## DUAL WIDE BAND OPERATIONAL AMPLIFIER WITH HIGH OUTPUT CURRENT

■ LOW NOISE: $3 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$, $1.2 \mathrm{pA} / \sqrt{ } \mathrm{Hz}$
■ HIGH OUTPUT CURRENT : 200mA

- VERY LOW HARMONIC AND INTERMODULATION DISTORTION

■ HIGH SLEW RATE : 40V/us
■ SPECIFIED FOR $25 \Omega$ LOAD

## DESCRIPTION

The TS613 is a dual operational amplifier featuring a high output current ( 200 mA min.), large gain-bandwidth product ( 130 MHz ) and capable of driving a $25 \Omega$ load with a 160 mA output current at $\pm 6 \mathrm{~V}$ power supply.

This device is particularly intended for applications where multiple carriers must be amplified simultaneously with very low intermodulation products.

The TS613 is housed in a SO8 plastic package and a SO8 Exposed-Pad plastic package.

## APPLICATION

- UPSTREAM line driver for Asymmetric Digital Subscriber Line (ADSL) (NT).

1. All voltages values, except differential voltage are with respect to network terminal.
2. Differential voltages are non-inverting input terminal with respect to the inverting input terminal.
3. The magnitude of input and output voltages must never exceed $\mathrm{V}_{\mathrm{CC}}+0.3 \mathrm{~V}$
4. An output current limitation protects the circuit from transient currents. Short-circuits can cause excessive heating. Destructive dissipation can result from short circuit on amplifiers.

## THERMAL INFORMATION

The TS613 is housed in an Exposed-Pad plastic package. As described on the figures below, this package uses a leadframe upon which the dice is mounted. This leadframe is exposed as a thermal pad on the underside of the package. The thermal contact is direct with the dice. This thermal path provide an excellent thermal performance.
The thermal pad is electrically isolated from all pins in the package. It can also be soldered to a copper area of the PCB underneath the package. Through these thermal paths within this copper area, heat can be conducted away from the package. In this case, the copper area must be connected to (-Vcc)

## INTERMODULATION DISTORTION

The curves shown below are the measurements results of a single operator wired as an adder with a gain of 15 dB .
The operational amplifier is supplied by a symmetric $\pm 6 \mathrm{~V}$ and is loaded with $25 \Omega$.
Two synthesizers (Rhode \& Schwartz SME) generate two frequencies (tones) ( 70 \& $80 \mathrm{kHz} ; 180 \&$ 280 kHz ).
An HP3585 spectrum analyzer measures the spurious level at different frequencies.
The curves are traced for different output levels (the value in the X ax is the value of each tone). The output levels of the two tones are the same. The generators and spectrum analyzer are phase locked to enhance measurement precision.

## 3rd ORDER INTERMODULATION

Gain $=15 \mathrm{~dB}, \mathrm{Vcc}= \pm 6 \mathrm{~V}, \mathrm{RL}=25 \Omega$, 2 tones $70 \mathrm{kHz} /$ 80 kHz

2nd ORDER INTERMODULATION
Gain $=15 \mathrm{~dB}, \mathrm{Vcc}= \pm 6 \mathrm{~V}, \mathrm{RL}=25 \Omega$, 2 tones $180 \mathrm{kHz} /$ 280 kHz , Spurious measurement @100kHz

## 3rd ORDER INTERMODULATION

Gain $=15 \mathrm{~dB}, \mathrm{Vcc}= \pm 6 \mathrm{~V}, \mathrm{RL}=25 \Omega$, 2 tones $180 \mathrm{kHz} /$ 280 kHz

Closed Loop Gain and Phase vs. Frequency
Gain=+2, Vcc= $\pm 6 \mathrm{~V}, \mathrm{RL}=25 \Omega$

Closed Loop Gain and Phase vs. Frequency
Gain $=+11$, $\mathrm{Vcc}= \pm 6 \mathrm{~V}, \mathrm{RL}=25 \Omega$

Maximum Output Swing
$\mathrm{Vcc}= \pm 6 \mathrm{~V}, \mathrm{RL}=25 \Omega$

Closed Loop Gain and Phase vs. Frequency
Gain $=+6$, $\mathrm{Vcc}= \pm 6 \mathrm{~V}$, RL=25 $\Omega$

Equivalent Input Voltage Noise
Gain $=+100, \mathrm{Vcc}= \pm 6 \mathrm{~V}$, no load

