

## TPS9264x 用于精密调光 LED 驱动器的同步降压控制器

### 1 特性

- $V_{IN}$  范围: 7V 至 85V
- 宽调光范围
  - 500:1 模拟调光
  - 2500:1 标准脉宽调制 (PWM) 调光
  - 20000:1 分流场效应晶体管 PWM 调光
- 可调节发光二极管 (LED) 电流感测电压
- 2 $\Omega$ 、1 A<sub>peak</sub> 金属氧化物半导体场效应晶体管 (MOSFET) 栅极驱动器
- 分流调光 MOSFET 栅极驱动器 (TPS92641)
- 可编程开关频率
- 精密电压基准 3V $\pm$ 2%
- 输入欠压锁定 (UVLO) 和输出过压保护 (OVP)
- 低功耗关断模式和热关断

### 2 应用

- LED 驱动器/恒流稳压器
- 建筑 LED 照明驱动器
- 汽车类 LED 驱动器
- 通用 LED 照明

### 3 说明

TPS92640 和 TPS92641 器件是用于降压电流稳压器的高电压、同步 N 沟道场效应晶体管 (NFET) 控制器。输出电流调节基于采用导通时间受控架构的谷值电流模式操作方式。这种控制方法可简化环路补偿设计, 同时使开关频率维持在近似恒定的水平。

TPS92640 和 TPS92641 器件包含一个高电压启动稳压器, 该稳压器在 7V 至 85V 的宽输入范围内工作。PWM 控制器专为高速性能而设计, 振荡器频率范围高达 1MHz。高侧和低侧栅极驱动器之间的死区时间进行了优化, 以在宽输入工作电压和输出功率范围内高效运行。TPS92640 和 TPS92641 能够接收模拟和 PWM 输入信号, 因此可提供优异的调光控制范围。输入命令和 LED 电流之间的线性响应特性可通过使用低偏移误差放大器 and 专用 PWM 调光逻辑实现真正的零 LED 电流的方式实现。两种器件还具备为低功耗微控制器提供精密基准电流的能力。保护特性包括: 逐周期电流保护、过压保护和热关断。TPS92641 器件包含一个用于高分辨率 PWM 调光的分流 FET 调光输入和 MOSFET 驱动器。

#### 器件信息<sup>(1)</sup>

部件号	封装	封装尺寸 (标称值)
TPS92640	HTSSOP (14)	4.40mm × 5.00mm
TPS92641	HTSSOP (16)	4.40mm × 5.00mm

(1) 要了解所有可用封装, 请见数据表末尾的可订购产品附录。

### Pin Functions

NAME	PIN		I/O	DESCRIPTION
	NO. (TPS92640)	NO. (TPS92641)		
BOOT	12	14	O	Connect 100-nF ceramic capacitor to switch node and diode to VCC to provide boosted voltage for high-side gate drive.
COMP	7	7	O	Connect ceramic capacitor to GND to set loop compensation.
CS	9	11	I	Connect to positive terminal of sense resistor at the bottom of the LED stack.
GND	8	10	—	System GND. Connect to DAP.
HG	14	16	O	Connect to gate of high-side NFET of buck regulator. Use series resistor to limit current slew-rate and mitigate EMI noise.
IADJ	6	6	I	Connect resistor divider from VREF to set analog dimming level. Use NTC resistor from pin to GND as resistor divider to implement thermal foldback operation.
LG	10	12	O	Connect to gate of low-side NFET of buck regulator. Use series resistor to limit current slew-rate and mitigate EMI noise.
RON	2	2	I	Connect a resistor to VIN and capacitor to GND to set switching frequency.
SDIM	—	8	I	PWM dimming input for shunt FET dimming.
SDRV	—	9	O	Connect to gate of external parallel NFET across LED load used for shunt dimming if desired.
SW	13	15	O	Connect to switch node of buck regulator.
UDIM	3	3	I	Connect resistor divider from VIN to set undervoltage lockout threshold.
VCC	11	13	O	Bypass with 2.2- $\mu$ F ceramic capacitor to provide bias supply for controller.
VIN	1	1	I	Connect to input voltage. Connect 1- $\mu$ F bypass capacitor
VOUT	4	4	I	Connect resistor divider from $V_{OUT}$ , scaled down feedback of $V_{OUT}$ .
VREF	5	5	O	System reference voltage. Bypass with 100-nF ceramic capacitor.
DAP	—	—	—	Place 6-9 vias from pad to GND plane for thermal relief.

## 6 Specifications

### 6.1 Absolute Maximum Ratings

 over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

	MIN	MAX	UNIT
V <sub>IN</sub> , UDIM, SW	-0.3	90	V
		-1	mA
BOOT	-0.3	98.5	V
HG	-0.3	90	V
		-2.5 (Pulse < 100 ns)	V
LG, SDRV, CS	-0.3	+V <sub>CC</sub>	V
		-2.5 (Pulse < 100 ns)	V
		V <sub>CC</sub> + 2.5 (Pulse < 100 ns)	V
V <sub>CC</sub>	-0.3	15	V
VREF, RON, COMP, VOUT, IADJ, SDIM	-0.3	6	V
		-200	200
GND	-0.3	0.3	V
		-2.5 (Pulse < 100 ns)	2.5 (Pulse < 100 ns)
Continuous power dissipation	Internally Limited		
Maximum lead temperature (soldering and reflow) <sup>(2)</sup>	260		°C
Maximum junction temperature	-40	125	°C
Storage temperature	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Refer to TI's packaging website for more detailed information and mounting techniques.

