

# Cool-Power® **ZVS Switching Regulators**

PI3740-00

# 8V - 60V<sub>IN</sub>, 10V - 50V<sub>OUT</sub>, 50 - 140W Cool-Power ZVS Buck-Boost Regulator

### **Product Description**

The PI3740-00 is a high efficiency, wide input and output range DC-DC ZVS Buck-Boost Regulator. This high density System-in-Package (SiP) integrates controller, power switches, and support components. The integration of a high performance Zero-Voltage Switching (ZVS) topology within the PI3740-00 increases point of load performance, providing best in class power efficiency.

The PI3740-00 requires an external inductor, resistive divider and minimal capacitors to form a complete DC-DC switching mode buck-boost regulator.

Dovice	Output Voltage		
Device	Set	Range	
PI3740-00-LGIZ	<b>Z</b> 12V 10 to 50V		

The ZVS architecture also enables high frequency operation while minimizing switching losses and maximizing efficiency. The high switching frequency operation reduces the size of the external filtering components, improves power density, and enables fast dynamic response to line and load transients.

### **Features & Benefits**

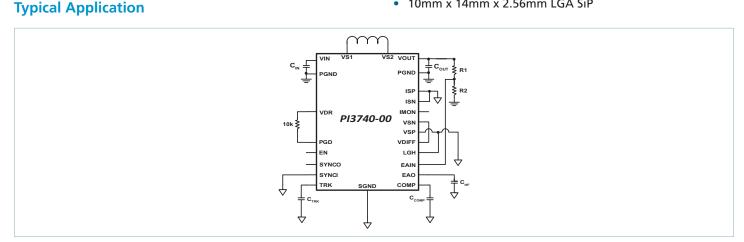

- Up to 96% efficiency
- 50 140W continuous output power
- Parallel capable with single wire current sharing
- External frequency synchronization / interleaving
- High Side Current Sense Amplifier
- **General Purpose Amplifier**
- Lighting / Constant Current Mode (LGH)
- Input Over / Undervoltage Lockout (OVLO / UVLO)
- Output Overvoltage Protection (OVP)
- Overtemperature Protection (OTP)
- · Fast and slow current limits
- -40°C to 115°C operating range (T<sub>I</sub>)
- Excellent light load efficiency

### **Applications**

- · Battery Charging and Conditioning, Telecom, Networking, Lighting
- Computing, Communications, Industrial, **Automotive Accessories**
- 12V, 24V, 48V and 60V DC-DC Applications

### **Package Information**

10mm x 14mm x 2.56mm LGA SiP

# **Pin Description**

Pin Number	Pin Name	Description
1–2, G–K	VIN	Input voltage and sense node for UVLO, OVLO and feed forward compensation.
4–5, G–K	VS1	Input side switching node and ZVS sense node for power switches.
10–11, G–K	VS2	Output side switching node and ZVS sense node for power switches.
13–14, G–K	VOUT	Output voltage and sense node for power switches, $V_{\text{OUT}}$ feed forward compensation, $V_{\text{OUT\_OV}}$ and internal signals.
1E	VDR	Internal 5.1V supply for gate drivers and internal logic. May be used as reference or low power bias supply for up to 2mA. Must be impedance limited by the user.
1D	PGD	Fault & Power Good indicator. PGD pulls low when the regulator is not operating or if EAIN is less than 1.4V.
1C	SYNCO	Synchronization output. Outputs a high signal for ½ of the programmed switching period at the beginning of each switching cycle, for synchronization of other regulators.
1B	SYNCI	Synchronization input. When a falling edge synchronization pulse is detected, the Pl3740-00 will delay the start of the next switching cycle until the next falling edge sync pulse arrives, up to a maximum delay of two times the programmed switching period. If the next pulse does not arrive within two times the programmed switching period, the controller will leave sync mode and start a switching cycle automatically. Connect to SGND when not in use.
1A	FT1	For factory use only. Connect to SGND or leave floating in application.
2A	FT2	For factory use only. Connect to SGND or leave floating in application.
3A	FT3	For factory use only. Connect to SGND in application.
4A	FT4	For factory use only. Connect to SGND in application.
5A	EN	Regulator Enable control. Asserted high or left floating – regulator enabled; Asserted low, regulator output disabled.
6A	TRK	Soft-start and track input. An external capacitor must be connected between TRK pin and SGND to decrease the rate of output rise during soft-start. Recommended value is 47nF for 1.6ms rise.
7A	LGH	Input for constant current lighting amplifier. Connect to SGND if not in use.
8A	COMP	Error amp compensation dominant pole. Connect a capacitor of 4700pF by default between COMP and SGND to set the control loop dominant pole.
9A	VSN	General purpose amplifier inverting input.
10A	VSP	General purpose amplifier non-inverting input.
11A	VDIFF	General Purpose amplifier output. When unused connect VDIFF to VSN and VSP to SGND.
12A	EAIN	Error amplifier inverting input and sense for PGD. Connect by resistive divider to the output.
13A	EAO	Error amp output: External connection for additional compensation and current sharing. Add 56pF capacitor from EAO to SGND.
14A	IMON	High side current sense amplifier output.
14D	ISN	High side current sense amplifier negative input.
14E	ISP	High side current sense amplifier positive input.
10–14, B + 10–12, C–E	SGND	Signal ground. Internal logic and analog ground for the regulator. SGND and PGND are star connected within the regulator package.
2–9, B–E + 7–-8, F–K	PGND	Power ground. $V_{\text{IN}}$ , $V_{\text{OUT}}$ , VS1 and VS2 power returns. SGND and PGND are star connected within the regulator package.

