## FEATURES

－Fast Responding Electronic VU Meter
－Drivers LEDs，LCDs，or Vacuum Fluorescents
－Bar or Dot Display Mode Externally Selectable by User
－Expandable to Displays of 70 dB
－Internal Voltage Reference from 1.2 V to 12 V
－Operates with Single Supply of 3 V to 25 V
－Inputs Operate Down to Ground
－Output Current Programmable from 1 mA to 30 mA
－Input Withstands $\mathbf{\pm 3 5 V}$ without Damage or False Outputs
－Outputs are Current Regulated，Open Collectors
－Directly Drives TTL or CMOS
－The Internal 10－step Divider is Floating and can be Referenced to a Wide Range of Voltages
The XD3916 is Rated for Operation from $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ ．The XD3916 is Available in an 18－ lead PDIP Package．

## DESCRIPTION

The XD3916 is a monolithic integrated circuit that senses analog voltage levels and drives ten LEDs， LCDs or vacuum fluorescent displays，providing an electronic version of the popular VU meter．One pin changes the display from a bar graph to a moving dot display．LED current drive is regulated and programmable，eliminating the need for current limiting resistors．The whole display system can operate from a single supply as low as 3 V or as high as 25 V ．

The IC contains an adjustable voltage reference and an accurate ten－step voltage divider．The high－ impedance input buffer accepts signals down to ground and up to within 1.5 V of the positive supply． Further，it needs no protection against inputs of $\pm 35 \mathrm{~V}$ ． The input buffer drives 10 individual comparators referenced to the precision divider．Accuracy is typically better than 0.2 dB ．
Audio applications include average or peak level indicators，and power meters．Replacing conventional meters with an LED bar graph results in a faster responding，more rugged display with high visibility that retains the ease of interpretation of an analog display．
The XD3916 is extremely easy to apply．A 1.2 V full－ scale meter requires only one resistor in addition to the ten LEDs．One more resistor programs the full－ scale anywhere from 1.2 V to 12 V independent of supply voltage．LED brightness is easily controlled with a single pot．
The XD3916 is very versatile．The outputs can drive LCDs，vacuum fluorescents and incandescent bulbs as well as LEDs of any color．Multiple devices can be cascaded for a dot or bar mode display for increased range and／or resolution．Useful in other applications are the linear XD3914 and the logarithmic XD3915．

## Typical Applications

$V_{R E F}=1.25 \mathrm{~V}\left(1+\frac{\mathrm{R} 2}{\mathrm{R} 1}\right)+\mathrm{R} 2 \times 80 \mu \mathrm{~A}$
$L_{\text {LED }}=\frac{12.5 \mathrm{~V}}{\mathrm{R} 1}+\frac{\mathrm{V}_{\text {REF }}}{2.2 \mathrm{k} \Omega}$
Notes: Capacitor C1 is required if leads to the LED supply are $6^{\prime \prime}$ or longer.
Circuit as shown is wired for dot mode. For bar mode, connect pin 9 to pin 3 . $\mathrm{V}_{\text {LED }}$ must be kept below 7 V or dropping resistor should be used to limit IC power dissipation.

Figure 1. 0 V to 10 V VU Meter

## ABSOLUTE MAXIMUM RATINGS ${ }^{(1)}$

| Power Dissipation ${ }^{(3)}$ |  |
| :--- | ---: |
| PDIP (NFK) |  |
| Supply Voltage |  |
| Voltage on Output Drivers |  |
| Input Signal Overvoltage ${ }^{(4)}$ | 25 VV |
| Divider Voltage | 25 V |
| Reference Load Current | $\pm 35 \mathrm{~V}$ |
| Storage Temperature Range |  |
| Lead Temperature <br> (Soldering, 10 seconds) | $-100 \mathrm{mV} \mathrm{to} \mathrm{V}^{+}$ |

(1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating ratings indicate conditions for which the device is functional, but do not ensure specific performance limits. Electrical Characteristics state DC and AC electrical specifications under particular test conditions which ensure specific performance limits. This assumes that the device is within the Operating Ratings. Specifications are not specified for parameters where no limit is given, however, the typical value is a good indication of device performance.
(3) The maximum junction temperature of the XD3916 is $100^{\circ} \mathrm{C}$. Devices must be derated for operation at elevated temperatures. Junction to ambient thermal resistance is $55^{\circ} \mathrm{C} / \mathrm{W}$ for the PDIP (NFK package).
(4) Pin 5 input current must be limited to $\pm 3 \mathrm{~mA}$. The addition of a 39 k resistor in series with pin 5 allows $\pm 100 \mathrm{~V}$ signals without damage.