### 6.2 ESD Ratings

			VALUE	UNIT
<b>TPS92640 PWP PACKAGE</b>				
V <sub>(ESD)</sub> Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>		±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>		±1000	
<b>TPS92641 PWP PACKAGE</b>				
V <sub>(ESD)</sub> Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>		±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>		±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	NOM	MAX	UNIT
V <sub>IN</sub> Input voltage	7		85	V
T <sub>J</sub> Junction temperature	-40		125	°C

## 6.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		TPS92640	TPS92641	UNIT
		PWP (HTSSOP)	PWP (HTSSOP)	
		14 PINS	16 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	40.1	38.7	°C/W

## 7 Detailed Description

### 7.1 Overview

The TPS92640 and TPS92641 devices are synchronous N-channel MOSFET (NFET) controllers for step-down (buck) current regulators, which are ideal for driving LED loads. They can accept wide input voltage range allowing for greater flexibility in powering different series connected LED string combinations. The single current sense pin with low adjustable threshold voltage provides an excellent method for regulating LED current while maintaining high system efficiency. The TPS92640 and TPS92641 devices use valley current control with a controlled on-time architecture that allows the converter to be operated at nearly constant switching frequency without the need for slope compensation. The extremely accurate adjustable current sense threshold together with the synchronous operation provides the capability to amplitude (analog) dim the LED current with high contrast ratios. Excellent PWM dimming is attainable using the main NFETs or the external shunt FET driver (TPS92641 only). The TPS92640 and TPS92641 devices incorporate 2- $\Omega$ , 1-A internal gate drivers and supports constant current operation up to 5 A. This simple controller contains all the features necessary to implement a high-efficiency, versatile LED driver with precise dimming response.

### 7.2 Functional Block Diagram

### 7.3 Feature Description

Figure 13. Synchronous Buck LED Driver

#### 7.3.1 Controlled On-Time Architecture

The control architecture is a combination of valley current control and a one-shot on-timer that varies with input and output voltage. The TPS92640 and TPS92641 devices use a series resistor in the LED path to sense both average LED current and valley inductor current. During the time that the high side NFET is turned on ( $t_{ON}$ ), the input voltage charges up the inductor. When it is turned off ( $t_{OFF}$ ) and the low side NFET is turned on, the inductor discharges. During both intervals, the current is supplied to the load keeping the LEDs forward biased. Figure 14 shows the inductor current ( $i_L$ ) waveform for a buck converter operating in continuous conduction mode (CCM). As the system changes input voltage or output voltage, duty cycle  $D$  is varied indirectly by changing both  $t_{ON}$  and  $t_{OFF}$  to regulate  $i_L$  and ultimately  $I_{LED}$ . For any buck regulator, duty cycle,  $D$ , is calculated using Equation 1.

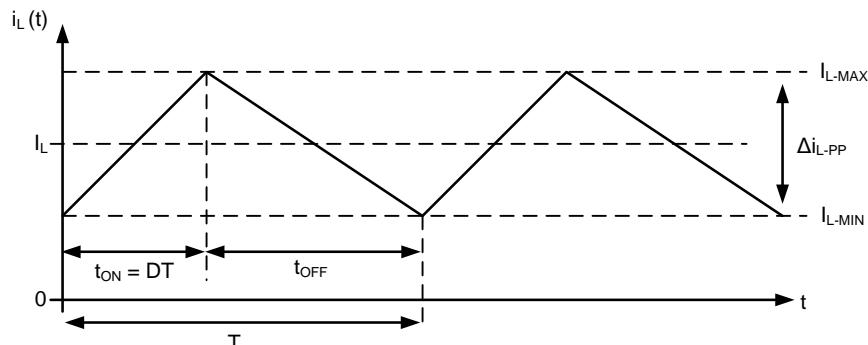

$$D = \frac{T_{ON}}{T_{ON} + T_{OFF}} = \frac{V_{OUT}}{\eta \times V_{IN}}$$

$$V_{OUT} = V_{LED} + V_{CS}$$

where

- $V_{CS}$  is the voltage measured at the CS pin of the IC and  $\eta$  is the estimated or actual converter efficiency. (1)

## Feature Description (continued)

**Figure 14. Ideal CCM Buck Converter Inductor Current  $i_L$  Waveform**

### 7.3.2 Switching Frequency

The on-time is determined based on the external resistor ( $R_{ON}$ ) connected between  $R_{ON}$  and  $V_{IN}$  pins in combination with a capacitor ( $C_{ON}$ ) between  $R_{ON}$  and GND pins. The input voltage and the  $R_{ON}$  resistor set the current sourced into the  $R_{ON}$  capacitor which governs the ramp speed. The ramp threshold is proportional to scaled down feedback of  $V_{OUT}$  at  $V_{OUT}$  pin. The proportionality of  $V_{OUT}$  is set by an external resistor divider ( $R_{V_{OUT}1}$ ,  $R_{V_{OUT}2}$ ) from  $V_{OUT}$ . The switching frequency,  $f_{SW}$  can be calculated based on on-time and off-time using [Equation 2](#).

$$\frac{V_{IN}}{R_{ON}} = C_{ON} \times \frac{V_{OUT} \times \frac{R_{V_{OUT}2}}{(R_{V_{OUT}1} + R_{V_{OUT}2})}}{t_{ON}}$$

$$\frac{V_{IN}}{R_{ON}} = C_{ON} \times \frac{V_{IN} \times \frac{t_{ON}}{T} \times \frac{R_{V_{OUT}2}}{(R_{V_{OUT}1} + R_{V_{OUT}2})}}{t_{ON}}$$

$$f_{SW} = \frac{1}{T} = \frac{(R_{V_{OUT}1} + R_{V_{OUT}2})}{R_{V_{OUT}2}} \times \frac{1}{R_{ON} \times C_{ON}} \quad (2)$$

Even though the on-time control is quasi-hysteretic, the input and output voltage proportionality creates a nearly constant switching frequency over the entire operating range. Quasi-hysteretic control minimizes the control loop compensation necessary in many switching regulators, simplifying the design process. It also mitigates current mode instability (also known as sub-harmonic oscillation) found in standard fixed frequency current mode control when operating near or above 50% duty cycle. The inductor current sensing and averaging mechanism in the valley detection control loop provides highly accurate LED current regulation over the entire operating range and temperature.

### 7.3.3 Average LED Current

Average LED current regulation is set using a sense resistor in series with the LEDs. The internal error-amplifier regulates the voltage across the sense resistor ( $V_{CS}$ ) to the  $I_{ADJ}$  voltage divided by 10. The error amplifier input offset voltage has been minimized using auto-zero calibration technique as shown in . In this chopping scheme, the noninverting and inverting inputs and outputs change polarity every switching cycle to cancel the offset, providing near zero input offset voltage.