### **MTBF**

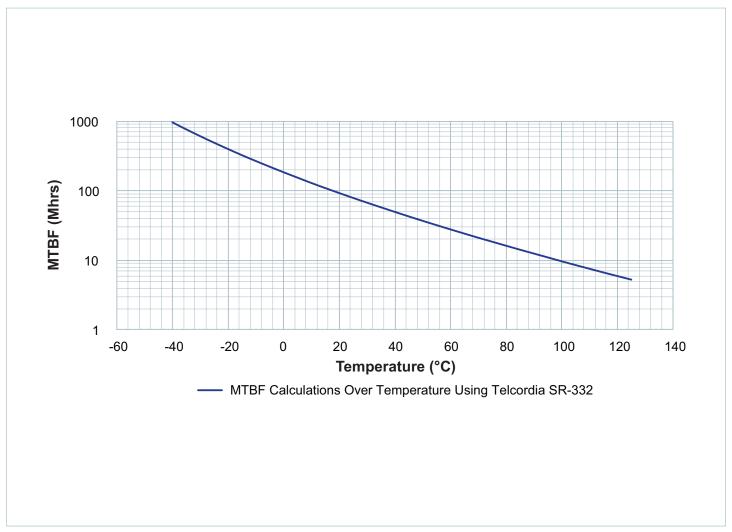

Figure 36 — PI3740-00 calculated MTBF Telcordia SR-332 GB\

### **Functional Description**

The PI3740-00 is a highly integrated ZVS Buck-Boost regulator. The PI3740-00 has an adjustable output voltage that is set with a resistive divider. Performance and maximum output current are characterized with a specific external power inductor as defined in the electrical specifications, and in the inductor pairing section.

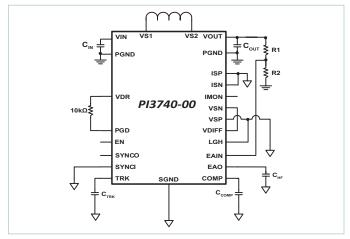

Figure 37 — PI3740-00 with required components

For basic operation, Figure 37 shows the minimum connections and components required.

#### **Enable**

The EN pin of the regulator is referenced to SGND and permits the user to turn the regulator on or off. The EN polarity is a positive logic assertion. If the EN pin is left floating or asserted high, the regulator output is enabled. Pulling the EN pin below 0.8V<sub>DC</sub> with respect to SGND will discharge the TRK pin until the output reaches zero or the EN pin is released. When the converter is disabled via the EN pin or due to a fault mode, the internal gate driver high side charge pumps are enabled as long as there is enough input voltage for the internal VDR supply voltage to be available. The return path for this charge pump supply is through the output. If the output load is disconnected or high impedance, the output capacitors will float up to about 3.4V maximum, sourced by 960µA of leakage current. This pre-biased condition poses no issue for the converter. The 960µA leakage current may be safely bypassed to SGND. A simple application circuit is available to bypass this current in a non-dissipative manner. Please contact Applications Engineering for details.

#### **Switching Frequency Synchronization**

The SYNCI input allows the user to synchronize the controller switching frequency to the falling edge of an external clock referenced to SGND. The external clock can synchronize the unit between 50% and 110% of the preset switching frequency (F<sub>SW</sub>). The SYNCI pin should be connected to SGND when not in use, and should never be left floating.

#### **Soft-Start and Tracking**

The PI3740-00 provides a soft start and tracking feature using the TRK pin. Programmable Soft Start requires an external capacitor from the TRK pin to SGND in addition to the internal 56pF soft-start capacitor to set the start-up ramp period equal to  $t_{SS}$ . The recommended value is 47nF. The Pl3740-00 internal reference and regulated output will proportionally follow the TRK ramp when it is below 1.7 $V_{DC}$ . When the ramp is greater than 1.7 $V_{DC}$ , the internal reference will remain at 1.7 $V_{DC}$  while the TRK ramp rises and clamps at 2.5 $V_{DC}$ . If the TRK pin goes below the disable threshold, the regulator will finish the current switching cycle and then stop switching.

#### **Remote Sensing Differential Amplifier**

A general purpose operational amplifier is provided to assist with differential remote sensing and/or level shifting of the output voltage. The VDIFF pin can be connected to the transconductance error amplifier input EAIN pin, or with proper configuration can also be connected to the EAO pin to drive the modulator directly. If unused, connect in unity gain with VSP connected to SGND.

#### **Power Good**

The PI3740-00 PGD pin functions as a power good indicator and pulls low when the regulator is not operating or if EAIN is less than 1.4V.

#### **Output Current Limit Protection**

PI3740-00 has three methods implemented to protect from output short circuit or over current condition.

**Slow Current Limit protection:** prevents the regulator load from sourcing current higher than the maximum rated regulator current. If the output current exceeds the  $V_{OUT}$  Slow Current Limit ( $V_{OUT\_SCL}$ ) a slow current limit fault is initiated and the regulator is shutdown, which eliminates output current flow. After the Fault Restart Delay ( $t_{FR\_DLY}$ ), a soft-start cycle is initiated. This restart cycle will be repeated indefinitely until the excessive load is removed.

