ST1S32

## 4 A DC step-down switching regulator

Datasheet — production data

## Features

- 4 A DC output current
- 2.8 V to 5.5 V input voltage
- Output voltage adjustable from 0.8 V
- 1.5 MHz switching frequency
- Internal soft-start and enable
- Integrated $60 \mathrm{~m} \Omega$ and $45 \mathrm{~m} \Omega$ Power MOSFETs
- All ceramic capacitor
- Power Good (POR)
- Cycle-by-cycle current limiting
- Current foldback short-circuit protection
- VFDFPN $84 \times 4 \times 1.0$ package

## Applications

- $\mu$ P/ASIC/DSP/FPGA core and I/O supplies
- Point of Load for: STB, TV, DVD
- Optical storage, hard disk drives, printers, audio/graphic cards

## Description

The ST1S32 is an internally compensated 1.5 MHz fixed-frequency PWM synchronous stepdown regulator. The ST1S32 operates from 2.8 V to 5.5 V input, while it regulates an output voltage as low as 0.8 V and up to $\mathrm{V}_{\mathrm{IN}}$.

The ST1S32 integrates a $60 \mathrm{~m} \Omega$ high-side switch and a $45 \mathrm{~m} \Omega$ synchronous rectifier, allowing very high efficiency with very low output voltages.
The peak current mode control with internal compensation delivers a very compact solution with a minimum component count.

The ST1S32 is available in $4 \mathrm{~mm} \times 4 \mathrm{~mm}$, 8-lead VFDFPN package.

## 1 <br> Pin settings

### 1.1 Pin connection

Figure 2. Pin connection (top view)

### 1.2 Pin description

Table 1. Pin description

| No. | Type | Description |
| :---: | :---: | :--- |
| 1 | VINA | Unregulated DC input voltage. |
| 2 | EN | Enable input. With EN higher than 1.5 V the device in ON and with EN <br> lower than 0.5 V the device is OFF. |
| 3 | FB | Feedback input. Connecting the output voltage directly to this pin the <br> output voltage is regulated at 0.8 V . To have higher regulated voltages an <br> external resistor divider is required from $\mathrm{V}_{\text {OUT }}$ to the FB pin. |
| 4 | AGND | Ground. |
| 5 | PG | Open drain Power Good (POR) pin. It is released (open drain) when the <br> output voltage is higher than 0.92 * $V_{\text {OUT }}$ with a delay of 170 us. If the <br> output voltage is below 0.92 * $\mathrm{V}_{\text {OUT }}$, the POR pin goes to low impedance <br> immediately. <br> If not used, it can be left floating or to GND. |
| 6 | VINSW | Power input voltage. |
| 7 | SW | Regulator output switching pin. |
| 8 | PGND | Power Ground. |

## 2 Maximum ratings

Table 2. Absolute maximum ratings

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {IN }}$ | Input voltage | -0.3 to 7 | V |
| $\mathrm{V}_{\mathrm{EN}}$ | Enable voltage | -0.3 to $\mathrm{V}_{\text {IN }}$ |  |
| $\mathrm{V}_{\text {SW }}$ | Output switching voltage | -1 to $\mathrm{V}_{\mathrm{IN}}$ |  |
| $V_{P G}$ | Power-on reset voltage (Power Good) | -0.3 to $\mathrm{V}_{\mathrm{IN}}$ |  |
| $V_{F B}$ | Feedback voltage | -0.3 to 1.5 |  |
| $\mathrm{P}_{\text {TOT }}$ | Power dissipation at $\mathrm{T}_{\mathrm{A}}<60^{\circ} \mathrm{C}$ | 2.25 | W |
| TOP | Operating junction temperature range | -40 to 150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {stg }}$ | Storage temperature range | -55 to 150 | ${ }^{\circ} \mathrm{C}$ |

1. Specifications referred to $\mathrm{T}_{J}$ from -40 to $+125^{\circ} \mathrm{C}$. Specifications in the -40 to $+125^{\circ} \mathrm{C}$ temperature range are assured by design, characterization and statistical correlation.
2. Guaranteed by design.

## 4 Functional description

The ST1S32 is based on a "peak current mode", constant frequency control. The output voltage $\mathrm{V}_{\text {OUT }}$ is sensed by the Feedback pin (FB) compared to an internal reference ( 0.8 V ) providing an error signal that, compared to the output of the current sense amplifier, controls the ON and OFF time of the power switch.

