

# PFM™ in a VIA™ Package **AC-DC Converter**

PFM4914xB6M24D0yAz

# Isolated AC-DC Converter with PFC

## **Features & Benefits**

- Universal input (85 264V<sub>AC</sub>)
- 24V output, regulated, isolated
- 400W maximum power
- High efficiency
- Built-in EMI filtering
- Chassis-mount or board-mount packaging options
- Always-on, self-protecting converter control architecture
- **SELV Output**
- Two temperature grades including operation to -40°C
- Robust package
- Versatile thermal management
- Safe and reliable secondary-side energy storage
- High MTBF
- 127W/in<sup>3</sup> power density
- 4914 package
- External rectification and transient protection required

## **Typical Applications**

- Small-cell base stations
- Telecom switching equipment
- LED lighting
- Industrial power systems

Product	Ratings
V <sub>IN</sub> = 85 – 264V	P <sub>OUT</sub> = up to 400W
V <sub>OUT</sub> = 24V	I <sub>OUT</sub> = 16.67A

## **Product Description**

The PFM in a VIA package is a highly advanced 400W AC-DC converter operating from a rectified universal AC input which delivers an isolated and regulated Safety Extra Low Voltage (SELV) 24V secondary output.

This unique, ultra-low-profile module incorporates AC-DC conversion, integrated filtering and transient surge protection in a chassis-mount or PCB-mount form factor.

The PFM in a VIA package enables a versatile two-sided thermal strategy which greatly simplifies thermal design challenges.

When combined with downstream Vicor DC-DC conversion components and regulators, the PFM in a VIA package allows the Power Design Engineer to employ a simple, low-profile design which will differentiate his end-system without compromising on cost or performance metrics.

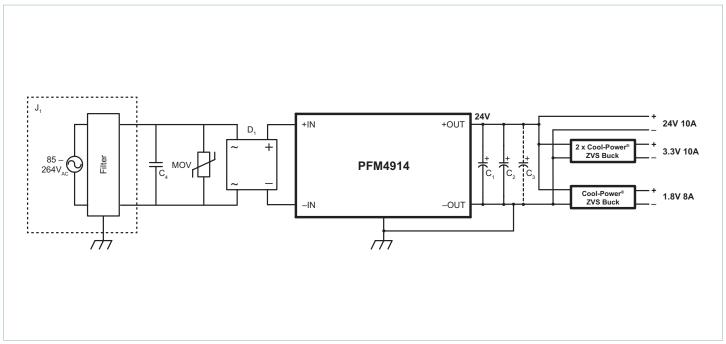

# **Part Ordering Information**

Product Function	Package Length	Package Width	Package Type	Input Voltage	Range Ratio	Output Voltage (Range)	Max Output Current	Product Grade	Option	n Field
PFM	49	14	Х	В6	М	24	D0	у	Z	Z
PFM = Power Factor Module	Length in Inches x 10	Width in Inches x 10	<b>B</b> = Board VIA <b>V</b> = Chassis VIA		Internal I	Reference		<b>C</b> = -20 to 100°C <b>T</b> = -40 to 100°C		s/Always On in/Always On in/Always On

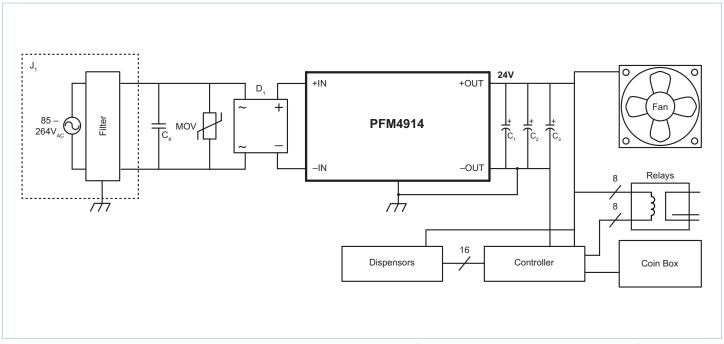

## **Typical PCB-Mount Applications**

The PCB terminal option allows mounting on an industry standard printed circuit board, with two different pin lengths. Vicor offers a variety of downstream DC-DC converters driven by the 24V output of the PFM in a VIA package. The 24V output is usable directly by loads that are tolerant of the PFC line ripple, such as fans, motors, relays, and some types of lighting. Use downstream DC-DC point-of-load converters where more precise regulation is required.