Fast Current Limit protection: monitors the external inductor current pulse-by-pulse to prevent the output from supplying saturation current. If the regulator senses a high inductor current pulse, it will initiate a fault and stop switching. After the Fault Restart Delay ( $t_{FR\_DLY}$ ), a soft-start cycle is initiated. This restart cycle will be repeated indefinitely until the excessive load is removed.

**Overload Timeout protection:** If the regulator is providing greater than the maximum output power for longer than the Overload Timeout delay ( $T_{OL}$ ), it will initiate a fault and stop switching. After Fault Restart Delay ( $t_{FR\_DLY}$ ), a soft-start cycle is initiated. This restart cycle will be repeated indefinitely until the overload load is removed.

#### **Input Undervoltage Lockout**

If  $V_{\rm IN}$  falls below the input Undervoltage Lockout (UVLO) threshold, the PI3740-00 will complete the current cycle and stop switching. The system will restart once the input voltage is reestablished.

### **Input Overvoltage Lockout**

If  $V_{\text{IN}}$  rises above the input Overvoltage Lockout (OVLO) threshold, the PI3740-00 will complete the current cycle and stop switching. The system will restart once the input voltage is reestablished and after the Fault Restart Delay.

#### **Output Overvoltage Protection**

The PI3740-00 is equipped with two methods of detecting an output over voltage condition. To prevent damage to input voltage sensitive devices, if the output voltage exceeds 20% of its set regulated value as measured by the EAIN pin ( $V_{EAIN\_OV}$ ), the regulator will complete the current cycle, stop switching and issue an OVP fault. Also if the output voltage of the regulator exceeds the  $V_{OUT}$  Overvoltage Threshold ( $V_{OUT\_OVT}$ ) then the regulator will complete the current cycle, stop switching and issue an OVP fault. The system will resume operation once the output voltage falls below the OVP threshold and after Fault Restart Delay.

#### **Overtemperature Protection**

The PI3740-00 features an over temperature protection (OTP), which will not engage until after the product is operated above the maximum rated temperature. The OTP circuit is only designed to protect against catastrophic failure due to excessive temperatures and should not be relied upon to ensure the device stays within the recommended operating temperature range. Thermal shutdown terminates switching and discharges the soft-start capacitor. As the temperature falls the PI3740-00 will restart, and this will always occur before the product returns to rated temperature range.

#### Pulse Skip Mode (PSM)

PI3740-00 features a hysteretic Pulse Skip Mode to achieve high efficiency at light loads. The regulator is setup to skip pulses if  $V_{\text{EAO}}$  falls below the Pulse Skip Threshold ( $V_{\text{EAO}\_PST}$ ). Depending on conditions and component values, this may result in single pulses or several consecutive pulses followed by skipped pulses. Skipping cycles significantly reduces gate drive power and improves light load efficiency. The regulator will leave Pulse Skip Mode once the control node rises above the Pulse Skip Mode threshold ( $V_{\text{EAO}\_PST}$ ).

#### **Variable Frequency Operation**

The PI3740-00 is preprogrammed to a fixed, maximum, base operating frequency. The frequency is selected with respect to the required power stage inductor to operate at peak efficiency across line and load variations. The switching frequency period will stretch as needed during each cycle to accommodate low line and or high load conditions. By stretching the switching frequency period, thus decreasing the switching frequency, the ZVS operation is preserved throughout the input line voltage range maintaining optimum efficiency.

#### **IMON Amplifier**

The PI3740-00 provides a differential amplifier with a level shifted, SGND referenced output, the IMON Pin, which is useful for sensing input or output current on high voltage rails. A fixed gain of 20:1 is provided over a large common mode range. When using the amplifier, the ISN pin must be referenced to the common mode voltage of the ISP pin for proper operation. See Absolute Maximum Ratings for more information. If not in use, the ISN and ISP pins should be connected to SGND and the IMON pin left floating.

### **Application Description**

#### **Output Voltage Trim**

The output voltage can be adjusted by feeding back a portion of the desired output through a voltage divider to the error amplifier's input (see Figure 37). Equation 1 can be used to determine resistor values needed for the voltage divider.

$$R1 = R2 \bullet \left(\frac{V_{OUT}}{1.7} - 1\right) \tag{1}$$

The R2 value is selected by the user; a 1.65k $\Omega$  resistor value is recommended.

If, for example, a 12V output is needed, the user can select a 1.65k $\Omega$  (1%) resistor for R2 and use Equation (1) to calculate R1. Once R1 value is calculated, the user should select the nearest resistor value available. In this example, R1 is 9.997k $\Omega$  so a 10.0k $\Omega$  should be selected.

#### **Soft-Start Adjustment and Tracking**

The TRK pin offers a means to increase the regulator's soft-start time or to track with additional regulators. The soft-start slope is controlled by an external capacitor and a fixed charge current to provide the startup ramp. The following equation can be used to calculate the proper capacitor for a desired soft-start time:

$$C_{TRK} = \frac{(t_{TRK} \cdot I_{SS})}{1.7} - 56 \cdot 10^{-12}$$
 (2)

Where  $t_{TRK}$  is the desired soft-start time and  $l_{SS}$  is the TRK pin source current (see Electrical Characteristics for limits).

The PI3740-00 allows the tracking of multiple like regulators. Two methods of tracking can be chosen: proportional or direct tracking. Proportional tracking will force all connected regulators to startup and reach regulation at the same time (see Figure 38 (a)). To implement proportional tracking, simply connect all devices TRK pins together.