Feature Description (continued)

Figure 15. Working Principle of the Chopper OTA to Minimize Input Offset Voltage

IADJ can be set to any value up to 2.54 V by connecting it to VREF through a resistor divider for static output current settings. IADJ can also be used to change the regulation point if connected to a controlled voltage source or potentiometer to provide analog dimming. It is also possible to configure IADJ to be used for thermal foldback functions.

$$I_{LED} = \frac{V_{CS}}{R_{CS}} \tag{3}$$

$$V_{CS} = \frac{V_{IADJ}}{10} \tag{4}$$

7.3.4 Analog Dimming and True-Zero Operation

In traditional Buck converters, discontinuous conduction mode (DCM) operation of inductor current results in loss of linearity at low dimming levels and limits the analog dimming range. When using TPS92640 and TPS92641 devices to implement synchronous buck converter, the inductor current is forced to maintain continuous conduction mode (CCM). As a result, it is possible to maintain linearity and achieve true-zero LED current operation with respect to analog dimming command. For true zero application, an external capacitor is required across the LED string to provide a negative current path for the inductor current loop. Figure 16 shows the inductor current ( $I_L$ ) and output voltage ( $V_{OUT}$ ) waveform for a buck converter operating at true zero average current level.

Figure 16. True Zero CCM Buck Converter Inductor Current  $I_L$  and Output Voltage  $V_{OUT}$  Waveform

In true zero application ( $V_{IADJ}=0$  V), there will be a certain amount of  $I_{LED}$  passing the LEDs even though the average inductor current is well-regulated at 0-A set-point. The shaped area in Figure 17 shows the current that will pass through the LED string ( $i_{LED}$ ).

**Feature Description (continued)**

**Figure 17. Output Current Waveform in True Zero Application with  $V_{IADJ} = 0\text{ V}$** 

An external resistor,  $R_{OFF}$  as shown in Figure 18 is recommended from  $V_{OUT}$  to CS to shunt the positive current ripple while maintaining the operation of error amplifier to cancel input offset voltage. The shunt current ( $I_{OFF}$ ) should be at least half of the output current ripple to ensure proper operation.

$$I_{OFF} = \frac{V_{OUT}}{R_{OFF} + R_F + R_{CS}} > 0.5 \times \Delta I_{LED}$$

$$R_{OFF} < \frac{V_{OUT}}{0.5 \times \Delta I_{LED}} - (R_F + R_{CS})$$

(5)

**Figure 18.  $R_{OFF}$  for True Zero Application**

The resistor  $R_{OFF}$  also impacts the start-up behavior of the circuit as it creates an DC shift in the voltage sensed at CS pin. To ensure proper start-up sequence and monotonic LED current behavior, the voltage  $V_{CS}$  should exceed a threshold voltage based on the native offset of the error amplifier before  $V_{OUT}$  exceeding the LED forward voltage,  $V_{LED}$ . Assuming a worst case native off-set (non-chopping) of error amplifier to be less than  $\pm 10\text{ mV}$ , the voltage  $V_{CS}$  must be greater than this threshold to initiate switching and auto-zero operation. Therefore,  $R_{OFF}$  should be sized to also meet following condition.

$$V_{CS} = V_{OUT} \times \left( \frac{R_F + R_{CS}}{R_{OFF} + R_F + R_{CS}} \right) > 0.01$$

$$R_{OFF} < \left[ V_{OUT} \times \left( \frac{R_F + R_{CS}}{0.01} \right) - (R_F + R_{CS}) \right]$$

$$R_F \gg R_{CS}$$

$$R_{OFF} < (100 \times V_{OUT}) \times R_F$$

(6)

## Feature Description (continued)

To conclude, an external resistor ( $R_{OFF}$ ) from  $V_{OUT}$  to CS pin is required for true zero application, where  $R_{OFF}$  should be:

$$R_{OFF} = \min \left[ \frac{V_{OUT}}{0.5 \times \Delta I_{LED}} - (R_F + R_{CS}); (100 \times V_{OUT}) \times R_F \right] \quad (7)$$

### 7.3.5 Undervoltage Lockout (UVLO)

The UDIM pin of the TPS92640 and TPS92641 devices is a dual function input that features an accurate 1.276-V threshold with programmable hysteresis. This pin functions as both the PWM dimming input of the LEDs and as an input UVLO with built-in hysteresis. When the pin voltage rises and exceeds the 1.276-V threshold, 21  $\mu$ A (typical) of current is driven out of the UDIM pin into the resistor divider ( $R_{UDIM1}$ ,  $R_{UDIM2}$ ) providing programmable hysteresis. The UVLO turnon threshold,  $V_{TURN\_ON}$ , is defined using Equation 8.

$$V_{TURN\_ON} = 1.276V \times \left( \frac{R_{UDIM1} + R_{UDIM2}}{R_{UDIM2}} \right) \quad (8)$$

Once the input voltage is above  $V_{TURN\_ON}$ , the current source is active and the UVLO hysteresis is determined by Equation 9.

$$V_{HYS} = 21\mu A \times (R_{UDIM1}) \quad (9)$$

When using the UDIM pin for UVLO and PWM dimming concurrently, the UVLO circuit can have an extra resistor ( $R_{UDIM3}$ ) to set the hysteresis. This allows the standard resistor divider to have smaller values minimizing delays that can incur with additional external PWM dimming circuitry. In general, at least 3 V of hysteresis is preferable when PWM dimming if operating near the UVLO threshold. Under these conditions, the UVLO hysteresis is defined using Equation 10.

$$V_{HYS} = 21\mu A \times \left( R_{UDIM1} + \frac{R_{UDIM3} \times (R_{UDIM1} + R_{UDIM2})}{R_{UDIM2}} \right) \quad (10)$$

### 7.3.6 PWM Dimming Using the UDIM Pin

The UDIM pin can be driven with a PWM signal, which controls the synchronous NFET operation. The brightness of the LEDs can be varied by modulating the duty cycle ( $D_{DIM}$ ) of this signal using a Schottky diode with anode connected to UDIM pin, as shown in Figure 13.