Parts List for Typical PCB-Mour	nt Applications
J1	<b>Delta</b> 06AR2 EMI Filter Entry Module, C14 6A 250V 5 x 20mm fuseholder
F1 (mount in J1)	<b>Littelfuse</b> 0216008.MXP 8A 250V <sub>AC</sub> 5 x 20mm holder
D1	Fairchild GBPC1210W 12A 1000V PTH
	<b>Nichicon</b> UVR1V153MRD 15,000μF 35V 4.3A 25 x 50mm bent 90°, x 3pcs <b>or</b>
C1, C2, (C3)	<b>CDE</b> 380LX153M035A022 15,000μF 35V 5.6A 35 x 30mm snap in, x 3pcs <b>or</b>

MOV	Littelfuse TMOV20RP300E VARISTOR 10kA 300V 250J 20mm

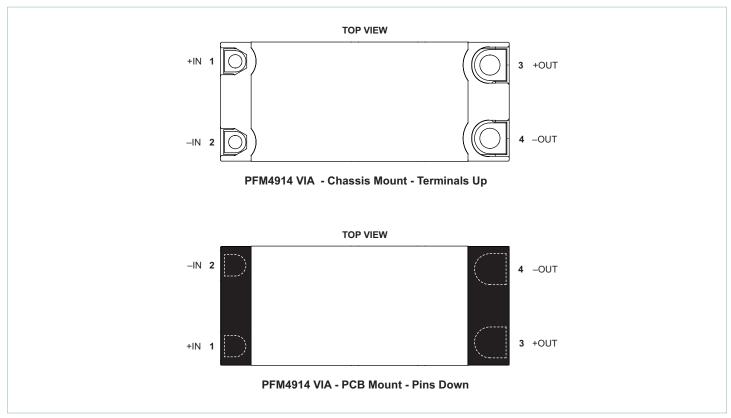

## **Typical Chassis-Mount Applications**

The PFM in a VIA package is available in chassis-mount option, saving the cost of a PCB and allowing access to both sides of the power supply for cooling. The parts list below minimizes the number of interconnects required between necessary components, and selects components with terminals traditionally used for point-to-point chassis wiring.

Parts List for Typical Chassis-Mo	ount Applications
J1	<b>Delta</b> 06AR2 EMI Filter Entry Module, C14 6A 250V 5 x 20mm fuseholder
F1 (mount in J1)	<b>Littelfuse</b> 0216008.MXP 8A 250V <sub>AC</sub> 5 x 20mm holder
D1	Fairchild GBPC1210FS 12A 1000V 0.25in QC TERMINAL

## **Product Details and Design Guidelines**

#### **Building Blocks and System Designs**

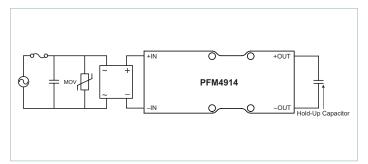

Figure 20 — 400W universal AC-DC supply

The PFM in a VIA package is a high-efficiency AC-DC converter, operating from a universal AC input to generate an isolated SELV  $24V_{DC}$  output bus with power factor correction. It is the key component of an AC-DC power supply system such as the one shown in Figure 20 above.

The input to the PFM in a VIA package is a rectified sinusoidal AC source with a power factor maintained by the module with harmonics conforming to IEC 61000-3-2. Internal filtering enables compliance with the standards relevant to the application (Surge, EMI, etc.). See EMI/EMC Compliance standards on Page 15.