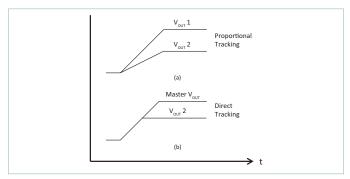

Figure 38 — PI3740-00 tracking methods

For Direct Tracking, choose the regulator with the highest output voltage as the master and connect the master to the TRK pin of the other regulators through a divider (Figure 39) with the same ratio as the slave's feedback divider (see Output Voltage Trim). The TRK pin should not be driven without  $1k\Omega$  minimum series resistance.

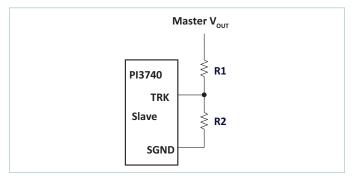

Figure 39 — Voltage divider connections for direct tracking

All connected regulators' soft-start slopes will track with this method. Direct tracking timing is demonstrated in Figure 38 (b). All tracking regulators should have their Enable (EN) pins connected together for proper operation.

### **Inductor Pairing**

Operations and characterization of the PI3740-00 was performed using a 420nH inductor, Part # HCV1206-R42-R, manufactured by Eaton. This Inductor has a form factor of 12.5mm x 10mm x 5mm. No other inductor is recommended for use with the PI3740-00. For additional inductor information and sourcing, please contact Eaton directly.

#### **Filter Considerations**

The PI3740-00 requires low impedance ceramic input capacitors (X7R/X5R or equivalent) to ensure proper start up and high frequency decoupling for the power stage. The PI3740-00 will draw nearly all of the high frequency current from the low impedance ceramic capacitors when the main high side MOSFET(s) are conducting. During the time the MOSFET(s) are off, the input capacitors are replenished from the source. Table 1 shows the recommended input and output capacitors to be used for the PI3740-00. Divide the total RMS current by the number of ceramic capacitors used to calculate the individual capacitor's RMS current. Table 2 includes the recommended input and output ceramic capacitor. It is very important to verify that the voltage supply source as well as the interconnecting line are stable and do not oscillate.

Input Filter case 1; Inductive source and local, external, input decoupling capacitance with negligible ESR (i.e.: ceramic type)

The voltage source impedance can be modeled as a series  $R_{line}$   $L_{line}$  circuit. The high performance ceramic decoupling capacitors will not significantly damp the network because of their low ESR; therefore in order to guarantee stability the following conditions must be verified:

$$R_{line} > \frac{L_{line}}{\left(C_{IN\_INT} + C_{IN\_EXT}\right) \cdot \left|r_{EQ\_IN}\right|} \tag{3}$$

$$R_{line} << \left| r_{EQ\_IN} \right| \tag{4}$$

Where  $r_{EQ\_IN}$  can be calculated by dividing the lowest line voltage by the full load input current. It is critical that the line source impedance be at least an octave lower than the converter's dynamic input resistance, Equation (4). However, Rline cannot be made arbitrarily low otherwise Equation (3) is violated and the system will show instability, due to underdamped RLC input network.

C <sub>INPUT</sub>	С <sub>ОИТРИТ</sub>
(see Table 2)	(see Table 2)
5 X 2.2μF	8 X 10μF or 2.2μF

**Table 1** — Minimum recommended input and output capacitance

Input Filter case 2; Inductive source and local, external input decoupling capacitance with significant  $R_{CIN\_EXT}$  ESR (i.e.: electrolytic type)

In order to simplify the analysis in this case, the voltage source impedance can be modeled as a simple inductor  $L_{line}$ . Notice that the high performance ceramic capacitors  $C_{IN\_INT}$  within the PI3740-00 should be included in the external electrolytic capacitance value for this purpose. The stability criteria will be:

$$\left| r_{EQ\_IN} \right| > R_{C_{IN\_EXT}} \tag{5}$$

$$\frac{L_{line}}{C_{lN\_INT} \cdot R_{C_{IN\_EXT}}} < |r_{EQ\_IN}| \tag{6}$$

Equation (6) shows that if the aggregate ESR is too small – for example by using very high quality input capacitors ( $C_{\text{IN\_EXT}}$ ) – the system will be under-damped and may even become destabilized. Again, an octave of design margin in satisfying Equation (5) should be considered the minimum.

**Note:** When applying an electrolytic capacitor for input filter damping the ESR value must be chosen to avoid loss of converter efficiency and excessive power dissipation in the electrolytic capacitor.

**Table 3** — Typical input and output ripple current / voltage with the recommended input and output capacitor recommended in Tables 1 and 2.

#### **Thermal Design**

Figure 40 (a) shows a thermal impedance model that can predict the maximum temperature of the highest temperature component for a given operating condition. This model assumes that all customer PCB connections are at one temperature, which is PCB equivalent Temperature  $T_{PCB}$  °C. The model can be simplified as shown in Figure 40 (b).