The main internal blocks are shown in the block diagram in Figure 3. They are:

- A fully integrated oscillator that provides the internal clock and the ramp for the slope compensation avoiding sub-harmonic instability
- The soft-start circuitry to limit inrush current during the startup phase
- The transconductance error amplifier
- The pulse width modulator and the relative logic circuitry necessary to drive the internal power switches
- The drivers for embedded P-channel and N-channel Power MOSFET switches
- The high-side current sensing block
- The low-side current sense to implement diode emulation
- A voltage monitor circuitry (UVLO) that checks the input and internal voltages
- A thermal shutdown block, to prevent thermal run-away.

Figure 3. Block diagram

### 4.1 Soft-start

The soft-start is essential to assure the correct and safe startup of the step-down converter. It avoids inrush current surge and makes the output voltage rise monothonically.

The soft-start is managed by ramping the reference of the error amplifier from 0 V to 0.8 V . The internal soft-start capacitor is charged with a resistor to 0.8 V , then the FB pin follows the reference so that the output voltage is regulated to rise to the set value monothonically.

### 4.2 Error amplifier and control loop stability

The error amplifier provides the error signal to be compared with the high-side switch current through the current sense circuitry. The non-inverting input is connected with the internal 0.8 V reference, whilst the inverting input is the FB pin. The compensation network is internal and connected between the E/A output and GND.

The error amplifier of the ST1S32 is a transconductance operational amplifier, with high bandwidth and high output impedance.

The characteristics of the uncompensated error amplifier are:

Table 5. Characteristics of the uncompensated error amplifier

| Description | Value |
| :---: | :---: |
| DC gain | 94 dB |
| gm | $238 \mu \mathrm{~A} / \mathrm{V}$ |
| Ro | $96 \mathrm{M} \Omega$ |

The ST1S32 embeds the compensation network that assures the stability of the loop in the whole operating range. Here below are all the tools needed to check the loop stability.

In Figure 4. the simple small signal model for the peak current mode control loop is shown.

Figure 4. Block diagram of the loop for the small signal analysis

Three main terms can be identified to obtain the loop transfer function:

1. from control (output of $E / A$ ) to output, $\mathrm{G}_{\mathrm{CO}}(\mathrm{s})$;
2. from output ( $\mathrm{V}_{\mathrm{OUT}}$ ) to the FB pin, $\mathrm{G}_{\text {DIV }}(\mathrm{s})$;
3. from the FB pin to control (output of $E / A), G_{E A}(s)$.

The transfer function from control to output $\mathrm{G}_{\mathrm{CO}}(\mathrm{s})$ results:

## Equation 1

$$
G_{C O}(s)=\frac{R_{L O A D}}{R_{i}} \cdot \frac{1}{1+\frac{R_{o u t} \cdot T_{S W}}{L} \cdot\left[m_{C} \cdot(1-D)-0.5\right]} \cdot \frac{\left(1+\frac{s}{\omega_{z}}\right)}{\left(1+\frac{s}{\omega_{p}}\right)} \cdot F_{H}(s)
$$

where $R_{\text {LOAD }}$ represents the load resistance, $R_{i}$ the equivalent sensing resistor of the current sense circuitry ( $0.369 \Omega$ ), $\omega_{p}$ the single pole introduced by the LC filter and $\omega_{z}$ the zero given by the ESR of the output capacitor.
$\mathrm{F}_{\mathrm{H}}(\mathrm{s})$ accounts for the sampling effect performed by the PWM comparator on the output of the error amplifier that introduces a double pole at one half of the switching frequency.

## Equation 2

$$
\omega_{Z}=\frac{1}{\mathrm{ESR} \cdot \mathrm{C}_{\mathrm{OUT}}}
$$

## Equation 3

$$
\omega_{\mathrm{p}}=\frac{1}{\mathrm{R}_{\mathrm{LOAD}} \cdot \mathrm{C}_{\mathrm{OUT}}}+\frac{\mathrm{m}_{\mathrm{C}} \cdot(1-\mathrm{D})-0.5}{\mathrm{~L} \cdot \mathrm{C}_{\mathrm{OUT}} \cdot \mathrm{f}_{\mathrm{SW}}}
$$

where:

## Equation 4

$$
\left(\begin{array}{l}
m_{C}=1+\frac{S_{e}}{S_{n}} \\
S_{e}=V_{p p} \cdot f_{S W} \\
S_{n}=\frac{V_{I N}-V_{O U T}}{L} \cdot R_{i}
\end{array}\right.
$$

$\mathrm{S}_{\mathrm{n}}$ represents the ON-time slope of the sensed inductor current, $\mathrm{S}_{\mathrm{e}}$ the slope of the external ramp ( $\mathrm{V}_{\mathrm{PP}}$ peak-to-peak amplitude -0.535 V ) that implements the slope compensation to avoid sub-harmonic oscillations at duty cycle over $50 \%$.

The sampling effect contribution $\mathrm{F}_{\mathrm{H}}(\mathrm{s})$ is:

## Equation 5

$$
F_{H}(s)=\frac{1}{1+\frac{s}{\omega_{h} \cdot Q_{P}}+\frac{s^{2}}{\omega_{h}^{2}}}
$$

where:

## Equation 6

$$
Q_{P}=\frac{1}{\pi \cdot\left[m_{C} \cdot(1-D)-0.5\right]}
$$

and

## Equation 7

$$
\omega_{h}=\pi \cdot f_{S W}
$$

The transfer function $\mathrm{G}_{\text {DIV }}(\mathrm{s})$ from $\mathrm{V}_{\text {OUT }}$ to FB results:

$$
G_{\text {DIV }}(s)=\frac{R_{2}}{R_{1}+R_{2}}
$$

The transfer function from FB to Vc (output of $E / A$ ) introduces the singularities (poles and zeroes) to stabilize the loop. In Figure 5, the small signal model of the error amplifier with the internal compensation network is shown.

Figure 5. Small signal model for the error amplifier

$R_{C}$ and $C_{C}$ introduce a pole and a zero in the open loop gain. $C_{P}$ does not significantly affect system stability and can be neglected.
So, $G_{E A}(s)$ results:

## Equation 8

$$
G_{E A}(s)=\frac{G_{E A O} \cdot\left(1+s \cdot R_{c} \cdot C_{c}\right)}{s^{2} \cdot R_{0} \cdot\left(C_{0}+C_{p}\right) \cdot R_{c} \cdot C_{c}+s \cdot\left(R_{0} \cdot C_{c}+R_{0} \cdot\left(C_{0}+C_{p}\right)+R_{c} \cdot C_{c}\right)+1}
$$

where $G_{E A}=G_{m} \cdot R_{0}$
The poles of this transfer function are (if $\mathrm{C}_{\mathrm{C}} \gg \mathrm{C}_{0}+\mathrm{C}_{\mathrm{P}}$ ):

## Equation 9

$$
\mathrm{f}_{\mathrm{PLF}}=\frac{1}{2 \cdot \pi \cdot \mathrm{R}_{0} \cdot \mathrm{C}_{\mathrm{c}}}
$$

## Equation 10

$$
\mathrm{f}_{\mathrm{PHF}}=\frac{1}{2 \cdot \pi \cdot \mathrm{R}_{\mathrm{c}} \cdot\left(\mathrm{C}_{0}+\mathrm{C}_{\mathrm{p}}\right)}
$$

whereas the zero is defined as:

## Equation 11

$$
f_{z}=\frac{1}{2 \cdot \pi \cdot R_{c} \cdot C_{c}}
$$

The embedded compensation network is $R_{C}=80 \mathrm{k} \Omega \mathrm{C}_{\mathrm{C}}=55 \mathrm{pF}$ while $\mathrm{C}_{\mathrm{P}}$ and $\mathrm{C}_{\mathrm{O}}$ can be considered as negligible. The error amplifier output resistance is $212 \mathrm{M} \Omega$, so the relevant singularities are:

## Equation 12

$$
\mathrm{f}_{\mathrm{Z}}=36,2 \mathrm{kHz} \quad \mathrm{f}_{\mathrm{PLF}}=30 \mathrm{~Hz}
$$

So, closing the loop, the loop gain $G_{\text {LOOP }}(\mathrm{s})$ is:

## Equation 13

$$
G_{\text {LOOP }}(s)=G_{C O}(s) \cdot G_{D I V}(s) \cdot G_{E A}(s)
$$

Example:
VIN=5 V, VOUT=1.2 V, Iomax=4 A, L=1.0 uH, Cout=47 uF (MLCC), R1=10 k $\Omega$ R2=20 $k \Omega$ (see Section 5.2 and Section 5.3 for inductor and output capacitor selection guidelines).
The module and phase Bode plot are reported in Figure 6.
The bandwidth is 117 kHz and the phase margin is 63 degrees.
Figure 6. Module Bode plot

Figure 7. Phase Bode plot

### 4.3 Overcurrent protection

The ST1S32 implements overcurrent protection sensing the current flowing through the high-side current switch.