## ELECTRICAL CHARACTERISTICS

| Parameter | Conditions ${ }^{(1)}$ | Min | Typ | Max | Units |

BLOCK DIAGRAM
(Showing Simplest Application)

## FUNCTIONAL DESCRIPTION

The simplified XD3916 block diagram is included to give the general idea of the circuit's operation. A high input impedance buffer operates with signals from ground to 12 V , and is protected against reverse and overvoltage signals. The signal is then applied to a series of 10 comparators; each of which is biased to a different comparison level by the resistor string.
In the example illustrated, the resistor string is connected to the internal 1.25 V reference voltage. As the input voltage varies from 0 to 1.25 , the comparator outputs are driven low one by one, switching on the LED indicators. The resistor divider can be connected between any 2 voltages, providing that they are at least 1.5 V below $\mathrm{V}^{+}$and no lower than $\mathrm{V}^{-}$.

## INTERNAL VOLTAGE REFERENCE

The reference is designed to be adjustable and develops a nominal 1.25 V between the REF OUT (pin 7 ) and REF ADJ (pin 8) terminals. The reference voltage is impressed across program resistor R1 and, since the voltage is constant, a constant current $\mathrm{I}_{1}$ then flows through the output set resistor R2 giving an output voltage of:

$$
v_{\text {OUT }}=v_{\text {REF }}\left(1+\frac{R 2}{R 1}\right)+I_{A D J} R 2
$$

Since the $120 \mu \mathrm{~A}$ current (max) from the adjust terminal represents an error term, the reference was designed to minimize changes of this current with $\mathrm{V}^{+}$and load changes. For correct operation, reference load current should be between $80 \mu \mathrm{~A}$ and 5 mA . Load capacitance should be less than $0.05 \mu \mathrm{~F}$.

## CURRENT PROGRAMMING

A feature not completely illustrated by the block diagram is the LED brightness control. The current drawn out of the reference voltage pin (pin 7) determines LED current. Approximately 10 times this current will be drawn through each lighted LED, and this current will be relatively constant despite supply voltage and temperature changes. Current drawn by the internal 10 -resistor divider, as well as by the external current and voltage-setting divider should be included in calculating LED drive current. The ability to modulate LED brightness with time, or in proportion to input voltage and other signals can lead to a number of novel displays or ways of indicating input overvoltages, alarms, etc.

The XD3916 outputs are current-limited NPN transistors as shown below. An internal feedback loop regulates the transistor drive. Output current is held at about 10 times the reference load current, independent of output voltage and processing variables, as long as the transistor is not saturated.

Figure 14. XD3916 Output Circuit
Outputs may be run in saturation with no adverse effects, making it possible to directly drive logic. The effective saturation resistance of the output transistors, equal to $R_{E}$ plus the transistors' collector resistance, is about $50 \Omega$. It's also possible to drive LEDs from rectified AC with no filtering. To avoid oscillations, the LED supply should be bypassed with a $2.2 \mu \mathrm{~F}$ tantalum or $10 \mu \mathrm{~F}$ aluminum electrolytic capacitor.