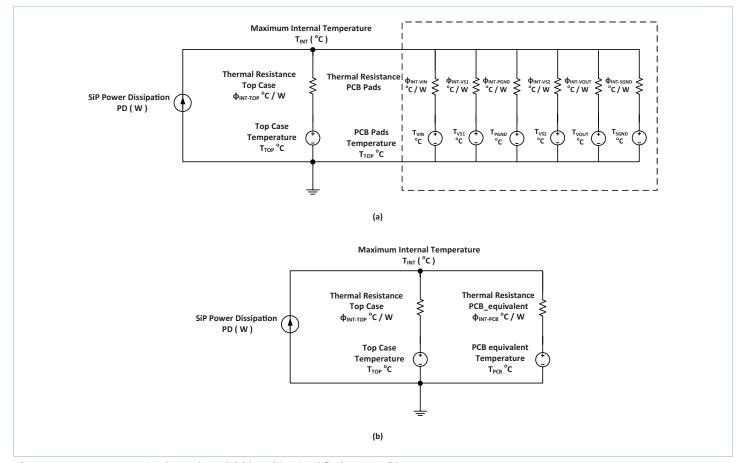

Figure 40 — PI3740-00 SiP Thermal Model (a) and its simplified version (b).

### Where the symbol in Figure 40 is defined as the following:

φ <sub>INT-TOP</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the top side of the package.
ф <sub>INT-PCB</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on, assuming all customer PCB connections at one temperature.
φ <sub>INT-VIN</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on at the $V_{\text{IN}}$ pad.
φ <sub>INT-VS1</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on at the VS1 pad.
φ <sub>INT-PGND</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on at the PGND pad.
φ <sub>INT-VS2</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on at the VS2 pad.
φ <sub>INT-VOUT</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on at the $V_{\text{OUT}}$ pad.
φ <sub>INT-SGND</sub>	is defined as the thermal impedance from the hottest component junction inside the SiP to the circuit board it is mounted on at the SGND pad.

The following equation can predict the junction temperature based on the heat load applied to the SiP and the known ambient conditions with the simplified thermal circuit model:

$$T_{INT} = \frac{PD + \frac{T_{TOP}}{\Phi_{INT-TOP}} + \frac{T_{PCB}}{\Phi_{INT-PCB}}}{\frac{I}{\Phi_{INT-PCB}} + \frac{I}{\Phi_{INT-PCB}}}$$
(7)

Dovice	Thermal Impedance								Thermal Impedance with the simplified version	
Device	<sup>φ</sup> INT-TOP (°C / W)	<sup>φ</sup> ιντ-νιν (°C / W)	<sup>ф</sup> інт-vs1 (°С / W)	<sup>φ</sup> INT-PGND (°C / W)	<sup>ф</sup> інт-vs2 (°С / W)	<sup>φ</sup> ιντ-νουτ (°C / W)	<sup>φ</sup> INT-SGND (°C / W)	<sup>ф</sup> інт-тор (°С / W)	<sup>ф</sup> інт-РСВ (°С / W)

#### **Thermal Design Inductor**

Figure 41 shows a thermal impedance model that can predict the maximum hot spot temperature of the inductor for a given operating condition. This model assumes that all customer PCB connections are at one temperature, which is PCB equivalent Temperature  $T_{PCB}$  °C. If the inductor top and bottom are not mounted to a heat sink, the simplified model is parallel combination of all resistances that connect to the PCB.

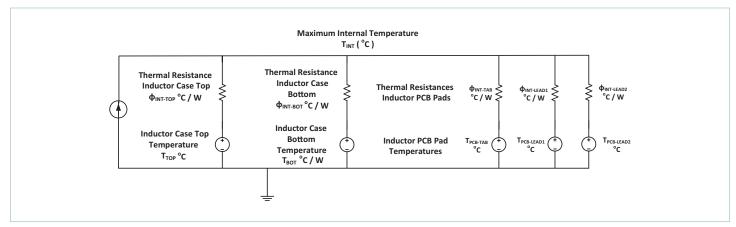

Figure 41 — Pl3740-00 Inductor Thermal Impedance Model

### Where the symbol in Figure 41 is defined as the following:

φ <sub>INT-TOP</sub>	is defined as the thermal impedance from the hot spot to the top surface of the core.
φ <sub>INT-PCB</sub>	is defined as the thermal impedance from the hot spot to the circuit board it is mounted on, assuming all customer PCB connections are at one temperature.
φ <sub>INT-BOT</sub>	is defined as the thermal impedance from the hot spot to the bottom surface of the core.
φ <sub>INT-TAB</sub>	is defined as the thermal impedance from the hot spot to the metal mounting tab on the core body.
φ <sub>INT-LEAD1</sub>	is defined as the thermal impedance from the hot spot to one of the mounting leads. Since the leads are the same thermal impedance, there is no need to specify by explicit pin number
φ <sub>INT-LEAD2</sub>	is defined as the thermal impedance from the hot spot to the other mounting lead

The following equation can predict the junction temperature based on the heat load applied to the inductor and the known ambient conditions with the simplified thermal circuit model:

$$T_{HOTSPOT} = \frac{PD + \frac{T_{TOP}}{\Phi_{INT-TOP}} + \frac{T_{PCB}}{\Phi_{INT-PCB}}}{\frac{I}{\Phi_{INT-PCB}} + \frac{I}{\Phi_{INT-PCB}}}$$

### **Evaluation Board Thermal De-rating**

Thermal de-rating curves are provided that are based on component temperature changes versus load current, input voltage and no air flow. It is recommended to use these curves as a guideline for proper thermal de-rating. These curves represent the entire system and are inclusive to both the Vicor SiP and the external inductor. Maximum thermal operation is limited by either the MOSFETs or inductor depending upon line and load conditions.