Channel Separation (Xtalk) vs. Frequency
XTalk=20Log(V2/V1), Vcc= $\pm 6 \mathrm{~V}$, RL=25 $\Omega$

# TYPICAL APPLICATION : TS613 AS DRIVER FOR ADSL LINE INTERFACES 

## A SINGLE SUPPLY IMPLEMENTATION WITH PASSIVE OR ACTIVE IMPEDANCE MATCHING

by C. PRUGNE

## ADSL CONCEPT

Asymmetric Digital Subscriber Line (ADSL), is a new modem technology, which converts the existing twisted-pair telephone lines into access paths for multimedia and high speed data communications.
ADSL transmits more than 8 Mbps to a subscriber, and can reach 1 Mbps from the subscriber to the central office. ADSL can literally transform the actual public information network by bringing movies, television, video catalogs, remote CD-ROMs, LANs, and the Internet into homes.

An ADSL modem is connected to a twisted-pair telephone line, creating three information channels: a high speed downstream channel (up to 1.1 MHz ) depending on the implementation of the ADSL architecture, a medium speed upstream channel (up to 130 kHz ) and a POTS (Plain Old Telephone Service), split off from the modem by filters.

## THE LINE INTERFACE - ADSL Remote Terminal (RT):

The Figure1 shows a typical analog line interface used for ADSL. The upstream and downstream signals are separated from the telephone line by using an hybrid circuit and a line transformer. On this note, the accent will be made on the emission path.
Figure 1 : Typical ADSL Line Interface

The TS613 is used as a dual line driver for the upstream signal.
For the remote terminal it is required to create an ADSL modem easy to plug in a PC. In such an application, the driver should be implemented with a +12 volts single power supply. This +12 V supply is available on PCl connector of purchase.
The figure 2 shows a single +12 V supply circuit that uses the TS613 as a remote terminal transmitter in differential mode.
Figure 2:TS613 as a differential line driver with a +12 V single supply

The driver is biased with a mid supply (nominaly +6 V ), in order to maintain the DC component of the signal at +6 V . This allows the maximum dynamic range between 0 and +12 V . Several options are possible to provide this bias supply (such as a virtual ground using an operational amplifier), such as a two-resistance divider which is the cheapest solution. A high resistance value is required to limit the current consumption. On the other hand, the current must be high enough to bias the inverting input of the TS613. If we consider this bias current $(5 \mu \mathrm{~A})$ as the $1 \%$ of the current through the resistance divider $(500 \mu \mathrm{~A})$ to keep a stable mid supply, two $47 \mathrm{k} \Omega$ resistances can be used.
The input provides two high pass filters with a break frequency of about 1.6 kHz which is necessary to remove the DC component of the input signal. To avoid DC current flowing in the primary of the transformer, an output capacitor is used. The
$1 \mu \mathrm{~F}$ capacitance provides a path for low frequencies, the 10 nF capacitance provides a path for high end of the spectrum.
In differential mode the TS613 is able to deliver a typical amplitude signal of 18 V peak to peak.
The dynamic line impedance is $100 \Omega$. The typical value of the amplitude signal required on the line is up to 12.4 V peak to peak. By using a $1: 2$ transformer ratio the reflected impedance back to the primary will be a quarter ( $25 \Omega$ ) and therefore the amplitude of the signal required with this impedance will be the half ( 6.2 V peak to peak). Assuming the $25 \Omega$ series resistance ( $12.5 \Omega$ for both outputs) necessary for impedance matching, the output signal amplitude required is 12.4 V peak to peak. This value is acceptable for the TS613. In this case the load impedance is $25 \Omega$ for each driver.
For the ADSL upstream path, a lowpass filter is absolutely necessary to cutoff the higher frequencies from the DAC analog output. In this simple non-inverting amplification configuration, it will be easy to implement a Sallen-Key lowpass filter by using the TS613. For ADSL over POTS, a maximum frequency of 135 kHz is reached. For ADSL over ISDN, the maximum frequency will be 276kHz.