The module uses secondary-side energy storage (at the SELV 24V bus) to maintain output hold up through line dropouts and brownouts. Downstream regulators also provide tighter voltage regulation, if required.

#### Traditional PFC Topology

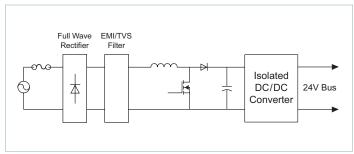

Figure 21 — Traditional PFC AC-DC supply

To cope with input voltages across worldwide AC mains  $(85-264V_{AC})$ , traditional AC-DC power supplies (Figure 21) use two power conversion stages: 1) a PFC boost stage to step up from a rectified input as low as  $85V_{AC}$  to  $\sim 380V_{DC}$ ; and 2) a DC-DC down converter from  $380V_{DC}$  to a 24V bus.

The efficiency of the boost stage and of traditional power supplies is significantly compromised operating from worldwide AC lines as low as  $85V_{AC}$ .

#### Adaptive Cell™ Topology

With its single stage Adaptive Cell™ topology, the PFM in a VIA package enables consistently high-efficiency conversion from worldwide AC mains to a 24V bus and efficient secondary-side power distribution.

#### **Input Fuse Selection**

PFM in a VIA package products are not internally fused in order to provide flexibility in configuring power systems. Input line fusing is recommended at system level, in order to provide thermal protection in case of catastrophic failure. The fuse shall be selected by closely matching system requirements with the following characteristics:

- Recommended fuse: 216 Series Littelfuse 8A or lower current rating (usually greater than the PFM maximum current at lowest input voltage)
- Maximum voltage rating (usually greater than the maximum possible input voltage)
- Ambient temperature
- Breaking capacity per application requirements
- Nominal melting I<sup>2</sup>t

#### **Source Inductance Considerations**

The PFM Powertrain uses a unique Adaptive Cell Topology that dynamically matches the powertrain architecture to the AC line voltage. In addition the PFM in a VIA package uses a unique control algorithm to reduce the AC line harmonics yet still achieve rapid response to dynamic load conditions presented to it at the DC output terminals. Given these unique power processing features, the PFM in a VIA package can expose deficiencies in the AC line source impedance that may result in unstable operation if ignored.

It is recommended that for a single PFM, the line source inductance should be no greater than 1mH for a universal AC input of 100 – 240V. If the PFM in a VIA package will be operated at 240V nominal only, the source impedance may be increased to 2mH. For either of the preceding operating conditions it is best to be conservative and stay below the maximum source inductance values. When multiple PFM in a VIA package's are used on a single AC line, the inductance should be no greater than 1mH/N, where N is the number of PFM in a VIA package's on the AC branch circuit, or 2mH/N for 240 $V_{AC}$  operation. It is important to consider all potential sources of series inductance including and not limited to, AC power distribution transformers, structure wiring inductance, AC line reactors, and additional line filters. Non-linear behavior of power distribution devices ahead of the PFM in a VIA package may further reduce the maximum inductance and require testing to ensure optimal performance.

If the PFM in a VIA package is to be utilized in large arrays, the PFM in a VIA packages should be spread across multiple phases or sources thereby minimizing the source inductance requirements, or be operated at a line voltage close to  $240V_{AC}$ . Vicor Applications should be contacted to assist in the review of the application when multiple devices are to be used in arrays.

#### **Fault Handling**

#### Input Undervoltage (UV) Fault Protection

The input voltage is monitored by the micro-controller to detect an input under voltage condition. When the input voltage is less than the UVLO threshold, a fault is detected. After a time  $t_{\rm UVLO}$ , the unit shuts down. Faults lasting less than  $t_{\rm UVLO}$  may not be detected. Such a fault does not go through an auto-restart cycle. Once the input voltage rises above the UVLO threshold, the unit recovers from the input UV fault, the powertrain resumes normal switching after a time  $t_{\rm ON}$  and the output voltage of the unit reaches the set point voltage within a time  $t_{\rm SC}$ .

