOSFET and, high side MOSFET are turned off and PGOOD goes low. In case the system detects an overvoltage the OVP pin goes high.

To recover the functionality the device must be shut down and restarted the SHDN pin, or by removing the supply, and restarting the devicewith the correct sequence.

### 4.7 Drivers

The integrated high-current drivers allow using different size of power MOSFET, maintaining fast switching transitions. The driver for the high side MOSFET uses the BOOT pin for supply and PHASE pin for return (floating driver). The driver for the low side MOSFET uses the VDR pin for the supply and PGND pin for the return. The drivers have the adaptive anti-cross-conduction protection, which prevents from having bothhigh side and low side MOSFET on at the same time, avoiding a high current to flow from VIN to GND. When high side MOSFET is turned off the voltage on the PHASE pin begins to fall; the low side MOSFET is turned on only when the voltage on PHASE pin reaches 250 mV . When low side is turned off, high side remains off until LGATE pin voltage reaches 500 mV . This is important since the driver can work properly with a large range of external power MOSFETS.
The current necessary to switch the external MOSFETS flows through the device, and it is proportional to the MOSFET gate charge the switching frequency and the driver voltage. So the power dissipation of the device is function of the external power MOSFET gate charge and switching frequency.

$$
\begin{equation*}
P_{\text {driver }}=V_{\mathrm{cc}} \cdot Q_{\mathrm{gTOT}} \cdot F_{\mathrm{SW}} \tag{14}
\end{equation*}
$$

The maximum gate charge values for the low side and high side are given by:

$$
\begin{align*}
& Q_{\text {MAXHS }}=\frac{f_{S W O}}{f_{S W}} \cdot 75 n C  \tag{15}\\
& Q_{\text {MAXLS }}=\frac{f_{S W O}}{f_{S W}} \cdot 125 n C \tag{16}
\end{align*}
$$

Where $f_{S W 0}=500 \mathrm{Khz}$. The equations above are valid for $T_{J}=150^{\circ} \mathrm{C}$. If the system temperature is lower the $Q_{G}$ can be higher.

For the Low Side driver the max output gate charge meets another limit due to the internal traces degradation; in this case the maximum value is $Q_{\text {MAXLS }}=125 n C$.

The low side driver has been designed to have a low resistance pull-down transistor, approximately 0.5 ohms This prevents undesired LS MOSFET Turn On during the fast rise-time of the pin PHASE, due to the Miller effect.
When the 3.3 V bus is used to supply the drivers, ULTRA LOGIC LEVEL MOSFETs should be selected , to be sure that the MOSFETs work in properly way.

## 5 APPLICATION INFORMATION

### 5.1 5A Demo board description

The demo board shows the device operation in this condition: $\mathrm{Vl}_{\mathrm{N}}$ from 3.3 V to 5 V , $\mathrm{I}_{\text {Out }}=5 \mathrm{~A} \mathrm{~V}_{\text {Out }}=1.25 \mathrm{~V}$. The evaluation board let use the system with 2 different voltages ( $\mathrm{V}_{\mathrm{CC}}$ the supply for the IC and $\mathrm{V}_{\text {IN }}$ the power input for the conversion) so replacing the input capacitors the power input voltage could be also 35 V . When instead the input voltage $\left(\mathrm{V}_{\mathrm{IN}}\right)$ is equal to the $\mathrm{V}_{\mathrm{CC}}$ it should be better joining them with a $10 \Omega$ resistor in order to filter the device input voltage. On the topside demo there are two different jumpers: one jumper, near the OVP and POWER GOOD test points, is used to shut down the device; when the jumper is present the device is in SHUTDOWN mode, to run the device remove the jumper. The other jumper, near the $\mathrm{V}_{\text {REF }}$ test point, is used to set the PFM/ PSK mode. When the jumper is present, at light load, the system will go in PFM mode; if there is not the jumper, at light load, the system will remain in PWM mode. In the demo bottom side there are two others different jumpers. They are used to set or remove the INTEGRATOR configuration. When the jumpers named with INT label are closed AND the jumpers named with the NOINT label are open the integrator configuration is set. Sometimes the integrator configuration needs a low frequency filter the to reduce the noise interaction. In this case instead close the INT jumpers put there a resistor and after a capacitor to ground (as in the schematic diagram); the pole value is around 500 Khz but it should be higher enough than the switching frequency (ten times). On the opposite when the jumpers named with the NOINT are closed and the jumpers named with INT are open the NON INTEGRATOR configuration is selected. Refer to the Table 1 and 2 for the jumpers connection.