If the current exceeds the overcurrent threshold, the high-side is turned off, implementing a cycle-by-cycle current limitation. Since the regulation loop is no longer fixing the duty cycle, the output voltage is unregulated and the FB pin falls accordingly to the new duty cycle.

If the FB pin falls below 0.2 V , the peak current limit is reduced to around 2.3 A and the switching frequency is reduced to assure that the inductor current is properly limited below the above mentioned value and above 1.2 A. This strategy is called "current foldback".
The mechanism to adjust the switching undercurrent foldback condition exploits the low-side current sense circuitry. If FB is lower than 0.2 V , the high-side Power MOSFET is turned off when the current reaches the current foldback threshold (2.3 A), then, after a proper dead time that avoids the cross conduction, the low-side is turned on until the low-side current is lower than a valley threshold (1.2 A). Once the low-side is turned off, the high-side is immediately turned on. In this way the frequency is adjusted to keep the inductor current ripple between the current foldback value (2.3 A) and valley threshold (1.2 A), therefore properly limiting the output current in case of overcurrent or short-circuit.

It should be noted that in some cases, mainly with very low output voltages, the hard overcurrent can make the FB find the new equilibrium just over the current foldback threshold ( 0.2 V ). In this case no frequency reduction is enabled, then the inductor current may diverge. That is, the ripple current during the minimum ON-time is higher than the ripple current during the OFF-time (the switching period minus the minimum ON-time), so pulse-by-pulse the average current is rising, exceeding the current limit.

In order to avoid too high current, a further protection is activated when the high-side current exceeds a further current threshold (OCP2) slightly over the current limit (OCP1). If the current triggers the second threshold, the converter stops switching, the reference of the error amplifier is pulled down and then it restarts with a soft-start procedure. If the overcurrent condition is still active, the current foldback with frequency reduction properly limits the output current to 2.3 A .

### 4.4 Enable function

The enable feature allows the device to be put into standby mode. With the EN pin lower than 0.4 V , the device is disabled and the power consumption is reduced to less than 10 uA . With the EN pin higher than 1.2 V , the device is enabled. If the EN pin is left floating, an internal pull-down ensures that the voltage at the pin reaches the inhibit threshold and the device is disabled. The pin is also $\mathrm{V}_{\mathrm{IN}}$ compatible.

### 4.5 Light load operation

With peak current mode control loop the output of the error amplifier is proportional to the load current. In the ST1S32, to increase light load efficiency, when the output of the error amplifier falls below a certain threshold, the high-side turn-on is prevented.

This mechanism reduces the switching frequency at light load in order to save the switching losses.

### 4.6 Hysteretic thermal shutdown

The thermal shutdown block generates a signal that turns off the power stage if the junction temperature goes above $150^{\circ} \mathrm{C}$. Once the junction temperature goes back to about $130^{\circ} \mathrm{C}$, the device restarts in normal operation.

## 5 Application information

### 5.1 Input capacitor selection

The capacitor connected to the input must be capable of supporting the maximum input operating voltage and the maximum RMS input current required by the device. The input capacitor is subject to a pulsed current, the RMS value of which is dissipated over its ESR, affecting the overall system efficiency.
So the input capacitor must have an RMS current rating higher than the maximum RMS input current and an ESR value compliant with the expected efficiency.

The maximum RMS input current flowing through the capacitor can be calculated as:

## Equation 14

$$
I_{R M S}=I_{O} \cdot \sqrt{D-\frac{2 \cdot D^{2}}{\eta}+\frac{D^{2}}{\eta^{2}}}
$$

where lo is the maximum DC output current, $D$ is the duty cycle, and $\eta$ is the efficiency. Considering $\uparrow=1$, this function has a maximum at $D=0.5$ and is equal to $\mathrm{lo} / 2$.

