## General Description

The 74C922／74C923 CMOS key encoders pro－ vide all the necessary logic to fully encode an array of SPST switches．The keyboard scan can be implemented by either an external clock or external capacitor．These encoders also have on－chip pull－up devices which permit switches with up to $50 \mathrm{k} \Omega$ on resistance to be used．No diodes in the switch array are needed to eliminate ghost switches．The internal debounce circuit needs only a single external capacitor and can be defeated by omitting the capacitor．A Data Available output goes to a high level when a valid keyboard entry has been made．The Data Available output returns to a low level when the entered key is released，even if another key is depressed．The Data Available will return high to indicate acceptance of the new key after a normal debounce period；this two－key roll－over is provided between any two switches．

An internal register remembers the last key pressed even after the key is released．The 3－STATE outputs provide for easy expansion and bus operation and are LPTTL compat－ ible．

## Features

■ $50 \mathrm{k} \Omega$ maximum switch on resistance
■ On or off chip clock
■ On－chip row pull－up devices
－ 2 key roll－over
－Keybounce elimination with single capacitor
－Last key register at outputs
■ 3－STATE output LPTTL compatible
■ Wide supply range： 3 V to 15 V
－Low power consumption

## Switching Time Waveforms

$T 1 \approx T 2 \approx R C, T 3 \approx 0.7 R C$, where $R \approx 10 k$ and $C$ is external capacitor at KBM input.
FIGURE 1.

FIGURE 2.

## Typical Performance Characteristics

## Typical Applications

Synchronous Handshake（74C922）

The keyboard may be synchronously scanned by omitting the capacitor at osc．and driving osc．directly if the system clock rate is lower than 10 kHz

Typical $\mathrm{R}_{\text {on }}$ vs $\mathrm{V}_{\text {OUT }}$ at Any X Output

Synchronous Data Entry Onto Bus（74C922）

Outputs are enabled when valid entry is made and go into 3－STATE when key is released．
The keyboard may be synchronously scanned by omitting the capacitor at osc．and driving osc．directly if the system clock rate is lower than 10 kHz

Outputs are in 3－STATE until key is pressed，then data is placed on bus．When key is released，outputs return to 3－STATE．
Expansion to 32 Key Encoder（74C922）

## Theory of Operation

The 74C922／74C923 Keyboard Encoders imple－ ment all the logic necessary to interface a 16 or 20 SPST key switch matrix to a digital system．The encoder will con－ vert a key switch closer to a 4（74C922）or 5 （74C923）bit nibble．The designer can control both the keyboard scan rate and the key debounce period by alter－ ing the oscillator capacitor，C COSE，and the key bounce mask capacitor， $\mathrm{C}_{\text {MSK }}$ ．Thus，the 74C922／74C923＇s performance can be optimized for many keyboards．
The keyboard encoders connect to a switch matrix that is 4 rows by 4 columns（74C922）or 5 rows by 4 columns （74C923）．When no keys are depressed，the row inputs are pulled high by internal pull－ups and the column outputs sequentially output a logic＂ 0 ＂．These outputs are open drain and are therefore low for $25 \%$ of the time and other－ wise off．The column scan rate is controlled by the oscilla－ tor input，which consists of a Schmitt trigger oscillator，a 2－ bit counter，and a 2－4－bit decoder．
When a key is depressed，key 0 ，for example，nothing will happen when the X 1 input is off，since Y 1 will remain high． When the X 1 column is scanned， X 1 goes low and Y 1 will go low．This disables the counter and keeps X1 low．Y1
going low also initiates the key bounce circuit timing and locks out the other Y inputs．The key code to be output is a combination of the frozen counter value and the decoded $Y$ inputs．Once the key bounce circuit times out，the data is latched，and the Data Available（DAV）output goes high．
If，during the key closure the switch bounces，Y1 input will go high again，restarting the scan and resetting the key bounce circuitry．The key may bounce several times，but as soon as the switch stays low for a debounce period，the closure is assumed valid and the data is latched．
A key may also bounce when it is released．To ensure that the encoder does not recognize this bounce as another key closure，the debounce circuit must time out before another closure is recognized．
The two－key roll－over feature can be illustrated by assum－ ing a key is depressed，and then a second key is depressed．Since all scanning has stopped，and all other $Y$ inputs are disabled，the second key is not recognized until the first key is lifted and the key bounce circuitry has reset． The output latches feed 3－STATE，which is enabled when the Output Enable（ $\overline{\mathrm{OE}})$ input is taken low．