## Notes: 1. N.M.=Not Mounted

2. The demoboard with this component list is set to give: $\mathrm{V}_{\mathrm{OUT}}=1.25 \mathrm{~V}$, $\mathrm{F}_{\text {SW }}=270 \mathrm{kHz}$ with an input voltage around $\mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{CC}}=$ $3.3 \mathrm{~V}-5 \mathrm{~V}$ and with the integrator feature.
3. The diode efficiency impact is very low; it is not a necessary component.
4. All capacitors are intended ceramic type otherwise specified.

### 5.4 EFFICIENCY CURVES

## Source mode

$\mathrm{V}_{\text {IN }}=3.3 \mathrm{~V} \mathrm{~V}_{\text {OUT }}=1.25 \mathrm{~V} \mathrm{~F}_{\text {Sw }}=270 \mathrm{kHz}$
Figure 15. Efficiency vs output current

## 6 STEP BY STEP DESIGN

Application conditions: $\mathrm{V}_{\mathrm{IN}}=3.3 \mathrm{~V}, \pm 10 \% \mathrm{~V}_{\text {OUT }}=1.25 \mathrm{~V}$ Iout $=5 \mathrm{~A}$ FSw $=270 \mathrm{kHz}$

### 6.1 Input capacitor.

A pulsed current (with zero average value) flows through the input capacitor of a buck converter. The AC component of this current is quite high and dissipates a considerable amount of power on the ESR of the capacitor:

$$
\begin{equation*}
P_{C I N}=E S R_{C I N} \cdot \text { lout }^{2} \cdot \frac{\text { Vin } \cdot(\text { Vin }- \text { Vout })}{\operatorname{Vin}^{2}} \tag{17}
\end{equation*}
$$

The RMS current, which the capacitor must provide, is given by:

$$
\begin{equation*}
\operatorname{Icin}_{r m s}=\sqrt{\operatorname{lout}^{2} \delta(1-\delta)+\frac{\delta}{12}\left(\Delta \mathrm{I}_{\mathrm{L}}\right)^{2}} \tag{18}
\end{equation*}
$$

Where $\delta$ is the duty cycle of the application
Neglecting the last term, the equation reduces to:

$$
\operatorname{Icin}_{\mathrm{rms}}=\operatorname{Iout} \sqrt{\delta(1-\delta)}(19)
$$

which maximum value corresponds to to $\delta=1 / 2$ and is equal $\mathrm{I}_{\text {out }} / 2$
Therefore, in worst case, the input capacitors should be selected with a RMS ripple current rating as high as half the respective maximum output current.
Electrolytic capacitors are the most used because theyare the cheapest ones and are available with a wide range of RMS current ratings. The only drawback is that, for a givenripple current rating, they are physically larger than other capacitors. Very good tantalum capacitors are coming available, with very low ESR and small size. The only problem is that they occasionally can burn if subjected to very high current during the charge. So, it is better avoid this type of capacitors for the input filter of the device. In fact, they can be subjected to high surge current when connected to the power supply. If available for the requested capacitance value and voltage rating, the ceramic capacitors have usually a higher RMS current rating for a given physical dimension (due to the very low ESR). The drawback is the quite high cost. Possible solutions:

| $10 \mu \mathrm{~F}$ | C34Y5U1E106ZTE12 TOKIN |
| :---: | :---: |
| $22 \mu \mathrm{~F}$ | JMK325BJ226MM <br> TAIYO-YUDEN |
| $47 \mu \mathrm{~F}$ | ECJ4XFOJ476Z <br> PANASONIC |
| $33 \mu \mathrm{~F}$ | C3225X5R0J476M <br> TDK |