The peak-to-peak voltage across the input capacitor can be calculated as:
Equation 15

$$
V_{P P}=\frac{I_{O}}{C_{I N} \cdot F_{S W}} \cdot\left[\left(1-\frac{D}{\eta}\right) \cdot D+\frac{D}{\eta} \cdot(1-D)\right]+E S R \cdot I_{O}
$$

where ESR is the equivalent series resistance of the capacitor.
Given the physical dimension, ceramic capacitors can well meet the requirements of the input filter sustaining a higher input RMS current than electrolytic / tantalum types. In this case, the equation of $\mathrm{C}_{\mathrm{IN}}$ as a function of the target peak-to-peak voltage ripple ( $\mathrm{V}_{\mathrm{PP}}$ ) can be written as follows:

Equation 16

$$
C_{I N}=\frac{I_{O}}{V_{P P} \cdot F_{S W}} \cdot\left[\left(1-\frac{D}{\eta}\right) \cdot D+\frac{D}{\eta} \cdot(1-D)\right]
$$

neglecting the small ESR of ceramic capacitors.
Considering ${ }_{\mathfrak{q}} 1$, this function has its maximum in $\mathrm{D}=0.5$, therefore, given the maximum peak-to-peak input voltage ( $\mathrm{V}_{\text {PP_MAX }}$ ), the minimum input capacitor ( $\mathrm{C}_{\text {IN_MIN }}$ ) value is:

## Equation 17

$$
\mathrm{C}_{\mathrm{IN} \_\mathrm{MIN}}=\frac{\mathrm{I}_{\mathrm{O}}}{2 \cdot \mathrm{~V}_{\mathrm{PP} \_M A X} \cdot \mathrm{~F}_{\mathrm{SW}}}
$$

Typically, $\mathrm{C}_{\mathrm{IN}}$ is dimensioned to keep the maximum peak-to-peak voltage ripple in the order of $1 \%$ of $\mathrm{V}_{\text {Inmax }}$.

The placement of the input capacitor is very important in order to avoid noise injection and voltage spikes on the input voltage pin. So the $\mathrm{C}_{\mathrm{IN}}$ must be placed as close as possible to the VIN_SW pin.

In Table 6 some multi-layer ceramic capacitors suitable for this device are reported.
Table 6. Input MLCC capacitors

| Manufacturer | Series | Cap value ( $\boldsymbol{\mathbf { F } )}$ | Rated voltage (V) |
| :---: | :---: | :---: | :---: |
| Murata | GRM21 | 10 | 10 |
| TDK | C3225 | 10 | 25 |
|  | C3216 | 10 | 16 |
| Taiyo Yuden | LMK212 | 22 | 10 |

A ceramic bypass capacitor, as close as possible to the VINA pin, so that additional parasitic ESR and ESL are minimized, is suggested in order to prevent instability on the output voltage due to noise. The value of the bypass capacitor can go from 330 nF to $1 \mu \mathrm{~F}$.

### 5.2 Inductor selection

The inductance value fixes the current ripple flowing through the output capacitor. So the minimum inductance value in order to have the expected current ripple must be selected. The rule to fix the current ripple value is to have a ripple at $20 \%-40 \%$ of the output current.

In continuous current mode (CCM), the inductance value can be calculated by the following equation:

## Equation 18

$$
\Delta \mathrm{I}_{\mathrm{L}}=\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~L}} \cdot \mathrm{~T}_{\mathrm{ON}}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~L}} \cdot \mathrm{~T}_{\mathrm{OFF}}
$$

where $\mathrm{T}_{\mathrm{ON}}$ is the conduction time of the high-side switch and $\mathrm{T}_{\text {OFF }}$ is the conduction time of the low-side switch (in CCM, $\mathrm{F}_{\mathrm{SW}}=1 /\left(\mathrm{T}_{\mathrm{ON}}+\mathrm{T}_{\mathrm{OFF}}\right)$ ). The maximum current ripple, given the $\mathrm{V}_{\text {OUT, }}$, is obtained at maximum $\mathrm{T}_{\text {OFF }}$ that is at minimum duty cycle (see previous section to calculate minimum duty). So by fixing $\Delta \mathrm{I}_{\mathrm{L}}=20 \%$ to $30 \%$ of the maximum output current, the minimum inductance value can be calculated as:

## Equation 19

$$
\mathrm{L}_{\text {MIN }}=\frac{\mathrm{V}_{\text {OUT }}}{\Delta \mathrm{I}_{\text {MAX }}} \cdot \frac{1-\mathrm{D}_{\text {MIN }}}{\mathrm{F}_{\text {SWMIN }}}
$$

where $\mathrm{F}_{\text {SWMIN }}$ is the minimum switching frequency, according to Table 4.