## MODE PIN USE

Pin 9, the Mode Select input, permits chaining of multiple devices, and controls bar or dot mode operation. The following tabulation shows the basic ways of using this input. Other more complex uses will be illustrated in the applications.
Bar Graph Display: Wire Mode Select (pin 9) directly to pin 3 ( $\mathrm{V}^{+}$pin).
Dot Display, Single XD3916 Driver: Leave the Mode Select pin open circuit.
Dot Display, $\mathbf{2 0}$ or More LEDs: Connect pin 9 of the first drivers in the series (i.e., the one with the lowest input voltage comparison points) to pin 1 of the next higher XD3916 driver. Continue connecting pin 9 of lower input drivers to pin 1 of higher input drivers for 30 or more LED displays. The last XD3916 driver in the chain will have pin 9 left open. All previous drivers should have a 20k resistor in parallel with LED \#9 (pin 11 to $\mathrm{V}_{\text {LED }}$ ).

## Mode Pin Functional Description

This pin actually performs two functions. Refer to the simplified block diagram below.

*High for bar
Figure 15. Block Diagram of Mode Pin Function

## DOT OR BAR MODE SELECTION

The voltage at pin 9 is sensed by comparator C 1 , nominally referenced to $\left(\mathrm{V}^{+}-100 \mathrm{mV}\right)$. The chip is in bar mode when pin 9 is above this level; otherwise it's in dot mode. The comparator is designed so that pin 9 can be left open circuit for dot mode.
Taking into account comparator gain and variation in the 100 mV reference level, pin 9 should be no more than 20 mV below $\mathrm{V}^{+}$for bar mode and more than 200 mV below $\mathrm{V}^{+}$(or open circuit) for dot mode. In most applications, pin 9 is either open (dot mode) or tied to $\mathrm{V}^{+}$(bar mode). In bar mode, pin 9 should be connected directly to pin 3 . Large currents drawn from the power supply (LED current, for example) should not share this path so that large IR drops are avoided.

## DOT MODE CARRY

In order for display to make sense when multiple drivers are cascaded in dot mode, special circuitry has been included to shut off LED \#10 of the first device when LED \#1 of the second device comes on. The connection for cascading in dot mode has already been described and is depicted in Figure 16.
As long as the input signal voltage is below the threshold of the second driver, LED \#11 is off. Pin 9 of driver \#1 thus sees effectively an open circuit so the chip is in dot mode. As soon as the input voltage reaches the threshold of LED \#11, pin 9 of driver \#1 is pulled an LED drop ( 1.5 V or more) below $\mathrm{V}_{\text {LED }}$. This condition is sensed by comparator C2, referenced 600 mV below $\mathrm{V}_{\text {LED }}$. This forces the output of C 2 low, which shuts off output transistor Q2, extinguishing LED \#10.
$\mathrm{V}_{\text {LED }}$ is sensed via the 20 k resistor connected to pin 11 . The very small current (less than $100 \mu \mathrm{~A}$ ) that is diverted from LED \#9 does not noticeably affect its intensity.
An auxiliary current source at pin 1 keeps at least $100 \mu$ A flowing through LED \#11 even if the input voltage rises high enough to extinguish the LED. This ensures that pin 9 of driver \#1 is held low enough to force LED \#10 off when any higher LED is illuminated. While $100 \mu$ A does not normally produce significant LED illumination, it may be noticeable when using high-efficiency LEDs in a dark environment. If this is bothersome, the simple cure is to shunt LED \#11 (and LED \#1) with a 10k resistor. The 1V 1R drop is more than the 900 mV worst case required to hold off LED \#10 yet small enough that LED \#11 does not conduct significantly.

In some circuits a number of outputs on the higher device are not used. Examples include the high resolution VU meter and the expanded range VU meter circuits (see Typical Applications). To provide the proper carry sense voltage in dot mode, the LEDs of the higher driver IC are tied to $\mathrm{V}_{\text {LED }}$ through two series-connected diodes as shown in Figure 17. Shunting the diodes with a 1 k resistor provides a path for driver leakage current.