**Figure 19. LED Current During UDIM Pin PWM Dimming**

Figure 19 shows the LED current waveform during PWM dimming where duty cycle ( $D_{DIM}$ ) is the percentage of the dimming period ( $T_{DIM}$ ) that the synchronous NFETs are switching. For the remainder of  $T_{DIM}$ , the NFETs are disabled. The resulting dimmed LED current ( $I_{DIM\_LED}$ ) is:

$$I_{DIM\_LED} = D_{DIM} \times I_{LED} \quad (11)$$

## Feature Description (continued)

### 7.3.7 External Shunt FET PWM Dimming

Extremely high dimming range and linearity can be achieved by using TPS92641 device for Shunt FET dimming operation with SDIM and SDRV pin. When higher frequency and time resolution PWM dimming signal is applied to the SDIM pin, the SDRV pin provides an inverted signal of the same frequency and duty cycle that can be used to drive the gate of a Shunt NFET directly across the LED load. Because the output voltage will go to near zero when the Shunt NFET is turned on, the internal on-timer at the RON pin will switch to a fixed minimum on-time during the off-time of the dimming cycle. This method keeps the inductor current slewed up and the converter regulating, without the presence of extremely high switching frequencies. During the on-time of the dimming cycle, the converter will switch in its regular fashion with the programmed on-time at the RON pin. An internal resistor pulls the SDIM pin to logic high if left open. In this case, the SDRV driver will be off.

**Figure 20. Ideal LED Current During Shunt FET PWM Dimming**

Figure 20 shows the ideal LED current waveform during Shunt FET PWM dimming which is very similar to the internal PWM dimming described and shown previously except with much faster rise and fall of the LED current. With this method, only the speed of the parallel Shunt NFET limits the dimming frequency and dimming duty cycle.

### 7.3.8 VCC Regulation and Start-up

The TPS92640 and TPS92641 devices include a high voltage, low-dropout bias regulator. When power is applied, the regulator is enabled and sources current into an external capacitor ( $C_{VCC}$ ) connected to the VCC pin. The recommended bypass capacitance for the VCC regulator is 2.2  $\mu\text{F}$  to 3.3  $\mu\text{F}$ . This capacitor should be rated for 10 V or greater and an X7R dielectric ceramic is recommended. The output of the VCC regulator is monitored by an internal UVLO circuit that protects the device from attempting to operate with insufficient supply voltage, and the supply current is also internally current-limited. When  $V_{IN}$  is close or lower than 8.5 V, the regulator will enter the by-pass mode and the VCC will closely follow  $V_{IN}$ . This linear regulator is the primary heat source generator of the device. The amount of heat generated is a function of input voltage ( $V_{IN}$ ), switching frequency ( $F_{SW}$ ) and the characteristics of the power MOSFET used. The thermal handling capability of the device imposes a limit on the maximum switching frequency can be used, especially when  $V_{IN}$  is higher than 48 V and high current power MOSFET is used.

### 7.3.9 Precision Reference

The device includes a precision 3-V reference. This can be used in conjunction with a resistor divider to set voltage levels for the IADJ pin and other external circuitry requiring a reference. It can also be used to supply current to low power micro-controllers. The source current capability from VREF pin is internally limited 2.1 mA. For the VREF regulator, TI recommends a bypass capacitance from 0.1  $\mu\text{F}$  to 1  $\mu\text{F}$ .

### 7.3.10 Control Loop Compensation

Compensating the TPS92640 and TPS92641 devices is relatively simple for most applications. The only compensation needed is a compensation capacitor,  $C_{COMP}$  across the COMP pin and ground to place a low-frequency dominant pole in the system. The pole must be placed low enough to ensure adequate phase margin at the crossover frequency. For most of the applications,  $C_{COMP}$  of 100 nF to 470 nF is good enough. Additionally, TI recommends a high quality ceramic capacitor with X7R dielectric rated for 25 V.

## Feature Description (continued)

### 7.3.11 Overcurrent Protection

The TPS92640 and TPS92641 devices has overcurrent protection to protect the high side NFET (HS-NFET) along with the rest of the system from overcurrent conditions. This peak current limit of 1.28 V (with  $V_{IN} = 85$  V at room temperature) is sensed across the high side FET  $R_{DS-ON}$  (from SW to VIN). If the threshold is reached or exceeded, HS-NFET will turn off and the low side NFET (LS-NFET) will turn on for approximately 800 ns. Then HS-NFET will turn on again, if the threshold is still reached or exceeded, both FETs are shutoff for 270- $\mu$ s typical. Figure 21 shows the waveforms of HG and LG under overcurrent protection.

Figure 21. HG and LG Waveforms Under Overcurrent Protection

### 7.3.12 Overvoltage Protection (OVP)

The TPS92640 and TPS92641 devices have programmable overvoltage protection by using the resistor divider at the VOUT pin. The OVP limit,  $V_{OVP\_ON}$ , is defined using Equation 12.

$$V_{OVP\_ON} = 3.05V \times \left( \frac{R_{VOUT1} + R_{VOUT2}}{R_{VOUT2}} \right) \quad (12)$$

If the output voltage reaches  $V_{OVP\_ON}$ , the HG, LG and SDRV pins are pulled low to prevent damage to the LEDs or the rest of the circuit. The OVP circuit has a fixed hysteresis of 100 mV before the driver attempts to switch again.

### 7.3.13 Boot Undervoltage Lockout (UVLO)

The BOOT UVLO circuit is implemented to ensure proper operation of the high-side gate driver under all operating conditions. The switching operation is commenced once the BOOT voltage exceeds 3.4 V above the SW pin. Comparator hysteresis of 1.8 V is included to prevent false tripping due to high-frequency switching noise. When the BOOT falls below the low voltage threshold (1.6 V typical), the high side NFET is disabled by pulling HG pin to SW pin. The next turnon transition of low-side NFET pulls SW pin down and charges the BOOT capacitor ( $C_{BOOT}$ ) through VCC. Normal operation is commenced once BOOT capacitor ( $C_{BOOT}$ ) is charged above BOOT UVLO turnon threshold of 3.4 V.

The bootstrap circuit behavior impacts the circuit behavior near dropout ( $V_{IN} = V_{OUT}$ ) conditions. A minimum off-time is implemented to restrict the maximum duty cycle and maintain charge on the external BOOT capacitor,  $C_{BOOT}$ . As the input voltage,  $V_{IN}$ , approaches close to the output voltage,  $V_{OUT}$ , the output current will fall with the switching frequency, as in conventional Buck regulator. This behavior ensures smooth operation in and out of dropout region while ensuring proper operation of high side gate driver and bootstrap circuit.