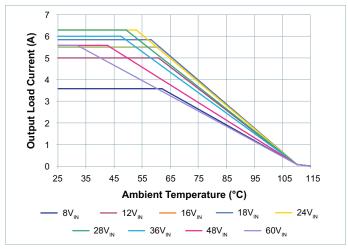

All thermal testing was performed using a 3in. x 3in., four 2oz. copper layers, FR4 evaluation board platform. Thermal measurements were made on the four internal MOSFETS and the external inductor.

### **Parallel Operation**

PI3740-00 can be connected in parallel to increase the output capability of a single output rail. When connecting modules in parallel, each EAO, TRK, EAIN and EN pin should be connected together. Current sharing will occur automatically in this manner so long as each inductor is the same value. A common viewing chain may be used to sense the output voltage. Up to three modules may be connected in parallel. The modules current sharing accuracy is determined by the inductor tolerance (±10%) and to a lesser extent, timing variation (±1.5%). Current sharing may be considered independent of synchronization and/or interleaving. Modules do not have to be interleaved or synchronized to share current. The following equation determines the output capability of N modules (up to three) to be determined:

$$I_{array} = I_{mod} + \left(I_{mod} \bullet (N - I) \bullet 0.77\right) \tag{9}$$

Where:

I<sub>array</sub> is the maximum output current of the array

 $I_{mod}$  is the maximum output per module

N is the number of modules

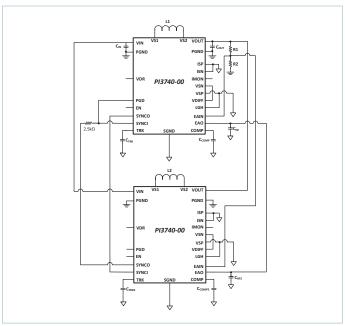

Figure 56 — PI3740-00 parallel operation

### **Synchronization**

PI3740-00 units may be synchronized to an external clock by driving the SYNCI pin. The synchronization frequency must not be higher than 110% of the programmed maximum value  $F_{SW}$ . This is the switching frequency during DCM of operation. The minimum synchronization frequency is  $F_{SW}$  / 2. In order to ensure proper power delivery during synchronization, the user should refer to the switching frequency vs. output current curves for the load current, output voltage and input voltage operating point. The synchronization frequency should not be lower than that determined by the curve or reduced output power will result. The power reduction is approximately the ratio between required frequency and synchronizing frequency. If the required frequency is 1MHz and the sync frequency is 600KHz, the user should expect a 40% reduction in output capability.

#### **Interleaving**

Interleaving is primarily done to reduce output ripple and the required number of output capacitors by introducing phase current cancellation. The PI3740-00 has a fixed delay that is proportional to to the maximum value of  $F_{SW}$  shown in the datasheet. When connecting two units as showin in Figure 56, they will operate at 180 degrees out of phase when the converters switching frequency is equal to  $F_{SW}$ . If the converter enters CrCM and the switching frequency is lower than  $F_{SW}$ , the phase delay will no longer be 180 degrees and ripple cancellation will begin to decay. Interleaving when the switching frequency is reduced to lower than 80% of the programmed maximum value is not recommended. Operation over high boost ratios such as 8V in to 36V out or narrow buck ratios like 28V in to 24V is not recommended for interleaving.

## **Small Signal Models CV-CC Modes**

#### Small Signal Model - Constant Voltage Mode

The PI3740-00 product is a variable frequency CrCM / DCM ZVS Buck Boost Regulator. The small signal model for this powertrain is that of a voltage controlled current source which has a trans-conductance that varies depending on the operating mode. When the converter is operating at its programmed frequency, it is in discontinuous mode. As the load increases to the point at which the boundary between discontinuous and continuous modes is reached, the powertrain changes frequency to remain in critical conduction mode. This mode of operation allows the PI3740-00 product family to have a very simple compensation scheme, as the control to output transfer function always has a slope of -1. In addition, when critical conduction is reached, the voltage controlled current source becomes more ideal with a higher output equivalent resistance with less variation.

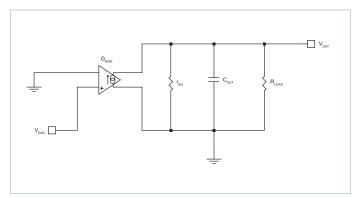

Figure 57 — PI3740-00 Small Signal Model Control-Output

The Control-Output transfer function (also known as the small signal modulator gain) has a single pole response determined by the parallel combination of Rload and  $r_{EQ}$  and the output capacitor  $C_{OUT}$ . Equation (10) determines the frequency of the modulator pole:

$$Fpmod = \frac{1}{2 \cdot \pi \cdot \left(\frac{R_{LOAD} \cdot r_{EQ}}{R_{LOAD} + r_{EQ}}\right) \cdot C_{OUT}}$$
(10)

#### **Error Amplifier**

The small signal model of the error amplifier and compensator is shown in Figure 56. The error amplifier is a wide bandwidth Trans-Conductance Amplifier (TCA). It is capable of sourcing and sinking  $\pm 400 \mu A$ . Here it is important to note that the external components are  $C_{COMP}$ ,  $C_{HF}$ , R1 and R2.  $R_{ZI}$  is pre-programmed by the factory and is internal to the PI3740-00 SiP.