Figure 16. Cascading XD3916 Series in Dot Mode

Figure 17. Cascading Drivers in Dot Mode with Pin 1 of Driver \#2 Unused

## OTHER DEVICE CHARACTERISTICS

The XD3915 is relatively low-powered itself, and since any number of LEDs can be powered from about 3 V , it is a very efficient display driver. Typical standby supply current (all LEDs OFF) is 1.6 mA . However, any reference loading adds 4 times that current drain to the $\mathrm{V}^{+}$(pin 3) supply input. For example, an XD3915 with a 1 mA reference pin load (1.3k) would supply almost 10 mA to every LED while drawing only 10 mA from its $\mathrm{V}^{+}$pin supply. At full-scale, the IC is typically drawing less than $10 \%$ of the current supplied to the display.
The display driver does not have built-in hysteresis so that the display does not jump instantly from one LED to the next. Under rapidly changing signal conditions, this cuts down high frequency noise and often an annoying flicker. An "overlap" is built in so that at no time are all segments completely off the dot mode. Generally one LED fades in while the other fades out over a 1 mV range. The change may be much more rapid between LED \#10 of one device and LED \#1 of a second device cascaded.

## Application Hints

The most difficult problem occurs when large LED currents are being drawn, especially in bar graph mode. These currents flowing out of the ground pin cause voltage drops in external wiring, and thus errors and oscillations. Bringing the return wires from signal sources, reference ground and bottom of the resistor string to a single point very near pin 2 is the best solution.
Long wires from $\mathrm{V}_{\text {LED }}$ to LED anode common can cause oscillations. The usual cure is bypassing the LED anodes with a $2.2 \mu \mathrm{~F}$ tantalum or $10 \mu \mathrm{~F}$ aluminum electrolytic capacitor. If the LED anode line wiring is inaccessible, often a $0.1 \mu \mathrm{~F}$ capacitor from pin 1 to pin 2 will be sufficient.
If there is a large amount of LED overlap in the bar mode, oscillation or excessive noise is usually the problem. In cases where proper wiring and bypassing fail to stop oscillations, $\mathrm{V}^{+}$voltage at pin 3 is usually below suggested limits. When several LEDs are lit in dot mode, the problem is usually an AC component of the input signal which should be filtered out. Expanded scale meter applications may have one or both ends of the internal voltage divider terminated at relatively high value resistors. These high-impedance ends should be bypassed to pin 2 with $0.1 \mu \mathrm{~F}$.

Power dissipation, especially in bar mode should be given consideration. For example, with a 5 V supply and all LEDs programmed to 20 mA the driver will dissipate over 600 mW . In this case a $7.5 \Omega$ resistor in series with the LED supply will cut device heating in half. The negative end of the resistor should be bypassed with a $2.2 \mu \mathrm{~F}$ solid tantalum or $10 \mu \mathrm{~F}$ aluminum electrolytic capacitor to pin 2.

## TIPS ON RECTIFIER CIRCUITS

The simplest way to display an AC signal using the XD3916 is to apply it right to pin 5 unrectified. Since the LED illuminated represents the instantaneous value of the AC waveform, one can readily discern both peak and average values of audio signals in this manner. The XD3916 will respond to positive half-cycles only but will not be damaged by signals up to $\pm 35 \mathrm{~V}$ (or up to $\pm 100 \mathrm{~V}$ if a 39 k resistor is in series with the input). A smear or bar type display results even though the XD3916 is connected for dot mode. The LEDs should be run at 20 mA to 30 mA for high enough average intensity.

True average or peak detection requires rectification. If an XD3916 is set up with 10V full scale across its voltage divider, the turn-on point for the first LED is only 450 mV . A simple silicon diode rectifier won't work well at the low end due to the 600 mV diode threshold. The half-wave peak detector in Figure 18 uses a PNP emitterfollower in front of the diode. Now, the transistor's base-emitter voltage cancels out the diode offset, within about 100 mV . This approach is usually satisfactory when a single XD3916 is used for a 23 dB display.