## 7.4 Device Functional Modes

### 7.4.1 Low Power Shutdown Using the UDIM Pin

The TPS92640 and TPS92641 devices can be placed into a low power shutdown mode by grounding the UDIM pin directly (any voltage below 370 mV) for more than 13 ms (typical).

### 7.4.2 Thermal Shutdown

Internal thermal shutdown circuitry is provided to protect the device in the event that the maximum junction temperature is exceeded. The threshold for thermal shutdown is 165°C with a 20°C hysteresis (both values typical). During thermal shutdown the NFETs and drivers are disabled.

## 8 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 8.1 Application Information

#### 8.1.1 Switching Frequency

Switching frequency is selected based on the trade-offs between efficiency, solution size/cost and the range of output voltage that can be regulated. Many applications place limits on switching frequency due to EMI sensitivity. The on-time of the TPS92640 and TPS92641 devices can be programmed for switching frequencies ranging from the tens of kHz to over 1 MHz. This on-time varies in proportion to both  $V_{IN}$  and  $V_{OUT}$ , as described in [Switching Frequency](#). However, in practice the switching frequency will shift in response to large swings in input or output voltage. The maximum switching frequency is limited only by the minimum on-time and minimum off-time requirements.

#### 8.1.2 LED Ripple Current

The LED manufacturers generally recommend values of current ripple,  $\Delta I_{LED}$ , to achieve optimal optical efficiency. The peak-to-peak current ripple values typically range from  $\pm 10\%$  to  $\pm 40\%$  of DC current,  $I_{LED}$ . Higher LED ripple current allows the use of smaller inductors, smaller output capacitors, or no output capacitors at all. Lower ripple current requires more inductance, higher switching frequency, or additional output capacitance. Based on the LED current ripple specification and desired switching frequency, the inductor value can be calculated using [Equation 13](#).

$$L = \frac{V_{IN} - V_{OUT}}{\Delta I_{LED}} \times t_{ON} \quad (13)$$

It is important to ensure that the rated inductor saturation current is greater than the worst case operating current ( $I_{LED} + \Delta I_{LED}/2$ ) under the wide operating temperature range.

#### 8.1.3 Buck Converters Without Output Capacitor

A Buck regulator is ideal for regulating current because of the direct connection between the inductor and the LED load. Because the current is being regulated, not voltage, a buck current regulator is free of load current transients, and has no need of output capacitance to supply the load and maintain output voltage. This is of great benefit when driving LEDs as large electrolytic capacitors impact the lifetimes and PWM dimming performance. The output capacitor can be eliminated by using a large inductor or higher switching frequency as discussed in [LED Ripple Current](#)

A capacitor placed in parallel with the LED or array of LEDs can be used to reduce  $\Delta I_{LED}$  while keeping the same average current through both the inductor and the LED array. With this topology the inductance can be lowered, making the magnetics smaller and less expensive. Alternatively, the circuit can be run at lower frequency with the same inductor value, improving the efficiency and expanding the range of output voltage that can be regulated.

[Figure 22](#) shows the equivalent impedances presented to the  $\Delta I_{L-PP}$  when an output capacitor,  $C_{OUT}$ , and its equivalent series resistance ( $R_{ESR}$ ) are placed in parallel with the LED array.

**Application Information (continued)**

**Figure 22. LED Ripple Current With  $C_{OUT}$** 

To calculate the respective ripple currents, the LED array is represented as the dynamic resistance, ( $r_D$ ). LED's dynamic resistance is not always specified on the manufacturer's data sheet, but it can be calculated as the inverse slope of the LED's  $V_{LED}$  vs  $I_{LED}$  curve at the operating point. However, this method only gives an rough estimate of  $r_D$ . Total dynamic resistance for a string of  $n$  LEDs connected in series can be calculated as the  $r_D$  of one device multiplied by  $n$ . Inductor ripple current,  $\Delta i_{L-PP}$  is still calculated as before. The following equations can then be used to estimate peak-to-peak LED current ripple,  $\Delta i_{LED-PP}$ , when using a parallel capacitor:

$$\Delta i_{LED-PP} = \frac{\Delta i_{L-PP}}{1 + \frac{r_D}{Z_{COUT}}} \quad Z_{COUT} = \frac{1}{2 \times \pi \times f_{SW} \times C_{OUT}} \quad (14)$$

The calculation for  $Z_{COUT}$  assumes that the shape of the inductor ripple current is approximately sinusoidal. Small values of  $C_{OUT}$  that do not significantly reduce  $\Delta i_{LED-PP}$  can also be used to control EMI generated by the switching action of the TPS92640 and TPS92641 devices. EMI reduction becomes more important as the length of the connections between the LED and the rest of the circuit increase.

**8.1.4 Input Capacitor**

Input capacitor is selected using requirements for minimum capacitance and rms ripple current. The input capacitor supply pulses of current approximately equal to  $I_{LED}$  while the high-side NFET is on, and is charged up by the input voltage while the high-side NFET is off. Switching converters such as the TPS92640 and TPS92641 devices have a negative input impedance due to the decrease in input current as input voltage increases. This inverse proportionality of input current to input voltage can cause oscillations (sometimes called power supply interaction) if the magnitude of the negative input impedance is greater than the input filter impedance. Minimum capacitance can be selected by comparing the input impedance to the converter's negative resistance; however, this requires accurate calculation of the input voltage source inductance and resistance, quantities which can be difficult to determine. An alternative method to select the minimum input capacitance ( $C_{IN-MIN}$ ) is to select the maximum voltage ripple ( $\Delta V_{IN-MAX}$ ), which can be tolerated.  $\Delta V_{IN-MAX}$  is equal to the change in voltage across  $C_{IN}$  during  $t_{ON}$  when it supplies the load current. A good starting point for selection of  $C_{IN}$  is to use an input voltage ripple of 2% to 10% of  $V_{IN}$ .  $C_{IN-MIN}$  can be selected using [Equation 15](#).

$$C_{IN-MIN} = \frac{I_{LED} \times t_{ON}}{\Delta V_{IN-MAX}} = \frac{I_{LED} \times \left( \frac{1}{f_{SW}} - t_{OFF} \right)}{\Delta V_{IN-MAX}} \quad (15)$$