#### Overcurrent (OC) Fault Protection

As long as the fault persists, the module goes through an autorestart cycle with off time equal to  $t_{OFF}$  +  $t_{ON}$  and on time equal to  $t_{OC}$ . Faults shorter than a time  $t_{OC}$  may not be detected. Once the fault is cleared, the module follows its normal start-up sequence after a time  $t_{OFF}$ .

#### Short Circuit (SC) Fault Protection

The module responds to a short circuit event within a time  $t_{SC}$ . The module then goes through an auto restart cycle, with an off time equal to  $t_{OFF}$  +  $t_{ON}$  and an on time equal to  $t_{SC}$ , for as long as the short circuit fault condition persists. Once the fault is cleared, the unit follows its normal start-up sequence after a time  $t_{OFF}$ . Faults shorter than a time  $t_{SC}$  may not be detected.

#### Temperature Fault Protection

The microcontroller monitors the temperature within the PFM in a VIA package. If this temperature exceeds  $T_{\text{INT-OTP+}}$ , an overtemperature fault is detected, and the output voltage of the PFM in a VIA package falls. Once the case temperature falls below  $T_{\text{CASE-OTP-}}$ , after a time greater than or equal to  $t_{\text{OFF}}$ , the converter recovers and undergoes a normal restart. For the C-grade version of the converter, this temperature is 75°C. Faults shorter than a time  $t_{\text{OTP}}$  may not be detected. If the temperature falls below  $T_{\text{CASE-UTP-}}$ , an undertemperature fault is detected and the output voltage of the unit falls. Once the case temperature rises above  $T_{\text{CASE-UTP}}$ , after a time greater than or equal to  $t_{\text{OFF}}$ , the unit recovers and undergoes a normal restart.

#### Output Overvoltage Protection (OVP)

The microcontroller monitors the primary sensed output voltage to detect output OVP. If the primary sensed output voltage exceeds  $V_{\text{OUT-OVLO+}}$ , a fault is latched and the output voltage of the module falls after a time  $t_{\text{SOVP}}$ . Faults shorter than a time  $t_{\text{SOVP}}$  may not be detected. This type of fault is a latched fault and requires that the input power be recycled to recover from the fault.

#### **Ruggedized Auto Range Functionality**

The input voltage range is determined at power up time, to cover the input voltage range of either  $85-132V_{RMS}$  or  $170-264V_{RMS}$ , called low range and high range. Once selected, dynamic range changes are limited by the logic explained below.

In low range, operation continues until the input either drops under the UVLO threshold (in which case the converter turns off), or until the input exceeds the range transition threshold.

The increase in input voltage can be temporary, as when handling a surge on the input, or it could be permanent, as can happen in the rare occasion when an input is turned on during a brown-out or sag condition on a high-voltage system:

- If the increase is temporary, and the input returns under range transition threshold within 0.8s, operation continues in low range.
- If the input stays over the range transition threshold, the converter changes to high range.

In high range, operation continue up to to the OVLO. A surge will cause the power train to turn off on a short-term basis to protect itself during the rise in input voltage, and it will return to operation when the input returns to the operating range.

When the input crosses under the range transition threshold, the input turns off as it considers this to be the high range UVLO threshold. If the converter returns above the range transition threshold within 50ms, the converter will resume operation in high range. If the converter does not return to operating range, the system will reset to the default power down condition, monitoring the input and waiting to decide whether it should start up into low range or high range.