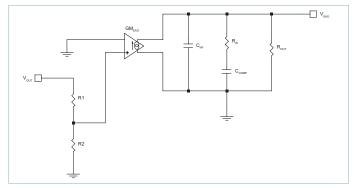

Figure 58 — Pl3740-00 Error Amplifier Model

When the amplifier is configured as shown in Figure 58, it forms a Type II amplifier configuration with poles and zeros determined by:

$$Fplf = \frac{1}{2 \cdot \pi \cdot (R_{ZI} + R_{OUT}) \cdot (C_{COMP} + C_{HF})}$$
(11)

$$Fzmb = \frac{1}{2 \bullet \pi \bullet (R_{zI}//R_{OUT}) \bullet C_{COMP}}$$
 (12)

$$Fphf = \frac{C_{HF+}C_{COMP}}{2 \cdot \pi \cdot (R_{ZI}//R_{OUT}) \cdot C_{COMP} \cdot C_{HF}}$$
(13)

#### **Lighting Mode (LGH)**

The Lighting (LGH) mode allows the PI3740-00 product to be able to operate in constant current mode (CC) so that it can support a wide range of applications that require the ability to regulate current or voltage. Primary applications are LED lighting, battery / super-capacitor charging and high peak current pulse transient load applications. The PI3740-00 product family can operate in dual modes, either as a constant voltage (CV) regulator or a constant current (CC) regulator. Both modes can be utilized in a single system. The PI3740-00 has a separate current amplifier, called LGH, and built in 100mV lighting reference that has its output connected to the EAO pin internally. If the current through an external shunt starts to develop 100mV at the LGH pin, the LGH amplifier will take over regulation by pulling down on the EAO output until the current is in regulation according to the designed shunt value. The LGH amplifier is a sink only transconductance amplifier (TCA). It does not source current. In the event of an open LED string or open current signal, the voltage loop can be set to regulate the output voltage to a safe or desired value in CV mode.

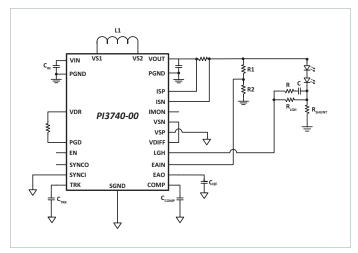

Figure 59 — Lighting Configuration Using CC Mode

When using the CC mode, it is important to set R1 and R2 appropriately to avoid voltage loop interaction with the current loop. In this case, the voltage setting at the EAIN pin should be set so that the error between it and the 1.7V reference is sufficient to force the EAO to be open loop and source current always. When not using the LGH amplifier, the LGH pin should be connected to SGND.

The LGH amplifier is able to sink more current than the error amplifier can source, thus avoiding arbitration issues when transitioning back and forth from LGH mode to voltage mode. The equation for setting the source current for EAO is shown in Equation (14).

$$I_{\scriptscriptstyle EAO} = (V_{\scriptscriptstyle EAIN} \hbox{-} V_{\scriptscriptstyle REF}) \bullet G_{\scriptscriptstyle MEA} > 400 \mu A \tag{14} \label{eq:eao}$$

### **LGH Amplifier Small Signal Model**

A small signal model of the LGH amplifier is shown in Figure 60.

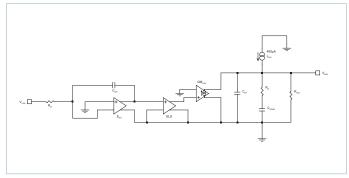

Figure 60 — LGH Amplifier Small Signal Model

The LGH amplifier consists of three distinct stages. The first is a wide bandwidth integrator stage, followed by a fixed gain level shift circuit. Finally, the level shift circuit drives a transconductance (TCA) amplifier with an open collector sink only output stage. Since the LGH output is internally connected to the output of the voltage error amplifier, the compensation components show up in the model and are used by both stages, depending on which one is in use. Only one stage should be in use at a time. When using LGH or if the LGH input rises above

the internal reference, the voltage error amplifier acts as a  $400\mu A$  current source pull up for the EAO pin.

The integrator pole is determined by the external input resistor  $R_{LGH}$  and the internal  $C_{INT}$ , which is 20pF. Assuming  $R_{LGH} = 100k$  and  $E_{INT} = 100000$ :

$$FpEint = \frac{1}{2 \cdot \pi \cdot (R_{LGHT} \cdot C_{INT} \cdot E_{INT})} = 0.795Hz \qquad (15)$$

Figure 58 shows a small signal model of the modulator gain when using the application circuit shown in Figure 59 with two high current LED's in series. R<sub>LED</sub> is the series combination of the AC resistance of each LED. R<sub>SHUNT</sub> is used to sense the current through the LED string. Equation (16) defines the pole of transfer function.

$$Fpled = \frac{1}{2 \cdot \pi \cdot ((R_{LED} + R_{SHUNT}) / / r_{EQ} \cdot C_{OUT}}$$
 (16)

When regulating in CC mode, it will be necessary to add a compensating zero to avoid loss of phase margin caused by the integrator stage of the LGH amplifier. A simple approach is to add a series R–C in parallel with R<sub>LGH</sub> as shown in the lighting application diagram in Figure 59. The capacitor will be chosen to work with R<sub>LGH</sub> to add a zero approximately 1.2kHz before the zero provided by the GM<sub>LGH</sub> transfer function (the transconductance stage of the LGH amplifier). The external added resistor will form a high frequency pole to roll the gain off at higher frequency. Note that it is very important to understand the AC resistance of the LED's that are being used. Please consult the LED manufacturer for details. For a series string, you should add the individual LED resistances and combine them into one lumped value to simplify the analysis.