With our parameter from the equation 3 it is found:

$$
\mathrm{Icin}_{\mathrm{rms}}=2.42 \mathrm{~A}
$$

### 6.2 Inductor

To define the inductor, it is necessary to determine firstly the inductance value. Its minimum value is given by:

$$
\begin{equation*}
\operatorname{Lmin} \geq \frac{V_{0} \cdot\left(\mathrm{Vin}_{\max }-\mathrm{V}_{\mathrm{o}}\right)}{\mathrm{F}_{\mathrm{SW}} \cdot \mathrm{I}_{\mathrm{out}} \cdot \mathrm{RF} \cdot \mathrm{Vin}_{\max }} \tag{20}
\end{equation*}
$$

where $R F=\Delta \mathrm{l} / \mathrm{l}_{\text {OUT }}$ (basically it is approximately $30 \%$ ).

With our parameters:

```
Lmin }\geq2\mu\textrm{H
```

The saturation current must be higher then 5 A

### 6.3 Output capacitor and ripple voltage

The output capacitor is selected based on both static and dynamic output voltage accuracy. The static output voltage accuracy depends mostly on the ERS of the output capacitor, while the dynamic accuracy usually depends both on the ESR and capacitance value.

If the static precision is $\pm 1 \%$ for the 1.25 V output voltage, the output ripple is $\pm 12.5 \mathrm{mV}$.
To determine the ESR value from the output precision is necessary to calculate the ripple current:

$$
\begin{equation*}
\Delta I=\frac{V_{i n}-V_{0}}{L} \cdot \frac{V_{0}}{V i n} \cdot T_{s w} \tag{21}
\end{equation*}
$$

Where $\mathrm{F}_{\mathrm{sw}}=270 \mathrm{kHz}$.
From the Eq. above the ripple current is around 1.25A.
So the ESR is given by:

$$
\begin{equation*}
\mathrm{ESR}=\frac{\Delta \mathrm{V}_{\text {ripple }}}{\frac{\Delta 1}{2}}=\frac{25 \mathrm{mV}}{1.25}=20 \mathrm{~m} \Omega \tag{22}
\end{equation*}
$$

The dynamic specifications are sometimes more relaxed than the static requirements, Anyway a minimum output capacitance must be ensured to avoid output voltage variation due to the charge and discharge of Cout during load transients.
To allow the device control loop to work properly, the zero introduced by the output capacitor ESR ( $\tau=$ ESR Cout) must be at least ten times smaller than switching frequency. Low ESR tantalum capacitors, which ESR zero is close to ten kHz, are suitable for output filtering. Output capacitor value Cout and its ESR, ESRC Out, should be large enough and small enough, respectively, to keep output voltage within the accuracy range during a load transient, and to give the device a minimum signal to noise ratio.
The current ripple flows through the output capacitors, so the should be calculated also to sustain this ripple: the RMS current value is given by Eq. 18.

$$
\begin{equation*}
\text { Icout }_{\text {rms }}=\frac{1}{2 \sqrt{3}} \Delta \mathrm{l}_{\mathrm{L}} \tag{23}
\end{equation*}
$$

But this is usually a negligible constrain.
Possible solutions:

| $330 \mu \mathrm{~F}$ | EEFUEOD331R <br> PANASONIC |
| :---: | :---: |
| $220 \mu \mathrm{~F}$ | 2R5TPE220M <br> POSCAP |

Multilayer capacitors can not be used because their very low ESR.