TI recommends a minimum input capacitance at least 75% greater than the  $C_{IN-MIN}$  value. To determine the RMS input current rating ( $I_{IN-RMS}$ ), use [Equation 16](#).

$$I_{IN-RMS} = I_{LED} \times \sqrt{D \times (1-D)} = I_{LED} \times f_{SW} \times \sqrt{t_{ON} \times t_{OFF}} \quad (16)$$

## Application Information (continued)

Because this approximation assumes there is no inductor ripple current, the value should be increased by 10-30% depending on the amount of ripple that is expected. Ceramic capacitors are the best choice for the input to the TPS92640 and TPS92641 devices due to their high ripple current rating, low ESR, low cost, and small size compared to other types. When selecting a ceramic capacitor, special attention must be paid to the operating conditions of the application. Ceramic capacitors can lose one-half or more of their capacitance at their rated DC voltage bias and also lose capacitance with extremes in temperature. Make sure to check any recommended deratings and also verify if there is any significant change in capacitance at the operating input voltage and the operating temperature.

### 8.1.5 NFETs

The TPS92640 and TPS92641 devices require two external NFETs for the switching regulator. The FETs should have a voltage rating at least 20% higher than the maximum input voltage to ensure safe operation during the ringing of the switch node. In practice, all switching converters have some ringing at the switch node due to the diode parasitic capacitance and the lead inductance. The NFETs should also have a current rating at least 50% higher than the average transistor current. Once NFETs are chosen, the power rating is verified by calculating the power loss.

## Typical Applications (continued)

$$V_{OUT} \times \frac{R_{VOUT2}}{R_{VOUT1} + R_{VOUT2}} = 2.5V$$

$$\frac{R_{VOUT2}}{R_{VOUT1} + R_{VOUT2}} = \frac{2.5}{V_{OUT}}$$

$$V_{OUT} = V_{LED} + I_{LED} \times R_{SNS} \quad (17)$$

### 8.2.1.2.2 Set Switching Frequency

The switching frequency is set as follows:

$$f_{SW} = \frac{\frac{R_{VOUT1} + R_{VOUT2}}{R_{VOUT2}}}{R_{ON} \times C_{ON}} \quad (18)$$

### 8.2.1.2.3 Set Average LED Current

The average LED current ( $I_{LED}$ ) is set by:

$$I_{LED} = \frac{V_{IADJ}}{10 \times R_{CS}}$$

$$V_{IADJ} = V_{REF} \times \frac{R_{IADJ2}}{R_{IADJ1} + R_{IADJ2}}$$

$$V_{REF} = 3.03V \quad (19)$$

### 8.2.1.2.4 Set Inductor Ripple Current

First, the expected duty cycle, D must be determined:

$$D = \frac{V_{OUT}}{\eta \times V_{IN}} \quad \eta : \text{expected efficiency} \quad (20)$$

With the inductor ripple current,  $\Delta i_{L-PP}$  specified and the expected duty cycle, the inductance (L) can be chosen:

$$L = \frac{(V_{IN} - V_{OUT}) \times D}{\Delta i_{L-PP} \times f_{SW}} \quad (21)$$

### 8.2.1.2.5 Set LED Ripple Current and Determine Output Capacitance, $C_{OUT}$

The LED ripple current ( $\Delta i_{LED-PP}$ ) is specified. With the target ripple current determined, the output capacitance ( $C_{OUT}$ ) can be chosen using [Equation 22](#).

$$C_{OUT} = \frac{\Delta i_{L-PP}}{8 \times f_{SW} \times r_D \times \Delta i_{LED-PP}} \quad (22)$$

### 8.2.1.2.6 Choose N-Channel MOSFETs

The suggested minimum voltage rating,  $V_{T-MAX}$  and current rating,  $I_{T-MAX}$  are:

$$V_{T-MAX} = 1.2 \times V_{IN-MAX}$$

$$I_{T-MAX} = 1.5 \times D_{MAX} \times I_{LED} \quad (23)$$

Selecting a proper power MOSFET is critical in a power application, other than the SOA limits, the gate characteristic and the  $R_{DS(ON)}$  can affect the system performance seriously.

## Typical Applications (continued)

Also, the peak current limit ( $I_{LIMIT}$ ) is governed by:

$$I_{LIMIT} \approx \frac{1.28V}{R_{DSON}} \quad V_{IN} = 85V, \text{ at room temperature} \quad (24)$$

Both the current limit threshold and MOSFET  $R_{DSON}$  are loosely specified and can vary a lot with temperature, input voltage and other operating conditions.

### 8.2.1.2.7 Choose Input Capacitance

Input capacitance is necessary to provide instantaneous current to the discontinuous portions of the circuit during the high side NFET on-time. The allowable input voltage ripple ( $\Delta V_{IN-PP}$ ) is specified at approximately 3% Pk-Pk of  $V_{IN}$ . The minimum required capacitance ( $C_{IN\_MIN}$ ) to achieve this specification is:

$$C_{IN\_MIN} = \frac{I_{LED} \times D}{\Delta V_{IN-PP} \times f_{SW}} \quad (25)$$

The necessary RMS input current rating ( $I_{IN-RMS}$ ) can be approximated as follows:

$$I_{IN-RMS} = I_{LED} \times \sqrt{D \times (1-D)} \quad (26)$$

### 8.2.1.2.8 Set the Turnon Voltage and Undervoltage Lockout Hysteresis

With the desired turnon threshold voltage ( $V_{TURN\_ON}$ ) stated, the resistor divider network composing with  $R_{UDIM1}$  and  $R_{UDIM2}$  can be calculated with the equation in below.

$$V_{TURN\_ON} = 1.276V \times \left( \frac{R_{UDIM1} + R_{UDIM2}}{R_{UDIM2}} \right)$$

$$R_{UDIM2} = \frac{1.276V \times R_{UDIM1}}{V_{TURN\_ON} - 1.276V} \quad (27)$$

Then  $R_{UDIM3}$  is optional and recommended for PWM. The  $R_{UDIM3}$  can be calculated based on [Equation 10](#) to provide the desired undervoltage lockout hysteresis ( $V_{HYS}$ ).