#### **VDR Bias Regulator**

The VDR internal bias regulator is a ZVS switching regulator that resides internal to the PI3740-00 SiP. It is intended primarily to power the internal controller and driver circuitry. The power capability of this regulator is sized only for the PI3740-00, with adequate reserve for the application it was intended for. It may be used as a pull-up source for open collector applications and for other very low power uses with the following restrictions:

- The total external loading on VDR must be less than 2mA.
- No direct connection is allowed. Any noise source that can disturb the VDR voltage can also affect the internal controller operation. A series impedance is required between the VDR pin and any external circuitry.
- All loads must be locally decoupled using a  $0.1\mu F$  ceramic capacitor. This capacitor must be connected to the VDR output through a series resistor no smaller than  $1k\Omega$ , which forms a low pass filter.

#### **System Design Considerations**

Inductive Loads: As with all power electronic applications, consideration must be given to driving inductive loads that may be exposed to a fault in the system which could result in consequences beyond the scope of the power supply primary protection mechanisms. An inductive load could be a filter, fan motor or even excessively long cables. Consider an instantaneous short circuit through an un-damped inductance that occurs when the output capacitors are already at an initial condition of fully charged. The only thing that limits the current is the inductance of the short circuit and any series resistance. Even if the power supply is off at the time of the short circuit, the current could ramp up in the external inductor and store considerable energy. The release of this energy will result in considerable ringing, with the possibility of ringing nodes connected to the output voltage below ground. The system designer should plan for this by considering the use of other external circuit protection such as load switches, fuses, and transient voltage protectors. The inductive filters should be critically damped to avoid excessive ringing or damaging voltages. Adding a high current Schottky diode from the output voltage to PGND close to the PI3740-00 is recommended for these applications.

Low Voltage Operation: There is no isolation from an SELV (Safety-Extra-Low-Voltage) power system. Powering low voltage loads from input voltages as high as 60V may require additional consideration to protect low voltage circuits from excessive voltage in the event of a short circuit from input to output. A fast TVS (transient voltage suppressor) gating an external load switch is an example of such protection.

# Vicor's comprehensive line of power solutions includes high density AC-DC and DC-DC modules and accessory components, fully configurable AC-DC and DC-DC power supplies, and complete custom power systems.

Information furnished by Vicor is believed to be accurate and reliable. However, no responsibility is assumed by Vicor for its use. Vicor makes no representations or warranties with respect to the accuracy or completeness of the contents of this publication. Vicor reserves the right to make changes to any products, specifications, and product descriptions at any time without notice. Information published by Vicor has been checked and is believed to be accurate at the time it was printed; however, Vicor assumes no responsibility for inaccuracies. Testing and other quality controls are used to the extent Vicor deems necessary to support Vicor's product warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

Specifications are subject to change without notice.

#### **Vicor's Standard Terms and Conditions**

All sales are subject to Vicor's Standard Terms and Conditions of Sale, which are available on Vicor's webpage or upon request.

#### **Product Warranty**

In Vicor's standard terms and conditions of sale, Vicor warrants that its products are free from non-conformity to its Standard Specifications (the "Express Limited Warranty"). This warranty is extended only to the original Buyer for the period expiring two (2) years after the date of shipment and is not transferable.

UNLESS OTHERWISE EXPRESSLY STATED IN A WRITTEN SALES AGREEMENT SIGNED BY A DULY AUTHORIZED VICOR SIGNATORY, VICOR DISCLAIMS ALL REPRESENTATIONS, LIABILITIES, AND WARRANTIES OF ANY KIND (WHETHER ARISING BY IMPLICATION OR BY OPERATION OF LAW) WITH RESPECT TO THE PRODUCTS, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OR REPRESENTATIONS AS TO MERCHANTABILITY, FITNESS FOR PARTICULAR PURPOSE, INFRINGEMENT OF ANY PATENT, COPYRIGHT, OR OTHER INTELLECTUAL PROPERTY RIGHT, OR ANY OTHER MATTER.

This warranty does not extend to products subjected to misuse, accident, or improper application, maintenance, or storage. Vicor shall not be liable for collateral or consequential damage. Vicor disclaims any and all liability arising out of the application or use of any product or circuit and assumes no liability for applications assistance or buyer product design. Buyers are responsible for their products and applications using Vicor products and components. Prior to using or distributing any products that include Vicor components, buyers should provide adequate design, testing and operating safeguards.

Vicor will repair or replace defective products in accordance with its own best judgment. For service under this warranty, the buyer must contact Vicor to obtain a Return Material Authorization (RMA) number and shipping instructions. Products returned without prior authorization will be returned to the buyer. The buyer will pay all charges incurred in returning the product to the factory. Vicor will pay all reshipment charges if the product was defective within the terms of this warranty.

#### **Life Support Policy**

VICOR'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE CHIEF EXECUTIVE OFFICER AND GENERAL COUNSEL OF VICOR CORPORATION. As used herein, life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness. Per Vicor Terms and Conditions of Sale, the user of Vicor products and components in life support applications assumes all risks of such use and indemnifies Vicor against all liability and damages.