## INCREASING THE LINE LEVEL BY USING AN ACTIVE IMPEDANCE MATCHING

With passive matching, the output signal amplitude of the driver must be twice the amplitude on the load. To go beyond this limitation an active maching impedance can be used. With this technique it is possible to keep good impedance matching with an amplitude on the load higher than the half of the ouput driver amplitude. This concept is shown in figure3 for a differential line.
Figure 3 : TS613 as a differential line driver with an active impedance matching

## Component calculation:

Let us consider the equivalent circuit for a single ended configuration, figure4.
Figure 4 : Single ended equivalent circuit

Let us consider the unloaded system. Assuming the currents through R1, R2 and R3 as respectively;

$$
\frac{2 V i}{R 1}, \frac{\left(V i-V o^{\circ}\right)}{R 2} \text { and } \frac{(V i+V o)}{R 3}
$$

As $V 0^{\circ}$ equals Vo without load, the gain in this case becomes :

$$
G=\frac{V o(\text { noload })}{V i}=\frac{1+\frac{2 R 2}{R 1}+\frac{R 2}{R 3}}{1-\frac{R 2}{R 3}}
$$

The gain, for the loaded system will be (1):

$$
G L=\frac{V o(\text { withload })}{V i}=\frac{1}{2} \frac{1+\frac{2 R 2}{R 1}+\frac{R 2}{R 3}}{1-\frac{R 2}{R 3}},(1)
$$

As shown in figure5, this system is an ideal generator with a synthesized impedance as the internal impedance of the system. From this, the output voltage becomes:

$$
V o=(V i G)-(\text { RoIout }),(2)
$$

with Ro the synthesized impedance and lout the output current. On the other hand Vo can be expressed as:

$$
V o=\frac{V i\left(1+\frac{2 R 2}{R 1}+\frac{R 2}{R 3}\right)}{1-\frac{R 2}{R 3}}-\frac{R s 1 \text { Iout }}{1-\frac{R 2}{R 3}}, \text { (3) }
$$

By identification of both equations (2) and (3), the synthesized impedance is, with Rs1=Rs2=Rs:

$$
R o=\frac{R s}{1-\frac{R 2}{R 3}},(4)
$$

Figure 5 : Equivalent schematic. Ro is the synthesized impedance

Unlike the level $V 0^{\circ}$ required for a passive impedance, $\mathrm{Vo}^{\circ}$ will be smaller than 2 Vo in our case. Let us write $\mathrm{Vo}^{\circ}=\mathrm{kVo}$ with k the matching factor varying between 1 and 2. Assuming that the current through R3 is negligeable, it comes the following resistance divider:

$$
R o=\frac{k V o R L}{R L+2 R s 1}
$$

After choosing the k factor, Rs will equal to $1 / 2 R L(k-1)$.
A good impedance matching assumes:

$$
R o=\frac{1}{2} R L,(5)
$$

From (4) and (5) it becomes:

$$
\frac{R 2}{R 3}=1-\frac{2 R s}{R L},(6)
$$

By fixing an arbitrary value for R2, (6) gives:

$$
R 3=\frac{R 2}{1-\frac{2 R s}{R L}}
$$

Finally, the values of R2 and R3 allow us to extract R1 from (1), and it comes:

$$
R 1=\frac{2 R 2}{2\left(1-\frac{R 2}{R 3}\right) G L-1-\frac{R 2}{R 3}},(7)
$$

with GL the required gain.

| GL (gain for the <br> loaded system) | GL is fixed for the application requirements <br> GL=Vo/Vi $=0.5(1+2 \mathrm{R} 2 / \mathrm{R} 1+\mathrm{R} 2 / \mathrm{R} 3) /(1-\mathrm{R} 2 / \mathrm{R} 3)$ |
| :---: | :--- |
| R1 | $2 \mathrm{R} 2 /[2(1-\mathrm{R} 2 / \mathrm{R} 3) \mathrm{GL}-1-\mathrm{R} 2 / \mathrm{R} 3]$ |
| R2 (=R4) | Abritrary fixed |
| R3 (=R5) | $\mathrm{R} 2 /(1-\mathrm{Rs} / 0.5 R L)$ |
| Rs | $0.5 R L(k-1)$ |

## CAPABILITIES

The table below shows the calculated components for different values of $k$. In this case $R 2=1000 \Omega$ and the gain $=16 \mathrm{~dB}$. The last column displays the maximum amplitude level on the line regarding the TS613 maximum output capabilities ( 18 Vpp diff.) and a $1: 2$ line transformer ratio.

| Active matching |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| k | R1 <br> $(\Omega)$ | R3 <br> $(\Omega)$ | Rs <br> $(\Omega)$ | TS613 Output <br> Level to get <br> 12.4Vpp on <br> the line <br> (Vpp diff) | Maximum <br> Line level <br> (Vpp diff) |
| 1.3 | 820 | 1500 | 3.9 | 8 | 27.5 |
