# 350mA, LED Lighting Driver 

UM1350 SOT23-5

## General Description

The UM1350 is capable of driving single or multiple series connected LEDs efficiently from a voltage source higher than the LED voltage. This step-down converter provides an externally adjustable output current of up to 350 mA from an input supply between 6 V and 30 V . It can even reach 8 watts of output power, depending on supply voltage and external components. The UM1350 consists of an output switch and a high-side output current sensing circuit that uses an external resistor to set the nominal average output current. Through applying an external control signal to the VSET pin, it can adjust the output current below the set value. The VSET pin will accept either a DC voltage or a PWM waveform to provide a continuous or a gated output current. The chip contains a PWM filter which provides a soft-start feature by controlling the rise of input/output current. It can raise the soft-start by using an external capacitor from the VSET pin to ground. Applying a voltage of 0.2 V or lower to the VSET pin turns the output off and switches the device into a low current standby state.
The UM1350 is available in a low profile SOT23-5 package.

## Applications

- MR16 and General Lighting
- Automotive Lighting
- Low Voltage Industrial Lighting
- LED Back Lighting
- Illuminated Signs

## Features

- Built in Thermal and Over-Current Shutdown
- Internal 40V NDMOS Switch
- 350 mA Output Current
- Single Pin On/Off and Dimming Control Using DC Voltage or PWM at VSET Pin
- Internal PWM Filter
- Soft-Start
- High Efficiency (Up to 95\%)
- Wide Input Voltage Range: 6 V to 30 V
- 40 V Transient Capability
- Output Shutdown
- Up to 1 MHz Switching Frequency
- Inherent Open-Circuit LED Protection
- Typical 5\% Output Current Accuracy

| $\mathrm{V}_{\text {SENSEHYS }}$ | Sense Threshold Hysteresis |  |  | $\pm 15 \%$ |  |  |
| $\mathrm{I}_{\text {SENSE }}$ | $\mathrm{I}_{\text {SENSE }}$ Pin Input Current | $\mathrm{V}_{\text {SENSE }}=\mathrm{V}_{\text {IN }}-0.1$ |  | 16 | 20 | $\mu \mathrm{A}$ |
| $\mathrm{V}_{\text {ReF }}$ | Internal Reference Voltage | Measured on VSET Pin with Pin Floating | 1.20 | 1.25 | 1.30 | V |
| $\mathrm{V}_{\text {VSET }}$ | External Control Voltage Range on VSET Pin for DC Brightness Control (Note 3) |  | 0.3 |  | 2.5 | V |
| $\mathrm{V}_{\text {VSEToff }}$ | DC Voltage on VSET Pin to Switch Device from Active (On) State to Quiescent (Off) State | $\mathrm{V}_{\text {vset }}$ Falling | 0.15 | 0.20 | 0.25 | V |
| $\mathrm{V}_{\text {VSETon }}$ | DC Voltage on VSET Pin to Switch Device from Quiescent (Off) State to Active (On) State | $\mathrm{V}_{\text {VSET }}$ Rising | 0.20 | 0.25 | 0.30 | V |
| $\mathrm{I}_{\text {LXmean }}$ | Continuous LX Switch Current |  |  |  | 0.37 | A |
| $\mathrm{R}_{\mathrm{LX}}$ | $\begin{gathered} \hline \text { LX Switch ‘On' } \\ \text { Resistance } \end{gathered}$ |  |  | 0.95 | 1.8 | $\Omega$ |
| $\mathrm{I}_{\text {LX(eak) }}$ | LX Switch Leakage Current |  |  |  | 1 | $\mu \mathrm{A}$ |

Note 3: $100 \%$ brightness corresponds to $\mathrm{V}_{\text {VSET }}=2.5 \mathrm{~V}$. Driving the VSET pin above 2.5 V will not increase the output current proportionally.

UM1350

Block Diagram

## Typical Application Circuit

## Device Description

The device, in conjunction with the coil (L1) and current sense resistor $\left(\mathrm{R}_{\mathrm{S}}\right)$, forms a self-oscillating continuous-mode buck converter.