Display circuits such as the extended range VU meter using two or more drivers for a dynamic range of 40 dB or greater require more accurate detection. In the precision half-wave rectifier of Figure 19 the effective diode offset is reduced by a factor equal to the open-loop gain of the op amp. Filter capacitor C2 charges through R3 and discharges through R2 and R3, so that appropriate selection of these values results in either a peak or an average detector. The circuit has a gain equal to R2/R1.
It's best to capacitively couple the input. Audio sources frequently have a small DC offset that can cause significant error at the low end of the log display. Op amps that slew quickly, such as the LF351, LF353 or LF356, are needed to faithfully respond to sudden transients. It may be necessary to trim out the op amp DC offset voltage to accurately cover a 60 dB range. Best results are obtained if the circuit is adjusted for the correct output when a low-level AC signal ( 10 to 20 mV ) is applied, rather than adjusting for zero output with zero input.

| R2 | 1 k | 100 k |  |  |
| R3 | 100 k | 1 k |  |  |

[^0]Figure 19. Precision Half-Wave Rectifier

For precision full-wave averaging use the circuit in Figure 20. Using 1\% resistors for R1 through R4, gain for positive and negative signal differs by only 0.5 dB worst case. Substituting $5 \%$ resistors increases this to 2 dB worst case. (A 2 dB gain difference means that the display may have a $\pm 1 \mathrm{~dB}$ error when the input is a nonsymmetrical transient). The averaging time constant is $\mathrm{R} 5 \cdot \mathrm{C} 2$. A simple modification results in the precision full-wave detector of Figure 21. Since the filter capacitor is not buffered, this circuit can drive only high impedance loads such as the input of an XD3916.

## AUDIO METER STANDARDS

## VU Meter

The audio level meter most frequently encountered is the VU meter. Its characteristics are defined as the ANSI specification C165. The XD3916 outputs correspond to the meter indications specified with the omission of the -2 VU indication. The VU scale divisions differ slightly from a linear scale in order to obtain whole numbers in dB.
Some of the most important specifications for an AC meter are its dynamic characteristics. These define how the meter responds to transients and how fast the reading decays. The VU meter is a relatively slow full-wave averaging type, specified to reach $99 \%$ deflection in 300 ms and overshoot by 1 to $1.5 \%$. In engineering terms this means a slightly underdamped second order response with a resonant frequency of 2.1 Hz and a Q of 0.62 . Figure 22 depicts a simple rectifier/filter circuit that meets these criteria.

$$
\begin{aligned}
& \text { Design Equations } \\
& \frac{1}{\mathrm{R} 5 \cdot \mathrm{R} 6 \cdot \mathrm{C} 2 \cdot \mathrm{C} 3}=\omega_{0}^{2}=177 \mathrm{sec}-2 \\
& \frac{1}{\mathrm{C} 2}\left(\frac{1}{\mathrm{R} 3}+\frac{1}{\mathrm{R} 4}+\frac{1}{\mathrm{R} 5}+\frac{1}{\mathrm{R} 6}\right)=\frac{\omega_{0}}{\mathrm{Q}}=21.5 \mathrm{sec}-1 \\
& \mathrm{R} 3=2 \mathrm{R} 4 \\
& \mathrm{R} 1=\mathrm{R} 2 \ll \mathrm{R} 4 \\

| 10 | 1 M | 100 k | 1.0 | $0.056 \mu \mathrm{~F}$ |

Figure 22. Full-Wave Average Detector to VU Meter Specifications*

## Peak Program Meter

The VU meter, originally intended for signals sent via telephone lines, has shortcomings when used in high fidelity systems. Due to its slow response time, a VU meter will not accurately display transients that can saturate a magnetic tape or drive an amplifier into clipping. The fast-attack peak program meter (PPM) which does not have this problem is becoming increasingly popular.
While several European organizations have specifications for peak program meters, the German DIN specification 45406 is becoming a de facto standard. Rather than respond instantaneously to peak, however, PPM specifications require a finite "integration time" so that only peaks wide enough to be audible are displayed. DIN 45406 calls for a response of 1 dB down from steady-state for a 10 ms tone burst and 4 dB down for a 3 ms tone burst. These requirements are consistent with the other frequently encountered spec of 2 dB down for a 5 ms burst and are met by an attack time constant of 1.7 ms .

The specified return time of 1.5 s to -20 dB requires a 650 ms decay time constant. The full-wave peak detector of Figure 21 satisfies both the attack and decay time criteria.