The slope compensation, to prevent the sub-harmonic instability in peak current control loop, is internally managed and so fixed. This implies a further lower limit for the inductor value. To assure the sub-harmonic stability:

## Equation 20

$$
L>V_{\text {out }} \prime\left(2 \bullet V_{p p} \bullet f_{s w}\right)
$$

where $\mathrm{V}_{\mathrm{pp}}$ is the peak-to-peak value of the slope compensation ramp.
The inductor value selected, based on Equation 19, must satisfy Equation 20.
The peak current through the inductor is given by:

## Equation 21

$$
\mathrm{I}_{\mathrm{L}, \mathrm{PK}}=\mathrm{I}_{\mathrm{O}}+\frac{\Delta \mathrm{I}_{\mathrm{L}}}{2}
$$

So if the inductor value decreases, the peak current (that must be lower than the current limit of the device) increases. The higher the inductor value, the higher the average output current that can be delivered, without reaching the current limit.

In Table 7 some inductor part numbers are listed.

Table 7. Inductors

| Manufacturer | Series | Inductor value $(\boldsymbol{\mu H})$ | Saturation current (A) |
| :---: | :---: | :---: | :---: |
| Coilcraft | XAL50xx | 1.2 to 3.3 | 6.3 to 9 |
|  | XAL60xx | 2.2 to 5.6 | 7.4 to 11 |
|  | MSS1048 | 1.0 to 3.8 | 6.5 to 11 |
| Wurth | WE-HCl 7030 | 1.5 to 4.7 | 7 to 14 |
|  | WE-PD type L | 1.5 to 3.5 | 6.4 to 10 |
|  | DR73 | 1.0 to 2.2 | 5.5 to 7.9 |
|  | DR74 | 1.5 to 3.3 | 5.4 to 8.35 |

### 5.3 Output capacitor selection

The current in the output capacitor has a triangular waveform which generates a voltage ripple across it. This ripple is due to the capacitive component (charge or discharge of the output capacitor) and the resistive component (due to the voltage drop across its ESR). So the output capacitor must be selected in order to have a voltage ripple compliant with the application requirements.
The amount of the voltage ripple can be calculated starting from the current ripple obtained by the inductor selection.

## Equation 22

$$
\Delta \mathrm{V}_{\mathrm{OUT}}=\mathrm{ESR} \cdot \Delta \mathrm{I}_{\mathrm{MAX}}+\frac{\Delta \mathrm{I}_{\mathrm{MAX}}}{8 \cdot \mathrm{C}_{\mathrm{OUT}} \cdot \mathrm{f}_{\mathrm{SW}}}
$$

For the ceramic (MLCC) capacitor the capacitive component of the ripple dominates the resistive one. While for the electrolythic capacitor the opposite is true.

As the compensation network is internal, the output capacitor should be selected in order to have a proper phase margin and then a stable control loop.

The equations of Section 4.2 help to check loop stability, given the application conditions, the value of the inductor and the output capacitor.

In Table 8 some capacitor series are listed.

Table 8. Output capacitors

| Manufacturer | Series | Cap value ( $\mu$ F) | Rated voltage (V) | ESR (m $\Omega$ ) |
| :---: | :---: | :---: | :---: | :---: |
| Murata | GRM32 | 22 to 100 | 6.3 to 25 | $<5$ |
|  | GRM31 | 10 to 47 | 6.3 to 25 | $<5$ |
| Panasonic | ECJ | 10 to 22 | 6.3 | $<5$ |
|  | EEFCD | 10 to 68 | 6.3 | 15 to 55 |
| Sanyo | TPA/B/C | 100 to 470 | 4 to 16 | 40 to 80 |
| TDK | C3225 | 22 to 100 | 6.3 | $<5$ |