Device Operation (Refer to block diagram (page 4) and Figure 1 (page 6)-Operating Waveforms)
Operation can be best understood by assuming that the VSET pin of the device is unconnected and the voltage on this pin ( $\mathrm{V}_{\text {VSET }}$ ) appears directly at the $(+)$ input of the comparator.
When input voltage $\mathrm{V}_{\text {IN }}$ is first applied, the initial current in L 1 and $\mathrm{R}_{\mathrm{S}}$ is zero and there is no output from the current sense circuit. Under this condition, the ( - ) input to the comparator is at ground and its output is high. This turns MN on and switches the LX pin low, causing current to flow from $\mathrm{V}_{\text {IN }}$ to ground, via $\mathrm{R}_{\mathrm{S}}, \mathrm{L} 1$ and the $\operatorname{LED}(\mathrm{s})$. The current rises at a rate determined by $\mathrm{V}_{\text {IN }}$ and L 1 to produce a voltage ramp ( $\mathrm{V}_{\text {SENSE }}$ ) across $\mathrm{R}_{\mathrm{S}}$. The supply referred voltage $\mathrm{V}_{\text {SENSE }}$ is forced across internal resistor R1 by the current sense circuit and produces a proportional current in internal resistors R2 and R3. This produces a ground referred rising voltage at the (-) input of the comparator. When this reaches the threshold voltage $\left(\mathrm{V}_{\mathrm{VSET}}\right)$, the comparator output switches low and MN turns off. The comparator output also drives another NMOS switch, which bypasses internal resistor R3 to provide a controlled amount of hysteresis. The hysteresis is set by R3 to be nominally $15 \%$ of $\mathrm{V}_{\text {VSET }}$.
When MN is off, the current in L1 continues to flow via D1 and the LED(s) back to $\mathrm{V}_{\mathrm{IN}}$. The current decays at a rate determined by the LED and diode forward voltages to produce a falling voltage at the input of the comparator. When this voltage returns to $\mathrm{V}_{\text {VSET }}$, the comparator output switches high again. This cycle of events repeats, with the comparator input ramping between limits of $\mathrm{V}_{\text {VSET }} \pm 15 \%$.

## Switching Thresholds

With $\mathrm{V}_{\text {VSET }}=\mathrm{V}_{\text {REF }}$, the ratios of R1, R2 and R3, define an average $\mathrm{V}_{\text {SENSE }}$ switching threshold of 100 mV (measured on the $\mathrm{I}_{\text {SENSE }}$ pin with respect to $\mathrm{V}_{\text {IN }}$ ). The average output current $\mathrm{I}_{\text {OUTnom }}$ is then defined by this voltage and Rs according to:
$\mathrm{I}_{\text {OUT } \mathrm{nom}}=100 \mathrm{mV} / \mathrm{R}_{\mathrm{S}}$
Nominal ripple current is $\pm 22 \mathrm{mV} / \mathrm{R}_{\mathrm{S}}$

## Adjusting Output Current

The VSET pin can be overdriven with either DC or pulse signals to change the $\mathrm{V}_{\text {SENSE }}$ switching threshold and adjust the output current.
Details of the different modes of adjusting output current are given in the applications section.

## Output Shutdown

The output of the low pass filter drives the shutdown circuit. When the input voltage to this circuit falls below the threshold ( 0.2 V nom $)$, the internal regulator and the output switch are turned off. The voltage reference remains powered during shutdown to provide the bias current for the shutdown circuit. Quiescent supply current during shutdown is nominally $40 \mu \mathrm{~A}$ and switch leakage is below $1 \mu \mathrm{~A}$.

## Applications Information

## Setting Nominal Average Output Current with External Resistor Rs

The nominal average output current in the LED(s) is determined by the value of the external current sense resistor ( $\mathrm{R}_{\mathrm{S}}$ ) connected between $\mathrm{V}_{\text {IN }}$ and $\mathrm{I}_{\text {SENSE }}$ and is given by:
$\mathrm{I}_{\text {ouTnom }}=0.1 / \mathrm{R}_{\mathrm{S}}(\mathrm{Rs} \geq 0.27 \Omega)$
The table below gives values of nominal average output current for several preferred values of current setting resistor $\left(\mathrm{R}_{\mathrm{S}}\right)$ in the typical application circuit shown on page 5 :

| $\mathbf{R}_{\mathbf{S}}(\boldsymbol{\Omega})$ | Nominal Average Output Current (mA) |
| :---: | :---: |
| 0.27 | 370 |
| 0.3 | 333 |
| 0.33 | 300 |
| 0.39 | 256 |

The above values assume that the VSET pin is floating and at a nominal voltage of $\mathrm{V}_{\text {REF }}$. Note that $\mathrm{R}_{\mathrm{S}}=0.27 \Omega$ is the minimum allowed value of sense resistor under these conditions to maintain switch current below the specified maximum value.

## Output Current Adjustment by External DC Control Voltage

The VSET pin can be driven by an external dc voltage, as shown, to adjust the output current to a value below the nominal average value defined by Rs.
The average output current is given by:
$\mathrm{I}_{\mathrm{OUT}}=\left(0.1 * \mathrm{~V}_{\mathrm{VSET}} / 2.5\right) / \mathrm{R}_{\mathrm{S}} \quad\left[\right.$ for $\left.0.3 \mathrm{~V}<\mathrm{V}_{\mathrm{VSET}}<2.5 \mathrm{~V}\right]$

## Output Current Adjustment by PWM Control

A Pulse Width Modulated (PWM) signal with duty cycle PWM can be applied to the VSET pin, as shown below, to adjust the output current to a value below the nominal average value set by resistor $\mathrm{R}_{\mathrm{S}}$ :
$\mathrm{I}_{\text {OUT }}=\left(\mathrm{V}_{\text {pulse }} * 0.1 * \mathrm{D}\right) /\left(2.5 * \mathrm{R}_{\mathrm{S}}\right) \quad\left(0 \leq \mathrm{D} \leq 100 \%, 0.3 \mathrm{~V}<\mathrm{V}_{\text {pulse }}<2.5 \mathrm{~V}\right)$

