### Application Notes

#### Input Fusing and Safety Considerations

The RDL100 series converters have no internal fuse. In order to achieve maximum safety and system protection, always use an input line fuse. We recommend a 4 A time delay fuse. It is recommended that the circuit has a transient voltage suppressor diode (TVS) across the input terminals to protect the unit against surge or spike voltages and input reverse voltage (as shown). A suitable part would be 1.5KE180A.

#### Output Voltage Adjustment

The Trim input permits the user to adjust the output voltage up or down by 10%. This is accomplished by connecting an external resistor between the Trim pin and either the +Sense pin or the -Sense pin.

#### To Trim Down

Connecting an external resistor ( $R_d$ ) between the Trim pin and the +Sense pin decreases the output voltage. The following table can be used to determine the required external resistor value to obtain a percentage output voltage change of  $\Delta\%$ .

Trim Down %	12 V	15 V	24 V	48 V
	R <sub>d</sub> (k $\Omega$ )			
1	660.32	932.00	1641.67	3500.43
2	300.11	432.00	745.83	1595.11

9	19.95	43.11	49.07	113.20
10	11.94	32.00	29.17	70.86

#### To Trim Up

Connecting an external resistor ( $R_u$ ) between the +Vout pin and the -Sense pin increases the output voltage. The following table can be used to determine the required external resistor value to obtain a percentage output voltage change of  $\Delta\%$ .

Trim Up%	12 V	15 V	24 V	48 V

#### Airflow Derating Graph

##### Example (Without Heatsink)

To determine the minimum airflow necessary for a RDL100110S12 operating at an input voltage of 110 V, an output current of 8.3 A, and a maximum ambient temperature of 40°C:

Determine Power dissipation (Pd):  $P_d = P_i - P_o = P_o(1-\eta)/\eta$ ,

$$P_d = 12\text{ V} \times 8.3\text{ A} \times (1-0.85)/0.85 = 17.58\text{ Watts}$$

Where  $P_i$  = Input power,  $P_o$  = Output Power and  $\eta$  = Efficiency

Determine airflow from airflow derating graph using data points for  $P_d=17.58\text{ W}$  and  $T_a = 40\text{ °C}$

Minimum airflow= 500 ft./min.

To check that the maximum case temp of 100 °C is not exceeded:

Maximum temperature rise is

$$\Delta T = P_d \times R_{ca} = 17.58 \times 2.96 = 52.2\text{ °C}$$

Maximum case temperature is

$$T_c = T_a + \Delta T = 92.2\text{ °C} < 100\text{ °C}$$

Where:  $R_{ca}$  is the thermal resistance from case to ambient environment.  $T_a$  is ambient temperature and  $T_c$  is case temperature.