### 6.4 MOSFET's and Schottky Diodes

A 3.3V bus powers the gate drivers of the device, the use ultra low level MOSFET is highly recommended, especially for high current applications. The MOSFET breakdown voltage $\mathrm{V}_{\text {BRDSs }}$ must be greater than VINMAX with a certain margin.
The RDSon can be selected once the allowable power dissipation has been established. By selecting identical

Power MOSFET for us and Is, the total power they dissipate does not depend on the duty cycle. Thus, if PON is this power loss (few percent of the rated output power), the required
RDSon (@ $25^{\circ} \mathrm{C}$ ) can be derived from:

$$
\begin{equation*}
\text { RDS }_{\mathrm{ON}}=\frac{\mathrm{P}_{\mathrm{ON}}}{\text { lout }^{2} \cdot(1+\alpha \cdot \Delta \mathrm{T})} \tag{24}
\end{equation*}
$$

$\alpha$ is the temperature coefficient of RDSon (typically, $\alpha=510^{-3}{ }^{\circ} \mathrm{C}^{-1}$ for these low-voltage classes) and T the admitted temperature rise. It is worth noticing, however, that generally the lower RDSon, the higher is the gate charge $Q_{G}$, which leads to a higher gate drive consumption. In fact, each switching cycle, a charge $Q_{G}$ moves from the input source to ground, resulting in an equivalent drive current:

$$
\begin{equation*}
\mathrm{Iq}=\mathrm{Qg} \cdot \mathrm{~F}_{\mathrm{SW}} \tag{25}
\end{equation*}
$$

A SCHOTTKY diode can be added to increase the system efficiency at high switching frequency (where the dead times could be an important part of total switching period).
This optional diode must be placed in parallel to the synchronous rectifier must have a reverse voltage VRRM greater than VIN MAX. The current size of the diode must be selected in order to keep it in safe operating conditions. In order to use less space than possible, a double MOSFET in a single package is chosen: STS5DNF20V

### 6.5 Output voltage setting

The first step is choosing the output divider to set the output voltage. To select this value there isn't a criteria, but a low divider network value (around $100 \Omega$ ) decries the efficiency at low current; instead a high value divider network ( $100 \mathrm{~K} \Omega$ ) increase the noise effects. A network divider values from $1 \mathrm{~K} \Omega$ to $10 \mathrm{~K} \Omega$ is right. We chose:
$R 3=1 K \Omega$
$\mathrm{R} 2=1.1 \mathrm{~K} \Omega$
The device output voltage is adjustable by connecting a voltage divider from output to VSENSE pin. Minimum output voltage is $\mathrm{V}_{\text {Out }}=\mathrm{VREF}=0.6 \mathrm{~V}$. Once output divider and frequency divider have been designed as to obtain the required output voltage and switching frequency, the following equation gives the smallest input voltage, which allows L6997S to regulate (which corresponds to Toff=Toffmin):

$$
\begin{equation*}
\delta<1-\frac{\alpha_{\text {OSC }}}{\alpha_{\text {OUT }}} \cdot \frac{1}{\left(\frac{\mathrm{~K}_{\text {OSC }}}{T_{\text {OFF,MIN }}}\right) \text { MAX }} \tag{26}
\end{equation*}
$$

### 6.6 Voltage Feedforward

From the equations 1,2 and 3 , choosing the switching frequency of 270 kHz the resistor divider can be selected.
For example:
$R 3=470 \mathrm{~K} \Omega$
$\mathrm{R} 4=8.5 \mathrm{~K} \Omega$

### 6.7 Current limit resistor

From the equation 8 the valley current limit can be set considering the RDSon $\operatorname{STS5DNF} 20 \mathrm{~V}$ and $\mathrm{I}_{\mathrm{CIR}}=5 \mathrm{~A}$ :
$R 8=120 \mathrm{~K} \Omega$

### 6.8 Integrator capacitor

Let's assume $F_{U}=15 \mathrm{kHz}$, $\mathrm{V}_{\text {OUt }}=1.25 \mathrm{~V}$.
Since $\mathrm{V}_{\text {REF }}=0.6 \mathrm{~V}$, from equation 2 , of the device description, it follows $\alpha \mathrm{O}_{\text {UT }}=0.348$ and, from equation 5 it follows $\mathrm{C}=250 \mathrm{pF}$. The output ripple is around 22 mV , so the system doesn't need the second integrator capacitor.