#### Input Line Cycle Skipping

This model does not have input line cycle skipping. As a result, the regulation spec is guaranteed from no load to full load. Because of this, this model does not present high peak to peak output voltage under low load conditions, limiting perturbation that may affect downstream regulators ability to regulate their outputs as tightly as desired. The only sources of output voltage perturbation (from largest to smallest amplitude) are:

- Discharge of output bulk caps during a dropout condition
- Surge transients that can cause similar dropout or short-term range change
- Input line cycle ripple, with amplitude proportional to output current
- Switching frequency ripple, which can be reduced further with a higher frequency filter stage if necessary

Noise-sensitive applications should still test to ensure they can handle or safely ignore these AC transitions on the PFM output bus, which are expected to be handled by the downstream point-of-load regulators.

#### **Hold-Up Capacitance**

The PFM in a VIA package uses secondary-side energy storage (at the SELV 24V bus) and downstream regulators to maintain output hold up through line dropouts and brownouts. The module's output bulk capacitance can be sized to achieve the required hold up functionality.

Hold-up time depends upon the output power drawn from the The PFM in a VIA package based AC-DC front end and the input voltage range of downstream DC-DC converters.

The following formula can be used to calculate hold-up capacitance for a system comprised of PFM in a VIA package and a downstream regulator:

$$C = 2 \cdot P_{OUT} \cdot (0.005 + t_d) / (V_2^2 - V_I^2)$$

Where:

C PFM's output bulk capacitance in Farads

 $\mathbf{t_d}$  Hold-up time in seconds

**P**out PFM's output power in Watts

**V<sub>2</sub>** Output voltage of PFM's converter in Volts

V<sub>1</sub> Downstream regulator undervoltage turn off (Volts)

P<sub>OUT</sub> / I<sub>OUT-PK</sub>, whichever is greater.

#### **Output Filtering**

The The PFM in a VIA package requires an output bulk capacitor in the range of  $27,000\mu F$  to  $60,000\mu F$  for proper operation of the PFC front-end. A minimum  $40,000\mu F$  is recommended for full rated output. Capacitance can be reduced proportionally for lower maximum loads.

- 1. Line frequency voltage ripple: 2 f<sub>LINE</sub> Hz component
- **2.** Switching frequency voltage ripple: 1MHz module switching frequency component (see Figure 5).

#### Line Frequency Filtering

Output line frequency ripple depends upon output bulk capacitance. Output bulk capacitor values should be calculated based on line frequency voltage ripple. High-grade electrolytic capacitors with adequate ripple current ratings, low ESR and a minimum voltage rating of 35V are recommended.

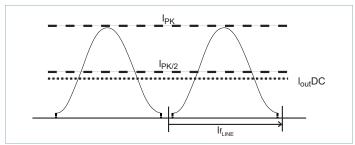

Figure 22 — Output current waveform

Based on the output current waveform, as seen in Figure 22, the following formula can be used to determine peak-to-peak line frequency output voltage ripple:

$$V_{PPL} \approx 0.2 \bullet P_{OUT} / (V_{OUT} \bullet f_{LINE} \bullet C)$$

Where:

**V**<sub>PPL</sub> Output voltage ripple peak-to-peak line frequency

**P**out Average output power

**V**<sub>OUT</sub> Output voltage set point, nominally 24V

f<sub>LINE</sub> Frequency of line voltageC Output bulk capacitance

I<sub>DC</sub> Maximum average output current

**I**<sub>PK</sub> Peak-to-peak line frequency output current ripple

In certain applications, the choice of bulk capacitance may be determined by hold-up requirements and low frequency output voltage filtering requirements. Such applications may use the greater capacitance value determined from these requirements. The ripple current rating for the bulk capacitors can be determined from the following equation:

$$I_{RIPPLE} \approx 0.8 \bullet P_{OUT} / V_{OUT}$$

#### Switching Frequency Filtering

This is included within the PFM in a VIA. No external filtering is necessary for most applications. For the most noise-sensitive applications, a common-mode choke followed by two caps to PE GND will reduce switching noise further.

#### **EMI Filtering and Transient Voltage Suppression**

#### EMI Filtering

The PFM in a VIA package with PFC is designed such that it will comply with EN55022 Class B for Conducted Emissions with a commercially available off-the-shelf EM filter. The emissions spectrum is shown in Figures 13 – 16. If one of the outputs is connected to earth ground, a small output common-mode choke is also recommended.