## Cascading The XD3916

The XD3916 by itself covers the 23 dB range of the conventional VU meter. To display signals of 40 dB or 70 dB dynamic range, the XD3916 may be cascaded with the $3 \mathrm{~dB} / \mathrm{step}$ XD3915. Alternatively, two XD3916s may be cascaded for increased resolution over a 28 dB range. Refer to the Extended Range VU Meter and High Resolution VU Meter in the Typical Applications section for the complete circuits for both dot and bar mode displays.
To obtain a display that makes sense when an XD3915 and an XD3916 are cascaded, the -20 dB output from the XD3916 is dropped. The full-scale display for the XD3915 is set at 3 dB below the XD3916-10 dB output and the rest of the thresholds continue the $3 \mathrm{~dB} /$ step spacing. A simple, low cost approach is to set the reference voltage of the two chips 16 dB apart as in Figure 20. The XD3915, with pin 8 grounded, runs at 1.25 V full-scale. R1 and R2 set the XD3916 reference 16 dB higher or 7.89 V . Variation in the two on-chip references and resistor tolerance may cause $a \pm 1 \mathrm{~dB}$ error in the -10 dB to -13 dB transition. If this is objectionable, R 2 can be trimmed.

The drawback of the aforementioned approach is that the threshold of LED \#1 on the XD3915 is only 56 mV . Since comparator offset voltage may be as high as 10 mV , large errors can occur at the first few thresholds. A better approach, as shown in Figure 24, is to keep the reference the same for both drivers ( 10 V in the example) and amplify the input signal by 16 dB ahead of the XD3915. Alternatively, instead of amplifying, input signals of sufficient amplitude can be fed directly to the XD3916 and attenuated by 16 dB to drive the XD3915.

$$
\mathrm{V}_{\mathrm{REF} 2} \simeq 7.89 \mathrm{~V}
$$

Figure 23. Low Cost Circuit for 40 dB Display

$$
\begin{align*}
& V_{R E F 1}=1.25 \mathrm{~V} \\
& \frac{7.89 \mathrm{~V}}{1.25}=6.31=-16 \mathrm{~dB} \tag{1}
\end{align*}
$$

Figure 24. Improved Circuit for 40 dB Display

$$
\begin{align*}
\frac{R 1+R 2}{R 1} & =6.31 \\
& =16 \mathrm{~dB} \tag{2}
\end{align*}
$$

To extend this approach to get a 70 dB display, another 30 dB of amplification must be placed in the signal path ahead of the lowest XD3915. Extreme care is required as the lowest XD3915 displays input signals down to 2 mV ! Several offset nulls may be required. High currents should not share the same path as the low level signal. Also power line wiring should be kept away from signal lines.

## TIPS ON REFERENCE VOLTAGE AND LED CURRENT PROGRAMMING

## Single Driver

The equations in Figure 25 illustrate how to choose resistor values to set reference voltage for the simple case where no LED intensity adjustment is required. A LED current of 10 mA to 20 mA generally produces adequate illumination. Having 10 V full-scale across the internal voltage divider gives best accuracy by keeping signal level high relative to the offset voltage of the internal comparators. However, this causes 1 mA to flow from pin 7 into the divider which means that the LED current will be at least 10 mA . R1 will typically be between $1 \mathrm{k} \Omega$ and $5 \mathrm{k} \Omega$. To trim the reference voltage, vary R2.

The current in Figure 26 shows how to add a LED intensity control which can vary LED current from 5 mA to 28 mA . Choosing $\mathrm{V}_{\text {REF }}=5 \mathrm{~V}$ lowers the current drawn by the ladder, increasing the intensity adjustment range. The reference adjustment has some effect on LED intensity but the reverse is not true.