### 6.9 Soft start capacitor

Considering the soft start equations (Eq. 11) at page 10, it can be found:
Css $=150 \mathrm{pF}$
The equations are valid without load. When an active load is present the equations result more complex; further some active loads have unexpected effect, as higher current than the expected one during the soft start, can change the start up time.
In this case the capacitor value can be selected on the application; anyway the Eq11 gives an idea about the Css value.

### 6.10 Sink mode

Figure 16. Efficiency vs output current

## 7 15A DEMO BOARD DESCRIPTION

The evaluation board shows the device operation in these conditions: $\mathrm{V}_{\text {IN }}=3.3 \mathrm{~V} \mathrm{~V}_{\text {OUT }}=1.8 \mathrm{~V} \mathrm{I}_{\text {OUT }}=15 \mathrm{~A}, \mathrm{~F}_{\text {SW }}$ $=200 \mathrm{KHz}$ without the integrator feature. The evaluation board has two different input voltages: $\mathrm{V}_{\mathrm{CC}}$ [from 3 V to 5.5 V ] used to supply the device and the $\mathrm{V}_{\mathbb{I}}$ [up to 35 V ] for the power conversion. In this way, changing the power components configuration ( $\mathrm{C}_{\mathrm{IN}}, \mathrm{C}_{\mathrm{OUT}}$, MOSFETs, L ) it is possible evaluate the device performance in different conditions. It is also possible to mount a linear regulator on board used to generate the $\mathrm{V}_{\mathrm{cc}}$. On the top side are also present two switches and four jumpers. The two switches have different goals: the one nearest to the $V_{C C}$ is used to turn on/off the device when the $V_{C C}$ and $V_{I N}$ are both present; the other one, near to $R 11$ is used to turn on/off the PFM feature. The device can be turned on also with the power supply, but a correct start up sequence is mandatory. $\mathrm{V}_{\mathbb{I N}}$ has to be raised first and then the $\mathrm{V}_{\mathrm{Cc}}$ can be applied too. If the correct sequence is not respected the device will not start up. The jumpers are used to set the integrator feature and to use the remote sensing; for more information refers to the Jumpers table. Sometimes when using the integrator configuration a low frequency filter is required in order to reduce the noise interaction. The pole value should be at least five times higher than the switching frequency. The low pass filter should be inserted in this way: the resistor, in the place of the INT jumper position and the capacitor between the resistor and ground (refers to the schematic).

### 7.5 DDR MEMORY AND TERMINATION SUPPLY

Double data rate (DDR) memories require a particular Power Management Architecture. This is due to fact that the trace between the driving chipset and the memory input must be terminated with resistors. Since the Chipset driving the Memory has a push pull output buffer, the Termination voltage must be capable of sourcing and sinking current. Moreover, the Termination voltage must be equal to one half of the memory supply (the input of the memory is a differential stage requiring a reference bias midpoint) and in tracking with it. For DDRI the Memory Supply is 2.5 V and the Termination voltage is 1.25 V while for the DDRII the Memory Supply is 1.8 V and the Termination voltage is 0.9 V . Figure 27 shows a complete DDRII Memory and Termination Supply realized by using $2 x$ L6997S. The 1.8 V section is powering the memory, while the 0.9 V section is providing the termination voltage.
Figure 27. Application Idea: DDRII Memory Supply

The current required by the Memory and Termination supply, depends on the memory type and size. The figures 28 and 29 show the efficiency for the termination section of the application shown in fig. 27.