## Typical Applications (continued)

### 8.2.2 TPS92640 – PWM Dimming Application

Figure 24. PWM Dimming Using UDIM Pin Schematic

#### 8.2.2.1 Design Requirements

- $V_{IN} = 48\text{ V} \pm 10\%$
- $V_{LED} = 3.25\text{ V}$ ,  $325\text{-m}\Omega$  dynamic resistance
- 10 LEDs in Series,  $r_D = 3.25\ \Omega$
- $I_{LED} = 1\text{ A}$
- $f_{SW} = 500\text{ kHz}$
- $V_{CS} = 200\text{ mV}$
- $\Delta i_{LED-PP} \leq 300\text{ mA}$
- $\Delta V_{IN-PP} \leq 1.5\text{ V}$
- $V_{TURN-ON} = 40\text{ V}$
- $V_{HYS} = 15\text{ V}$

#### 8.2.2.2 Detailed Design Procedure

##### 8.2.2.2.1 Calculate Operating Points

Calculate the operating points using [Equation 28](#) to [Equation 30](#), and assume approximately 90% conversion efficiency ( $\eta = 0.9$ ).

$$V_{OUT} = n \times V_{LED} + 200\text{mV} = 10 \times 3.25\text{V} + 200\text{mV} = 32.7\text{V} \quad (28)$$

**Typical Applications (continued)**

$$D = \frac{V_{OUT}}{\eta \times V_{IN}} = \frac{32.7}{0.9 \times 48V} = 0.76 \quad (29)$$

$$D_{MAX} = \frac{V_{OUT}}{\eta \times V_{IN-MIN}} = \frac{32.7}{0.9 \times 43.2V} = 0.84 \quad (30)$$

**8.2.2.2.2 Output Voltage Feedback**

Calculate the V<sub>OUT</sub> pin resistors by setting **R<sub>VOUT2</sub> = 10 kΩ** and calculating R<sub>VOUT1</sub>.

$$R_{VOUT1} = \frac{R_{VOUT2} \times V_{OUT}}{2.5V} - R_{VOUT2} = \frac{10k\Omega \times 32.7V}{2.5V} - 10k\Omega = 120.8k\Omega \quad (31)$$

Choose **R<sub>VOUT1</sub> = 120 kΩ**.

**8.2.2.2.3 Switching Frequency**

Using the values calculated above choose a value of **C<sub>ON</sub> = 1 nF** and calculate the value of R<sub>ON</sub>:

$$R_{ON} = \frac{R_{VOUT1} + R_{VOUT2}}{C_{ON} \times f_{SW}} = \frac{120k\Omega + 10k\Omega}{1nF \times 500kHz} = 26k\Omega \quad (32)$$

Choose the closest standard resistor value of **R<sub>ON</sub> = 26.1 kΩ**.

**8.2.2.2.4 Set the Feedback Reference and LED Current**

To get a value of V<sub>CS</sub> = 200 mV V<sub>IADJ</sub> must be set to 2 V. Choose a value of **R<sub>IADJ1</sub> = 10 kΩ** and solve for R<sub>IADJ2</sub>:

$$R_{IADJ2} = \frac{V_{IADJ} \times R_{IADJ1}}{V_{REF} - V_{IADJ}} = \frac{2V \times 10k\Omega}{3.03V - 2V} = 19.4k\Omega \quad (33)$$

Choose the standard resistor value of **R<sub>IADJ2</sub> = 19.6 kΩ** and solve for R<sub>CS</sub> using [Equation 34](#).

$$R_{CS} = \frac{V_{IADJ}}{10 \times I_{LED}} = \frac{2V}{10 \times 1A} = 0.2\Omega \quad (34)$$

**R<sub>CS</sub> = 0.2 Ω** is a standard resistor value.

**8.2.2.2.5 Calculate the Inductor Value**

Because this is a PWM dimming application, TI does not recommend much output capacitance for faster current rise and fall times, so the inductor ripple current should be close to the 300-mA peak-to-peak LED ripple current. Calculate and inductor value that will give you 350-mA peak-to-peak inductor ripple current or less:

$$L = \frac{(V_{IN} - V_{OUT}) \times D}{\Delta i_{L-PP} \times f_{SW}} = \frac{(48V - 32.7V) \times 0.76}{350mA \times 500kHz} = 66.4\mu H \quad (35)$$

Choose the standard value of **L = 68 μH** which results in an actual Δi<sub>L-PP</sub> of 342 mA.

**8.2.2.2.6 Calculate the Output Capacitor Value**

Given the actual inductor ripple current of 342-mA peak-to-peak, use [Equation 36](#) to calculate the required output capacitor value.

$$C_{OUT} = \frac{\Delta i_{L-PP}}{8 \times r_D \times \Delta i_{LED-PP} \times f_{SW}} = \frac{342mA}{8 \times 3.25\Omega \times 300mA \times 500kHz} = 88nF \quad (36)$$

Choose **C<sub>OUT</sub> = 0.1 μF**.

**8.2.2.2.7 Calculate the MOSFET Parameters**

The MOSFETs must have a minimum voltage and current rating for the application. The minimum ratings are calculated using [Equation 37](#) and [Equation 38](#).

## Typical Applications (continued)

$$V_{T-MAX} = 1.2 \times V_{IN-MAX} = 1.2 \times 52.8V = 63V \quad (37)$$

$$I_{T-MAX} = 1.5 \times D_{MAX} \times I_{LED} = 1.5 \times 0.84 \times 1A = 1.26A \quad (38)$$

Choose MOSFETs that have a drain-to-source voltage rating of greater than 63 V and a current rating greater than 1.26 A.

### 8.2.2.2.8 Calculate the Minimum Input Capacitance

The minimum input capacitance to achieve 1.5-V peak-to-peak input voltage ripple is calculated using Equation 39.

$$C_{IN\_MIN} = \frac{I_{LED} \times D}{\Delta V_{IN-PP} \times f_{SW}} = \frac{1A \times 0.76}{1.5V \times 500kHz} = 1\mu F \quad (39)$$

For PWM dimming applications more input voltage ripple will be present at the PWM dimming frequency. For these applications, TI recommends using 10 times the amount of minimum input capacitance or more. Choose  $C_{IN} = 10 \mu F$ .