Adjust R2 to vary $V_{\text {REF }}$
Pick R1 $=\frac{12.5 \mathrm{~V}}{\mathrm{~L}_{\mathrm{LED}}-\mathrm{V}_{\text {REF }} / 1 \mathrm{k} \Omega}$
Pick R2 $=\frac{\left(V_{\text {REF }}-1.25 V\right)}{1.25 V / R 1+0.08 \mathrm{~mA}}$
Figure 25. Design Equations for Fixed LED Intensity

$5 \mathrm{~mA} \leq \mathrm{I}_{\mathrm{LED}} \leq 28 \mathrm{~mA} @ \mathrm{~V}_{\mathrm{REF}}=5 \mathrm{~V}$
Figure 26. Varying LED Intensity

## Multiple Drivers

Figure 27 shows how to obtain a common reference trim and intensity control for two drivers. The two ICs may be connected in cascade or may be handling separate channels for stereo. This technique can be extended for larger numbers of drivers by varying the values of R1, R2 and R3. Because the XD3915 has a greater ladder resistance, R5 was picked less than R7 in such a way as to provide equal reference load currents. The ICs' internal references track within 100 mV so that worst case error from chip to chip is only 0.2 dB for $\mathrm{V}_{\text {REF }}=5 \mathrm{~V}$.

The scheme in Figure 28 is useful when the reference and LED intensity must be adjusted independently over a wide range. The $\mathrm{R}_{\text {HI }}$ voltage can be adjusted from 1.2 V to 10 V with no effect on LED current. Since the internal divider here does not load down the reference, minimum LED current is much lower. At the minimum recommended reference load of $80 \mu \mathrm{~A}$, LED current is about 0.8 mA . The resistor values shown give a LED current range from 1.5 mA to 25 mA .

At the low end of the intensity adjustment, the voltage drop across the $510 \Omega$ current-sharing resistors is so small that chip to chip variation in reference voltage may yield a visible variation in LED intensity. The optional approach shown of connecting the bottom end of the intensity control pot to a negative supply overcomes this problem by allowing a larger voltage drop across the (larger) current-sharing resistors.

$$
\begin{aligned}
& 5 \mathrm{~mA} \leq \mathrm{I}_{\mathrm{LED}} \leq 28 \mathrm{~mA} \\
& \mathrm{~V}_{\mathrm{REF}}=5 \mathrm{~V}
\end{aligned}
$$

## Other Applications

For increased resolution, it's possible to obtain a display with a smooth transition between LEDs. This is accomplished by superimposing an AC waveform on top of the input level as shown in Figure 29. The signal can be a triangle, sawtooth or sine wave from 60 Hz to 1 kHz . The display can be run in either dot or bar mode.

## Definition of Terms

Absolute Accuracy: The difference between the observed threshold voltage and the ideal threshold voltage for each comparator. Specified and tested with 10 V across the internal voltage divider so that resistor ratio matching error predominates over comparator offset voltage.
Adjust Pin Current: Current flowing out of the reference amplifier pin when the reference amplifier is in the linear region.
Comparator Gain: The ratio of the change in output current ( $\mathrm{l}_{\text {LED }}$ ) to the change in input voltage $\left(\mathrm{V}_{\text {IN }}\right)$ required to produce it for a comparator in the linear region.
Dropout Voltage: The voltage measured at the current source outputs required to make the output current fall by $10 \%$.
Input Bias Current: Current flowing out of the signal input when the input buffer is in the linear region.
LED Current Regulation: The change in output current over the specified range of LED supply voltage ( $\mathrm{V}_{\text {LED }}$ ) as measured th the current source outputs. As the forward voltage of an LED does not change significantly with a small change in forward current, this is equivalent to changing the voltage at the LED anodes by the same amount.
Line Regulation: The average change in reference output voltage ( $\mathrm{V}_{\text {REF }}$ ) over the specified range of supply voltage ( $\mathrm{V}^{+}$).
Load Regulation: The change in reference output voltage over the specified range of load current ( $\left.\mathrm{I}_{\text {L(REF) }}\right)$.
Offset Voltage: The differential input voltage which must be applied to each comparator to bias the output in the linear region. Most significant error when the voltage across the internal voltage divider is small. Specified and tested with pin 6 voltage $\left(\mathrm{V}_{\mathrm{RHI}}\right)$ equal to pin 4 voltage $\left(\mathrm{V}_{\mathrm{RLO}}\right)$.
Relative Accuracy: The difference between any two adjacent threshold points. Specified and tested with 10V across the internal voltage divider so that resistor ratio matching error predominates over comparator offset voltage.