### 5.4 Thermal dissipation

The thermal design is important to prevent the thermal shutdown of the device if junction temperature goes above $150^{\circ} \mathrm{C}$. The three different sources of loss within the device are:
a) conduction losses due to the on-resistance of the high-side switch $\left(\mathrm{R}_{\mathrm{HS}}\right)$ and lowside switch ( $R_{\text {LS }}$ ); these are equal to:

Equation 23

$$
\mathrm{P}_{\text {COND }}=\mathrm{R}_{\mathrm{HS}} \cdot \mathrm{I}_{\mathrm{OUT}}{ }^{2} \cdot \mathrm{D}+\mathrm{R}_{\mathrm{LS}} \cdot \mathrm{I}_{\mathrm{OUT}}{ }^{2} \cdot(1-\mathrm{D})
$$

where D is the duty cycle of the application. Note that the duty cycle is theoretically given by the ratio between $\mathrm{V}_{\mathrm{OUT}}$ and $\mathrm{V}_{\mathrm{IN}}$, but actually it is slightly higher to compensate the losses of the regulator.
b) switching losses due to high-side Power MOSFET turn-on and off; these can be calculated as:

## Equation 24

$$
P_{S W}=V_{I N} \cdot I_{\text {OUT }} \cdot \frac{\left(T_{\text {RISE }}+T_{\text {FALL }}\right)}{2} \cdot F S W=V_{I N} \cdot I_{O U T} \cdot T_{S W} \cdot F_{S W}
$$

where $T_{\text {RISE }}$ and $T_{\text {FALL }}$ are the overlap times of the voltage across the high-side power switch ( $\mathrm{V}_{\mathrm{DS}}$ ) and the current flowing into it during turn-on and turn-off phases, as shown in Figure 8. $\mathrm{T}_{\mathrm{SW}}$ is the equivalent switching time. For this device the typical value for the equivalent switching time is 20 ns .
c) Quiescent current losses, calculated as:

## Equation 25

$$
P_{Q}=V_{I N} \cdot I_{Q}
$$

where $\mathrm{I}_{\mathrm{Q}}$ is the quiescent current $\left(\mathrm{I}_{\mathrm{Q}}=1.2 \mathrm{~mA}\right.$ maximum $)$.
The junction temperature $T_{J}$ can be calculated as:

## Equation 26

$$
\mathrm{T}_{\mathrm{J}}=\mathrm{T}_{\mathrm{A}}+\operatorname{Rth}_{\mathrm{JA}} \cdot \mathrm{P}_{\mathrm{TOT}}
$$

where $T_{A}$ is the ambient temperature and $P_{\text {TOT }}$ is the sum of the power losses just seen.
Rth $_{\mathrm{JA}}$ is the equivalent thermal resistance junction-to-ambient of the device; it can be calculated as the parallel of many paths of heat conduction from the junction to the ambient. For this device the path through the exposed pad is the one conducting the largest amount of heat. The Rth ${ }_{\text {JA }}$ measured on the demonstration board described in Section 5.5 is about $40^{\circ} \mathrm{C} / \mathrm{W}$ for the VFDFPN package.

### 5.5 Layout considerations

The PC board layout of the switching DC/DC regulator is very important to minimize the noise injected in high impedance nodes, to reduce interference generated by the high switching current loops and to optimize the reliability of the device.

In order to avoid EMC problems, the high switching current loops must be as short as possible. In the buck converter there are two high switching current loops: during the ONtime, the pulsed current flows through the input capacitor, the high-side power switch, the inductor and the output capacitor; during the OFF-time, through the low-side power switch, the inductor and the output capacitor.

The input capacitor connected to VINSW must be placed as close as possible to the device, to avoid spikes on VINSW due to the stray inductance and the pulsed input current.
In order to prevent dynamic unbalance between VINSW and VINA, the trace connecting the VINA pin to the input must be derived from VINSW.

The feedback pin (FB) connection to the external resistor divider is a high impedance node, so interference can be minimized by routing the feedback node with a very short trace and as far as possible from the high current paths.
A single point connection from signal ground to power ground is suggested.
Thanks to the exposed pad of the device, the ground plane helps to reduce the thermal resistance junction-to-ambient; so a large ground plane, soldered to the exposed pad, enhances the thermal performance of the converter allowing high power conversion.

## 8 Package mechanical data

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK ${ }^{\circledR}$ packages, depending on their level of environmental compliance. ECOPACK specifications, grade definitions and product status are available at: www.st.com. ECOPACK is an ST trademark.
