| TDE1898C |
| INDUSTRIAL INTELLIGENT POWER SWITCH |

- 0.5A OUTPUT CURRENT
- 18 V TO 35 V SUPPLY VOLTAGE RANGE
- INTERNAL CURRENT LIMITING
- THERMAL SHUTDOWN
- OPEN GROUND PROTECTION
- INTERNAL NEGATIVE VOLTAGE CLAMPING TO Vs - 45V FOR FAST DEMAGNETIZATION
- DIFFERENTIAL INPUTS WITH LARGE COMMON MODE RANGE AND THRESHOLD HYSTERESIS
- UNDERVOLTAGE LOCKOUT WITH HYSTERESIS
- OPEN LOAD DETECTION
- TWO DIAGNOSTIC OUTPUTS
- OUTPUT STATUS LED DRIVER

## DESCRIPTION

The TDE1897C/TDE1898C is a monolithic Intelligent Power Switch in Multipower BCD Technol-

${ }^{(*)}$ ) According to the intervention of the current limiting block.
$(* *)$ A cold lamp filament, or a capacitive load may activate the current limiting circuit of the IPS, when the IPS is initially turned on. TDE1897 uses Diag2 to signal such condition, TDE1898 does not.

## APPLICATION INFORMATION

DEMAGNETIZATION OF INDUCTIVE LOADS
An internal zener diode, limiting the voltage across the Power MOS to between 45 and 55 V $\left(\mathrm{V}_{\mathrm{Cl}}\right)$, provides safe and fast demagnetization of inductive loads without external clamping devices.
The maximum energy that can be absorbed from an inductive load is specified as 200 mJ (at $\mathrm{T}_{\mathrm{j}}=85^{\circ} \mathrm{C}$ ).
To define the maximum switching frequency three points have to be considered:

1) The total power dissipation is the sum of the On State Power and of the Demagnetization Energy multiplied by the frequency.
2) The total energy $W$ dissipated in the device during a demagnetization cycle (figg. 2, 3) is:
$\mathrm{W}=\mathrm{V}_{\mathrm{Cl}} \frac{\mathrm{L}}{R_{\mathrm{L}}}\left[l_{0}-\frac{\mathrm{V}_{\mathrm{Cl}}-\mathrm{V}_{\mathrm{S}}}{R_{\mathrm{L}}} \log \left(1+\frac{\mathrm{V}_{\mathrm{S}}}{\mathrm{V}_{\mathrm{Cl}}-\mathrm{V}_{\mathrm{S}}}\right)\right]$
Where:
$\mathrm{V}_{\mathrm{Cl}}=$ clamp voltage;
$\mathrm{L}=$ inductive load;
$R_{L}=$ resistive load;
Vs = supply voltage;
$\mathrm{lo}=\mathrm{l}$ LOAD
3) In normal conditions the operating Junction temperature should remain below $125^{\circ} \mathrm{C}$.

Figure 2: Inductive Load Equivalent Circuit

Figure 3: Demagnetization Cycle Waveforms

Figure 4: Normalized Rdson vs. Junction Temperature

## WORST CONDITION POWER DISSIPATION IN THE ON-STATE

In IPS applications the maximum average power dissipation occurs when the device stays for a long time in the ON state. In such a situation the internal temperature depends on delivered current (and related power), thermal characteristics of the package and ambient temperature.
At ambient temperature close to upper limit $\left(+85^{\circ} \mathrm{C}\right)$ and in the worst operating conditions, it is possible that the chip temperature could increase so much to make the thermal shutdown procedure untimely intervene.
Our aim is to find the maximum current the IPS can withstand in the ON state without thermal shutdown intervention, related to ambient temperature. To this end, we should consider the following points:

1) The ON resistance RDSON of the output NDMOS (the real switch) of the device increases with its temperature.
Experimental results show that silicon resistivity increases with temperature at a constant rate, rising of $60 \%$ from $25^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
The relationship between RDson and temperature is therefore:

$$
R_{\text {DSON }}=R_{\text {DSONO }}(1+k)^{\left(T_{j}-25\right)}
$$

where:
$\mathrm{T}_{\mathrm{j}}$ is the silicon temperature in ${ }^{\circ} \mathrm{C}$
$R_{\text {DSONO }}$ is $R_{\text {DSON }}$ at $\mathrm{T}_{\mathrm{j}}=25^{\circ} \mathrm{C}$
k is the constant rate $\left(\mathrm{k}=4.711 \cdot 10^{-3}\right)$ (see fig. 4).
2) In the ON state the power dissipated in the device is due to three contributes:
a) power lost in the switch:
$P_{\text {out }}=I_{\text {out }}{ }^{2} \cdot R_{\text {DSON ( }}$ (lout is the output current);
b) power due to quiescent current in the ON state Iq, sunk by the device in addition to $I_{\text {out: }} \mathrm{P}_{\mathrm{q}}=\mathrm{I}_{\mathrm{q}} \cdot \mathrm{V}_{\mathrm{s}}\left(\mathrm{V}_{\mathrm{s}}\right.$ is the supply voltage);
c) an external LED could be used to visualize the switch state (OUTPUT STATUS pin). Such a LED is driven by an internal current source (delivering los) and therefore, if $V_{\text {os }}$ is the voltage drop across the LED, the dissipated power is: P os $=\mathrm{I}_{\text {os }} \cdot\left(\mathrm{V}_{\mathrm{s}}-\mathrm{V}_{\text {os }}\right)$.