### 8.2.2.2.9 Undervoltage Lockout and Hysteresis

Choose a value of  $R_{UDIM1} = 100 \text{ k}\Omega$  and calculate the values of  $R_{UDIM2}$  and  $R_{UDIM3}$  using Equation 40 and Equation 41.

$$R_{UDIM2} = \frac{1.276V \times R_{UDIM1}}{V_{TURN-ON} - 1.276V} = \frac{1.276V \times 100k\Omega}{40V - 1.276V} = 3.3k\Omega \quad (40)$$

$$R_{UDIM3} = \frac{\left(\frac{V_{HYS}}{21\mu A} - R_{UDIM1}\right) \times R_{UDIM2}}{R_{UDIM1} + R_{UDIM2}} = \frac{\left(\frac{15V}{21\mu A} - 100k\Omega\right) \times 3.24k\Omega}{100k\Omega + 3.24k\Omega} = 19.3k\Omega \quad (41)$$

Choose the nearest standard resistor values of  $R_{UDIM2} = 3.32 \text{ k}\Omega$  and  $R_{UDIM3} = 19.1 \text{ k}\Omega$ .

### 8.2.2.3 Application Curve

Figure 25. UDIM Dimming Waveform

## 9 Power Supply Recommendations

Any DC output power supply may be used provided it has a high enough voltage and current range for the particular application required.

## 10 Layout

### 10.1 Layout Guidelines

The performance of any switching converter depends as much upon the layout of the PCB as the component selection. Following a few simple guidelines will maximize noise rejection and minimize the generation of EMI within the circuit.

Discontinuous currents are the most likely to generate EMI, therefore take care when routing these paths. The main path for discontinuous current in the TPS92640 and TPS92641 buck converters contain the input capacitor ( $C_{IN}$ ), the low side MOSFET ( $Q_{LS}$ ), and the high side MOSFET ( $Q_{HS}$ ). This loop should be kept as small as possible and the connections between all three components should be short and thick to minimize parasitic inductance. In particular, the switch node (where  $L$ ,  $Q_{LS}$  and  $Q_{HS}$  connect) should be just large enough to connect the components without excessive heating from the current it carries. The current sense trace (CS pin) should be run along with a ground plane or have differential traces run for CS and ground.

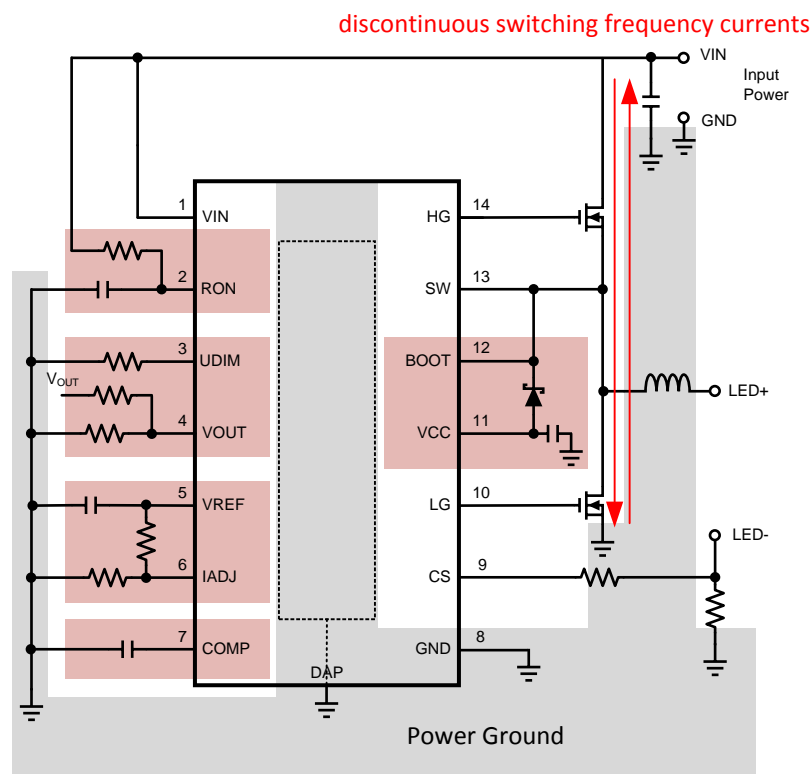

In some applications, the LED or LED array can be far away (several inches or more) from the circuit, or on a separate PCB connected by a wiring harness. When an output capacitor is used and the LED array is large or separated from the rest of the converter, the output capacitor should be placed close to the LEDs to reduce the effects of parasitic inductance on the AC impedance of the capacitor.

### 10.2 Layout Example

Note critical paths and component placement:

- Minimize power loop containing discontinuous currents
- Minimize signal current loops (components close to IC)

- Ground plane under IC for signal routing helps minimize noise coupling

**Figure 26. Layout Recommendation**

### 10.3 EMI and Noise Considerations

In synchronous rectifier, the high speed gate drive signals can generate significant conducted and radiated EMI. This noise can couple with high impedance nodes of the IC and result in undesirable operation. A small ( $4\ \Omega$  to  $10\ \Omega$ ) resistors,  $R_{HG}$  and  $R_{LG}$ , in series with the gate drive signals are recommended to slow the slew-rate of the SW node and reduce the noise signature. They also improve the robustness of the circuit by reducing the noise coupling in to sensitive nodes such as UDIM, CS, RON and IADJ.

In other to further reduce EMI signature, good PCB layout techniques must be implemented. The loop area between the synchronous NFET, inductor and output capacitor should be minimized to reduce radiated EMI due to switching action. The trace lengths of high impedance nodes (UDIM, CS, RON and IADJ) should be minimized and shielded from switching noise. The parasitic capacitance between switching node and ground node should be minimized to reduce common mode noise. Other common layout techniques such as star ground and noise suppression using local bypass capacitors should be followed to maximize noise rejection and minimize EMI within the circuit.

## 11 器件和文档支持

### 11.1 相关链接

下面的表格列出了快速访问链接。 范围包括技术文档、支持和社区资源、工具和软件，以及样片或购买的快速访问。

表 1. 相关链接

器件	产品文件夹	样片与购买	技术文档	工具与软件	支持与社区

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSELETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