EMI performance is subject to a wide variety of external influences such as PCB construction, circuit layout etc. As such, external components in addition to those listed herein may be required in specific instances to gain full compliance to the standards specified. Radiated emissions require certification at the system level. For best results, enclose the product in a steel enclosure. Filtering must be considered for every conductor leaving the enclosure, which can present itself as a potential transmission antenna.

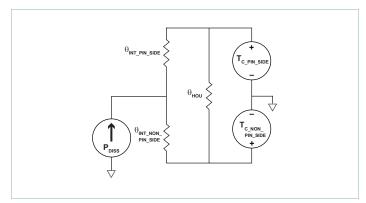

#### Transient Voltage Suppression

The PFM in a VIA package contains line transient suppression circuitry to meet specifications for surge (i.e. EN61000-4-5) and fast transient conditions (i.e. EN61000-4-4 fast transient/"burst") when coupled with an external TMOV as shown on pages 2 and 3.

When more than one PFM is used in a system, each PFM should have its own fuse, TMOV and bridge rectifier.

#### **Thermal Considerations**

The VIA package provides effective conduction cooling from either of the two module surfaces. Heat may be removed from the pin-side surface, the non-pin-side surface or both. The extent to which these two surfaces are cooled is a key component for determining the maximum power that can be processed by a PFM, as can be seen from specified thermal operating area on Page 5. Since the PFM has a maximum internal temperature rating, it is necessary to estimate this internal temperature based on a system-level thermal solution. To this purpose, it is helpful to simplify the thermal solution into a roughly equivalent circuit where power dissipation is modeled as a current source, isothermal surface temperatures are represented as voltage sources and the thermal resistances are represented as resistors. Figure 23 shows the "thermal circuit" for the PFM in a VIA package.

**Figure 23** — Double-sided cooling thermal model

In this case, the internal power dissipation is  $P_{DISS}$ ,  $\theta_{INT\_PIN\_SIDE}$  and  $\theta_{INT\_NON\_PIN\_SIDE}$  are thermal resistance characteristics of the VIA module and the pin-side and non-pin-side surface temperatures are represented as  $T_{C\_PIN\_SIDE}$ , and  $T_{C\_NON\_PIN\_SIDE}$ . It interesting to notice that the package itself provides a high degree of thermal coupling between the pin-side and non-pin-side case surfaces (represented in the model by the resistor  $\theta_{HOU}$ ). This feature enables two main options regarding thermal designs:

Single-side cooling: the model of Figure 23 can be simplified by calculating the parallel resistor network and using one simple thermal resistance number and the internal power dissipation curves; an example for non-pin-side cooling only is shown in Figure 24.

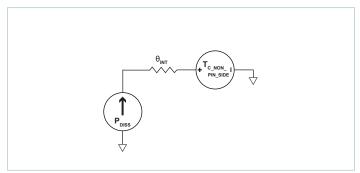

Figure 24 — Single-sided cooling thermal model

In this case,  $\theta_{INT}$  can be derived as following:

$$\theta_{\mathit{INT}} = \frac{\left(\theta_{\mathit{INT\_PIN\_SIDE}} + \theta_{\mathit{HOU}}\right) \bullet \theta_{\mathit{INT\_NON\_PIN\_SIDE}}}{\theta_{\mathit{INT\_PIN\_SIDE}} + \theta_{\mathit{HOU}} + \theta_{\mathit{INT\_NON\_PIN\_SIDE}}}$$

■ Double-side cooling: while this option might bring limited advantage to the module internal components (given the surface-to-surface coupling provided), it might be appealing in cases where the external thermal system requires allocating power to two different elements, like for example heat sinks with independent airflows or a combination of chassis/air cooling.