Thus the total ON state power consumption is given by:

$$
\begin{equation*}
\mathrm{P}_{\text {on }}=\mathrm{P}_{\text {out }}+\mathrm{P}_{\mathrm{q}}+\mathrm{P}_{\text {os }} \tag{1}
\end{equation*}
$$

In the right side of equation 1, the second and
the third element are constant, while the first one increases with temperature because Rdson increases as well.
3) The chip temperature must not exceed $\Theta$ Lim in order do not lose the control of the device. The heat dissipation path is represented by the thermal resistance of the system device-board-ambient ( $\mathrm{R}_{\text {th }}$ ). In steady state conditions, this parameter relates the power dissipated $P_{o n}$ to the silicon temperature $T_{j}$ and the ambient temperature $\mathrm{T}_{\mathrm{amb}}$ :

$$
\begin{equation*}
\mathrm{T}_{\mathrm{j}}-\mathrm{T}_{\mathrm{amb}}=\mathrm{P}_{\text {on }} \cdot \mathrm{R}_{\mathrm{th}} \tag{2}
\end{equation*}
$$

From this relationship, the maximum power $P_{\text {on }}$ which can be dissipated without exceeding $\Theta \operatorname{Lim}$ at a given ambient temperature Tamb is:

$$
\mathrm{P}_{\text {on }}=\frac{\Theta \mathrm{Lim}-\mathrm{T}_{\mathrm{amb}}}{\mathrm{R}_{\mathrm{th}}}
$$

Replacing the expression (1) in this equation and solving for lout, we can find the maximum current versus ambient temperature relationship:

where R Rsonx is RDSon at $T_{j}=\Theta \operatorname{Lim}$. Of course, loutx values are top limited by the maximum operative current $l_{\text {outx }}$ ( 500 mA nominal).
From the expression (2) we can also find the maximum ambient temperature $T_{\text {amb }}$ at which a given power Pon can be dissipated:

$$
\begin{gathered}
\mathrm{T}_{\mathrm{amb}}=\Theta \operatorname{Lim}-\mathrm{P}_{\text {on }} \cdot \mathrm{R}_{\text {th }}= \\
=\Theta \operatorname{Lim}-\left(\mathrm{I}_{\text {out }}{ }^{2} \cdot \mathrm{R}_{\mathrm{DSONx}}+\mathrm{P}_{\mathrm{q}}+\mathrm{P}_{\text {os }}\right) \cdot \mathrm{R}_{\text {th }}
\end{gathered}
$$

In particular, this relation is useful to find the maximum ambient temperature $\mathrm{T}_{\text {ambx }}$ at which loutx can be delivered:

$$
\begin{align*}
& \mathrm{T}_{\text {ambx }}=\Theta \operatorname{Lim}-\left(\mathrm{I}_{\text {outx }}{ }^{2} \cdot \mathrm{R}_{\text {DSONx }}+\right. \\
& \left.+\mathrm{P}_{\mathrm{q}}+\mathrm{P}_{\text {os }}\right) \cdot \mathrm{R}_{\text {th }} \tag{4}
\end{align*}
$$

Referring to application circuit in fig. 5, let us consider the worst case:

- The supply voltage is at maximum value of industrial bus ( 30 V instead of the 24 V nominal value). This means also that loutx rises of $25 \%$
( 625 mA instead of 500 mA ).
- All electrical parameters of the device, concerning the calculation, are at maximum values.
- Thermal shutdown threshold is at minimum value.
- No heat sink nor air circulation ( $R_{\text {th }}$ equal to $\left.R_{t h j}-a m b\right)$.

Therefore:
$\mathrm{V}_{\mathrm{s}}=30 \mathrm{~V}, \mathrm{R}_{\text {DSON }}=0.6 \Omega, \mathrm{I}_{\mathrm{q}}=6 \mathrm{~mA}, \mathrm{I}_{\mathrm{os}}=4 \mathrm{~mA} @$ $\mathrm{V}_{\text {os }}=2.5 \mathrm{~V}, \Theta \mathrm{Lim}=135^{\circ} \mathrm{C}$
$R_{\text {thj-amb }}=100^{\circ} \mathrm{C} / \mathrm{W}$ (Minidip); $90^{\circ} \mathrm{C} / \mathrm{W}$ (SO20); $70^{\circ} \mathrm{C} / \mathrm{W}$ (SIP9)

It follows:
$l_{\text {outx }}=0.625 \mathrm{~mA}, \mathrm{R}_{\mathrm{DSONx}}=1.006 \Omega, \mathrm{Pq}_{\mathrm{q}}=180 \mathrm{~mW}$, $P_{o s}=110 \mathrm{~mW}$

From equation 4, we can find:

$$
\begin{aligned}
& \mathrm{T}_{\text {ambx }}= 66.7^{\circ} \mathrm{C}(\text { Minidip }) ; \\
& 73.5^{\circ} \mathrm{C}(\mathrm{SO} 20) ; \\
& 87.2^{\circ} \mathrm{C}(\mathrm{SIP9})
\end{aligned}
$$

Therefore, the IPS TDE1897/1898, although guaranteed to operate up to $85^{\circ} \mathrm{C}$ ambient temperature, if used in the worst conditions, can meet some limitations.
SIP9 package, which has the lowest $R_{\text {thj-amb, }}$ can work at maximum operative current over the entire ambient temperature range in the worst conditions too. For other packages, it is necessary to consider some reductions.
With the aid of equation 3 , we can draw a derating curve giving the maximum current allowable versus ambient temperature. The diagrams, computed using parameter values above given, are depicted in figg. 6 to 8.
If an increase of the operating area is needed, heat dissipation must be improved (Rth reduced) e.g. by means of air cooling.