PWM dimming provides reduced brightness by modulating the LED's forward current between $0 \%$ and $100 \%$. The LED brightness is controlled by adjusting the relative ratios of the on time to the off time. A $25 \%$ brightness level of $\left(\mathrm{V}_{\text {pulse }} * 0.1 / \mathrm{R}_{\mathrm{S}}\right)$ is achieved by turning the LED on at full current for $25 \%$ of one cycle. To ensure this switching process between on and off state is invisible by human eyes, the switching frequency must be greater than 100 Hz . Above 100 Hz , the human eyes average the on and off times, seeing only an effective brightness that is proportional to the LED's on-time duty cycle. The advantage of PWM
dimming is that the forward current is always constant, therefore the LED color does not vary with brightness as it does with analog dimming. Pulsing the current provides precise brightness control while preserving the color purity.

## Capacitor Selection

A low ESR capacitor should be used for input decoupling, as the ESR of this capacitor appears in series with the supply source impedance and lowers overall efficiency. This capacitor has to supply the relatively high peak current to the coil and smooth the current ripple on the input supply. A minimum value of $1 \mu \mathrm{~F}$ is acceptable if the input source is close to the device, but higher values will improve performance at lower input voltages, especially when the source impedance is high. The input capacitor should be placed as close as possible to the IC.
For maximum stability over temperature and voltage, capacitors with X7R, X5R, or better dielectric are recommended. Capacitors with Y5V dielectric are not suitable for decoupling in this application and should NOT be used.

## Inductor Selection

Recommended inductor values for the UM1350 are in the range $47 \mu \mathrm{H}$ to $220 \mu \mathrm{H}$. Higher values of inductance are recommended at lower output current in order to minimize errors due to switching delays, which result in increased ripple and lower efficiency. Higher values of inductance also result in a smaller change in output current over the supply voltage range.
The inductor should be mounted as close to the device as possible with low resistance connections to the LX and $\mathrm{V}_{\text {IN }}$ pins. The chosen coil should have a saturation current higher than the peak output current and a continuous current rating above the required mean output current.
The inductor value should be chosen to maintain operating duty cycle and switch 'on'/'off' times within the specified limits over the supply voltage and load current range. The following equations can be used as a guide.
SW Switch 'On' time
$\mathrm{T}_{\mathrm{ON}}=(\mathrm{L} * \Delta \mathrm{I}) /\left(\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{LED}}-\mathrm{I}_{\mathrm{LED}} *\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\mathrm{L}}+\mathrm{R}_{\mathrm{LX}}\right)\right)$
SW Switch 'Off' time
$\mathrm{T}_{\mathrm{OFF}}=(\mathrm{L} * \Delta \mathrm{I}) /\left(\mathrm{V}_{\mathrm{LED}}+\mathrm{V}_{\mathrm{D}}+\mathrm{I}_{\mathrm{LED}} *\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\mathrm{L}}\right)\right)$
Where:
$L$ is the coil inductance ( H )
$\mathrm{R}_{\mathrm{L}}$ is the coil resistance ( $\Omega$ )
$\mathrm{R}_{\mathrm{S}}$ is the current sense resistance ( $\Omega$ )
$\mathrm{I}_{\text {LED }}$ is the required LED current (A)
$\Delta \mathrm{I}$ is the coil peak-peak ripple current (A) \{Internally set to $\left.0.3 \times \mathrm{I}_{\text {LED }}\right\}$
$\mathrm{V}_{\text {IN }}$ is the supply voltage ( V )
$\mathrm{V}_{\mathrm{LED}}$ is the total LED forward voltage ( V )
$\mathrm{R}_{\mathrm{LX}}$ is the switch resistance ( $\Omega$ )
$\mathrm{V}_{\mathrm{D}}$ is the diode forward voltage at the required load current (V)

## Diode Selection

For maximum efficiency and performance, the rectifier (D1) should be a fast low capacitance Schottky diode with low reverse leakage at the maximum operating voltage and temperature.
They also provide better efficiency than silicon diodes, due to a combination of lower forward voltage and reduced recovery time.
It is important to select parts with a peak current rating above the peak coil current and a continuous current rating higher than the maximum output load current. It is very important to

#### Abstract

consider the reverse leakage of the diode when operating above $85^{\circ} \mathrm{C}$. Excess leakage will increase the power dissipation in the device and if close to the load may create a thermal runaway condition. The higher forward voltage and overshoot due to reverse recovery time in silicon diodes will increase the peak voltage on the LX output. If a silicon diode is used, care should be taken to ensure that the total voltage appearing on the LX pin including supply ripple, does not exceed the specified maximum value.

## PCB Layout Guidelines

Careful PCB layout is critical to achieve low switching losses and stable operation. Minimize ground noise by connecting high current ground returns, the input bypass capacitor ground lead, and the output filter ground lead to a single point. Place Rs as close as possible to the Isense and $\mathrm{V}_{\mathrm{IN}}$. For better noise immunity, a Kelvin connection is strongly recommended between Isense and Rs.