#### **Powering a Constant-Power Load**

When the output voltage of the PFM in a VIA package module is applied to the input of the downstream regulator, the regulator turns on and acts as a constant-power load. When the module's output voltage reaches the input undervoltage turn on of the regulator, the regulator will attempt to start. However, the current demand of the downstream regulator at the undervoltage turn-on point and the hold-up capacitor charging current may force the PFM in a VIA package into current limit. In this case, the unit may shut down and restart repeatedly. In order to prevent this multiple restart scenario, it is necessary to delay enabling a constant-power load when powered up by the upstream PFM in a VIA package until after the output set point of the PFM in a VIA package is reached.

This can be achieved by:

 Keeping the downstream constant-power load off during power up sequence,

and

**2.** Turning the downstream constant-power load on after the output voltage of the module reaches 24V steady state.

After the initial start up, the output of the PFM in a VIA package can be allowed to fall to 15V during a line dropout at full load. In this case, the circuit should not disable the downstream regulator if the input voltage falls after it is turned on; therefore, some form of hysteresis or latching is needed on the enable signal for the constant-power load. The output capacitance of the PFM in a VIA package should also be sized appropriately for a constant-power load to prevent collapse of the output voltage of the module during line dropout (see Hold-Up Capacitance on Page 18). A constant-power load can be turned off after completion of the required hold up time during the power-down sequence or can be allowed to turn off when it reaches its own undervoltage shutdown point.

The timing diagram in Figure 25 shows the output voltage of the PFM in a VIA package and the downstream regulator's enable pin voltage and output voltage of the PRM regulator for the power up and power down sequence. It is recommended to keep the time delay approximately 10-20 ms.

**Figure 25** — PRM enable hold-off waveforms

#### Dielectric Withstand

The chassis of the PFM is required to be connected to Protective Earth when installed in the end application and must satisfy the requirements of IEC 60950-1 for Class I products. Protective earthing can be accomplished through dedicated wiring harness (example: ring terminal clamped by mounting screw) or surface contact (example: pressure contact on bare conductive chassis or PCB copper layer with no solder mask).

The PFM contains an internal safety approved isolating component (ChiP™) that provides the Reinforced Insulation from Input to Output. The isolating component is individually tested for Reinforced Insulation from Input to Output at 3000V<sub>AC</sub> or 4242V<sub>DC</sub> prior to the final assembly of the PFM in a VIA package.

When the VIA assembly is complete the Reinforced Insulation can only be tested at Basic Insulation values as specified in the electric strength Test Procedure noted in clause 5.2.2 of IEC 60950-1.

#### **Test Procedure Note from IEC 60950-1**

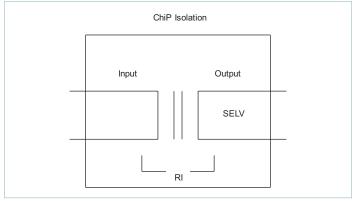

"For equipment incorporating both REINFORCED INSULATION and lower grades of insulation, care is taken that the voltage applied to the REINFORCED INSULATION does not overstress BASIC INSULATION or SUPPLEMENTARY INSULATION."

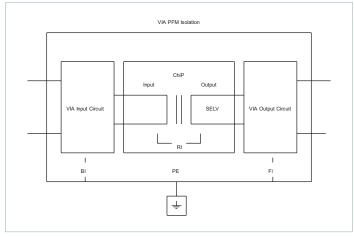

#### **Summary**

The final package assembly contains basic insulation from input to case, reinforced insulation from input to output, and functional insulation from output to case.

The output of the PFM in a VIA package complies with the requirements of SELV circuits so only functional insulation is required from the output (SELV) to case (PE) because the case is required to be connected to protective earth in the final installation. The construction of the PFM in a VIA package can be summarized by describing it as a "Class II" component installed in a "Class I" subassembly. The reinforced insulation from input to output can only be tested at a basic insulation value of 2121V $_{\rm DC}$  on the completely assembled VIA package.
